- 1 Specify the CIDR configuration used for nodes on the additional overlay network. The **hybridClusterNetwork** CIDR cannot overlap with the **clusterNetwork** CIDR.
- 2 Specify a custom VXLAN port for the additional overlay network. This is required for running Windows nodes in a cluster installed on vSphere, and must not be configured for any other cloud provider. The custom port can be any open port excluding the default **4789** port. For more information on this requirement, see the Microsoft documentation on [Pod-to-pod connectivity between hosts is broken](#).

**NOTE**

Windows Server Long-Term Servicing Channel (LTSC): Windows Server 2019 is not supported on clusters with a custom **hybridOverlayVXLANPort** value because this Windows server version does not support selecting a custom VXLAN port.

4. Save the **cluster-network-03-config.yml** file and quit the text editor.
5. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program deletes the **manifests/** directory when creating the cluster.

**NOTE**

For more information on using Linux and Windows nodes in the same cluster, see [Understanding Windows container workloads](#).

**Additional resources**

- For more details about Accelerated Networking, see [Accelerated Networking for Microsoft Azure VMs](#).

**5.6.10. Installing the OpenShift CLI by downloading the binary**

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

## Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 5.6.11. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring an Azure cluster to use short-term credentials](#).

#### 5.6.11.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

## Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \ ❶
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ ❷
 --to=<path_to_directory_for_credentials_requests> ❸
```

- ❶ The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- ❷ Specify the location of the **install-config.yaml** file.
- ❸ Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
```

```
...
secretRef:
 name: <component_secret>
 namespace: <component_namespace>
...
```

### Sample Secret object

```
apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 azure_subscription_id: <base64_encoded_azure_subscription_id>
 azure_client_id: <base64_encoded_azure_client_id>
 azure_client_secret: <base64_encoded_azure_client_secret>
 azure_tenant_id: <base64_encoded_azure_tenant_id>
 azure_resource_prefix: <base64_encoded_azure_resource_prefix>
 azure_resourcegroup: <base64_encoded_azure_resourcegroup>
 azure_region: <base64_encoded_azure_region>
```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

#### 5.6.11.2. Configuring an Azure cluster to use short-term credentials

To install a cluster that uses Microsoft Entra Workload ID, you must configure the Cloud Credential Operator utility and create the required Azure resources for your cluster.

##### 5.6.11.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).
- You have created a global Microsoft Azure account for the **ccoctl** utility to use with the following permissions:

#### Example 5.28. Required Azure permissions

- Microsoft.Resources/subscriptions/resourceGroups/read
- Microsoft.Resources/subscriptions/resourceGroups/write

- Microsoft.Resources/subscriptions/resourceGroups/delete
- Microsoft.Authorization/roleAssignments/read
- Microsoft.Authorization/roleAssignments/delete
- Microsoft.Authorization/roleAssignments/write
- Microsoft.Authorization/roleDefinitions/read
- Microsoft.Authorization/roleDefinitions/write
- Microsoft.Authorization/roleDefinitions/delete
- Microsoft.Storage/storageAccounts/listkeys/action
- Microsoft.Storage/storageAccounts/delete
- Microsoft.Storage/storageAccounts/read
- Microsoft.Storage/storageAccounts/write
- Microsoft.Storage/storageAccounts/blobServices/containers/write
- Microsoft.Storage/storageAccounts/blobServices/containers/delete
- Microsoft.Storage/storageAccounts/blobServices/containers/read
- Microsoft.ManagedIdentity/userAssignedIdentities/delete
- Microsoft.ManagedIdentity/userAssignedIdentities/read
- Microsoft.ManagedIdentity/userAssignedIdentities/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/read
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/delete
- Microsoft.Storage/register/action
- Microsoft.ManagedIdentity/register/action

## Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

■

**NOTE**

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

**Verification**

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccoctl.rhel9
```

**Example output**

OpenShift credentials provisioning tool

Usage:

ccoctl [command]

Available Commands:

alibabacloud Manage credentials objects for alibaba cloud  
aws Manage credentials objects for AWS cloud  
azure Manage credentials objects for Azure  
gcp Manage credentials objects for Google cloud  
help Help about any command  
ibmcloud Manage credentials objects for IBM Cloud  
nutanix Manage credentials objects for Nutanix

Flags:

-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

**5.6.11.2.2. Creating Azure resources with the Cloud Credential Operator utility**

You can use the **ccoctl azure create-all** command to automate the creation of Azure resources.

**NOTE**

By default, **ccoctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccoctl\_output\_dir>** to refer to this directory.

## Prerequisites

You must have:

- Extracted and prepared the **ccoctl** binary.
- Access to your Microsoft Azure account by using the Azure CLI.

## Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

### NOTE

This command might take a few moments to run.

3. To enable the **ccoctl** utility to detect your Azure credentials automatically, log in to the Azure CLI by running the following command:

```
$ az login
```

4. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl azure create-all \
 --name=<azure_infra_name> \1
 --output-dir=<ccoctl_output_dir> \2
 --region=<azure_region> \3
 --subscription-id=<azure_subscription_id> \4
```

```
--credentials-requests-dir=<path_to_credentials_requests_directory> \ 5
--dnszone-resource-group-name=<azure_dns_zone_resource_group_name> \ 6
--tenant-id=<azure_tenant_id> 7
```

- 1 Specify the user-defined name for all created Azure resources used for tracking.
- 2 Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 3 Specify the Azure region in which cloud resources will be created.
- 4 Specify the Azure subscription ID to use.
- 5 Specify the directory containing the files for the component **CredentialsRequest** objects.
- 6 Specify the name of the resource group containing the cluster's base domain Azure DNS zone.
- 7 Specify the Azure tenant ID to use.

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

To see additional optional parameters and explanations of how to use them, run the **azure create-all --help** command.

#### Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

#### Example output

```
azure-ad-pod-identity-webhook-config.yaml
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-azure-cloud-credentials-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capz-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-disk-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-file-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-azure-cloud-credentials-credentials.yaml
```

You can verify that the Microsoft Entra ID service accounts are created by querying Azure. For more information, refer to Azure documentation on listing Entra ID service accounts.

#### 5.6.11.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccctl**) created to the correct directories for the installation program.

## Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccctl** utility.

## Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you used the **ccctl** utility to create a new Azure resource group instead of using an existing resource group, modify the **resourceGroupName** parameter in the **install-config.yaml** as shown:

### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
...
platform:
 azure:
 resourceGroupName: <azure_infra_name> 1
...
```

- 1** This value must match the user-defined name for Azure resources that was specified with the **--name** argument of the **ccctl azure create-all** command.

3. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

4. Copy the manifests that the **ccctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccctl_output_dir>/manifests/* ./manifests/
```

5. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

### 5.6.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.

#### Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

#### Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

#### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

#### Example output

```
...
INFO Install complete!
```

```
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrap** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 5.6.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

## Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 5.6.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

## Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 5.6.15. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

## 5.7. INSTALLING A CLUSTER ON AZURE INTO AN EXISTING VNET

In OpenShift Container Platform version 4.14, you can install a cluster into an existing Azure Virtual Network (VNet) on Microsoft Azure. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### 5.7.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure account](#) to host the cluster and determined the tested and validated region to deploy the cluster to.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- If you use customer-managed encryption keys, you [prepared your Azure environment for encryption](#).

### 5.7.2. About reusing a VNet for your OpenShift Container Platform cluster

In OpenShift Container Platform 4.14, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid

service limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

### 5.7.2.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups

#### NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet's CIDR block must contain the **Networking.MachineCIDR** range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

#### NOTE

By default, if you specify availability zones in the **install-config.yaml** file, the installation program distributes the control plane machines and the compute machines across [these availability zones](#) within [a region](#). To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for. If required, the installation program creates public load balancers that manage the control plane and worker nodes, and Azure allocates a public IP address to them.

#### NOTE

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

##### 5.7.2.1.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

#### IMPORTANT

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

Table 5.10. Required ports

| Port         | Description                                                                          | Control plane | Compute |
|--------------|--------------------------------------------------------------------------------------|---------------|---------|
| <b>80</b>    | Allows HTTP traffic                                                                  |               | x       |
| <b>443</b>   | Allows HTTPS traffic                                                                 |               | x       |
| <b>6443</b>  | Allows communication to the control plane machines                                   | x             |         |
| <b>22623</b> | Allows internal communication to the machine config server for provisioning machines | x             |         |

1. If you are using Azure Firewall to restrict the internet access, then [you can configure Azure Firewall to allow the Azure APIs](#). A network security group rule is not needed.

## IMPORTANT

Currently, there is no supported way to block or restrict the machine config server endpoint. The machine config server must be exposed to the network so that newly-provisioned machines, which have no existing configuration or state, are able to fetch their configuration. In this model, the root of trust is the certificate signing requests (CSR) endpoint, which is where the kubelet sends its certificate signing request for approval to join the cluster. Because of this, machine configs should not be used to distribute sensitive information, such as secrets and certificates.

To ensure that the machine config server endpoints, ports 22623 and 22624, are secured in bare metal scenarios, customers must configure proper network policies.

Because cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

**Table 5.11. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If you configure an external NTP time server, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

**Table 5.12. Ports used for control plane machine to control plane machine communications**

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

### Additional resources

- [About the OpenShift SDN network plugin](#)
- [Configuring your firewall](#)

### 5.7.2.2. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as VNets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make VNets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

### 5.7.2.3. Isolation between clusters

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

## 5.7.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 5.7.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 5.7.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 5.7.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

## Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the `~/.azure/` directory and delete the **osServicePrincipal.json** configuration file.  
Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.

2. Create the **install-config.yaml** file.

- a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

### NOTE

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
      - i. Optional: Select an SSH key to use to access your cluster machines.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **azure** as the platform to target.  
If the installation program cannot locate the **osServicePrincipal.json** configuration file from a previous installation, you are prompted for Azure subscription and authentication values.
      - iii. Enter the following Azure parameter values for your subscription:

- **azure subscription id** Enter the subscription ID to use for the cluster.
  - **azure tenant id** Enter the tenant ID.
- iv. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client id**
    - If you are using a service principal, enter its application ID.
    - If you are using a system-assigned managed identity, leave this value blank.
    - If you are using a user-assigned managed identity, specify its client ID.
  - v. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**
    - If you are using a service principal, enter its password.
    - If you are using a system-assigned managed identity, leave this value blank.
    - If you are using a user-assigned managed identity, leave this value blank.
  - vi. Select the region to deploy the cluster to.
  - vii. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.
  - viii. Enter a descriptive name for your cluster.

### IMPORTANT

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

3. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
4. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

If previously not detected, the installation program creates an **osServicePrincipal.json** configuration file and stores this file in the `~/.azure/` directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

### Additional resources

- [Installation configuration parameters for Azure](#)

### 5.7.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 5.13. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

#### NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

#### IMPORTANT

You are required to use Azure virtual machines that have the **premiumIO** parameter set to **true**.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

#### Additional resources

- [Optimizing storage](#)

#### 5.7.6.2. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

##### Example 5.29. Machine types based on 64-bit x86 architecture

- **c4.\***
- **c5.\***
- **c5a.\***
- **i3.\***
- **m4.\***
- **m5.\***
- **m5a.\***
- **m6a.\***
- **m6i.\***
- **r4.\***
- **r5.\***
- **r5a.\***
- **r6i.\***
- **t3.\***
- **t3a.\***

#### 5.7.6.3. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

##### Example 5.30. Machine types based on 64-bit ARM architecture

- **c6g.\***
- **c7g.\***
- **m6g.\***

- m7g.\*
- r8g.\*

#### 5.7.6.4. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: [secure boot](#) and [virtualized Trusted Platform Modules](#).

See the Azure documentation about [virtual machine sizes](#) to learn what sizes of virtual machines support these features.

#### IMPORTANT

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add the following stanza:

```
controlPlane: ❶
 platform:
 azure:
 settings:
 securityType: TrustedLaunch ❷
 trustedLaunch:
 uefiSettings:
 secureBoot: Enabled ❸
 virtualizedTrustedPlatformModule: Enabled ❹
```

- ❶ Specify **controlPlane.platform.azure** or **compute.platform.azure** to enable trusted launch on only control plane or compute nodes respectively. Specify **platform.azure.defaultMachinePlatform** to enable trusted launch on all nodes.
- ❷ Enable trusted launch features.
- ❸ Enable secure boot. For more information, see the Azure documentation about [secure boot](#).
- ❹ Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about [virtualized Trusted Platform Modules](#).

### 5.7.6.5. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.

#### IMPORTANT

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

#### IMPORTANT

Confidential VMs are currently not supported on 64-bit ARM architectures.

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add the following stanza:

```
controlPlane: ❶
platform:
 azure:
 settings:
 securityType: ConfidentialVM ❷
 confidentialVM:
 uefiSettings:
 secureBoot: Enabled ❸
 virtualizedTrustedPlatformModule: Enabled ❹
 osDisk:
 securityProfile:
 securityEncryptionType: VMGuestStateOnly ❺
```

- 1 Specify **controlPlane.platform.azure** or **compute.platform.azure** to deploy confidential VMs on only control plane or compute nodes respectively. Specify **platform.azure.defaultMachinePlatform** to deploy confidential VMs on all nodes.
- 2 Enable confidential VMs.
- 3 Enable secure boot. For more information, see the Azure documentation about [secure boot](#).
- 4 Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about [virtualized Trusted Platform Modules](#).
- 5 Specify **VMGuestStateOnly** to encrypt the VM guest state.

#### 5.7.6.6. Sample customized install-config.yaml file for Azure

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com 1
controlPlane: 2
 hyperthreading: Enabled 3 4
 name: master
 platform:
 azure:
 encryptionAtHost: true
 ultraSSDCapability: Enabled
 osDisk:

 cloudName: AzurePublicCloud
 pullSecret: '{"auths": ...}' 20
 fips: false 21
 sshKey: ssh-ed25519 AAAA... 22

```

**1 10 14 20** Required. The installation program prompts you for this value.

- 2 6 If you do not provide these parameters and values, the installation program provides the default value.
- 3 7 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 4 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as **Standard\_D8s\_v3**, for your machines if you disable simultaneous multithreading.

- 5 8 You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.
- 9 Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.
- 11 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 12 Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The **publisher**, **offer**, **sku**, and **version** parameters under **platform.azure.defaultMachinePlatform.osImage** apply to both control plane and compute machines. If the parameters under **controlPlane.platform.azure.osImage** or **compute.platform.azure.osImage** are set, they override the **platform.azure.defaultMachinePlatform.osImage** parameters.
- 13 Specify the name of the resource group that contains the DNS zone for your base domain.
- 15 Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
- 16 If you use an existing VNet, specify the name of the resource group that contains it.
- 17 If you use an existing VNet, specify its name.
- 18 If you use an existing VNet, specify the name of the subnet to host the control plane machines.
- 19 If you use an existing VNet, specify the name of the subnet to host the compute machines.
- 21 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

22

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

## NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 5.7.6.7. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
```

```

httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
noProxy: example.com 3
additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5

```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

## Additional resources

- For more details about Accelerated Networking, see [Accelerated Networking for Microsoft Azure VMs](#).

### 5.7.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

##### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 5.7.8. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring an Azure cluster to use short-term credentials](#).

### 5.7.8.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included 1 \
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2 \
 --to=<path_to_directory_for_credentials_requests> 3
```

- 1** The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2** Specify the location of the **install-config.yaml** file.
- 3** Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...
```

### Sample **Secret** object

```
apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 azure_subscription_id: <base64_encoded_azure_subscription_id>
 azure_client_id: <base64_encoded_azure_client_id>
 azure_client_secret: <base64_encoded_azure_client_secret>
 azure_tenant_id: <base64_encoded_azure_tenant_id>
```

```
azure_resource_prefix: <base64_encoded_azure_resource_prefix>
azure_resourcegroup: <base64_encoded_azure_resourcegroup>
azure_region: <base64_encoded_azure_region>
```

## IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### 5.7.8.2. Configuring an Azure cluster to use short-term credentials

To install a cluster that uses Microsoft Entra Workload ID, you must configure the Cloud Credential Operator utility and create the required Azure resources for your cluster.

#### 5.7.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

## NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).
- You have created a global Microsoft Azure account for the **ccoctl** utility to use with the following permissions:

#### Example 5.31. Required Azure permissions

- Microsoft.Resources/subscriptions/resourceGroups/read
- Microsoft.Resources/subscriptions/resourceGroups/write
- Microsoft.Resources/subscriptions/resourceGroups/delete
- Microsoft.Authorization/roleAssignments/read
- Microsoft.Authorization/roleAssignments/delete
- Microsoft.Authorization/roleAssignments/write
- Microsoft.Authorization/roleDefinitions/read
- Microsoft.Authorization/roleDefinitions/write
- Microsoft.Authorization/roleDefinitions/delete
- Microsoft.Storage/storageAccounts/listkeys/action
- Microsoft.Storage/storageAccounts/delete

- Microsoft.Storage/storageAccounts/read
- Microsoft.Storage/storageAccounts/write
- Microsoft.Storage/storageAccounts/blobServices/containers/write
- Microsoft.Storage/storageAccounts/blobServices/containers/delete
- Microsoft.Storage/storageAccounts/blobServices/containers/read
- Microsoft.ManagedIdentity/userAssignedIdentities/delete
- Microsoft.ManagedIdentity/userAssignedIdentities/read
- Microsoft.ManagedIdentity/userAssignedIdentities/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/read
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/delete
- Microsoft.Storage/register/action
- Microsoft.ManagedIdentity/register/action

## Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

## Verification

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccoctl.rhel9
```

## Example output

OpenShift credentials provisioning tool

Usage:

ccoctl [command]

Available Commands:

alibabacloud Manage credentials objects for alibaba cloud

aws Manage credentials objects for AWS cloud

azure Manage credentials objects for Azure

gcp Manage credentials objects for Google cloud

help Help about any command

ibmcloud Manage credentials objects for IBM Cloud

nutanix Manage credentials objects for Nutanix

Flags:

-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

### 5.7.8.2.2. Creating Azure resources with the Cloud Credential Operator utility

You can use the **ccoctl azure create-all** command to automate the creation of Azure resources.

## NOTE

By default, **ccoctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccoctl\_output\_dir>** to refer to this directory.

## Prerequisites

You must have:

- Extracted and prepared the **ccoctl** binary.
- Access to your Microsoft Azure account by using the Azure CLI.

## Procedure

- Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

#### NOTE

This command might take a few moments to run.

3. To enable the **ccoctl** utility to detect your Azure credentials automatically, log in to the Azure CLI by running the following command:

```
$ az login
```

4. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl azure create-all \
 --name=<azure_infra_name> \1
 --output-dir=<ccoctl_output_dir> \2
 --region=<azure_region> \3
 --subscription-id=<azure_subscription_id> \4
 --credentials-requests-dir=<path_to_credentials_requests_directory> \5
 --dnszone-resource-group-name=<azure_dns_zone_resource_group_name> \6
 --tenant-id=<azure_tenant_id> \7
```

- 1 Specify the user-defined name for all created Azure resources used for tracking.
- 2 Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 3 Specify the Azure region in which cloud resources will be created.
- 4 Specify the Azure subscription ID to use.
- 5 Specify the directory containing the files for the component **CredentialsRequest** objects.
- 6 Specify the name of the resource group containing the cluster's base domain Azure DNS zone.

## 7 Specify the Azure tenant ID to use.

### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

To see additional optional parameters and explanations of how to use them, run the **azure create-all --help** command.

### Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

### Example output

```
azure-ad-pod-identity-webhook-config.yaml
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-azure-cloud-credentials-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capz-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-disk-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-file-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-azure-cloud-credentials-credentials.yaml
```

You can verify that the Microsoft Entra ID service accounts are created by querying Azure. For more information, refer to Azure documentation on listing Entra ID service accounts.

#### 5.7.8.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccoctl**) created to the correct directories for the installation program.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccoctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccoctl** utility.

### Procedure

- If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you used the **ccoctl** utility to create a new Azure resource group instead of using an existing resource group, modify the **resourceGroupName** parameter in the **install-config.yaml** as shown:

### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
...
platform:
 azure:
 resourceGroupName: <azure_infra_name> 1
...
```

- 1** This value must match the user-defined name for Azure resources that was specified with the **--name** argument of the **ccoctl azure create-all** command.

3. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

4. Copy the manifests that the **ccoctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

5. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

## 5.7.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 5.7.10. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 5.7.11. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

## 5.8. INSTALLING A PRIVATE CLUSTER ON AZURE

In OpenShift Container Platform version 4.14, you can install a private cluster into an existing Azure Virtual Network (VNet) on Microsoft Azure. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### 5.8.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.

- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure account](#) to host the cluster and determined the tested and validated region to deploy the cluster to.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- If you use customer-managed encryption keys, you [prepared your Azure environment for encryption](#).

### 5.8.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

#### IMPORTANT

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.
- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company's guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

#### 5.8.2.1. Private clusters in Azure

To create a private cluster on Microsoft Azure, you must provide an existing private VNet and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

Depending how your network connects to the private VNET, you might need to use a DNS forwarder to resolve the cluster's private DNS records. The cluster's machines use **168.63.129.16** internally for DNS resolution. For more information, see [What is Azure Private DNS?](#) and [What is IP address 168.63.129.16?](#) in the Azure documentation.

The cluster still requires access to internet to access the Azure APIs.

The following items are not required or created when you install a private cluster:

- A **BaseDomainResourceGroup**, since the cluster does not create public records
- Public IP addresses
- Public DNS records
- Public endpoints

The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

#### 5.8.2.1.1. Limitations

Private clusters on Azure are subject to only the limitations that are associated with the use of an existing VNet.

#### 5.8.2.2. User-defined outbound routing

In OpenShift Container Platform, you can choose your own outbound routing for a cluster to connect to the internet. This allows you to skip the creation of public IP addresses and the public load balancer.

You can configure user-defined routing by modifying parameters in the **install-config.yaml** file before installing your cluster. A pre-existing VNet is required to use outbound routing when installing a cluster; the installation program is not responsible for configuring this.

When configuring a cluster to use user-defined routing, the installation program does not create the following resources:

- Outbound rules for access to the internet.
- Public IPs for the public load balancer.
- Kubernetes Service object to add the cluster machines to the public load balancer for outbound requests.

You must ensure the following items are available before setting user-defined routing:

- Egress to the internet is possible to pull container images, unless using an OpenShift image registry mirror.
- The cluster can access Azure APIs.
- Various allowlist endpoints are configured. You can reference these endpoints in the *Configuring your firewall* section.

There are several pre-existing networking setups that are supported for internet access using user-defined routing.

#### Private cluster with network address translation

You can use [Azure VNET network address translation \(NAT\)](#) to provide outbound internet access for the subnets in your cluster. You can reference [Create a NAT gateway using Azure CLI](#) in the Azure documentation for configuration instructions.

When using a VNet setup with Azure NAT and user-defined routing configured, you can create a private cluster with no public endpoints.

#### **Private cluster with Azure Firewall**

You can use Azure Firewall to provide outbound routing for the VNet used to install the cluster. You can learn more about [providing user-defined routing with Azure Firewall](#) in the Azure documentation.

When using a VNet setup with Azure Firewall and user-defined routing configured, you can create a private cluster with no public endpoints.

#### **Private cluster with a proxy configuration**

You can use a proxy with user-defined routing to allow egress to the internet. You must ensure that cluster Operators do not access Azure APIs using a proxy; Operators must have access to Azure APIs outside of the proxy.

When using the default route table for subnets, with **0.0.0.0/0** populated automatically by Azure, all Azure API requests are routed over Azure's internal network even though the IP addresses are public. As long as the Network Security Group rules allow egress to Azure API endpoints, proxies with user-defined routing configured allow you to create private clusters with no public endpoints.

#### **Private cluster with no internet access**

You can install a private network that restricts all access to the internet, except the Azure API. This is accomplished by mirroring the release image registry locally. Your cluster must have access to the following:

- An OpenShift image registry mirror that allows for pulling container images
- Access to Azure APIs

With these requirements available, you can use user-defined routing to create private clusters with no public endpoints.

### **5.8.3. About reusing a VNet for your OpenShift Container Platform cluster**

In OpenShift Container Platform 4.14, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

#### **5.8.3.1. Requirements for using your VNet**

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet's CIDR block must contain the **Networking.MachineCIDR** range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

**NOTE**

By default, if you specify availability zones in the **install-config.yaml** file, the installation program distributes the control plane machines and the compute machines across [these availability zones](#) within [a region](#). To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for.

**NOTE**

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

#### 5.8.3.1.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

### IMPORTANT

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

**Table 5.14. Required ports**

| Port         | Description                                                                          | Control plane | Compute |
|--------------|--------------------------------------------------------------------------------------|---------------|---------|
| <b>80</b>    | Allows HTTP traffic                                                                  |               | x       |
| <b>443</b>   | Allows HTTPS traffic                                                                 |               | x       |
| <b>6443</b>  | Allows communication to the control plane machines                                   | x             |         |
| <b>22623</b> | Allows internal communication to the machine config server for provisioning machines | x             |         |

1. If you are using Azure Firewall to restrict the internet access, then [you can configure Azure Firewall to allow the Azure APIs](#). A network security group rule is not needed.

### IMPORTANT

Currently, there is no supported way to block or restrict the machine config server endpoint. The machine config server must be exposed to the network so that newly-provisioned machines, which have no existing configuration or state, are able to fetch their configuration. In this model, the root of trust is the certificate signing requests (CSR) endpoint, which is where the kubelet sends its certificate signing request for approval to join the cluster. Because of this, machine configs should not be used to distribute sensitive information, such as secrets and certificates.

To ensure that the machine config server endpoints, ports 22623 and 22624, are secured in bare metal scenarios, customers must configure proper network policies.

Because cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

**Table 5.15. Ports used for all-machine to all-machine communications**

| Protocol | Port        | Description                |
|----------|-------------|----------------------------|
| ICMP     | N/A         | Network reachability tests |
| TCP      | <b>1936</b> | Metrics                    |

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| UDP      | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
|          | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
| TCP/UDP  | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If you configure an external NTP time server, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

Table 5.16. Ports used for control plane machine to control plane machine communications

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

#### Additional resources

- [About the OpenShift SDN network plugin](#)
- [Configuring your firewall](#)

#### 5.8.3.2. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as VNets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions

that are required to make VNets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

### 5.8.3.3. Isolation between clusters

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

### 5.8.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 5.8.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ❶
```

- ❶ Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**5.8.6. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 5.8.7. Manually creating the installation configuration file

When installing a private OpenShift Container Platform cluster, you must manually generate the installation configuration file.

### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

### NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

#### Additional resources

- [Installation configuration parameters for Azure](#)

#### 5.8.7.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 5.17. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

## IMPORTANT

You are required to use Azure virtual machines that have the **premiumIO** parameter set to **true**.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### Additional resources

- [Optimizing storage](#)

### 5.8.7.2. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

#### Example 5.32. Machine types based on 64-bit x86 architecture

- **c4.\***
- **c5.\***
- **c5a.\***
- **i3.\***
- **m4.\***
- **m5.\***
- **m5a.\***
- **m6a.\***
- **m6i.\***
- **r4.\***
- **r5.\***

- **r5a.\***
- **r6i.\***
- **t3.\***
- **t3a.\***

### 5.8.7.3. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

#### Example 5.33. Machine types based on 64-bit ARM architecture

- **c6g.\***
- **c7g.\***
- **m6g.\***
- **m7g.\***
- **r8g.\***

### 5.8.7.4. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: [secure boot](#) and [virtualized Trusted Platform Modules](#).

See the Azure documentation about [virtual machine sizes](#) to learn what sizes of virtual machines support these features.

#### IMPORTANT

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add the following stanza:

```

controlPlane: ❶
platform:
 azure:
 settings:
 securityType: TrustedLaunch ❷
 trustedLaunch:
 uefiSettings:
 secureBoot: Enabled ❸
 virtualizedTrustedPlatformModule: Enabled ❹

```

- ❶ Specify **controlPlane.platform.azure** or **compute.platform.azure** to enable trusted launch on only control plane or compute nodes respectively. Specify **platform.azure.defaultMachinePlatform** to enable trusted launch on all nodes.
- ❷ Enable trusted launch features.
- ❸ Enable secure boot. For more information, see the Azure documentation about [secure boot](#).
- ❹ Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about [virtualized Trusted Platform Modules](#).

#### 5.8.7.5. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.

#### IMPORTANT

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

#### IMPORTANT

Confidential VMs are currently not supported on 64-bit ARM architectures.

#### Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add the following stanza:

```
controlPlane: ❶
 platform:
 azure:
 settings:
 securityType: ConfidentialVM ❷
 confidentialVM:
 uefiSettings:
 secureBoot: Enabled ❸
 virtualizedTrustedPlatformModule: Enabled ❹
 osDisk:
 securityProfile:
 securityEncryptionType: VMGuestStateOnly ❺
```

- ❶ Specify **controlPlane.platform.azure** or **compute.platform.azure** to deploy confidential VMs on only control plane or compute nodes respectively. Specify **platform.azure.defaultMachinePlatform** to deploy confidential VMs on all nodes.
- ❷ Enable confidential VMs.
- ❸ Enable secure boot. For more information, see the Azure documentation about [secure boot](#).
- ❹ Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about [virtualized Trusted Platform Modules](#).
- ❺ Specify **VMGuestStateOnly** to encrypt the VM guest state.

### 5.8.7.6. Sample customized install-config.yaml file for Azure

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com ❶
controlPlane: ❷
 hyperthreading: Enabled ❸ ❹
 name: master
 platform:
 azure:
 encryptionAtHost: true
```

```

ultraSSDCapability: Enabled
osDisk:
 diskSizeGB: 1024 5
 diskType: Premium_LRS
 diskEncryptionSet:
 resourceGroup: disk_encryption_set_resource_group

```

1 10 14 21 Required. The installation program prompts you for this value.

2 6 If you do not provide these parameters and values, the installation program provides the default value.

3 7 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

4 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as **Standard\_D8s\_v3**, for your machines if you disable simultaneous multithreading.

5 8 You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

9 Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

11 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

12 Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The **publisher**, **offer**, **sku**, and **version** parameters under **platform.azure.defaultMachinePlatform.osImage** apply to both control plane and compute machines. If the parameters under **controlPlane.platform.azure.osImage** or **compute.platform.azure.osImage** are set, they override the

`platform.azure.defaultMachinePlatform.osImage` parameters.

- 13 Specify the name of the resource group that contains the DNS zone for your base domain.
- 15 Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
- 16 If you use an existing VNet, specify the name of the resource group that contains it.
- 17 If you use an existing VNet, specify its name.
- 18 If you use an existing VNet, specify the name of the subnet to host the control plane machines.
- 19 If you use an existing VNet, specify the name of the subnet to host the compute machines.
- 20 You can customize your own outbound routing. Configuring user-defined routing prevents exposing external endpoints in your cluster. User-defined routing for egress requires deploying your cluster to an existing VNet.
- 22 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 23 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- 24 How to publish the user-facing endpoints of your cluster. Set **publish** to **Internal** to deploy a private cluster, which cannot be accessed from the internet. The default value is **External**.

#### 5.8.7.7. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when

**http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### Additional resources

- For more details about Accelerated Networking, see [Accelerated Networking for Microsoft Azure VMs](#).

### 5.8.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.

To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

**NOTE**

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

**Verification**

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

**5.8.9. Alternatives to storing administrator-level secrets in the kube-system project**

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring an Azure cluster to use short-term credentials](#).

**5.8.9.1. Manually creating long-term credentials**

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

**Procedure**

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

**Sample configuration file snippet**

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

- Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

- Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- Specify the location of the **install-config.yaml** file.
- Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
```

- Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
```

```

namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...

```

### Sample Secret object

```

apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 azure_subscription_id: <base64_encoded_azure_subscription_id>
 azure_client_id: <base64_encoded_azure_client_id>
 azure_client_secret: <base64_encoded_azure_client_secret>
 azure_tenant_id: <base64_encoded_azure_tenant_id>
 azure_resource_prefix: <base64_encoded_azure_resource_prefix>
 azure_resourcegroup: <base64_encoded_azure_resourcegroup>
 azure_region: <base64_encoded_azure_region>

```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

#### 5.8.9.2. Configuring an Azure cluster to use short-term credentials

To install a cluster that uses Microsoft Entra Workload ID, you must configure the Cloud Credential Operator utility and create the required Azure resources for your cluster.

##### 5.8.9.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

- You have created a global Microsoft Azure account for the **ccctl** utility to use with the following permissions:

**Example 5.34. Required Azure permissions**

- Microsoft.Resources/subscriptions/resourceGroups/read
- Microsoft.Resources/subscriptions/resourceGroups/write
- Microsoft.Resources/subscriptions/resourceGroups/delete
- Microsoft.Authorization/roleAssignments/read
- Microsoft.Authorization/roleAssignments/delete
- Microsoft.Authorization/roleAssignments/write
- Microsoft.Authorization/roleDefinitions/read
- Microsoft.Authorization/roleDefinitions/write
- Microsoft.Authorization/roleDefinitions/delete
- Microsoft.Storage/storageAccounts/listkeys/action
- Microsoft.Storage/storageAccounts/delete
- Microsoft.Storage/storageAccounts/read
- Microsoft.Storage/storageAccounts/write
- Microsoft.Storage/storageAccounts/blobServices/containers/write
- Microsoft.Storage/storageAccounts/blobServices/containers/delete
- Microsoft.Storage/storageAccounts/blobServices/containers/read
- Microsoft.ManagedIdentity/userAssignedIdentities/delete
- Microsoft.ManagedIdentity/userAssignedIdentities/read
- Microsoft.ManagedIdentity/userAssignedIdentities/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/read
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/delete
- Microsoft.Storage/register/action
- Microsoft.ManagedIdentity/register/action

**Procedure**

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

- Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

#### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccctl** tool.

- Extract the **ccctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccctl" -a ~/.pull-secret
```

- Change the permissions to make **ccctl** executable by running the following command:

```
$ chmod 775 ccctl
```

#### Verification

- To verify that **ccctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccctl.rhel9
```

#### Example output

OpenShift credentials provisioning tool

Usage:

ccctl [command]

Available Commands:

|              |                                              |
|--------------|----------------------------------------------|
| alibabacloud | Manage credentials objects for alibaba cloud |
| aws          | Manage credentials objects for AWS cloud     |
| azure        | Manage credentials objects for Azure         |
| gcp          | Manage credentials objects for Google cloud  |
| help         | Help about any command                       |
| ibmcloud     | Manage credentials objects for IBM Cloud     |
| nutanix      | Manage credentials objects for Nutanix       |

Flags:

-h, --help help for ccctl

Use "ccctl [command] --help" for more information about a command.

#### 5.8.9.2.2. Creating Azure resources with the Cloud Credential Operator utility

You can use the **ccoctl azure create-all** command to automate the creation of Azure resources.

## NOTE

By default, **ccoctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccoctl\_output\_dir>** to refer to this directory.

## Prerequisites

You must have:

- Extracted and prepared the **ccoctl** binary.
- Access to your Microsoft Azure account by using the Azure CLI.

## Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

## NOTE

This command might take a few moments to run.

3. To enable the **ccoctl** utility to detect your Azure credentials automatically, log in to the Azure CLI by running the following command:

```
$ az login
```

4. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

■

```
$ ccoctl azure create-all \
 --name=<azure_infra_name> \ ❶
 --output-dir=<ccoctl_output_dir> \ ❷
 --region=<azure_region> \ ❸
 --subscription-id=<azure_subscription_id> \ ❹
 --credentials-requests-dir=<path_to_credentials_requests_directory> \ ❺
 --dnszone-resource-group-name=<azure_dns_zone_resource_group_name> \ ❻
 --tenant-id=<azure_tenant_id> \ ❼
```

- ❶ Specify the user-defined name for all created Azure resources used for tracking.
- ❷ Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- ❸ Specify the Azure region in which cloud resources will be created.
- ❹ Specify the Azure subscription ID to use.
- ❺ Specify the directory containing the files for the component **CredentialsRequest** objects.
- ❻ Specify the name of the resource group containing the cluster's base domain Azure DNS zone.
- ❼ Specify the Azure tenant ID to use.

## NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

To see additional optional parameters and explanations of how to use them, run the **azure create-all --help** command.

## Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

## Example output

```
azure-ad-pod-identity-webhook-config.yaml
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-azure-cloud-credentials-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capz-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-disk-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-file-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-azure-cloud-credentials-credentials.yaml
```

You can verify that the Microsoft Entra ID service accounts are created by querying Azure. For more information, refer to Azure documentation on listing Entra ID service accounts.

### 5.8.9.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccocctl**) created to the correct directories for the installation program.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccocctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccocctl** utility.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you used the **ccocctl** utility to create a new Azure resource group instead of using an existing resource group, modify the **resourceGroupName** parameter in the **install-config.yaml** as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
...
platform:
 azure:
 resourceGroupName: <azure_infra_name> 1
...
```

- 1** This value must match the user-defined name for Azure resources that was specified with the **--name** argument of the **ccocctl azure create-all** command.

3. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

4. Copy the manifests that the **ccoctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

5. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

### 5.8.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

#### Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the **~/.azure/** directory and delete the **osServicePrincipal.json** configuration file.  
Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.
2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the installation program cannot locate the **osServicePrincipal.json** configuration file from a previous installation, you are prompted for Azure subscription and authentication values.

3. Enter the following Azure parameter values for your subscription:
  - **azure subscription id** Enter the subscription ID to use for the cluster.
  - **azure tenant id** Enter the tenant ID.
4. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client id**
  - If you are using a service principal, enter its application ID.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, specify its client ID.
5. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**
  - If you are using a service principal, enter its password.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, leave this value blank.

If previously not detected, the installation program creates an **osServicePrincipal.json** configuration file and stores this file in the **~/.azure/** directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
```

```
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 5.8.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

## 5.8.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

## 5.8.13. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

## 5.9. INSTALLING A CLUSTER ON AZURE INTO A GOVERNMENT REGION

In OpenShift Container Platform version 4.14, you can install a cluster on Microsoft Azure into a government region. To configure the government region, you modify parameters in the **install-config.yaml** file before you install the cluster.

### 5.9.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure account](#) to host the cluster and determined the tested and validated government region to deploy the cluster to.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the **kube-system** namespace, you can [manually create and maintain long-term credentials](#).
- If you use customer-managed encryption keys, you [prepared your Azure environment for encryption](#).

### 5.9.2. Azure government regions

OpenShift Container Platform supports deploying a cluster to [Microsoft Azure Government \(MAG\)](#) regions. MAG is specifically designed for US government agencies at the federal, state, and local level, as well as contractors, educational institutions, and other US customers that must run sensitive workloads on Azure. MAG is composed of government-only data center regions, all granted an [Impact Level 5 Provisional Authorization](#).

Installing to a MAG region requires manually configuring the Azure Government dedicated cloud instance and region in the **install-config.yaml** file. You must also update your service principal to reference the appropriate government environment.

#### NOTE

The Azure government region cannot be selected using the guided terminal prompts from the installation program. You must define the region manually in the **install-config.yaml** file. Remember to also set the dedicated cloud instance, like **AzureUSGovernmentCloud**, based on the region specified.

### 5.9.3. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

#### IMPORTANT

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.
- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company's guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

#### 5.9.3.1. Private clusters in Azure

To create a private cluster on Microsoft Azure, you must provide an existing private VNet and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster

requires. The installation program configures the Ingress Operator and API server for only internal traffic.

Depending how your network connects to the private VNET, you might need to use a DNS forwarder to resolve the cluster's private DNS records. The cluster's machines use **168.63.129.16** internally for DNS resolution. For more information, see [What is Azure Private DNS?](#) and [What is IP address 168.63.129.16?](#) in the Azure documentation.

The cluster still requires access to internet to access the Azure APIs.

The following items are not required or created when you install a private cluster:

- A **BaseDomainResourceGroup**, since the cluster does not create public records
- Public IP addresses
- Public DNS records
- Public endpoints

The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

#### 5.9.3.1.1. Limitations

Private clusters on Azure are subject to only the limitations that are associated with the use of an existing VNet.

#### 5.9.3.2. User-defined outbound routing

In OpenShift Container Platform, you can choose your own outbound routing for a cluster to connect to the internet. This allows you to skip the creation of public IP addresses and the public load balancer.

You can configure user-defined routing by modifying parameters in the **install-config.yaml** file before installing your cluster. A pre-existing VNet is required to use outbound routing when installing a cluster; the installation program is not responsible for configuring this.

When configuring a cluster to use user-defined routing, the installation program does not create the following resources:

- Outbound rules for access to the internet.
- Public IPs for the public load balancer.
- Kubernetes Service object to add the cluster machines to the public load balancer for outbound requests.

You must ensure the following items are available before setting user-defined routing:

- Egress to the internet is possible to pull container images, unless using an OpenShift image registry mirror.
- The cluster can access Azure APIs.
- Various allowlist endpoints are configured. You can reference these endpoints in the *Configuring your firewall* section.

There are several pre-existing networking setups that are supported for internet access using user-defined routing.

#### 5.9.4. About reusing a VNet for your OpenShift Container Platform cluster

In OpenShift Container Platform 4.14, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

##### 5.9.4.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups

#### NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet's CIDR block must contain the **Networking.MachineCIDR** range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

NOTE

By default, if you specify availability zones in the **install-config.yaml** file, the installation program distributes the control plane machines and the compute machines across [these availability zones](#) within [a region](#). To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for. If required, the installation program creates public load balancers that manage the control plane and worker nodes, and Azure allocates a public IP address to them.

NOTE

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

5.9.4.1.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

IMPORTANT

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

Table 5.18. Required ports

| Port  | Description                                                                          | Control plane | Compute |
|-------|--------------------------------------------------------------------------------------|---------------|---------|
| 80    | Allows HTTP traffic                                                                  |               | x       |
| 443   | Allows HTTPS traffic                                                                 |               | x       |
| 6443  | Allows communication to the control plane machines                                   | x             |         |
| 22623 | Allows internal communication to the machine config server for provisioning machines | x             |         |

1. If you are using Azure Firewall to restrict the internet access, then [you can configure Azure Firewall to allow the Azure APIs](#). A network security group rule is not needed.

## IMPORTANT

Currently, there is no supported way to block or restrict the machine config server endpoint. The machine config server must be exposed to the network so that newly-provisioned machines, which have no existing configuration or state, are able to fetch their configuration. In this model, the root of trust is the certificate signing requests (CSR) endpoint, which is where the kubelet sends its certificate signing request for approval to join the cluster. Because of this, machine configs should not be used to distribute sensitive information, such as secrets and certificates.

To ensure that the machine config server endpoints, ports 22623 and 22624, are secured in bare metal scenarios, customers must configure proper network policies.

Because cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

**Table 5.19. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If you configure an external NTP time server, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |

| Protocol | Port | Description                                |
|----------|------|--------------------------------------------|
| ESP      | N/A  | IPsec Encapsulating Security Payload (ESP) |

**Table 5.20. Ports used for control plane machine to control plane machine communications**

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

**Additional resources**

- [About the OpenShift SDN network plugin](#)
- [Configuring your firewall](#)

**5.9.4.2. Division of permissions**

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as VNets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make VNets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

**5.9.4.3. Isolation between clusters**

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

**5.9.5. Internet access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

## IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 5.9.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

## IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

## NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

## NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 5.9.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

## Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

## Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 5.9.8. Manually creating the installation configuration file

When installing OpenShift Container Platform on Microsoft Azure into a government region, you must manually generate your installation configuration file.

## Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

## Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- [Installation configuration parameters for Azure](#)

5.9.8.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 5.21. Minimum resource requirements

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio:  $(\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}$ .
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

## IMPORTANT

You are required to use Azure virtual machines that have the **premiumIO** parameter set to **true**.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### Additional resources

- [Optimizing storage](#)

### 5.9.8.2. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

#### Example 5.35. Machine types based on 64-bit x86 architecture

- **c4.\***
- **c5.\***
- **c5a.\***

- **i3.\***
- **m4.\***
- **m5.\***
- **m5a.\***
- **m6a.\***
- **m6i.\***
- **r4.\***
- **r5.\***
- **r5a.\***
- **r6i.\***
- **t3.\***
- **t3a.\***

### 5.9.8.3. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: [secure boot](#) and [virtualized Trusted Platform Modules](#).

See the Azure documentation about [virtual machine sizes](#) to learn what sizes of virtual machines support these features.

#### IMPORTANT

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add the following stanza:

```
controlPlane: 1
platform:
```

```

azure:
 settings:
 securityType: TrustedLaunch ❷
 trustedLaunch:
 uefiSettings:
 secureBoot: Enabled ❸
 virtualizedTrustedPlatformModule: Enabled ❹

```

- ❶ Specify **controlPlane.platform.azure** or **compute.platform.azure** to enable trusted launch on only control plane or compute nodes respectively. Specify **platform.azure.defaultMachinePlatform** to enable trusted launch on all nodes.
- ❷ Enable trusted launch features.
- ❸ Enable secure boot. For more information, see the Azure documentation about [secure boot](#).
- ❹ Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about [virtualized Trusted Platform Modules](#).

#### 5.9.8.4. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.

#### IMPORTANT

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

#### IMPORTANT

Confidential VMs are currently not supported on 64-bit ARM architectures.

#### Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add the following stanza:

```
controlPlane: ❶
 platform:
 azure:
 settings:
 securityType: ConfidentialVM ❷
 confidentialVM:
 uefiSettings:
 secureBoot: Enabled ❸
 virtualizedTrustedPlatformModule: Enabled ❹
 osDisk:
 securityProfile:
 securityEncryptionType: VMGuestStateOnly ❺
```

- ❶ Specify **controlPlane.platform.azure** or **compute.platform.azure** to deploy confidential VMs on only control plane or compute nodes respectively. Specify **platform.azure.defaultMachinePlatform** to deploy confidential VMs on all nodes.
- ❷ Enable confidential VMs.
- ❸ Enable secure boot. For more information, see the Azure documentation about [secure boot](#).
- ❹ Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about [virtualized Trusted Platform Modules](#).
- ❺ Specify **VMGuestStateOnly** to encrypt the VM guest state.

### 5.9.8.5. Sample customized install-config.yaml file for Azure

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com ❶
controlPlane: ❷
 hyperthreading: Enabled ❸ ❹
 name: master
 platform:
 azure:
 encryptionAtHost: true
 ultraSSDCapability: Enabled
 osDisk:
 diskSizeGB: 1024 ❺
```

```

 diskType: Premium_LRS
 diskEncryptionSet:
 resourceGroup: disk_encryption_set_resource_group
 name: disk_encryption_set_name
 subscriptionId: secondary_subscription_id
 osImage:
 publisher: example_publisher_name
 offer: example_image_offer
 sku: example_offer_sku
 version: example_image_version
 type: Standard_D8s_v3
 replicas: 3
 compute: 6
 - hyperthreading: Enabled 7
 name: worker
 platform:
 azure:
 ultraSSDCapability: Enabled
 type: Standard_D2s_v3
 encryptionAtHost: true
 osDisk:
 diskSizeGB: 512 8
 diskType: Standard_LRS
 diskEncryptionSet:
 resourceGroup: disk_encryption_set_resource_group
 name: disk_encryption_set_name
 subscriptionId: secondary_subscription_id
 osImage:
 publisher: example_publisher_name
 offer: example_image_offer
 sku: example_offer_sku
 version: example_image_version
 zones: 9
 - "1"
 - "2"
 - "3"
 replicas: 5
 metadata:
 name: test-cluster 10
 networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes 11
 serviceNetwork:
 - 172.30.0.0/16
 platform:
 azure:
 defaultMachinePlatform:
 osImage: 12
 publisher: example_publisher_name
 offer: example_image_offer
 sku: example_offer_sku

```

```

version: example_image_version
ultraSSDCapability: Enabled
baseDomainResourceGroupName: resource_group 13
region: usgovvirginia
resourceGroupName: existing_resource_group 14
networkResourceGroupName: vnet_resource_group 15
virtualNetwork: vnet 16
controlPlaneSubnet: control_plane_subnet 17
computeSubnet: compute_subnet 18
outboundType: UserDefinedRouting 19
cloudName: AzureUSGovernmentCloud 20
pullSecret: '{"auths": ...}' 21
fips: false 22
sshKey: ssh-ed25519 AAAA... 23
publish: Internal 24

```

1 10 21 Required.

2 6 If you do not provide these parameters and values, the installation program provides the default value.

3 7 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

4 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as **Standard\_D8s\_v3**, for your machines if you disable simultaneous multithreading.

5 8 You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

9 Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

11 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

12 Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The **publisher**, **offer**, **sku**, and **version** parameters under **platform.azure.defaultMachinePlatform.osImage** apply to both control plane and compute machines. If the parameters under **controlPlane.platform.azure.osImage** or **compute.platform.azure.osImage** are set, they override the **platform.azure.defaultMachinePlatform.osImage** parameters.

13 Specify the name of the resource group that contains the DNS zone for your base domain.

- 14 Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
- 15 If you use an existing VNet, specify the name of the resource group that contains it.
- 16 If you use an existing VNet, specify its name.
- 17 If you use an existing VNet, specify the name of the subnet to host the control plane machines.
- 18 If you use an existing VNet, specify the name of the subnet to host the compute machines.
- 19 You can customize your own outbound routing. Configuring user-defined routing prevents exposing external endpoints in your cluster. User-defined routing for egress requires deploying your cluster to an existing VNet.
- 20 Specify the name of the Azure cloud environment to deploy your cluster to. Set **AzureUSGovernmentCloud** to deploy to a Microsoft Azure Government (MAG) region. The default value is **AzurePublicCloud**.
- 22 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 23 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- 24 How to publish the user-facing endpoints of your cluster. Set **publish** to **Internal** to deploy a private cluster, which cannot be accessed from the internet. The default value is **External**.

#### 5.9.8.6. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when

**http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### Additional resources

- For more details about Accelerated Networking, see [Accelerated Networking for Microsoft Azure VMs](#).

### 5.9.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.

- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

## Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the `~/.azure/` directory and delete the **osServicePrincipal.json** configuration file.  
Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.
2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the installation program cannot locate the **osServicePrincipal.json** configuration file from a previous installation, you are prompted for Azure subscription and authentication values.

3. Enter the following Azure parameter values for your subscription:
  - **azure subscription id** Enter the subscription ID to use for the cluster.
  - **azure tenant id** Enter the tenant ID.
4. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client id**
  - If you are using a service principal, enter its application ID.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, specify its client ID.
5. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**
  - If you are using a service principal, enter its password.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, leave this value blank.

If previously not detected, the installation program creates an **osServicePrincipal.json** configuration file and stores this file in the `~/.azure/` directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target

platform.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 5.9.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

## Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

## 5.9.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

### Example output

```
system:admin
```

### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

## 5.9.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

## 5.9.13. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

## 5.10. INSTALLING A CLUSTER ON AZURE IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform, you can install a cluster on Microsoft Azure by using infrastructure that you provide.

Several [Azure Resource Manager](#) (ARM) templates are provided to assist in completing these steps or to help model your own.

### IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several ARM templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.

### Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.

- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure account](#) to host the cluster and determined the tested and validated region to deploy the cluster to.
- You [mirrored the images for a disconnected installation](#) to your registry and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

### IMPORTANT

Because the installation media is on the mirror host, you must use that computer to complete all installation steps.

- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the **kube-system** namespace, you have [manually created long-term credentials](#).
- If you use customer-managed encryption keys, you [prepared your Azure environment for encryption](#).

## 5.10.1. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

### IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

### 5.10.1.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.

- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

### 5.10.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 5.10.2. Configuring your Azure project

Before you can install OpenShift Container Platform, you must configure an Azure project to host it.

#### IMPORTANT

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

#### 5.10.2.1. Azure account limits

The OpenShift Container Platform cluster uses a number of Microsoft Azure components, and the default [Azure subscription and service limits, quotas, and constraints](#) affect your ability to install OpenShift Container Platform clusters.

#### IMPORTANT

Default limits vary by offer category types, such as Free Trial and Pay-As-You-Go, and by series, such as Dv2, F, and G. For example, the default for Enterprise Agreement subscriptions is 350 cores.

Check the limits for your subscription type and if necessary, increase quota limits for your account before you install a default cluster on Azure.

The following table summarizes the Azure components whose limits can impact your ability to install and run OpenShift Container Platform clusters.

| Component          | Number of components required by default | Default Azure limit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vCPU               | 44                                       | 20 per region       | <p>A default cluster requires 44 vCPUs, so you must increase the account limit.</p> <p>By default, each cluster creates the following instances:</p> <ul style="list-style-type: none"> <li>• One bootstrap machine, which is removed after installation</li> <li>• Three control plane machines</li> <li>• Three compute machines</li> </ul> <p>Because the bootstrap and control plane machines use <b>Standard_D8s_v3</b> virtual machines, which use 8 vCPUs, and the compute machines use <b>Standard_D4s_v3</b> virtual machines, which use 4 vCPUs, a default cluster requires 44 vCPUs. The bootstrap node VM, which uses 8 vCPUs, is used only during installation.</p> <p>To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, you must further increase the vCPU limit for your account to ensure that your cluster can deploy the machines that you require.</p> |
| OS Disk            | 7                                        |                     | <p>Each cluster machine must have a minimum of 100 GB of storage and 300 IOPS. While these are the minimum supported values, faster storage is recommended for production clusters and clusters with intensive workloads. For more information about optimizing storage for performance, see the page titled "Optimizing storage" in the "Scalability and performance" section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

#### 5.10.2.2. Configuring a public DNS zone in Azure

To install OpenShift Container Platform, the Microsoft Azure account you use must have a dedicated public hosted DNS zone in your account. This zone must be authoritative for the domain. This service provides cluster DNS resolution and name lookup for external connections to the cluster.

### Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through Azure or another source.

### NOTE

For more information about purchasing domains through Azure, see [Buy a custom domain name for Azure App Service](#) in the Azure documentation.

2. If you are using an existing domain and registrar, migrate its DNS to Azure. See [Migrate an active DNS name to Azure App Service](#) in the Azure documentation.
3. Configure DNS for your domain. Follow the steps in the [Tutorial: Host your domain in Azure DNS](#) in the Azure documentation to create a public hosted zone for your domain or subdomain, extract the new authoritative name servers, and update the registrar records for the name servers that your domain uses.  
Use an appropriate root domain, such as **openshiftcorp.com**, or subdomain, such as **clusters.openshiftcorp.com**.
4. If you use a subdomain, follow your company's procedures to add its delegation records to the parent domain.

You can view Azure's DNS solution by visiting this [example for creating DNS zones](#).

#### 5.10.2.3. Increasing Azure account limits

To increase an account limit, file a support request on the Azure portal.

**NOTE**

You can increase only one type of quota per support request.

**Procedure**

1. From the Azure portal, click **Help + support** in the lower left corner.
2. Click **New support request** and then select the required values:
  - a. From the **Issue type** list, select **Service and subscription limits (quotas)**
  - b. From the **Subscription** list, select the subscription to modify.
  - c. From the **Quota type** list, select the quota to increase. For example, select **Compute-VM (cores-vCPUs) subscription limit increases** to increase the number of vCPUs, which is required to install a cluster.
  - d. Click **Next: Solutions**.
3. On the **Problem Details** page, provide the required information for your quota increase:
  - a. Click **Provide details** and provide the required details in the **Quota details** window.
  - b. In the SUPPORT METHOD and CONTACT INFO sections, provide the issue severity and your contact details.
4. Click **Next: Review + create** and then click **Create**.

**5.10.2.4. Certificate signing requests management**

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

**5.10.2.5. Required Azure roles**

An OpenShift Container Platform cluster requires an Azure identity to create and manage Azure resources. Before you create the identity, verify that your environment meets the following requirements:

- The Azure account that you use to create the identity is assigned the **User Access Administrator** and **Contributor** roles. These roles are required when:
  - Creating a service principal or user-assigned managed identity.
  - Enabling a system-assigned managed identity on a virtual machine.
- If you are going to use a service principal to complete the installation, verify that the Azure account that you use to create the identity is assigned the **microsoft.directory/servicePrincipals/createAsOwner** permission in Microsoft Entra ID.

To set roles on the Azure portal, see the [Manage access to Azure resources using RBAC and the Azure portal](#) in the Azure documentation.

#### 5.10.2.6. Required Azure permissions for user-provisioned infrastructure

The installation program requires access to an Azure service principal or managed identity with the necessary permissions to deploy the cluster and to maintain its daily operation. These permissions must be granted to the Azure subscription that is associated with the identity.

The following options are available to you:

- You can assign the identity the **Contributor** and **User Access Administrator** roles. Assigning these roles is the quickest way to grant all of the required permissions. For more information about assigning roles, see the Azure documentation for [managing access to Azure resources using the Azure portal](#).
- If your organization's security policies require a more restrictive set of permissions, you can create a [custom role](#) with the necessary permissions.

The following permissions are required for creating an OpenShift Container Platform cluster on Microsoft Azure.

##### Example 5.36. Required permissions for creating authorization resources

- **Microsoft.Authorization/policies/audit/action**
- **Microsoft.Authorization/policies/auditIfNotExists/action**
- **Microsoft.Authorization/roleAssignments/read**
- **Microsoft.Authorization/roleAssignments/write**

##### Example 5.37. Required permissions for creating compute resources

- **Microsoft.Compute/images/read**
- **Microsoft.Compute/images/write**
- **Microsoft.Compute/images/delete**
- **Microsoft.Compute/availabilitySets/read**
- **Microsoft.Compute/disks/beginGetAccess/action**
- **Microsoft.Compute/disks/delete**
- **Microsoft.Compute/disks/read**
- **Microsoft.Compute/disks/write**
- **Microsoft.Compute/galleries/images/read**
- **Microsoft.Compute/galleries/images/versions/read**
- **Microsoft.Compute/galleries/images/versions/write**

- **Microsoft.Compute/galleries/images/write**
- **Microsoft.Compute/galleries/read**
- **Microsoft.Compute/galleries/write**
- **Microsoft.Compute/snapshots/read**
- **Microsoft.Compute/snapshots/write**
- **Microsoft.Compute/snapshots/delete**
- **Microsoft.Compute/virtualMachines/delete**
- **Microsoft.Compute/virtualMachines/powerOff/action**
- **Microsoft.Compute/virtualMachines/read**
- **Microsoft.Compute/virtualMachines/write**
- **Microsoft.Compute/virtualMachines/deallocate/action**

Example 5.38. Required permissions for creating identity management resources

- **Microsoft.ManagedIdentity/userAssignedIdentities/assign/action**
- **Microsoft.ManagedIdentity/userAssignedIdentities/read**
- **Microsoft.ManagedIdentity/userAssignedIdentities/write**

Example 5.39. Required permissions for creating network resources

- **Microsoft.Network/dnsZones/A/write**
- **Microsoft.Network/dnsZones/CNAME/write**
- **Microsoft.Network/dnszones/CNAME/read**
- **Microsoft.Network/dnszones/read**
- **Microsoft.Network/loadBalancers/backendAddressPools/join/action**
- **Microsoft.Network/loadBalancers/backendAddressPools/read**
- **Microsoft.Network/loadBalancers/backendAddressPools/write**
- **Microsoft.Network/loadBalancers/read**
- **Microsoft.Network/loadBalancers/write**
- **Microsoft.Network/networkInterfaces/delete**
- **Microsoft.Network/networkInterfaces/join/action**
- **Microsoft.Network/networkInterfaces/read**

- **Microsoft.Network/networkInterfaces/write**
- **Microsoft.Network/networkSecurityGroups/join/action**
- **Microsoft.Network/networkSecurityGroups/read**
- **Microsoft.Network/networkSecurityGroups/securityRules/delete**
- **Microsoft.Network/networkSecurityGroups/securityRules/read**
- **Microsoft.Network/networkSecurityGroups/securityRules/write**
- **Microsoft.Network/networkSecurityGroups/write**
- **Microsoft.Network/privateDnsZones/A/read**
- **Microsoft.Network/privateDnsZones/A/write**
- **Microsoft.Network/privateDnsZones/A/delete**
- **Microsoft.Network/privateDnsZones/SOA/read**
- **Microsoft.Network/privateDnsZones/read**
- **Microsoft.Network/privateDnsZones/virtualNetworkLinks/read**
- **Microsoft.Network/privateDnsZones/virtualNetworkLinks/write**
- **Microsoft.Network/privateDnsZones/write**
- **Microsoft.Network/publicIPAddresses/delete**
- **Microsoft.Network/publicIPAddresses/join/action**
- **Microsoft.Network/publicIPAddresses/read**
- **Microsoft.Network/publicIPAddresses/write**
- **Microsoft.Network/virtualNetworks/join/action**
- **Microsoft.Network/virtualNetworks/read**
- **Microsoft.Network/virtualNetworks/subnets/join/action**
- **Microsoft.Network/virtualNetworks/subnets/read**
- **Microsoft.Network/virtualNetworks/subnets/write**
- **Microsoft.Network/virtualNetworks/write**

Example 5.40. Required permissions for checking the health of resources

- **Microsoft.Resourcehealth/healthevent/Activated/action**
- **Microsoft.Resourcehealth/healthevent/InProgress/action**
- **Microsoft.Resourcehealth/healthevent/Pending/action**

- **Microsoft.Resourcehealth/healthevent/Resolved/action**
- **Microsoft.Resourcehealth/healthevent/Updated/action**

Example 5.41. Required permissions for creating a resource group

- **Microsoft.Resources/subscriptions/resourceGroups/read**
- **Microsoft.Resources/subscriptions/resourcegroups/write**

Example 5.42. Required permissions for creating resource tags

- **Microsoft.Resources/tags/write**

Example 5.43. Required permissions for creating storage resources

- **Microsoft.Storage/storageAccounts/blobServices/read**
- **Microsoft.Storage/storageAccounts/blobServices/containers/write**
- **Microsoft.Storage/storageAccounts/fileServices/read**
- **Microsoft.Storage/storageAccounts/fileServices/shares/read**
- **Microsoft.Storage/storageAccounts/fileServices/shares/write**
- **Microsoft.Storage/storageAccounts/fileServices/shares/delete**
- **Microsoft.Storage/storageAccounts/listKeys/action**
- **Microsoft.Storage/storageAccounts/read**
- **Microsoft.Storage/storageAccounts/write**

Example 5.44. Required permissions for creating deployments

- **Microsoft.Resources/deployments/read**
- **Microsoft.Resources/deployments/write**
- **Microsoft.Resources/deployments/validate/action**
- **Microsoft.Resources/deployments/operationstatuses/read**

Example 5.45. Optional permissions for creating compute resources

- **Microsoft.Compute/availabilitySets/delete**
- **Microsoft.Compute/availabilitySets/write**

Example 5.46. Optional permissions for creating marketplace virtual machine resources

- **Microsoft.MarketplaceOrdering/offertypes/publishers/offers/plans/agreements/read**
- **Microsoft.MarketplaceOrdering/offertypes/publishers/offers/plans/agreements/write**

Example 5.47. Optional permissions for enabling user-managed encryption

- **Microsoft.Compute/diskEncryptionSets/read**
- **Microsoft.Compute/diskEncryptionSets/write**
- **Microsoft.Compute/diskEncryptionSets/delete**
- **Microsoft.KeyVault/vaults/read**
- **Microsoft.KeyVault/vaults/write**
- **Microsoft.KeyVault/vaults/delete**
- **Microsoft.KeyVault/vaults/deploy/action**
- **Microsoft.KeyVault/vaults/keys/read**
- **Microsoft.KeyVault/vaults/keys/write**
- **Microsoft.Features/providers/features/register/action**

The following permissions are required for deleting an OpenShift Container Platform cluster on Microsoft Azure.

Example 5.48. Required permissions for deleting authorization resources

- **Microsoft.Authorization/roleAssignments/delete**

Example 5.49. Required permissions for deleting compute resources

- **Microsoft.Compute/disks/delete**
- **Microsoft.Compute/galleries/delete**
- **Microsoft.Compute/galleries/images/delete**
- **Microsoft.Compute/galleries/images/versions/delete**
- **Microsoft.Compute/virtualMachines/delete**
- **Microsoft.Compute/images/delete**

Example 5.50. Required permissions for deleting identity management resources

- **Microsoft.ManagedIdentity/userAssignedIdentities/delete**

Example 5.51. Required permissions for deleting network resources

- **Microsoft.Network/dnszones/read**
- **Microsoft.Network/dnsZones/A/read**
- **Microsoft.Network/dnsZones/A/delete**
- **Microsoft.Network/dnsZones/CNAME/read**
- **Microsoft.Network/dnsZones/CNAME/delete**
- **Microsoft.Network/loadBalancers/delete**
- **Microsoft.Network/networkInterfaces/delete**
- **Microsoft.Network/networkSecurityGroups/delete**
- **Microsoft.Network/privateDnsZones/read**
- **Microsoft.Network/privateDnsZones/A/read**
- **Microsoft.Network/privateDnsZones/delete**
- **Microsoft.Network/privateDnsZones/virtualNetworkLinks/delete**
- **Microsoft.Network/publicIPAddresses/delete**
- **Microsoft.Network/virtualNetworks/delete**

Example 5.52. Required permissions for checking the health of resources

- **Microsoft.Resourcehealth/healthevent/Activated/action**
- **Microsoft.Resourcehealth/healthevent/Resolved/action**
- **Microsoft.Resourcehealth/healthevent/Updated/action**

Example 5.53. Required permissions for deleting a resource group

- **Microsoft.Resources/subscriptions/resourcegroups/delete**

Example 5.54. Required permissions for deleting storage resources

- **Microsoft.Storage/storageAccounts/delete**
- **Microsoft.Storage/storageAccounts/listKeys/action**

## NOTE

To install OpenShift Container Platform on Azure, you must scope the permissions related to resource group creation to your subscription. After the resource group is created, you can scope the rest of the permissions to the created resource group. If the public DNS zone is present in a different resource group, then the network DNS zone related permissions must always be applied to your subscription.

You can scope all the permissions to your subscription when deleting an OpenShift Container Platform cluster.

### 5.10.2.7. Creating a service principal

Because OpenShift Container Platform and its installation program create Microsoft Azure resources by using the Azure Resource Manager, you must create a service principal to represent it.

#### Prerequisites

- Install or update the [Azure CLI](#).
- Your Azure account has the required roles for the subscription that you use.
- If you want to use a custom role, you have created a [custom role](#) with the required permissions listed in the *Required Azure permissions for user-provisioned infrastructure* section.

#### Procedure

1. Log in to the Azure CLI:

```
$ az login
```

2. If your Azure account uses subscriptions, ensure that you are using the right subscription:
  - a. View the list of available accounts and record the **tenantId** value for the subscription you want to use for your cluster:

```
$ az account list --refresh
```

#### Example output

```
[
 {
 "cloudName": "AzureCloud",
 "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
 "isDefault": true,
 "name": "Subscription Name",
 "state": "Enabled",
 "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee",
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
 }
]
```

- b. View your active account details and confirm that the **tenantId** value matches the subscription you want to use:

```
$ az account show
```

#### Example output

```
{
 "environmentName": "AzureCloud",
 "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
 "isDefault": true,
 "name": "Subscription Name",
 "state": "Enabled",
 "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee", 1
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
}
```

- 1 Ensure that the value of the **tenantId** parameter is the correct subscription ID.

- c. If you are not using the right subscription, change the active subscription:

```
$ az account set -s <subscription_id> 1
```

- 1 Specify the subscription ID.

- d. Verify the subscription ID update:

```
$ az account show
```

#### Example output

```
{
 "environmentName": "AzureCloud",
 "id": "33212d16-bdf6-45cb-b038-f6565b61edda",
 "isDefault": true,
 "name": "Subscription Name",
 "state": "Enabled",
 "tenantId": "8049c7e9-c3de-762d-a54e-dc3f6be6a7ee",
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
}
```

3. Record the **tenantId** and **id** parameter values from the output. You need these values during the OpenShift Container Platform installation.
4. Create the service principal for your account:

```
$ az ad sp create-for-rbac --role <role_name> \ ❶
--name <service_principal> \ ❷
--scopes /subscriptions/<subscription_id> ❸
```

- ❶ Defines the role name. You can use the **Contributor** role, or you can specify a custom role which contains the necessary permissions.
- ❷ Defines the service principal name.
- ❸ Specifies the subscription ID.

### Example output

```
Creating 'Contributor' role assignment under scope '/subscriptions/<subscription_id>'
The output includes credentials that you must protect. Be sure that you do not
include these credentials in your code or check the credentials into your source
control. For more information, see https://aka.ms/azadsp-cli
{
 "appId": "ac461d78-bf4b-4387-ad16-7e32e328aec6",
 "displayName": <service_principal>,
 "password": "00000000-0000-0000-0000-000000000000",
 "tenantId": "8049c7e9-c3de-762d-a54e-dc3f6be6a7ee"
}
```

5. Record the values of the **appId** and **password** parameters from the previous output. You need these values during OpenShift Container Platform installation.
6. If you applied the **Contributor** role to your service principal, assign the **User Administrator Access** role by running the following command:

```
$ az role assignment create --role "User Access Administrator" \
--assignee-object-id $(az ad sp show --id <appId> --query id -o tsv) ❶
```

- ❶ Specify the **appId** parameter value for your service principal.

### Additional resources

- For more information about CCO modes, see [About the Cloud Credential Operator](#).

#### 5.10.2.8. Supported Azure regions

The installation program dynamically generates the list of available Microsoft Azure regions based on your subscription.

#### Supported Azure public regions

- **australiacentral** (Australia Central)
- **australiaeast** (Australia East)
- **australiasoutheast** (Australia South East)
- **brazilsouth** (Brazil South)

- **canadacentral** (Canada Central)
- **canadaeast** (Canada East)
- **centralindia** (Central India)
- **centralus** (Central US)
- **eastasia** (East Asia)
- **eastus** (East US)
- **eastus2** (East US 2)
- **francecentral** (France Central)
- **germanywestcentral** (Germany West Central)
- **israelcentral** (Israel Central)
- **italynorth** (Italy North)
- **japaneast** (Japan East)
- **japanwest** (Japan West)
- **koreacentral** (Korea Central)
- **koreasouth** (Korea South)
- **mexicocentral** (Mexico Central)
- **northcentralus** (North Central US)
- **northeurope** (North Europe)
- **norwayeast** (Norway East)
- **polandcentral** (Poland Central)
- **qatarcentral** (Qatar Central)
- **southafricanorth** (South Africa North)
- **southcentralus** (South Central US)
- **southeastasia** (Southeast Asia)
- **southindia** (South India)
- **spaincentral** (Spain Central)
- **swedencentral** (Sweden Central)
- **switzerlandnorth** (Switzerland North)
- **uaenorth** (UAE North)

- **uksouth** (UK South)
- **ukwest** (UK West)
- **westcentralus** (West Central US)
- **westeurope** (West Europe)
- **westindia** (West India)
- **westus** (West US)
- **westus2** (West US 2)
- **westus3** (West US 3)

### Supported Azure Government regions

Support for the following Microsoft Azure Government (MAG) regions was added in OpenShift Container Platform version 4.6:

- **usgovtexas** (US Gov Texas)
- **usgovvirginia** (US Gov Virginia)

You can reference all available MAG regions in the [Azure documentation](#). Other provided MAG regions are expected to work with OpenShift Container Platform, but have not been tested.

## 5.10.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

### 5.10.3.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 5.22. Minimum required hosts**

| Hosts                                                                   | Description                                                                                                                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine                                         | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines                                            | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.                                                                                                             |

## IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

### 5.10.3.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 5.23. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

## IMPORTANT

You are required to use Azure virtual machines that have the **premiumIO** parameter set to **true**.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### 5.10.3.3. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

#### Example 5.55. Machine types based on 64-bit x86 architecture

- **c4.\***
- **c5.\***
- **c5a.\***
- **i3.\***
- **m4.\***
- **m5.\***
- **m5a.\***
- **m6a.\***
- **m6i.\***
- **r4.\***
- **r5.\***
- **r5a.\***
- **r6i.\***

- **t3.\***
- **t3a.\***

#### 5.10.3.4. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

##### Example 5.56. Machine types based on 64-bit ARM architecture

- **c6g.\***
- **c7g.\***
- **m6g.\***
- **m7g.\***
- **r8g.\***

#### 5.10.4. Using the Azure Marketplace offering

Using the Azure Marketplace offering lets you deploy an OpenShift Container Platform cluster, which is billed on pay-per-use basis (hourly, per core) through Azure, while still being supported directly by Red Hat.

To deploy an OpenShift Container Platform cluster using the Azure Marketplace offering, you must first obtain the Azure Marketplace image. The installation program uses this image to deploy worker nodes. When obtaining your image, consider the following:

- While the images are the same, the Azure Marketplace publisher is different depending on your region. If you are located in North America, specify **redhat** as the publisher. If you are located in EMEA, specify **redhat-limited** as the publisher.
- The offer includes a **rh-ocp-worker** SKU and a **rh-ocp-worker-gen1** SKU. The **rh-ocp-worker** SKU represents a Hyper-V generation version 2 VM image. The default instance types used in OpenShift Container Platform are version 2 compatible. If you plan to use an instance type that is only version 1 compatible, use the image associated with the **rh-ocp-worker-gen1** SKU. The **rh-ocp-worker-gen1** SKU represents a Hyper-V version 1 VM image.

#### IMPORTANT

Installing images with the Azure marketplace is not supported on clusters with 64-bit ARM instances.

#### Prerequisites

- You have installed the Azure CLI client (**az**).
- Your Azure account is entitled for the offer and you have logged into this account with the Azure CLI client.

## Procedure

1. Display all of the available OpenShift Container Platform images by running one of the following commands:

- North America:

```
$ az vm image list --all --offer rh-ocp-worker --publisher redhat -o table
```

### Example output

| Offer              | Publisher | Skus               | Urn                                                       | Version           |
|--------------------|-----------|--------------------|-----------------------------------------------------------|-------------------|
| rh-ocp-worker      | RedHat    | rh-ocp-worker      | RedHat:rh-ocp-worker:rh-ocp-worker:413.92.2023101700      | 413.92.2023101700 |
| rh-ocp-worker-gen1 | RedHat    | rh-ocp-worker-gen1 | RedHat:rh-ocp-worker:rh-ocp-worker-gen1:413.92.2023101700 | 413.92.2023101700 |

- EMEA:

```
$ az vm image list --all --offer rh-ocp-worker --publisher redhat-limited -o table
```

### Example output

| Offer              | Publisher      | Skus               | Urn                                                               | Version           |
|--------------------|----------------|--------------------|-------------------------------------------------------------------|-------------------|
| rh-ocp-worker      | redhat-limited | rh-ocp-worker      | redhat-limited:rh-ocp-worker:rh-ocp-worker:413.92.2023101700      | 413.92.2023101700 |
| rh-ocp-worker-gen1 | redhat-limited | rh-ocp-worker-gen1 | redhat-limited:rh-ocp-worker:rh-ocp-worker-gen1:413.92.2023101700 | 413.92.2023101700 |

### NOTE

Regardless of the version of OpenShift Container Platform that you install, the correct version of the Azure Marketplace image to use is 4.13. If required, your VMs are automatically upgraded as part of the installation process.

2. Inspect the image for your offer by running one of the following commands:

- North America:

```
$ az vm image show --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
```

- EMEA:

```
$ az vm image show --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
```

3. Review the terms of the offer by running one of the following commands:

- North America:

```
$ az vm image terms show --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
```

- EMEA:

```
$ az vm image terms show --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
```

4. Accept the terms of the offering by running one of the following commands:

- North America:

```
$ az vm image terms accept --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
```

- EMEA:

```
$ az vm image terms accept --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
```

5. Record the image details of your offer. If you use the Azure Resource Manager (ARM) template to deploy your worker nodes:

- Update **storageProfile.imageReference** by deleting the **id** parameter and adding the **offer**, **publisher**, **sku**, and **version** parameters by using the values from your offer.
- Specify a **plan** for the virtual machines (VMs).

**Example 06\_workers.json ARM template with an updated storageProfile.imageReference object and a specified plan**

```
...
 "plan" : {
 "name": "rh-ocp-worker",
 "product": "rh-ocp-worker",
 "publisher": "redhat"
 },
 "dependsOn" : [
 "[concat('Microsoft.Network/networkInterfaces/', concat(variables('vmNames')
[copyIndex()], '-nic'))]"
],
 "properties" : {
 ...
 "storageProfile": {
 "imageReference": {
 "offer": "rh-ocp-worker",
 "publisher": "redhat",
 "sku": "rh-ocp-worker",
 "version": "413.92.2023101700"
 }
 }
 ...
 }
 ...
}
```

#### 5.10.4.1. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

## Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

## Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 5.10.4.2. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **`./openshift-install gather`** command.

### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

### 5.10.5. Creating the installation files for Azure

To install OpenShift Container Platform on Microsoft Azure using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the **install-config.yaml** file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate **var** partition during the preparation phases of installation.

#### 5.10.5.1. Optional: Creating a separate **/var** partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

## IMPORTANT

If you follow the steps to create a separate **/var** partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

## Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
```

## Example output

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and
$HOME/clusterconfig/openshift
```

3. Optional: Confirm that the installation program created manifests in the **clusterconfig/openshift** directory:

```
$ ls $HOME/clusterconfig/openshift/
```

## Example output

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

4. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example

places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
 labels:
 machineconfiguration.openshift.io/role: worker
 name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> ❶
 partitions:
 - label: var
 start_mib: <partition_start_offset> ❷
 size_mib: <partition_size> ❸
 number: 5
 filesystems:
 - device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] ❹
 with_mount_unit: true
```

- ❶ The storage device name of the disk that you want to partition.
- ❷ When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ❸ The size of the data partition in mebibytes.
- ❹ The **prjquota** mount option must be enabled for filesystems used for container storage.

#### NOTE

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

6. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 5.10.5.2. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the **imageContentSources** values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.
- You have retrieved a Red Hat Enterprise Linux CoreOS (RHCOS) image and uploaded it to an accessible location.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

#### Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the **~/.azure/** directory and delete the **osServicePrincipal.json** configuration file.  
Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.
2. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **azure** as the platform to target.  
If the installation program cannot locate the **osServicePrincipal.json** configuration file from a previous installation, you are prompted for Azure subscription and authentication values.
- iii. Enter the following Azure parameter values for your subscription:
  - **azure subscription id** Enter the subscription ID to use for the cluster.
  - **azure tenant id** Enter the tenant ID.
- iv. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client id**
  - If you are using a service principal, enter its application ID.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, specify its client ID.
- v. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**
  - If you are using a service principal, enter its password.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, leave this value blank.

- 

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

- 1 Replace **<vnet\_resource\_group>** with the resource group name that contains the existing virtual network (VNet).
- 2 Replace **<vnet>** with the existing virtual network name.
- 3 Replace **<control\_plane\_subnet>** with the existing subnet name to deploy the control plane machines.

- 4** Replace `<compute_subnet>` with the existing subnet name to deploy compute machines.

- d. Add the image content resources, which resemble the following YAML excerpt:

```
imageContentSources:
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
 source: quay.io/openshift-release-dev/ocp-release
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
 source: registry.redhat.io/ocp/release
```

For these values, use the **imageContentSources** that you recorded during mirror registry creation.

- e. Optional: Set the publishing strategy to **Internal**:

```
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

#### IMPORTANT

Azure Firewall [does not work seamlessly](#) with Azure Public Load balancers. Thus, when using Azure Firewall for restricting internet access, the **publish** field in **install-config.yaml** should be set to **Internal**.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

#### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

If previously not detected, the installation program creates an **osServicePrincipal.json** configuration file and stores this file in the `~/.azure/` directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

#### 5.10.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

- Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 5.10.5.4. Exporting common variables for ARM templates

You must export a common set of variables that are used with the provided Azure Resource Manager (ARM) templates used to assist in completing a user-provided infrastructure install on Microsoft Azure.

**NOTE**

Specific ARM templates can also require additional exported variables, which are detailed in their related procedures.

### Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Export common variables found in the **install-config.yaml** to be used by the provided ARM templates:

```
$ export CLUSTER_NAME=<cluster_name> 1
$ export AZURE_REGION=<azure_region> 2
$ export SSH_KEY=<ssh_key> 3
$ export BASE_DOMAIN=<base_domain> 4
$ export BASE_DOMAIN_RESOURCE_GROUP=<base_domain_resource_group> 5
```

- 1 The value of the **.metadata.name** attribute from the **install-config.yaml** file.
- 2 The region to deploy the cluster into, for example **centralus**. This is the value of the **.platform.azure.region** attribute from the **install-config.yaml** file.

- 3 The SSH RSA public key file as a string. You must enclose the SSH key in quotes since it contains spaces. This is the value of the **.sshKey** attribute from the **install-config.yaml**
- 4 The base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster. This is the value of the **.baseDomain** attribute from the **install-config.yaml** file.
- 5 The resource group where the public DNS zone exists. This is the value of the **.platform.azure.baseDomainResourceGroupName** attribute from the **install-config.yaml** file.

For example:

```
$ export CLUSTER_NAME=test-cluster
$ export AZURE_REGION=centralus
$ export SSH_KEY="ssh-rsa xxx/xxx/xxx= user@email.com"
$ export BASE_DOMAIN=example.com
$ export BASE_DOMAIN_RESOURCE_GROUP=ocp-cluster
```

2. Export the kubeadmin credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

#### 5.10.5.5. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

#### IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrap** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

#### Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

## Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

### IMPORTANT

If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

5. Check that the **mastersSchedulable** parameter in the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
  - a. Open the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** file.
  - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
6. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the **<installation\_directory>/manifests/cluster-dns-02-config.yml** DNS configuration file:

```

apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
 privateZone: ❶
 id: mycluster-100419-private-zone
 publicZone: ❷
 id: example.openshift.com
status: {}

```

- ❶ ❷ Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

7. When configuring Azure on user-provisioned infrastructure, you must export some common variables defined in the manifest files to use later in the Azure Resource Manager (ARM) templates:

- a. Export the infrastructure ID by using the following command:

```
$ export INFRA_ID=<infra_id> ❶
```

- ❶ The OpenShift Container Platform cluster has been assigned an identifier (**INFRA\_ID**) in the form of **<cluster\_name>-<random\_string>**. This will be used as the base name for most resources created using the provided ARM templates. This is the value of the **.status.infrastructureName** attribute from the **manifests/cluster-infrastructure-02-config.yml** file.

- b. Export the resource group by using the following command:

```
$ export RESOURCE_GROUP=<resource_group> ❶
```

- ❶ All resources created in this Azure deployment exists as part of a [resource group](#). The resource group name is also based on the **INFRA\_ID**, in the form of **<cluster\_name>-<random\_string>-rg**. This is the value of the **.status.platformStatus.azure.resourceGroupName** attribute from the **manifests/cluster-infrastructure-02-config.yml** file.

8. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> ❶
```

- ❶ For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

### 5.10.6. Creating the Azure resource group

You must create a Microsoft Azure [resource group](#) and an identity for that resource group. These are both used during the installation of your OpenShift Container Platform cluster on Azure.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

#### Procedure

1. Create the resource group in a supported Azure region:

```
$ az group create --name ${RESOURCE_GROUP} --location ${AZURE_REGION}
```

2. Create an Azure identity for the resource group:

```
$ az identity create -g ${RESOURCE_GROUP} -n ${INFRA_ID}-identity
```

This is used to grant the required access to Operators in your cluster. For example, this allows the Ingress Operator to create a public IP and its load balancer. You must assign the Azure identity to a role.

3. Grant the Contributor role to the Azure identity:

- a. Export the following variables required by the Azure role assignment:

```
$ export PRINCIPAL_ID=`az identity show -g ${RESOURCE_GROUP} -n ${INFRA_ID}-identity --query principalId --out tsv`
```

```
$ export RESOURCE_GROUP_ID=`az group show -g ${RESOURCE_GROUP} --query id --out tsv`
```

- b. Assign the Contributor role to the identity:

```
$ az role assignment create --assignee "${PRINCIPAL_ID}" --role 'Contributor' --scope "${RESOURCE_GROUP_ID}"
```

**NOTE**

If you want to assign a custom role with all the required permissions to the identity, run the following command:

```
$ az role assignment create --assignee "${PRINCIPAL_ID}" --role
<custom_role> \ 1
--scope "${RESOURCE_GROUP_ID}"
```

**1**

Specifies the custom role name.

### 5.10.7. Uploading the RHCOS cluster image and bootstrap Ignition config file

The Azure client does not support deployments based on files existing locally. You must copy and store the RHCOS virtual hard disk (VHD) cluster image and bootstrap Ignition config file in a storage container so they are accessible during deployment.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

#### Procedure

1. Create an Azure storage account to store the VHD cluster image:

```
$ az storage account create -g ${RESOURCE_GROUP} --location ${AZURE_REGION} --
name ${CLUSTER_NAME}sa --kind Storage --sku Standard_LRS
```

**WARNING**

The Azure storage account name must be between 3 and 24 characters in length and use numbers and lower-case letters only. If your **CLUSTER\_NAME** variable does not follow these restrictions, you must manually define the Azure storage account name. For more information on Azure storage account name restrictions, see [Resolve errors for storage account names](#) in the Azure documentation.

2. Export the storage account key as an environment variable:

```
$ export ACCOUNT_KEY=`az storage account keys list -g ${RESOURCE_GROUP} --
account-name ${CLUSTER_NAME}sa --query "[0].value" -o tsv`
```

3. Export the URL of the RHCOS VHD to an environment variable:

```
$ export VHD_URL=`openshift-install coreos print-stream-json | jq -r '.architectures.
<architecture>."rhel-coreos-extensions"."azure-disk".url`
```

where:

### <architecture>

Specifies the architecture, valid values include **x86\_64** or **aarch64**.

### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must specify an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

4. Create the storage container for the VHD:

```
$ az storage container create --name vhd --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY}
```

5. Copy the local VHD to a blob:

```
$ az storage blob copy start --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} --destination-blob "rhcos.vhd" --destination-container vhd --source-uri "${VHD_URL}"
```

6. Create a blob storage container and upload the generated **bootstrap.ign** file:

```
$ az storage container create --name files --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY}
```

```
$ az storage blob upload --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} -c "files" -f "<installation_directory>/bootstrap.ign" -n "bootstrap.ign"
```

## 5.10.8. Example for creating DNS zones

DNS records are required for clusters that use user-provisioned infrastructure. You should choose the DNS strategy that fits your scenario.

For this example, [Azure's DNS solution](#) is used, so you will create a new public DNS zone for external (internet) visibility and a private DNS zone for internal cluster resolution.

### NOTE

The public DNS zone is not required to exist in the same resource group as the cluster deployment and might already exist in your organization for the desired base domain. If that is the case, you can skip creating the public DNS zone; be sure the installation config you generated earlier reflects that scenario.

### Prerequisites

- Configure an Azure account.

- Generate the Ignition config files for your cluster.

## Procedure

1. Create the new public DNS zone in the resource group exported in the **BASE\_DOMAIN\_RESOURCE\_GROUP** environment variable:

```
$ az network dns zone create -g ${BASE_DOMAIN_RESOURCE_GROUP} -n
${CLUSTER_NAME}.${BASE_DOMAIN}
```

You can skip this step if you are using a public DNS zone that already exists.

2. Create the private DNS zone in the same resource group as the rest of this deployment:

```
$ az network private-dns zone create -g ${RESOURCE_GROUP} -n
${CLUSTER_NAME}.${BASE_DOMAIN}
```

You can learn more about [configuring a public DNS zone in Azure](#) by visiting that section.

## 5.10.9. Creating a VNet in Azure

You must create a virtual network (VNet) in Microsoft Azure for your OpenShift Container Platform cluster to use. You can customize the VNet to meet your requirements. One way to create the VNet is to modify the provided Azure Resource Manager (ARM) template.

### NOTE

If you do not use the provided ARM template to create your Azure infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

## Procedure

1. Copy the template from the **ARM template for the VNet** section of this topic and save it as **01\_vnet.json** in your cluster's installation directory. This template describes the VNet that your cluster requires.
2. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/01_vnet.json" \
 --parameters baseName="${INFRA_ID}" 1
```

- 1** The base name to be used in resource names; this is usually the cluster's infrastructure ID.

3. Link the VNet template to the private DNS zone:

```
$ az network private-dns link vnet create -g ${RESOURCE_GROUP} -z
${CLUSTER_NAME}.${BASE_DOMAIN} -n ${INFRA_ID}-network-link -v "${INFRA_ID}-vnet"
-e false
```

### 5.10.9.1. ARM template for the VNet

You can use the following Azure Resource Manager (ARM) template to deploy the VNet that you need for your OpenShift Container Platform cluster:

#### Example 5.57. 01\_vnet.json ARM template

```
{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 }
 },
 "variables" : {
 "location" : "[resourceGroup().location]",
 "virtualNetworkName" : "[concat(parameters('baseName'), '-vnet')]",
 "addressPrefix" : "10.0.0.0/16",
 "masterSubnetName" : "[concat(parameters('baseName'), '-master-subnet')]",
 "masterSubnetPrefix" : "10.0.0.0/24",
 "nodeSubnetName" : "[concat(parameters('baseName'), '-worker-subnet')]",
 "nodeSubnetPrefix" : "10.0.1.0/24",
 "clusterNsgName" : "[concat(parameters('baseName'), '-nsg')]"
 },
 "resources" : [
 {
 "apiVersion" : "2018-12-01",
 "type" : "Microsoft.Network/virtualNetworks",
 "name" : "[variables('virtualNetworkName')]",
 "location" : "[variables('location')]",
 "dependsOn" : [
 "[concat('Microsoft.Network/networkSecurityGroups/', variables('clusterNsgName'))]"
],
 "properties" : {
 "addressSpace" : {
 "addressPrefixes" : [
 "[variables('addressPrefix')]"
]
 },
 "subnets" : [
 {
 "name" : "[variables('masterSubnetName')]",
 "properties" : {
 "addressPrefix" : "[variables('masterSubnetPrefix')]",
 "serviceEndpoints": [],
```

```

 "networkSecurityGroup" : {
 "id" : "[resourceId('Microsoft.Network/networkSecurityGroups',
variables('clusterNsgName'))]"
 }
 },
 {
 "name" : "[variables('nodeSubnetName')]",
 "properties" : {
 "addressPrefix" : "[variables('nodeSubnetPrefix')]",
 "serviceEndpoints" : [],
 "networkSecurityGroup" : {
 "id" : "[resourceId('Microsoft.Network/networkSecurityGroups',
variables('clusterNsgName'))]"
 }
 }
 }
]
 },
 {
 "type" : "Microsoft.Network/networkSecurityGroups",
 "name" : "[variables('clusterNsgName')]",
 "apiVersion" : "2018-10-01",
 "location" : "[variables('location')]",
 "properties" : {
 "securityRules" : [
 {
 "name" : "apiserver_in",
 "properties" : {
 "protocol" : "Tcp",
 "sourcePortRange" : "*",
 "destinationPortRange" : "6443",
 "sourceAddressPrefix" : "*",
 "destinationAddressPrefix" : "*",
 "access" : "Allow",
 "priority" : 101,
 "direction" : "Inbound"
 }
 }
]
 }
 }
]
}

```

#### 5.10.10. Deploying the RHCOS cluster image for the Azure infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Microsoft Azure for your OpenShift Container Platform nodes.

##### Prerequisites

- Configure an Azure account.

- Generate the Ignition config files for your cluster.
- Store the RHCOS virtual hard disk (VHD) cluster image in an Azure storage container.
- Store the bootstrap Ignition config file in an Azure storage container.

## Procedure

1. Copy the template from the **ARM template for image storage** section of this topic and save it as **02\_storage.json** in your cluster's installation directory. This template describes the image storage that your cluster requires.
2. Export the RHCOS VHD blob URL as a variable:

```
$ export VHD_BLOB_URL=`az storage blob url --account-name ${CLUSTER_NAME}sa --
account-key ${ACCOUNT_KEY} -c vhd -n "rhcos.vhd" -o tsv`
```

3. Deploy the cluster image:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
--template-file "<installation_directory>/02_storage.json" \
--parameters vhdBlobURL="${VHD_BLOB_URL}" \ ❶
--parameters baseName="${INFRA_ID}" \ ❷
--parameters storageAccount="${CLUSTER_NAME}sa" \ ❸
--parameters architecture="<architecture>" ❹
```

- ❶ The blob URL of the RHCOS VHD to be used to create master and worker machines.
- ❷ The base name to be used in resource names; this is usually the cluster's infrastructure ID.
- ❸ The name of your Azure storage account.
- ❹ Specify the system architecture. Valid values are **x64** (default) or **Arm64**.

### 5.10.10.1. ARM template for image storage

You can use the following Azure Resource Manager (ARM) template to deploy the stored Red Hat Enterprise Linux CoreOS (RHCOS) image that you need for your OpenShift Container Platform cluster:

#### Example 5.58. 02\_storage.json ARM template

```
{
 "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
 "contentVersion": "1.0.0.0",
 "parameters": {
 "architecture": {
 "type": "string",
 "metadata": {
 "description": "The architecture of the Virtual Machines"
 },
 "defaultValue": "x64",
 "allowedValues": [
```

```

 "Arm64",
 "x64"
],
},
"baseName": {
 "type": "string",
 "minLength": 1,
 "metadata": {
 "description": "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
},
"storageAccount": {
 "type": "string",
 "metadata": {
 "description": "The Storage Account name"
 }
},
"vhdBlobURL": {
 "type": "string",
 "metadata": {
 "description": "URL pointing to the blob where the VHD to be used to create master and
worker machines is located"
 }
}
},
"variables": {
 "location": "[resourceGroup().location]",
 "galleryName": "[concat('gallery_', replace(parameters('baseName'), '-', '_'))]",
 "imageName": "[parameters('baseName')]",
 "imageNameGen2": "[concat(parameters('baseName'), '-gen2')]",
 "imageRelease": "1.0.0"
},
"resources": [
 {
 "apiVersion": "2021-10-01",
 "type": "Microsoft.Compute/galleries",
 "name": "[variables('galleryName')]",
 "location": "[variables('location')]",

 "id": "[resourceId('Microsoft.Storage/storageAccounts',
parameters('storageAccount'))]",
 "uri": "[parameters('vhdBlobURL')]"
 }
 }
 }
 }
 },
 {
 "apiVersion": "2021-10-01",
 "type": "images",
 "name": "[variables('imageNameGen2')]",
 "location": "[variables('location')]",
 "dependsOn": [
 "[variables('galleryName')]"
],
 "properties": {
 "architecture": "[parameters('architecture')]",
 "hyperVGeneration": "V2",
 "identifier": {
 "offer": "rhcos-gen2",
 "publisher": "RedHat-gen2",
 "sku": "gen2"
 },
 "osState": "Generalized",
 "osType": "Linux"
 }
 },
 {
 "apiVersion": "2021-10-01",

```

```

 "type": "versions",
 "name": "[variables('imageRelease')]",
 "location": "[variables('location')]",
 "dependsOn": [
 "[variables('imageNameGen2')]"
],
 "properties": {
 "publishingProfile": {
 "storageAccountType": "Standard_LRS",
 "targetRegions": [
 {
 "name": "[variables('location')]",
 "regionalReplicaCount": "1"
 }
]
 },
 "storageProfile": {
 "osDiskImage": {
 "source": {
 "id": "[resourceId('Microsoft.Storage/storageAccounts',
parameters('storageAccount'))]",
 "uri": "[parameters('vhdBlobURL')]"
 }
 }
 }
 }
 }
}
]
}
]
}
]
}
]
}
}

```

### 5.10.11. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

#### 5.10.11.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

#### IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 5.24. Ports used for all-machine to all-machine communications

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
|          | <b>10256</b>       | openshift-sdn                                                                                                                               |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

Table 5.25. Ports used for all-machine to control plane communications

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

Table 5.26. Ports used for control plane machine to control plane machine communications

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

## 5.10.12. Creating networking and load balancing components in Azure

You must configure networking and load balancing in Microsoft Azure for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Azure Resource Manager (ARM) template.

### NOTE

If you do not use the provided ARM template to create your Azure infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.

### Procedure

1. Copy the template from the **ARM template for the network and load balancers** section of this topic and save it as **03\_infra.json** in your cluster's installation directory. This template describes the networking and load balancing objects that your cluster requires.
2. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/03_infra.json" \
 --parameters privateDNSZoneName="${CLUSTER_NAME}.${BASE_DOMAIN}" \ 1
 --parameters baseName="${INFRA_ID}" 2
```

- 1** The name of the private DNS zone.
- 2** The base name to be used in resource names; this is usually the cluster's infrastructure ID.

3. Create an **api** DNS record in the public zone for the API public load balancer. The **\${BASE\_DOMAIN\_RESOURCE\_GROUP}** variable must point to the resource group where the public DNS zone exists.

- a. Export the following variable:

```
$ export PUBLIC_IP=`az network public-ip list -g ${RESOURCE_GROUP} --query "[?name=='${INFRA_ID}-master-pip'] | [0].ipAddress" -o tsv`
```

- b. Create the **api** DNS record in a new public zone:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -
z ${CLUSTER_NAME}.${BASE_DOMAIN} -n api -a ${PUBLIC_IP} --ttl 60
```

If you are adding the cluster to an existing public zone, you can create the **api** DNS record in it instead:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -
z ${BASE_DOMAIN} -n api.${CLUSTER_NAME} -a ${PUBLIC_IP} --ttl 60
```

### 5.10.12.1. ARM template for the network and load balancers

You can use the following Azure Resource Manager (ARM) template to deploy the networking objects and load balancers that you need for your OpenShift Container Platform cluster:

#### Example 5.59. 03\_infra.json ARM template

```
{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-
01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 },
 "vnetBaseName" : {
 "type" : "string",
 "defaultValue" : "",
 "metadata" : {
 "description" : "The specific customer vnet's base name (optional)"
 }
 },
 "privateDNSZoneName" : {
 "type" : "string",
 "metadata" : {
 "description" : "Name of the private DNS zone"
 }
 }
 },
 "variables" : {
 "location" : "[resourceGroup().location]",
 "virtualNetworkName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-vnet')]",
 "virtualNetworkID" : "[resourceId('Microsoft.Network/virtualNetworks',
variables('virtualNetworkName'))]",
 "masterSubnetName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-master-subnet')]",
 "masterSubnetRef" : "[concat(variables('virtualNetworkID'), '/subnets/',
variables('masterSubnetName'))]",
 "masterPublicIpAddressName" : "[concat(parameters('baseName'), '-master-pip')]",
 "masterPublicIpAddressID" : "[resourceId('Microsoft.Network/publicIPAddresses',
variables('masterPublicIpAddressName'))]",
 "masterLoadBalancerName" : "[parameters('baseName')]",
 "masterLoadBalancerID" : "[resourceId('Microsoft.Network/loadBalancers',
variables('masterLoadBalancerName'))]",
 "internalLoadBalancerName" : "[concat(parameters('baseName'), '-internal-lb')]",
 "internalLoadBalancerID" : "[resourceId('Microsoft.Network/loadBalancers',
variables('internalLoadBalancerName'))]",
```

```

 "skuName": "Standard"
 },
 "resources" : [
 {
 "apiVersion" : "2018-12-01",

```

### 5.10.13. Creating the bootstrap machine in Azure

You must create the bootstrap machine in Microsoft Azure to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Azure Resource Manager (ARM) template.

## NOTE

If you do not use the provided ARM template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.

## Procedure

1. Copy the template from the **ARM template for the bootstrap machine** section of this topic and save it as **04\_bootstrap.json** in your cluster's installation directory. This template describes the bootstrap machine that your cluster requires.

2. Export the bootstrap URL variable:

```
$ bootstrap_url_expiry=`date -u -d "10 hours" '+%Y-%m-%dT%H:%MZ'`
```

```
$ export BOOTSTRAP_URL=`az storage blob generate-sas -c 'files' -n 'bootstrap.ign' --https-only --full-uri --permissions r --expiry $bootstrap_url_expiry --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} -o tsv`
```

3. Export the bootstrap ignition variable:

```
$ export BOOTSTRAP_IGNITION=`jq -rcnM --arg v "3.2.0" --arg url ${BOOTSTRAP_URL} '{ignition:{version:$v,config:{replace:{source:$url}}}}' | base64 | tr -d '\n'`
```

4. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/04_bootstrap.json" \
 --parameters bootstrapIgnition="${BOOTSTRAP_IGNITION}" \
 --parameters baseName="${INFRA_ID}"
```

- 1 The bootstrap Ignition content for the bootstrap cluster.
- 2 The base name to be used in resource names; this is usually the cluster's infrastructure ID.

### 5.10.13.1. ARM template for the bootstrap machine

You can use the following Azure Resource Manager (ARM) template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

#### Example 5.60. 04\_bootstrap.json ARM template

```
{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 },
 "vnetBaseName": {
 "type": "string",
 "defaultValue": "",
 "metadata" : {
 "description" : "The specific customer vnet's base name (optional)"
 }
 },
 "bootstrapIgnition" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Bootstrap ignition content for the bootstrap cluster"
 }
 },
 "sshKeyData" : {
 "type" : "securestring",
 "defaultValue" : "Unused",
 "metadata" : {
 "description" : "Unused"
 }
 },
 "bootstrapVMSize" : {
 "type" : "string",
 "defaultValue" : "Standard_D4s_v3",
 "metadata" : {
 "description" : "The size of the Bootstrap Virtual Machine"
 }
 },
 "hyperVGen": {
 "type": "string",
 "metadata": {
 "description": "VM generation image to use"
 },
 "defaultValue": "V2",
 "allowedValues": [
 "V1",
 "V2"
]
 }
 }
}
```

```

]
 }
},
"variables" : {
 "location" : "[resourceGroup().location]",

 }
}
]
}

```

#### 5.10.14. Creating the control plane machines in Azure

You must create the control plane machines in Microsoft Azure for your cluster to use. One way to create these machines is to modify the provided Azure Resource Manager (ARM) template.

## NOTE

By default, Microsoft Azure places control plane machines and compute machines in a pre-set availability zone. You can manually set an availability zone for a compute node or control plane node. To do this, modify a vendor's Azure Resource Manager (ARM) template by specifying each of your availability zones in the **zones** parameter of the virtual machine resource.

If you do not use the provided ARM template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, consider contacting Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.
- Create the bootstrap machine.

## Procedure

1. Copy the template from the **ARM template for control plane machines** section of this topic and save it as **05\_masters.json** in your cluster's installation directory. This template describes the control plane machines that your cluster requires.
2. Export the following variable needed by the control plane machine deployment:

```
$ export MASTER_IGNITION=`cat <installation_directory>/master.ign | base64 | tr -d '\n'`
```

3. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/05_masters.json" \
 --parameters masterIgnition="${MASTER_IGNITION}" ❶
 --parameters baseName="${INFRA_ID}" ❷
```

- ❶ The Ignition content for the control plane nodes.
- ❷ The base name to be used in resource names; this is usually the cluster's infrastructure ID.

### 5.10.14.1. ARM template for control plane machines

You can use the following Azure Resource Manager (ARM) template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

#### Example 5.61. 05\_masters.json ARM template

–

```

{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 },
 "vnetBaseName": {
 "type": "string",
 "defaultValue": "",
 "metadata" : {
 "description" : "The specific customer vnet's base name (optional)"
 }
 },
 "masterIgnition" : {
 "type" : "string",
 "metadata" : {
 "description" : "Ignition content for the master nodes"
 }
 },
 "numberOfMasters" : {
 "type" : "int",
 "defaultValue" : 3,
 "minValue" : 2,
 "maxValue" : 30,
 "metadata" : {
 "description" : "Number of OpenShift masters to deploy"
 }
 },
 "sshKeyData" : {
 "type" : "securestring",
 "defaultValue" : "Unused",
 "metadata" : {
 "description" : "Unused"
 }
 },
 "privateDNSZoneName" : {
 "type" : "string",
 "defaultValue" : "",
 "metadata" : {
 "description" : "unused"
 }
 },
 "masterVMSize" : {
 "type" : "string",
 "defaultValue" : "Standard_D8s_v3",
 "metadata" : {
 "description" : "The size of the Master Virtual Machines"
 }
 },
 "diskSizeGB" : {

```

```

 "type" : "int",
 "defaultValue" : 1024,
 "metadata" : {
 "description" : "Size of the Master VM OS disk, in GB"
 }
 },
 "hyperVGen": {
 "type": "string",
 "metadata": {
 "description": "VM generation image to use"
 },
 "defaultValue": "V2",
 "allowedValues": [
 "V1",
 "V2"
]
 },
 "variables" : {
 "location" : "[resourceGroup().location]",
 "virtualNetworkName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-vnet')]",
 "virtualNetworkID" : "[resourceId('Microsoft.Network/virtualNetworks',
variables('virtualNetworkName'))]",
 "masterSubnetName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-master-subnet')]",
 "masterSubnetRef" : "[concat(variables('virtualNetworkID'), '/subnets/',
variables('masterSubnetName'))]",
 "masterLoadBalancerName" : "[parameters('baseName')]",
 "internalLoadBalancerName" : "[concat(parameters('baseName'), '-internal-lb')]",
 "sshKeyPath" : "/home/core/.ssh/authorized_keys",
 "identityName" : "[concat(parameters('baseName'), '-identity')]",
 "galleryName": "[concat('gallery_', replace(parameters('baseName'), '-', '_'))]",
 "imageName" : "[concat(parameters('baseName'), if(equals(parameters('hyperVGen'), 'V2'), '-
gen2', ''))]",
 "copy" : [
 {
 "name" : "vmNames",
 "count" : "[parameters('numberOfMasters')]",
 "input" : "[concat(parameters('baseName'), '-master-', copyIndex('vmNames'))]"
 }
]
 },
 "resources" : [
 {
 "apiVersion" : "2018-06-01",
 "type" : "Microsoft.Network/networkInterfaces",
 "copy" : {
 "name" : "nicCopy",

 {
 "id": "[resourceId('Microsoft.Network/networkInterfaces', concat(variables('vmNames')
[copyIndex()], '-nic'))]",
 "properties": {
 "primary": false
 }
 }
]
 }
 }
}
]
}

```

### 5.10.15. Wait for bootstrap completion and remove bootstrap resources in Azure

After you create all of the required infrastructure in Microsoft Azure, wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.
- Create the bootstrap machine.

- Create the control plane machines.

## Procedure

1. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install wait-for bootstrap-complete --dir <installation_directory> \ 1
--log-level info 2
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the command exits without a **FATAL** warning, your production control plane has initialized.

2. Delete the bootstrap resources:

```
$ az network nsg rule delete -g ${RESOURCE_GROUP} --nsg-name ${INFRA_ID}-nsg --
name bootstrap_ssh_in
$ az vm stop -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap
$ az vm deallocate -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap
$ az vm delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap --yes
$ az disk delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap_OSDisk --no-
wait --yes
$ az network nic delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap-nic --no-
wait
$ az storage blob delete --account-key ${ACCOUNT_KEY} --account-name
${CLUSTER_NAME}sa --container-name files --name bootstrap.ign
$ az network public-ip delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap-
ssh-pip
```

### NOTE

If you do not delete the bootstrap server, installation may not succeed due to API traffic being routed to the bootstrap server.

## 5.10.16. Creating additional worker machines in Azure

You can create worker machines in Microsoft Azure for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Azure Resource Manager (ARM) template. Additional instances can be launched by including additional resources of type **06\_workers.json** in the file.

## NOTE

By default, Microsoft Azure places control plane machines and compute machines in a pre-set availability zone. You can manually set an availability zone for a compute node or control plane node. To do this, modify a vendor's ARM template by specifying each of your availability zones in the **zones** parameter of the virtual machine resource.

If you do not use the provided ARM template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, consider contacting Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

## Procedure

1. Copy the template from the **ARM template for worker machines** section of this topic and save it as **06\_workers.json** in your cluster's installation directory. This template describes the worker machines that your cluster requires.
2. Export the following variable needed by the worker machine deployment:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign | base64 | tr -d '\n`
```

3. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/06_workers.json" \
 --parameters workerIgnition="${WORKER_IGNITION}" \ 1
 --parameters baseName="${INFRA_ID}" 2
```

- 1** The Ignition content for the worker nodes.
- 2** The base name to be used in resource names; this is usually the cluster's infrastructure ID.

### 5.10.16.1. ARM template for worker machines

You can use the following Azure Resource Manager (ARM) template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

## Example 5.62. 06\_workers.json ARM template

```

{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",

-

## Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

## Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

## Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

## Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 5.10.18. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

## Example output

```
system:admin
```

### 5.10.19. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

## Prerequisites

- You added machines to your cluster.

## Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

### Example output

| NAME     | STATUS | ROLES  | AGE | VERSION |
|----------|--------|--------|-----|---------|
| master-0 | Ready  | master | 63m | v1.27.3 |
| master-1 | Ready  | master | 63m | v1.27.3 |
| master-2 | Ready  | master | 64m | v1.27.3 |

The output lists all of the machines that you created.

### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

| NAME      | AGE | REQUESTOR                                                                     | CONDITION |
|-----------|-----|-------------------------------------------------------------------------------|-----------|
| csr-8b2br | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstraptrapper | Pending   |
| csr-8vnps | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstraptrapper | Pending   |
| ...       |     |                                                                               |           |

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

### NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

## NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrap** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

## NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

## 5.10.20. Adding the Ingress DNS records

If you removed the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the Ingress load balancer. You can create either a wildcard **\*.apps.{baseDomain}**, or specific records. You can use A, CNAME, and other records per your requirements.

### Prerequisites

- You deployed an OpenShift Container Platform cluster on Microsoft Azure by using infrastructure that you provisioned.
- Install the OpenShift CLI (**oc**).
- Install or update the [Azure CLI](#).

### Procedure

1. Confirm the Ingress router has created a load balancer and populated the **EXTERNAL-IP** field:

```
$ oc -n openshift-ingress get service router-default
```

### Example output

| NAME           | TYPE         | CLUSTER-IP   | EXTERNAL-IP    | PORT(S)                    | AGE |
|----------------|--------------|--------------|----------------|----------------------------|-----|
| router-default | LoadBalancer | 172.30.20.10 | 35.130.120.110 | 80:32288/TCP,443:31215/TCP | 20  |

2. Export the Ingress router IP as a variable:

```
$ export PUBLIC_IP_ROUTER=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
```

3. Add a **\*.apps** record to the public DNS zone.

- a. If you are adding this cluster to a new public zone, run:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps -a ${PUBLIC_IP_ROUTER} --ttl 300
```

- b. If you are adding this cluster to an already existing public zone, run:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${BASE_DOMAIN} -n *.apps.${CLUSTER_NAME} -a ${PUBLIC_IP_ROUTER} --ttl 300
```

4. Add a **\*.apps** record to the private DNS zone:

- a. Create a **\*.apps** record by using the following command:

```
$ az network private-dns record-set a create -g ${RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps --ttl 300
```

- b. Add the **\*.apps** record to the private DNS zone by using the following command:

```
$ az network private-dns record-set a add-record -g ${RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps -a ${PUBLIC_IP_ROUTER}
```

If you prefer to add explicit domains instead of using a wildcard, you can create entries for each of the cluster's current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}{"\n"}{end}{end}' routes
```

### Example output

```
oauth-openshift.apps.cluster.basedomain.com
console-openshift-console.apps.cluster.basedomain.com
downloads-openshift-console.apps.cluster.basedomain.com
alertmanager-main-openshift-monitoring.apps.cluster.basedomain.com
prometheus-k8s-openshift-monitoring.apps.cluster.basedomain.com
```

### 5.10.21. Completing an Azure installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Microsoft Azure user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

## Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned Azure infrastructure.
- Install the **oc** CLI and log in.

## Procedure

- Complete the cluster installation:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

## Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 5.10.22. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

## Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

## 5.11. INSTALLING A CLUSTER ON AZURE USING ARM TEMPLATES

In OpenShift Container Platform version 4.14, you can install a cluster on Microsoft Azure by using infrastructure that you provide.

Several [Azure Resource Manager](#) (ARM) templates are provided to assist in completing these steps or to help model your own.

### IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several ARM templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

#### 5.11.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure account](#) to host the cluster.
- You downloaded the Azure CLI and installed it on your computer. See [Install the Azure CLI](#) in the Azure documentation. The documentation below was last tested using version **2.38.0** of the Azure CLI. Azure CLI commands might perform differently based on the version you use.
- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the **kube-system** namespace, see [Alternatives to storing administrator-level secrets in the kube-system project](#).
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

### NOTE

Be sure to also review this site list if you are configuring a proxy.

#### 5.11.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

**5.11.3. Configuring your Azure project**

Before you can install OpenShift Container Platform, you must configure an Azure project to host it.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

**5.11.3.1. Azure account limits**

The OpenShift Container Platform cluster uses a number of Microsoft Azure components, and the default [Azure subscription and service limits, quotas, and constraints](#) affect your ability to install OpenShift Container Platform clusters.

**IMPORTANT**

Default limits vary by offer category types, such as Free Trial and Pay-As-You-Go, and by series, such as Dv2, F, and G. For example, the default for Enterprise Agreement subscriptions is 350 cores.

Check the limits for your subscription type and if necessary, increase quota limits for your account before you install a default cluster on Azure.

The following table summarizes the Azure components whose limits can impact your ability to install and run OpenShift Container Platform clusters.

| Component | Number of components required by default | Default Azure limit | Description |
|-----------|------------------------------------------|---------------------|-------------|
|-----------|------------------------------------------|---------------------|-------------|

| Component          | Number of components required by default | Default Azure limit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vCPU               | 40                                       | 20 per region       | <p>A default cluster requires 40 vCPUs, so you must increase the account limit.</p> <p>By default, each cluster creates the following instances:</p> <ul style="list-style-type: none"> <li>• One bootstrap machine, which is removed after installation</li> <li>• Three control plane machines</li> <li>• Three compute machines</li> </ul> <p>Because the bootstrap machine uses <b>Standard_D4s_v3</b> machines, which use 4 vCPUs, the control plane machines use <b>Standard_D8s_v3</b> virtual machines, which use 8 vCPUs, and the worker machines use <b>Standard_D4s_v3</b> virtual machines, which use 4 vCPUs, a default cluster requires 40 vCPUs. The bootstrap node VM, which uses 4 vCPUs, is used only during installation.</p> <p>To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, you must further increase the vCPU limit for your account to ensure that your cluster can deploy the machines that you require.</p> |
| OS Disk            | 7                                        |                     | <p>Each cluster machine must have a minimum of 100 GB of storage and 300 IOPS. While these are the minimum supported values, faster storage is recommended for production clusters and clusters with intensive workloads. For more information about optimizing storage for performance, see the page titled "Optimizing storage" in the "Scalability and performance" section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 5.11.3.2. Configuring a public DNS zone in Azure

To install OpenShift Container Platform, the Microsoft Azure account you use must have a dedicated public hosted DNS zone in your account. This zone must be authoritative for the domain. This service provides cluster DNS resolution and name lookup for external connections to the cluster.

#### Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through Azure or another source.

#### NOTE

For more information about purchasing domains through Azure, see [Buy a custom domain name for Azure App Service](#) in the Azure documentation.

2. If you are using an existing domain and registrar, migrate its DNS to Azure. See [Migrate an active DNS name to Azure App Service](#) in the Azure documentation.
3. Configure DNS for your domain. Follow the steps in the [Tutorial: Host your domain in Azure DNS](#) in the Azure documentation to create a public hosted zone for your domain or subdomain, extract the new authoritative name servers, and update the registrar records for the name servers that your domain uses.  
Use an appropriate root domain, such as **openshiftcorp.com**, or subdomain, such as **clusters.openshiftcorp.com**.
4. If you use a subdomain, follow your company's procedures to add its delegation records to the parent domain.

You can view Azure's DNS solution by visiting this [example for creating DNS zones](#).

### 5.11.3.3. Increasing Azure account limits

To increase an account limit, file a support request on the Azure portal.

**NOTE**

You can increase only one type of quota per support request.

**Procedure**

1. From the Azure portal, click **Help + support** in the lower left corner.
2. Click **New support request** and then select the required values:
  - a. From the **Issue type** list, select **Service and subscription limits (quotas)**
  - b. From the **Subscription** list, select the subscription to modify.
  - c. From the **Quota type** list, select the quota to increase. For example, select **Compute-VM (cores-vCPUs) subscription limit increases** to increase the number of vCPUs, which is required to install a cluster.
  - d. Click **Next: Solutions**.
3. On the **Problem Details** page, provide the required information for your quota increase:
  - a. Click **Provide details** and provide the required details in the **Quota details** window.
  - b. In the SUPPORT METHOD and CONTACT INFO sections, provide the issue severity and your contact details.
4. Click **Next: Review + create** and then click **Create**.

**5.11.3.4. Certificate signing requests management**

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

**5.11.3.5. Recording the subscription and tenant IDs**

The installation program requires the subscription and tenant IDs that are associated with your Azure account. You can use the Azure CLI to gather this information.

**Prerequisites**

- You have installed or updated the [Azure CLI](#).

**Procedure**

1. Log in to the Azure CLI by running the following command:

```
$ az login
```

2. Ensure that you are using the right subscription:

- a. View a list of available subscriptions by running the following command:

```
$ az account list --refresh
```

### Example output

```
[
 {
 "cloudName": "AzureCloud",
 "id": "8xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "isDefault": true,
 "name": "Subscription Name 1",
 "state": "Enabled",
 "tenantId": "6xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
 },
 {
 "cloudName": "AzureCloud",
 "id": "9xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "isDefault": false,
 "name": "Subscription Name 2",
 "state": "Enabled",
 "tenantId": "7xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "user": {
 "name": "you2@example.com",
 "type": "user"
 }
 }
]
```

- b. View the details of the active account, and confirm that this is the subscription you want to use, by running the following command:

```
$ az account show
```

### Example output

```
{
 "environmentName": "AzureCloud",
 "id": "8xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "isDefault": true,
 "name": "Subscription Name 1",
 "state": "Enabled",
 "tenantId": "6xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
}
```

3. If you are not using the right subscription:

- a. Change the active subscription by running the following command:

```
$ az account set -s <subscription_id>
```

- b. Verify that you are using the subscription you need by running the following command:

```
$ az account show
```

#### Example output

```
{
 "environmentName": "AzureCloud",
 "id": "9xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "isDefault": true,
 "name": "Subscription Name 2",
 "state": "Enabled",
 "tenantId": "7xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "user": {
 "name": "you2@example.com",
 "type": "user"
 }
}
```

4. Record the **id** and **tenantId** parameter values from the output. You require these values to install an OpenShift Container Platform cluster.

#### 5.11.3.6. Supported identities to access Azure resources

An OpenShift Container Platform cluster requires an Azure identity to create and manage Azure resources. As such, you need one of the following types of identities to complete the installation:

- A service principal
- A system-assigned managed identity
- A user-assigned managed identity

#### 5.11.3.7. Required Azure permissions for user-provisioned infrastructure

The installation program requires access to an Azure service principal or managed identity with the necessary permissions to deploy the cluster and to maintain its daily operation. These permissions must be granted to the Azure subscription that is associated with the identity.

The following options are available to you:

- You can assign the identity the **Contributor** and **User Access Administrator** roles. Assigning these roles is the quickest way to grant all of the required permissions. For more information about assigning roles, see the Azure documentation for [managing access to Azure resources using the Azure portal](#).
- If your organization's security policies require a more restrictive set of permissions, you can create a [custom role](#) with the necessary permissions.

The following permissions are required for creating an OpenShift Container Platform cluster on Microsoft Azure.

**Example 5.63. Required permissions for creating authorization resources**

- **Microsoft.Authorization/policies/audit/action**
- **Microsoft.Authorization/policies/auditIfNotExists/action**
- **Microsoft.Authorization/roleAssignments/read**
- **Microsoft.Authorization/roleAssignments/write**

**Example 5.64. Required permissions for creating compute resources**

- **Microsoft.Compute/images/read**
- **Microsoft.Compute/images/write**
- **Microsoft.Compute/images/delete**
- **Microsoft.Compute/availabilitySets/read**
- **Microsoft.Compute/disks/beginGetAccess/action**
- **Microsoft.Compute/disks/delete**
- **Microsoft.Compute/disks/read**
- **Microsoft.Compute/disks/write**
- **Microsoft.Compute/galleries/images/read**
- **Microsoft.Compute/galleries/images/versions/read**
- **Microsoft.Compute/galleries/images/versions/write**
- **Microsoft.Compute/galleries/images/write**
- **Microsoft.Compute/galleries/read**
- **Microsoft.Compute/galleries/write**
- **Microsoft.Compute/snapshots/read**
- **Microsoft.Compute/snapshots/write**
- **Microsoft.Compute/snapshots/delete**
- **Microsoft.Compute/virtualMachines/delete**
- **Microsoft.Compute/virtualMachines/powerOff/action**
- **Microsoft.Compute/virtualMachines/read**
- **Microsoft.Compute/virtualMachines/write**

- **Microsoft.Compute/virtualMachines/deallocate/action**

Example 5.65. Required permissions for creating identity management resources

- **Microsoft.ManagedIdentity/userAssignedIdentities/assign/action**
- **Microsoft.ManagedIdentity/userAssignedIdentities/read**
- **Microsoft.ManagedIdentity/userAssignedIdentities/write**

Example 5.66. Required permissions for creating network resources

- **Microsoft.Network/dnsZones/A/write**
- **Microsoft.Network/dnsZones/CNAME/write**
- **Microsoft.Network/dnszones/CNAME/read**
- **Microsoft.Network/dnszones/read**
- **Microsoft.Network/loadBalancers/backendAddressPools/join/action**
- **Microsoft.Network/loadBalancers/backendAddressPools/read**
- **Microsoft.Network/loadBalancers/backendAddressPools/write**
- **Microsoft.Network/loadBalancers/read**
- **Microsoft.Network/loadBalancers/write**
- **Microsoft.Network/networkInterfaces/delete**
- **Microsoft.Network/networkInterfaces/join/action**
- **Microsoft.Network/networkInterfaces/read**
- **Microsoft.Network/networkInterfaces/write**
- **Microsoft.Network/networkSecurityGroups/join/action**
- **Microsoft.Network/networkSecurityGroups/read**
- **Microsoft.Network/networkSecurityGroups/securityRules/delete**
- **Microsoft.Network/networkSecurityGroups/securityRules/read**
- **Microsoft.Network/networkSecurityGroups/securityRules/write**
- **Microsoft.Network/networkSecurityGroups/write**
- **Microsoft.Network/privateDnsZones/A/read**
- **Microsoft.Network/privateDnsZones/A/write**
- **Microsoft.Network/privateDnsZones/A/delete**

- **Microsoft.Network/privateDnsZones/SOA/read**
- **Microsoft.Network/privateDnsZones/read**
- **Microsoft.Network/privateDnsZones/virtualNetworkLinks/read**
- **Microsoft.Network/privateDnsZones/virtualNetworkLinks/write**
- **Microsoft.Network/privateDnsZones/write**
- **Microsoft.Network/publicIPAddresses/delete**
- **Microsoft.Network/publicIPAddresses/join/action**
- **Microsoft.Network/publicIPAddresses/read**
- **Microsoft.Network/publicIPAddresses/write**
- **Microsoft.Network/virtualNetworks/join/action**
- **Microsoft.Network/virtualNetworks/read**
- **Microsoft.Network/virtualNetworks/subnets/join/action**
- **Microsoft.Network/virtualNetworks/subnets/read**
- **Microsoft.Network/virtualNetworks/subnets/write**
- **Microsoft.Network/virtualNetworks/write**

Example 5.67. Required permissions for checking the health of resources

- **Microsoft.Resourcehealth/healthevent/Activated/action**
- **Microsoft.Resourcehealth/healthevent/InProgress/action**
- **Microsoft.Resourcehealth/healthevent/Pending/action**
- **Microsoft.Resourcehealth/healthevent/Resolved/action**
- **Microsoft.Resourcehealth/healthevent/Updated/action**

Example 5.68. Required permissions for creating a resource group

- **Microsoft.Resources/subscriptions/resourceGroups/read**
- **Microsoft.Resources/subscriptions/resourcegroups/write**

Example 5.69. Required permissions for creating resource tags

- **Microsoft.Resources/tags/write**

**Example 5.70. Required permissions for creating storage resources**

- **Microsoft.Storage/storageAccounts/blobServices/read**
- **Microsoft.Storage/storageAccounts/blobServices/containers/write**
- **Microsoft.Storage/storageAccounts/fileServices/read**
- **Microsoft.Storage/storageAccounts/fileServices/shares/read**
- **Microsoft.Storage/storageAccounts/fileServices/shares/write**
- **Microsoft.Storage/storageAccounts/fileServices/shares/delete**
- **Microsoft.Storage/storageAccounts/listKeys/action**
- **Microsoft.Storage/storageAccounts/read**
- **Microsoft.Storage/storageAccounts/write**

**Example 5.71. Required permissions for creating deployments**

- **Microsoft.Resources/deployments/read**
- **Microsoft.Resources/deployments/write**
- **Microsoft.Resources/deployments/validate/action**
- **Microsoft.Resources/deployments/operationstatuses/read**

**Example 5.72. Optional permissions for creating compute resources**

- **Microsoft.Compute/availabilitySets/delete**
- **Microsoft.Compute/availabilitySets/write**

**Example 5.73. Optional permissions for creating marketplace virtual machine resources**

- **Microsoft.MarketplaceOrdering/offertypes/publishers/offers/plans/agreements/read**
- **Microsoft.MarketplaceOrdering/offertypes/publishers/offers/plans/agreements/write**

**Example 5.74. Optional permissions for enabling user-managed encryption**

- **Microsoft.Compute/diskEncryptionSets/read**
- **Microsoft.Compute/diskEncryptionSets/write**
- **Microsoft.Compute/diskEncryptionSets/delete**
- **Microsoft.KeyVault/vaults/read**

- **Microsoft.KeyVault/vaults/write**
- **Microsoft.KeyVault/vaults/delete**
- **Microsoft.KeyVault/vaults/deploy/action**
- **Microsoft.KeyVault/vaults/keys/read**
- **Microsoft.KeyVault/vaults/keys/write**
- **Microsoft.Features/providers/features/register/action**

The following permissions are required for deleting an OpenShift Container Platform cluster on Microsoft Azure.

#### Example 5.75. Required permissions for deleting authorization resources

- **Microsoft.Authorization/roleAssignments/delete**

#### Example 5.76. Required permissions for deleting compute resources

- **Microsoft.Compute/disks/delete**
- **Microsoft.Compute/galleries/delete**
- **Microsoft.Compute/galleries/images/delete**
- **Microsoft.Compute/galleries/images/versions/delete**
- **Microsoft.Compute/virtualMachines/delete**
- **Microsoft.Compute/images/delete**

#### Example 5.77. Required permissions for deleting identity management resources

- **Microsoft.ManagedIdentity/userAssignedIdentities/delete**

#### Example 5.78. Required permissions for deleting network resources

- **Microsoft.Network/dnszones/read**
- **Microsoft.Network/dnsZones/A/read**
- **Microsoft.Network/dnsZones/A/delete**
- **Microsoft.Network/dnsZones/CNAME/read**
- **Microsoft.Network/dnsZones/CNAME/delete**
- **Microsoft.Network/loadBalancers/delete**
- **Microsoft.Network/networkInterfaces/delete**

- **Microsoft.Network/networkSecurityGroups/delete**
- **Microsoft.Network/privateDnsZones/read**
- **Microsoft.Network/privateDnsZones/A/read**
- **Microsoft.Network/privateDnsZones/delete**
- **Microsoft.Network/privateDnsZones/virtualNetworkLinks/delete**
- **Microsoft.Network/publicIPAddresses/delete**
- **Microsoft.Network/virtualNetworks/delete**

Example 5.79. Required permissions for checking the health of resources

- **Microsoft.Resourcehealth/healthevent/Activated/action**
- **Microsoft.Resourcehealth/healthevent/Resolved/action**
- **Microsoft.Resourcehealth/healthevent/Updated/action**

Example 5.80. Required permissions for deleting a resource group

- **Microsoft.Resources/subscriptions/resourcegroups/delete**

Example 5.81. Required permissions for deleting storage resources

- **Microsoft.Storage/storageAccounts/delete**
- **Microsoft.Storage/storageAccounts/listKeys/action**

#### NOTE

To install OpenShift Container Platform on Azure, you must scope the permissions related to resource group creation to your subscription. After the resource group is created, you can scope the rest of the permissions to the created resource group. If the public DNS zone is present in a different resource group, then the network DNS zone related permissions must always be applied to your subscription.

You can scope all the permissions to your subscription when deleting an OpenShift Container Platform cluster.

### 5.11.3.8. Using Azure managed identities

The installation program requires an Azure identity to complete the installation. You can use either a system-assigned or user-assigned managed identity.

If you are unable to use a managed identity, you can use a service principal.

#### Procedure

1. If you are using a system-assigned managed identity, enable it on the virtual machine that you will run the installation program from.
2. If you are using a user-assigned managed identity:
  - a. Assign it to the virtual machine that you will run the installation program from.
  - b. Record its client ID. You require this value when installing the cluster.  
For more information about viewing the details of a user-assigned managed identity, see the Microsoft Azure documentation for [listing user-assigned managed identities](#).
3. Verify that the required permissions are assigned to the managed identity.

### 5.11.3.9. Creating a service principal

The installation program requires an Azure identity to complete the installation. You can use a service principal.

If you are unable to use a service principal, you can use a managed identity.

#### Prerequisites

- You have installed or updated the [Azure CLI](#).
- You have an Azure subscription ID.
- If you are not going to assign the **Contributor** and **User Administrator Access** roles to the service principal, you have created a custom role with the required Azure permissions.

#### Procedure

1. Create the service principal for your account by running the following command:

```
$ az ad sp create-for-rbac --role <role_name> \ ❶
--name <service_principal> \ ❷
--scopes /subscriptions/<subscription_id> ❸
```

- ❶ Defines the role name. You can use the **Contributor** role, or you can specify a custom role which contains the necessary permissions.
- ❷ Defines the service principal name.
- ❸ Specifies the subscription ID.

#### Example output

```
Creating 'Contributor' role assignment under scope '/subscriptions/<subscription_id>'
The output includes credentials that you must protect. Be sure that you do not
include these credentials in your code or check the credentials into your source
control. For more information, see https://aka.ms/azadsp-cli
{
 "appId": "axxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
 "displayName": <service_principal>,

```

```
"password": "00000000-0000-0000-0000-000000000000",
"tenantId": "8xxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxxx"
}
```

- Record the values of the **appld** and **password** parameters from the output. You require these values when installing the cluster.
- If you applied the **Contributor** role to your service principal, assign the **User Administrator Access** role by running the following command:

```
$ az role assignment create --role "User Access Administrator" \
 --assignee-object-id $(az ad sp show --id <appld> --query id -o tsv) 1
 --scope /subscriptions/<subscription_id> 2
```

- 1** Specify the **appld** parameter value for your service principal.
- 2** Specifies the subscription ID.

### Additional resources

- For more information about CCO modes, see [About the Cloud Credential Operator](#).

### 5.11.3.10. Supported Azure regions

The installation program dynamically generates the list of available Microsoft Azure regions based on your subscription.

#### Supported Azure public regions

- **australiacentral** (Australia Central)
- **australiaeast** (Australia East)
- **australiasoutheast** (Australia South East)
- **brazilsouth** (Brazil South)
- **canadacentral** (Canada Central)
- **canadaeast** (Canada East)
- **centralindia** (Central India)
- **centralus** (Central US)
- **eastasia** (East Asia)
- **eastus** (East US)
- **eastus2** (East US 2)
- **francecentral** (France Central)
- **germanywestcentral** (Germany West Central)

- **israelcentral** (Israel Central)
- **italynorth** (Italy North)
- **japaneast** (Japan East)
- **japanwest** (Japan West)
- **koreacentral** (Korea Central)
- **koreasouth** (Korea South)
- **mexicocentral** (Mexico Central)
- **northcentralus** (North Central US)
- **northeurope** (North Europe)
- **norwayeast** (Norway East)
- **polandcentral** (Poland Central)
- **qatarcentral** (Qatar Central)
- **southafricanorth** (South Africa North)
- **southcentralus** (South Central US)
- **southeastasia** (Southeast Asia)
- **southindia** (South India)
- **spaincentral** (Spain Central)
- **swedencentral** (Sweden Central)
- **switzerlandnorth** (Switzerland North)
- **uaenorth** (UAE North)
- **uksouth** (UK South)
- **ukwest** (UK West)
- **westcentralus** (West Central US)
- **westeurope** (West Europe)
- **westindia** (West India)
- **westus** (West US)
- **westus2** (West US 2)
- **westus3** (West US 3)

Supported Azure Government regions

Support for the following Microsoft Azure Government (MAG) regions was added in OpenShift Container Platform version 4.6:

- **usgovtexas** (US Gov Texas)
- **usgovvirginia** (US Gov Virginia)

You can reference all available MAG regions in the [Azure documentation](#). Other provided MAG regions are expected to work with OpenShift Container Platform, but have not been tested.

#### 5.11.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

##### 5.11.4.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 5.27. Minimum required hosts**

| Hosts                                                                   | Description                                                                                                                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine                                         | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines                                            | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.                                                                                                             |

#### IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

##### 5.11.4.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 5.28. Minimum resource requirements

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

## IMPORTANT

You are required to use Azure virtual machines that have the **premiumIO** parameter set to **true**.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 5.11.4.3. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

#### Example 5.82. Machine types based on 64-bit x86 architecture

- **c4.\***
- **c5.\***
- **c5a.\***
- **i3.\***
- **m4.\***
- **m5.\***
- **m5a.\***
- **m6a.\***
- **m6i.\***
- **r4.\***
- **r5.\***
- **r5a.\***
- **r6i.\***
- **t3.\***
- **t3a.\***

### 5.11.4.4. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

#### Example 5.83. Machine types based on 64-bit ARM architecture

- **c6g.\***
- **c7g.\***
- **m6g.\***
- **m7g.\***
- **r8g.\***

### 5.11.5. Using the Azure Marketplace offering

Using the Azure Marketplace offering lets you deploy an OpenShift Container Platform cluster, which is billed on pay-per-use basis (hourly, per core) through Azure, while still being supported directly by Red Hat.

To deploy an OpenShift Container Platform cluster using the Azure Marketplace offering, you must first obtain the Azure Marketplace image. The installation program uses this image to deploy worker nodes. When obtaining your image, consider the following:

- While the images are the same, the Azure Marketplace publisher is different depending on your region. If you are located in North America, specify **redhat** as the publisher. If you are located in EMEA, specify **redhat-limited** as the publisher.
- The offer includes a **rh-ocp-worker** SKU and a **rh-ocp-worker-gen1** SKU. The **rh-ocp-worker** SKU represents a Hyper-V generation version 2 VM image. The default instance types used in OpenShift Container Platform are version 2 compatible. If you plan to use an instance type that is only version 1 compatible, use the image associated with the **rh-ocp-worker-gen1** SKU. The **rh-ocp-worker-gen1** SKU represents a Hyper-V version 1 VM image.

**IMPORTANT**

Installing images with the Azure marketplace is not supported on clusters with 64-bit ARM instances.

**Prerequisites**

- You have installed the Azure CLI client (**az**).
- Your Azure account is entitled for the offer and you have logged into this account with the Azure CLI client.

**Procedure**

1. Display all of the available OpenShift Container Platform images by running one of the following commands:

- North America:

```
$ az vm image list --all --offer rh-ocp-worker --publisher redhat -o table
```

**Example output**

| Offer              | Publisher | SKU                | URN                                                       | Version           |
|--------------------|-----------|--------------------|-----------------------------------------------------------|-------------------|
| rh-ocp-worker      | RedHat    | rh-ocp-worker      | RedHat:rh-ocp-worker:rh-ocp-worker:413.92.2023101700      | 413.92.2023101700 |
| rh-ocp-worker-gen1 | RedHat    | rh-ocp-worker-gen1 | RedHat:rh-ocp-worker:rh-ocp-worker-gen1:413.92.2023101700 | 413.92.2023101700 |

- EMEA:

-

```
$ az vm image list --all --offer rh-ocp-worker --publisher redhat-limited -o table
```

### Example output

| Offer<br>Version                     | Publisher      | SKU                | URN                                                               |
|--------------------------------------|----------------|--------------------|-------------------------------------------------------------------|
| rh-ocp-worker:413.92.2023101700      | redhat-limited | rh-ocp-worker      | redhat-limited:rh-ocp-worker:rh-ocp-worker:413.92.2023101700      |
| rh-ocp-worker-gen1:413.92.2023101700 | redhat-limited | rh-ocp-worker-gen1 | redhat-limited:rh-ocp-worker:rh-ocp-worker-gen1:413.92.2023101700 |

### NOTE

Regardless of the version of OpenShift Container Platform that you install, the correct version of the Azure Marketplace image to use is 4.13. If required, your VMs are automatically upgraded as part of the installation process.

2. Inspect the image for your offer by running one of the following commands:

- North America:

```
$ az vm image show --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
```

- EMEA:

```
$ az vm image show --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
```

3. Review the terms of the offer by running one of the following commands:

- North America:

```
$ az vm image terms show --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
```

- EMEA:

```
$ az vm image terms show --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
```

4. Accept the terms of the offering by running one of the following commands:

- North America:

```
$ az vm image terms accept --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
```

- EMEA:

```
$ az vm image terms accept --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
```

5. Record the image details of your offer. If you use the Azure Resource Manager (ARM) template to deploy your worker nodes:

- a. Update **storageProfile.imageReference** by deleting the **id** parameter and adding the **offer**, **publisher**, **sku**, and **version** parameters by using the values from your offer.
- b. Specify a **plan** for the virtual machines (VMs).

**Example 06\_workers.json ARM template with an updated storageProfile.imageReference object and a specified plan**

```
...
 "plan" : {
 "name": "rh-ocp-worker",
 "product": "rh-ocp-worker",
 "publisher": "redhat"
 },
 "dependsOn" : [
 "[concat('Microsoft.Network/networkInterfaces/', concat(variables('vmNames')
[copyIndex()], '-nic'))]"
],
 "properties" : {
...
 "storageProfile": {
 "imageReference": {
 "offer": "rh-ocp-worker",
 "publisher": "redhat",
 "sku": "rh-ocp-worker",
 "version": "413.92.2023101700"
 }
 }
...
 }
...
}
```

### 5.11.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 5.11.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

## 5.11.8. Creating the installation files for Azure

To install OpenShift Container Platform on Microsoft Azure using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the **install-config.yaml** file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate **var** partition during the preparation phases of installation.

### 5.11.8.1. Optional: Creating a separate /var partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

## IMPORTANT

If you follow the steps to create a separate **/var** partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

### Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
```

### Example output

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and
$HOME/clusterconfig/openshift
```

3. Optional: Confirm that the installation program created manifests in the **clusterconfig/openshift** directory:

```
$ ls $HOME/clusterconfig/openshift/
```

### Example output

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

4. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
 labels:
 machineconfiguration.openshift.io/role: worker
 name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> 1
 partitions:
```

```

- label: var
 start_mib: <partition_start_offset> 2
 size_mib: <partition_size> 3
 number: 5
filesystems:
- device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] 4
 with_mount_unit: true

```

- 1 The storage device name of the disk that you want to partition.
- 2 When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- 3 The size of the data partition in mebibytes.
- 4 The **prjquota** mount option must be enabled for filesystems used for container storage.

#### NOTE

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

6. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 5.11.8.2. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

## Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the `~/.azure/` directory and delete the **osServicePrincipal.json** configuration file.  
Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.
2. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

### NOTE

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **azure** as the platform to target.  
If the installation program cannot locate the **osServicePrincipal.json** configuration file from a previous installation, you are prompted for Azure subscription and authentication values.
- iii. Enter the following Azure parameter values for your subscription:
  - **azure subscription id** Enter the subscription ID to use for the cluster.
  - **azure tenant id** Enter the tenant ID.
- iv. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client id**
  - If you are using a service principal, enter its application ID.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, specify its client ID.
- v. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**
  - If you are using a service principal, enter its password.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, leave this value blank.
- vi. Select the region to deploy the cluster to.
- vii. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.
- viii. Enter a descriptive name for your cluster.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

3. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.

**NOTE**

If you are installing a three-node cluster, be sure to set the **compute.replicas** parameter to **0**. This ensures that the cluster's control planes are schedulable. For more information, see "Installing a three-node cluster on Azure".

4. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

If previously not detected, the installation program creates an **osServicePrincipal.json** configuration file and stores this file in the **~/.azure/** directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

### 5.11.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
```

```

additionalTrustBundle: | 4
-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5

```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 5.11.8.4. Exporting common variables for ARM templates

You must export a common set of variables that are used with the provided Azure Resource Manager (ARM) templates used to assist in completing a user-provided infrastructure install on Microsoft Azure.

## NOTE

Specific ARM templates can also require additional exported variables, which are detailed in their related procedures.

## Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

## Procedure

1. Export common variables found in the **install-config.yaml** to be used by the provided ARM templates:

```
$ export CLUSTER_NAME=<cluster_name> 1
$ export AZURE_REGION=<azure_region> 2
$ export SSH_KEY=<ssh_key> 3
$ export BASE_DOMAIN=<base_domain> 4
$ export BASE_DOMAIN_RESOURCE_GROUP=<base_domain_resource_group> 5
```

- 1 The value of the **.metadata.name** attribute from the **install-config.yaml** file.
- 2 The region to deploy the cluster into, for example **centralus**. This is the value of the **.platform.azure.region** attribute from the **install-config.yaml** file.
- 3 The SSH RSA public key file as a string. You must enclose the SSH key in quotes since it contains spaces. This is the value of the **.sshKey** attribute from the **install-config.yaml** file.
- 4 The base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster. This is the value of the **.baseDomain** attribute from the **install-config.yaml** file.
- 5 The resource group where the public DNS zone exists. This is the value of the **.platform.azure.baseDomainResourceGroupName** attribute from the **install-config.yaml** file.

For example:

```
$ export CLUSTER_NAME=test-cluster
$ export AZURE_REGION=centralus
$ export SSH_KEY="ssh-rsa xxx/xxx/xxx= user@email.com"
$ export BASE_DOMAIN=example.com
$ export BASE_DOMAIN_RESOURCE_GROUP=ocp-cluster
```

2. Export the kubeadmin credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

#### 5.11.8.5. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

#### IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

#### Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

#### Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

### IMPORTANT

If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

### WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

### IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

5. Check that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
  - a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
  - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
6. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
```

```
privateZone: ❶
 id: mycluster-100419-private-zone
publicZone: ❷
 id: example.openshift.com
status: {}
```

- ❶ ❷ Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

7. When configuring Azure on user-provisioned infrastructure, you must export some common variables defined in the manifest files to use later in the Azure Resource Manager (ARM) templates:

- a. Export the infrastructure ID by using the following command:

```
$ export INFRA_ID=<infra_id> ❶
```

- ❶ The OpenShift Container Platform cluster has been assigned an identifier (**INFRA\_ID**) in the form of **<cluster\_name>-<random\_string>**. This will be used as the base name for most resources created using the provided ARM templates. This is the value of the **.status.infrastructureName** attribute from the **manifests/cluster-infrastructure-02-config.yml** file.

- b. Export the resource group by using the following command:

```
$ export RESOURCE_GROUP=<resource_group> ❶
```

- ❶ All resources created in this Azure deployment exists as part of a [resource group](#). The resource group name is also based on the **INFRA\_ID**, in the form of **<cluster\_name>-<random\_string>-rg**. This is the value of the **.status.platformStatus.azure.resourceGroupName** attribute from the **manifests/cluster-infrastructure-02-config.yml** file.

8. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> ❶
```

- ❶ For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

```
.
├── auth
│ ├── kubeadmin-password
│ └── kubeconfig
└── bootstrap.ign
```

### 5.11.9. Creating the Azure resource group

You must create a Microsoft Azure [resource group](#) and an identity for that resource group. These are both used during the installation of your OpenShift Container Platform cluster on Azure.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

#### Procedure

1. Create the resource group in a supported Azure region:

```
$ az group create --name ${RESOURCE_GROUP} --location ${AZURE_REGION}
```

2. Create an Azure identity for the resource group:

```
$ az identity create -g ${RESOURCE_GROUP} -n ${INFRA_ID}-identity
```

This is used to grant the required access to Operators in your cluster. For example, this allows the Ingress Operator to create a public IP and its load balancer. You must assign the Azure identity to a role.

3. Grant the Contributor role to the Azure identity:

- a. Export the following variables required by the Azure role assignment:

```
$ export PRINCIPAL_ID=`az identity show -g ${RESOURCE_GROUP} -n ${INFRA_ID}-identity --query principalId --out tsv`
```

```
$ export RESOURCE_GROUP_ID=`az group show -g ${RESOURCE_GROUP} --query id --out tsv`
```

- b. Assign the Contributor role to the identity:

```
$ az role assignment create --assignee "${PRINCIPAL_ID}" --role 'Contributor' --scope "${RESOURCE_GROUP_ID}"
```

**NOTE**

If you want to assign a custom role with all the required permissions to the identity, run the following command:

```
$ az role assignment create --assignee "${PRINCIPAL_ID}" --role
<custom_role> \ 1
--scope "${RESOURCE_GROUP_ID}"
```

**1** Specifies the custom role name.

### 5.11.10. Uploading the RHCOS cluster image and bootstrap Ignition config file

The Azure client does not support deployments based on files existing locally. You must copy and store the RHCOS virtual hard disk (VHD) cluster image and bootstrap Ignition config file in a storage container so they are accessible during deployment.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

#### Procedure

1. Create an Azure storage account to store the VHD cluster image:

```
$ az storage account create -g ${RESOURCE_GROUP} --location ${AZURE_REGION} --
name ${CLUSTER_NAME}sa --kind Storage --sku Standard_LRS
```

**WARNING**

The Azure storage account name must be between 3 and 24 characters in length and use numbers and lower-case letters only. If your **CLUSTER\_NAME** variable does not follow these restrictions, you must manually define the Azure storage account name. For more information on Azure storage account name restrictions, see [Resolve errors for storage account names](#) in the Azure documentation.

2. Export the storage account key as an environment variable:

```
$ export ACCOUNT_KEY=`az storage account keys list -g ${RESOURCE_GROUP} --
account-name ${CLUSTER_NAME}sa --query "[0].value" -o tsv`
```

3. Export the URL of the RHCOS VHD to an environment variable:

```
$ export VHD_URL=`openshift-install coreos print-stream-json | jq -r '.architectures.
<architecture>."rhel-coreos-extensions"."azure-disk".url`
```

where:

### <architecture>

Specifies the architecture, valid values include **x86\_64** or **aarch64**.

### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must specify an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

4. Create the storage container for the VHD:

```
$ az storage container create --name vhd --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY}
```

5. Copy the local VHD to a blob:

```
$ az storage blob copy start --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} --destination-blob "rhcos.vhd" --destination-container vhd --source-uri "${VHD_URL}"
```

6. Create a blob storage container and upload the generated **bootstrap.ign** file:

```
$ az storage container create --name files --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY}
```

```
$ az storage blob upload --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} -c "files" -f "<installation_directory>/bootstrap.ign" -n "bootstrap.ign"
```

### 5.11.11. Example for creating DNS zones

DNS records are required for clusters that use user-provisioned infrastructure. You should choose the DNS strategy that fits your scenario.

For this example, [Azure's DNS solution](#) is used, so you will create a new public DNS zone for external (internet) visibility and a private DNS zone for internal cluster resolution.

### NOTE

The public DNS zone is not required to exist in the same resource group as the cluster deployment and might already exist in your organization for the desired base domain. If that is the case, you can skip creating the public DNS zone; be sure the installation config you generated earlier reflects that scenario.

### Prerequisites

- Configure an Azure account.

- Generate the Ignition config files for your cluster.

## Procedure

1. Create the new public DNS zone in the resource group exported in the **BASE\_DOMAIN\_RESOURCE\_GROUP** environment variable:

```
$ az network dns zone create -g ${BASE_DOMAIN_RESOURCE_GROUP} -n
${CLUSTER_NAME}.${BASE_DOMAIN}
```

You can skip this step if you are using a public DNS zone that already exists.

2. Create the private DNS zone in the same resource group as the rest of this deployment:

```
$ az network private-dns zone create -g ${RESOURCE_GROUP} -n
${CLUSTER_NAME}.${BASE_DOMAIN}
```

You can learn more about [configuring a public DNS zone in Azure](#) by visiting that section.

## 5.11.12. Creating a VNet in Azure

You must create a virtual network (VNet) in Microsoft Azure for your OpenShift Container Platform cluster to use. You can customize the VNet to meet your requirements. One way to create the VNet is to modify the provided Azure Resource Manager (ARM) template.

### NOTE

If you do not use the provided ARM template to create your Azure infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

## Procedure

1. Copy the template from the **ARM template for the VNet** section of this topic and save it as **01\_vnet.json** in your cluster's installation directory. This template describes the VNet that your cluster requires.
2. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/01_vnet.json" \
 --parameters baseName="${INFRA_ID}" 1
```

**1**

The base name to be used in resource names; this is usually the cluster's infrastructure ID.

3. Link the VNet template to the private DNS zone:

```
$ az network private-dns link vnet create -g ${RESOURCE_GROUP} -z
${CLUSTER_NAME}.${BASE_DOMAIN} -n ${INFRA_ID}-network-link -v "${INFRA_ID}-vnet"
-e false
```

### 5.11.12.1. ARM template for the VNet

You can use the following Azure Resource Manager (ARM) template to deploy the VNet that you need for your OpenShift Container Platform cluster:

#### Example 5.84. 01\_vnet.json ARM template

```
{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 }
 },
 "variables" : {
 "location" : "[resourceGroup().location]",
 "virtualNetworkName" : "[concat(parameters('baseName'), '-vnet')]",
 "addressPrefix" : "10.0.0.0/16",

### 5.11.13. Deploying the RHCOS cluster image for the Azure infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Microsoft Azure for your OpenShift Container Platform nodes.

#### Prerequisites

- Configure an Azure account.

- Generate the Ignition config files for your cluster.
- Store the RHCOS virtual hard disk (VHD) cluster image in an Azure storage container.
- Store the bootstrap Ignition config file in an Azure storage container.

## Procedure

1. Copy the template from the **ARM template for image storage** section of this topic and save it as **02\_storage.json** in your cluster's installation directory. This template describes the image storage that your cluster requires.
2. Export the RHCOS VHD blob URL as a variable:

```
$ export VHD_BLOB_URL=`az storage blob url --account-name ${CLUSTER_NAME}sa --
account-key ${ACCOUNT_KEY} -c vhd -n "rhcos.vhd" -o tsv`
```

3. Deploy the cluster image:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
--template-file "<installation_directory>/02_storage.json" \
--parameters vhdBlobURL="${VHD_BLOB_URL}" \ ❶
--parameters baseName="${INFRA_ID}" \ ❷
--parameters storageAccount="${CLUSTER_NAME}sa" \ ❸
--parameters architecture="<architecture>" ❹
```

- ❶ The blob URL of the RHCOS VHD to be used to create master and worker machines.
- ❷ The base name to be used in resource names; this is usually the cluster's infrastructure ID.
- ❸ The name of your Azure storage account.
- ❹ Specify the system architecture. Valid values are **x64** (default) or **Arm64**.

### 5.11.13.1. ARM template for image storage

You can use the following Azure Resource Manager (ARM) template to deploy the stored Red Hat Enterprise Linux CoreOS (RHCOS) image that you need for your OpenShift Container Platform cluster:

#### Example 5.85. 02\_storage.json ARM template

```
{
 "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
 "contentVersion": "1.0.0.0",
 "parameters": {
 "architecture": {
 "type": "string",
 "metadata": {
 "description": "The architecture of the Virtual Machines"
 },
 "defaultValue": "x64",
 "allowedValues": [
```

```

 "Arm64",
 "x64"
],
},
"baseName": {
 "type": "string",
 "minLength": 1,
 "metadata": {
 "description": "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
},
"storageAccount": {
 "type": "string",
 "metadata": {
 "description": "The Storage Account name"
 }
},
"vhdBlobURL": {
 "type": "string",
 "metadata": {
 "description": "URL pointing to the blob where the VHD to be used to create master and
worker machines is located"
 }
}
},
"variables": {
 "location": "[resourceGroup().location]",
 "galleryName": "[concat('gallery_', replace(parameters('baseName'), '-', '_'))]",
 "imageName": "[parameters('baseName')]",
 "imageNameGen2": "[concat(parameters('baseName'), '-gen2')]",
 "imageRelease": "1.0.0"
},
"resources": [
{
 "apiVersion": "2021-10-01",
 "type": "Microsoft.Compute/galleries",
 "name": "[variables('galleryName')]",
 "location": "[variables('location')]",
 "resources": [
 {
 "apiVersion": "2021-10-01",
 "type": "images",
 "name": "[variables('imageName')]",
 "location": "[variables('location')]",
 "dependsOn": [
 "[variables('galleryName')]"
],
 "properties": {
 "architecture": "[parameters('architecture')]",
 "hyperVGeneration": "V1",
 "identifier": {
 "offer": "rhcos",
 "publisher": "RedHat",
 "sku": "basic"
 }
 },
 "osState": "Generalized",

```

```

 "osType": "Linux"
 },
 "resources": [
 {
 "apiVersion": "2021-10-01",

 "source": {
 "id": "[resourceId('Microsoft.Storage/storageAccounts',
parameters('storageAccount'))]",
 "uri": "[parameters('vhdBlobURL')]"
 }
 }
 }
 }
 },
 {
 "apiVersion": "2021-10-01",
 "type": "images",
 "name": "[variables('imageNameGen2')]",
 "location": "[variables('location')]",
 "dependsOn": [
 "[variables('galleryName')]"
],
 "properties": {
 "architecture": "[parameters('architecture')]",
 "hyperVGeneration": "V2",
 "identifier": {
 "offer": "rhcos-gen2",
 "publisher": "RedHat-gen2",
 "sku": "gen2"
 },
 "osState": "Generalized",
 "osType": "Linux"
 }
 },
 {
 "apiVersion": "2021-10-01",

```

```

 "type": "versions",
 "name": "[variables('imageRelease')]",
 "location": "[variables('location')]",
 "dependsOn": [
 "[variables('imageNameGen2')]"
],
 "properties": {
 "publishingProfile": {
 "storageAccountType": "Standard_LRS",
 "targetRegions": [
 {
 "name": "[variables('location')]",
 "regionalReplicaCount": "1"
 }
]
 },
 "storageProfile": {
 "osDiskImage": {
 "source": {
 "id": "[resourceId('Microsoft.Storage/storageAccounts',
parameters('storageAccount'))]",
 "uri": "[parameters('vhdBlobURL')]"
 }
 }
 }
 }
 }
}
]
}
]
}
]
}
]
}

```

#### 5.11.14. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

##### 5.11.14.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

#### IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 5.29. Ports used for all-machine to all-machine communications

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
|          | <b>10256</b>       | openshift-sdn                                                                                                                               |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

Table 5.30. Ports used for all-machine to control plane communications

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

Table 5.31. Ports used for control plane machine to control plane machine communications

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

### 5.11.15. Creating networking and load balancing components in Azure

You must configure networking and load balancing in Microsoft Azure for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Azure Resource Manager (ARM) template.

#### NOTE

If you do not use the provided ARM template to create your Azure infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.

#### Procedure

1. Copy the template from the **ARM template for the network and load balancers** section of this topic and save it as **03\_infra.json** in your cluster's installation directory. This template describes the networking and load balancing objects that your cluster requires.
2. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/03_infra.json" \
 --parameters privateDNSZoneName="${CLUSTER_NAME}.${BASE_DOMAIN}" \ 1
 --parameters baseName="${INFRA_ID}" 2
```

- 1** The name of the private DNS zone.
- 2** The base name to be used in resource names; this is usually the cluster's infrastructure ID.

3. Create an **api** DNS record in the public zone for the API public load balancer. The **\${BASE\_DOMAIN\_RESOURCE\_GROUP}** variable must point to the resource group where the public DNS zone exists.

- a. Export the following variable:

```
$ export PUBLIC_IP=`az network public-ip list -g ${RESOURCE_GROUP} --query "[?
 name=='${INFRA_ID}-master-pip'] | [0].ipAddress" -o tsv`
```

- b. Create the **api** DNS record in a new public zone:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -
 z ${CLUSTER_NAME}.${BASE_DOMAIN} -n api -a ${PUBLIC_IP} --ttl 60
```

If you are adding the cluster to an existing public zone, you can create the **api** DNS record in it instead:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -
z ${BASE_DOMAIN} -n api.${CLUSTER_NAME} -a ${PUBLIC_IP} --ttl 60
```

### 5.11.15.1. ARM template for the network and load balancers

You can use the following Azure Resource Manager (ARM) template to deploy the networking objects and load balancers that you need for your OpenShift Container Platform cluster:

#### Example 5.86. 03\_infra.json ARM template

```
{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-
01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 },
 "vnetBaseName" : {
 "type" : "string",
 "defaultValue" : "",
 "metadata" : {
 "description" : "The specific customer vnet's base name (optional)"
 }
 },
 "privateDNSZoneName" : {
 "type" : "string",
 "metadata" : {
 "description" : "Name of the private DNS zone"
 }
 }
 },
 "variables" : {
 "location" : "[resourceGroup().location]",
 "virtualNetworkName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-vnet')]",
 "virtualNetworkID" : "[resourceId('Microsoft.Network/virtualNetworks',
variables('virtualNetworkName'))]",
 "masterSubnetName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-master-subnet')]",
 "masterSubnetRef" : "[concat(variables('virtualNetworkID'), '/subnets/',
variables('masterSubnetName'))]",
 "masterPublicIpAddressName" : "[concat(parameters('baseName'), '-master-pip')]",
 "masterPublicIpAddressID" : "[resourceId('Microsoft.Network/publicIPAddresses',
variables('masterPublicIpAddressName'))]",
 "masterLoadBalancerName" : "[parameters('baseName')]",
 "masterLoadBalancerID" : "[resourceId('Microsoft.Network/loadBalancers',
variables('masterLoadBalancerName'))]",
 "internalLoadBalancerName" : "[concat(parameters('baseName'), '-internal-lb')]",
 "internalLoadBalancerID" : "[resourceId('Microsoft.Network/loadBalancers',
variables('internalLoadBalancerName'))]",
```

```

 "skuName": "Standard"
 },
 "resources" : [

```

### 5.11.16. Creating the bootstrap machine in Azure

You must create the bootstrap machine in Microsoft Azure to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Azure Resource Manager (ARM) template.

## NOTE

If you do not use the provided ARM template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.

## Procedure

1. Copy the template from the **ARM template for the bootstrap machine** section of this topic and save it as **04\_bootstrap.json** in your cluster's installation directory. This template describes the bootstrap machine that your cluster requires.

2. Export the bootstrap URL variable:

```
$ bootstrap_url_expiry=`date -u -d "10 hours" '+%Y-%m-%dT%H:%MZ`
```

```
$ export BOOTSTRAP_URL=`az storage blob generate-sas -c 'files' -n 'bootstrap.ign' --https-only --full-uri --permissions r --expiry $bootstrap_url_expiry --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} -o tsv`
```

3. Export the bootstrap ignition variable:

```
$ export BOOTSTRAP_IGNITION=`jq -rcnM --arg v "3.2.0" --arg url ${BOOTSTRAP_URL} '{ignition:{version:$v,config:{replace:{source:$url}}}}' | base64 | tr -d '\n`
```

4. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/04_bootstrap.json" \
 --parameters bootstrapIgnition="${BOOTSTRAP_IGNITION}" \
 --parameters baseName="${INFRA_ID}"
```

- 1 The bootstrap Ignition content for the bootstrap cluster.
- 2 The base name to be used in resource names; this is usually the cluster's infrastructure ID.

### 5.11.16.1. ARM template for the bootstrap machine

You can use the following Azure Resource Manager (ARM) template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

#### Example 5.87. 04\_bootstrap.json ARM template

```
{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 },
 "vnetBaseName": {
 "type": "string",
 "defaultValue": "",
 "metadata" : {
 "description" : "The specific customer vnet's base name (optional)"
 }
 },
 "bootstrapIgnition" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Bootstrap ignition content for the bootstrap cluster"
 }
 },
 "sshKeyData" : {
 "type" : "securestring",
 "defaultValue" : "Unused",
 "metadata" : {
 "description" : "Unused"
 }
 },
 "bootstrapVMSize" : {
 "type" : "string",
 "defaultValue" : "Standard_D4s_v3",
 "metadata" : {
 "description" : "The size of the Bootstrap Virtual Machine"
 }
 },
 "hyperVGen": {
 "type": "string",
 "metadata": {
 "description": "VM generation image to use"
 },
 "defaultValue": "V2",
 "allowedValues": [
 "V1",
 "V2"
]
 }
 }
}
```

```

]
 }
},
"variables" : {
 "location" : "[resourceGroup().location]",
 "virtualNetworkName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-vnet')]",

}

```

### 5.11.17. Creating the control plane machines in Azure

You must create the control plane machines in Microsoft Azure for your cluster to use. One way to create these machines is to modify the provided Azure Resource Manager (ARM) template.

## NOTE

By default, Microsoft Azure places control plane machines and compute machines in a pre-set availability zone. You can manually set an availability zone for a compute node or control plane node. To do this, modify a vendor's Azure Resource Manager (ARM) template by specifying each of your availability zones in the **zones** parameter of the virtual machine resource.

If you do not use the provided ARM template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, consider contacting Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.
- Create the bootstrap machine.

## Procedure

1. Copy the template from the **ARM template for control plane machines** section of this topic and save it as **05\_masters.json** in your cluster's installation directory. This template describes the control plane machines that your cluster requires.
2. Export the following variable needed by the control plane machine deployment:

```
$ export MASTER_IGNITION=`cat <installation_directory>/master.ign | base64 | tr -d '\n'`
```

3. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/05_masters.json" \
 --parameters masterIgnition="${MASTER_IGNITION}" ❶
 --parameters baseName="${INFRA_ID}" ❷
```

- ❶ The Ignition content for the control plane nodes.
- ❷ The base name to be used in resource names; this is usually the cluster's infrastructure ID.

### 5.11.17.1. ARM template for control plane machines

You can use the following Azure Resource Manager (ARM) template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

#### Example 5.88. 05\_masters.json ARM template

```

{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 },
 "vnetBaseName" : {
 "type" : "string",
 "defaultValue" : "",
 "metadata" : {
 "description" : "The specific customer vnet's base name (optional)"
 }
 },
 "masterIgnition" : {
 "type" : "string",
 "metadata" : {
 "description" : "Ignition content for the master nodes"
 }
 },
 "numberOfMasters" : {
 "type" : "int",
 "defaultValue" : 3,
 "minValue" : 2,
 "maxValue" : 30,
 "metadata" : {
 "description" : "Number of OpenShift masters to deploy"
 }
 },
 "sshKeyData" : {
 "type" : "securestring",
 "defaultValue" : "Unused",
 "metadata" : {
 "description" : "Unused"
 }
 },
 "privateDNSZoneName" : {
 "type" : "string",
 "defaultValue" : "",
 "metadata" : {
 "description" : "unused"
 }
 },
 "masterVMSize" : {
 "type" : "string",
 "defaultValue" : "Standard_D8s_v3",
 "metadata" : {
 "description" : "The size of the Master Virtual Machines"
 }
 },
 "diskSizeGB" : {

```

```

 "type" : "int",
 "defaultValue" : 1024,
 "metadata" : {
 "description" : "Size of the Master VM OS disk, in GB"
 }
 },
 "hyperVGen": {
 "type": "string",
 "metadata": {
 "description": "VM generation image to use"
 },
 "defaultValue": "V2",
 "allowedValues": [
 "V1",
 "V2"
]
 },
 "variables" : {
 "location" : "[resourceGroup().location]",
 "virtualNetworkName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-vnet')]",
 "virtualNetworkID" : "[resourceId('Microsoft.Network/virtualNetworks',
variables('virtualNetworkName'))]",
 "masterSubnetName" : "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-master-subnet')]",
 "masterSubnetRef" : "[concat(variables('virtualNetworkID'), '/subnets/',
variables('masterSubnetName'))]",
 "masterLoadBalancerName" : "[parameters('baseName')]",
 "internalLoadBalancerName" : "[concat(parameters('baseName'), '-internal-lb')]",
 "sshKeyPath" : "/home/core/.ssh/authorized_keys",
 "identityName" : "[concat(parameters('baseName'), '-identity')]",
 "galleryName": "[concat('gallery_', replace(parameters('baseName'), '-', '_'))]",
 "imageName" : "[concat(parameters('baseName'), if(equals(parameters('hyperVGen'), 'V2'), '-
gen2', ''))]",
 "copy" : [
 {
 "name" : "vmNames",
 "count" : "[parameters('numberOfMasters')]",
 "input" : "[concat(parameters('baseName'), '-master-', copyIndex('vmNames'))]"
 }
]
 },
 "resources" : [
 {
 "apiVersion" : "2018-06-01",
 "type" : "Microsoft.Network/networkInterfaces",
 "copy" : {
 "name" : "nicCopy",
 "count" : "[length(variables('vmNames'))]"
 },
 "name" : "[concat(variables('vmNames')[copyIndex()], '-nic')]",
 "location" : "[variables('location')]",
 "properties" : {
 "ipConfigurations" : [
 {

```

```

 "name" : "pipConfig",
 "properties" : {
 "privateIPAllocationMethod" : "Dynamic",
 "subnet" : {
 "id" : "[variables('masterSubnetRef')]"
 },
 "loadBalancerBackendAddressPools" : [
 {
 "id" : "[concat('/subscriptions/', subscription().subscriptionId, '/resourceGroups/',
resourceGroup().name, '/providers/Microsoft.Network/loadBalancers/',
variables('masterLoadBalancerName'), '/backendAddressPools/',
variables('masterLoadBalancerName'))]"
 },
 {
 "id" : "[concat('/subscriptions/', subscription().subscriptionId, '/resourceGroups/',
resourceGroup().name, '/providers/Microsoft.Network/loadBalancers/',
variables('internalLoadBalancerName'), '/backendAddressPools/internal-lb-backend')]"
 }
]
 }
 }
}
],
{
 "apiVersion" : "2018-06-01",
 "type" : "Microsoft.Compute/virtualMachines",
 "copy" : {
 "name" : "vmCopy",
 "count" : "[length(variables('vmNames'))]"
 },
 "name" : "[variables('vmNames')[copyIndex()]]",
 "location" : "[variables('location')]",
 "identity" : {
 "type" : "userAssigned",
 "userAssignedIdentities" : {
 "[resourceID('Microsoft.ManagedIdentity/userAssignedIdentities/',
variables('identityName'))]" : {}
 }
 },
 "dependsOn" : [
 "[concat('Microsoft.Network/networkInterfaces/', concat(variables('vmNames')[copyIndex()], '-
nic'))]"
],
 "properties" : {
 "hardwareProfile" : {
 "vmSize" : "[parameters('masterVMSize')]"
 },
 "osProfile" : {
 "computerName" : "[variables('vmNames')[copyIndex()]]",
 "adminUsername" : "core",
 "adminPassword" : "NotActuallyApplied!",
 "customData" : "[parameters('masterIgnition')]",
 "linuxConfiguration" : {
 "disablePasswordAuthentication" : false
 }
 }
 }
}

```

```

 },
 "storageProfile" : {
 "imageReference": {
 "id": "[resourceId('Microsoft.Compute/galleries/images', variables('galleryName'),
variables('imageName'))]"
 },
 "osDisk" : {
 "name": "[concat(variables('vmNames')[copyIndex()], '_OSDisk')]",
 "osType" : "Linux",
 "createOption" : "FromImage",
 "caching": "ReadOnly",
 "writeAcceleratorEnabled": false,
 "managedDisk": {
 "storageAccountType": "Premium_LRS"
 },
 "diskSizeGB" : "[parameters('diskSizeGB')]"
 }
 },
 "networkProfile" : {
 "networkInterfaces" : [
 {
 "id": "[resourceId('Microsoft.Network/networkInterfaces', concat(variables('vmNames')
[copyIndex()], '-nic'))]",
 "properties": {
 "primary": false
 }
 }
]
 }
 }
}
]
}

```

### 5.11.18. Wait for bootstrap completion and remove bootstrap resources in Azure

After you create all of the required infrastructure in Microsoft Azure, wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.
- Create the bootstrap machine.

- Create the control plane machines.

## Procedure

1. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install wait-for bootstrap-complete --dir <installation_directory> \ 1
--log-level info 2
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the command exits without a **FATAL** warning, your production control plane has initialized.

2. Delete the bootstrap resources:

```
$ az network nsg rule delete -g ${RESOURCE_GROUP} --nsg-name ${INFRA_ID}-nsg --
name bootstrap_ssh_in
$ az vm stop -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap
$ az vm deallocate -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap
$ az vm delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap --yes
$ az disk delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap_OSDisk --no-
wait --yes
$ az network nic delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap-nic --no-
wait
$ az storage blob delete --account-key ${ACCOUNT_KEY} --account-name
${CLUSTER_NAME}sa --container-name files --name bootstrap.ign
$ az network public-ip delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap-
ssh-pip
```

### NOTE

If you do not delete the bootstrap server, installation may not succeed due to API traffic being routed to the bootstrap server.

## 5.11.19. Creating additional worker machines in Azure

You can create worker machines in Microsoft Azure for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

### NOTE

If you are installing a three-node cluster, skip this step. A three-node cluster consists of three control plane machines, which also act as compute machines.

In this example, you manually launch one instance by using the Azure Resource Manager (ARM) template. Additional instances can be launched by including additional resources of type **06\_workers.json** in the file.

## NOTE

By default, Microsoft Azure places control plane machines and compute machines in a pre-set availability zone. You can manually set an availability zone for a compute node or control plane node. To do this, modify a vendor's ARM template by specifying each of your availability zones in the **zones** parameter of the virtual machine resource.

If you do not use the provided ARM template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, consider contacting Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

## Procedure

1. Copy the template from the **ARM template for worker machines** section of this topic and save it as **06\_workers.json** in your cluster's installation directory. This template describes the worker machines that your cluster requires.
2. Export the following variable needed by the worker machine deployment:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign | base64 | tr -d '\n'`
```

3. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/06_workers.json" \
 --parameters workerIgnition="${WORKER_IGNITION}" \ 1
 --parameters baseName="${INFRA_ID}" 2
```

- 1** The Ignition content for the worker nodes.
- 2** The base name to be used in resource names; this is usually the cluster's infrastructure ID.

### 5.11.19.1. ARM template for worker machines

You can use the following Azure Resource Manager (ARM) template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

Example 5.89. **06\_workers.json** ARM template

```

{
 "$schema" : "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
 "contentVersion" : "1.0.0.0",
 "parameters" : {
 "baseName" : {
 "type" : "string",
 "minLength" : 1,
 "metadata" : {
 "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
 }
 },
 "vnetBaseName": {
 "type": "string",
 "defaultValue": "",
 "metadata" : {
 "description" : "The specific customer vnet's base name (optional)"
 }
 },
 "workerIgnition" : {
 "type" : "string",
 "metadata" : {
 "description" : "Ignition content for the worker nodes"
 }
 },
 "numberOfNodes" : {
 "type" : "int",
 "defaultValue" : 3,
 "minValue" : 2,
 "maxValue" : 30,
 "metadata" : {
 "description" : "Number of OpenShift compute nodes to deploy"
 }
 },
 "sshKeyData" : {
 "type" : "securestring",
 "defaultValue" : "Unused",
 "metadata" : {
 "description" : "Unused"
 }
 },
 "nodeVMSize" : {
 "type" : "string",
 "defaultValue" : "Standard_D4s_v3",
 "metadata" : {
 "description" : "The size of the each Node Virtual Machine"
 }
 },
 "hyperVGen": {
 "type": "string",
 "metadata": {
 "description": "VM generation image to use"
 },
 "defaultValue": "V2",

```

```

 "allowedValues": [
 "V1",
 "V2"
]
 },
 "variables": {
 "location": "[resourceGroup().location]",
 "virtualNetworkName": "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-vnet')]",
 "virtualNetworkID": "[resourceId('Microsoft.Network/virtualNetworks',
variables('virtualNetworkName'))]",
 "nodeSubnetName": "[concat(if(not(empty(parameters('vnetBaseName'))),
parameters('vnetBaseName'), parameters('baseName')), '-worker-subnet')]",

 },
 "diskSizeGB": 128
 }
 }
 }
 }
}

```

-

## Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

## Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

## Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

## Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 5.11.21. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

## Example output

```
system:admin
```

### 5.11.22. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

## Prerequisites

- You added machines to your cluster.

## Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

### Example output

| NAME     | STATUS | ROLES  | AGE | VERSION |
|----------|--------|--------|-----|---------|
| master-0 | Ready  | master | 63m | v1.27.3 |
| master-1 | Ready  | master | 63m | v1.27.3 |
| master-2 | Ready  | master | 64m | v1.27.3 |

The output lists all of the machines that you created.

### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

| NAME      | AGE | REQUESTOR                                                              | CONDITION |
|-----------|-----|------------------------------------------------------------------------|-----------|
| csr-8b2br | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstrap | Pending   |
| csr-8vnps | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstrap | Pending   |
| ...       |     |                                                                        |           |

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

### NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

## NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrap** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

## NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

## 5.11.23. Adding the Ingress DNS records

If you removed the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the Ingress load balancer. You can create either a wildcard **\*.apps.{baseDomain}**, or specific records. You can use A, CNAME, and other records per your requirements.

### Prerequisites

- You deployed an OpenShift Container Platform cluster on Microsoft Azure by using infrastructure that you provisioned.
- Install the OpenShift CLI (**oc**).
- Install or update the [Azure CLI](#).

### Procedure

1. Confirm the Ingress router has created a load balancer and populated the **EXTERNAL-IP** field:

```
$ oc -n openshift-ingress get service router-default
```

### Example output

| NAME           | TYPE         | CLUSTER-IP   | EXTERNAL-IP    | PORT(S)                    | AGE |
|----------------|--------------|--------------|----------------|----------------------------|-----|
| router-default | LoadBalancer | 172.30.20.10 | 35.130.120.110 | 80:32288/TCP,443:31215/TCP | 20  |

2. Export the Ingress router IP as a variable:

```
$ export PUBLIC_IP_ROUTER=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
```

3. Add a **\*.apps** record to the public DNS zone.

- a. If you are adding this cluster to a new public zone, run:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps -a ${PUBLIC_IP_ROUTER} --ttl 300
```

- b. If you are adding this cluster to an already existing public zone, run:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${BASE_DOMAIN} -n *.apps.${CLUSTER_NAME} -a ${PUBLIC_IP_ROUTER} --ttl 300
```

4. Add a **\*.apps** record to the private DNS zone:

- a. Create a **\*.apps** record by using the following command:

```
$ az network private-dns record-set a create -g ${RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps --ttl 300
```

- b. Add the **\*.apps** record to the private DNS zone by using the following command:

```
$ az network private-dns record-set a add-record -g ${RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps -a ${PUBLIC_IP_ROUTER}
```

If you prefer to add explicit domains instead of using a wildcard, you can create entries for each of the cluster's current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}{"\n"}{end}{end}' routes
```

### Example output

```
oauth-openshift.apps.cluster.basedomain.com
console-openshift-console.apps.cluster.basedomain.com
downloads-openshift-console.apps.cluster.basedomain.com
alertmanager-main-openshift-monitoring.apps.cluster.basedomain.com
prometheus-k8s-openshift-monitoring.apps.cluster.basedomain.com
```

## 5.11.24. Completing an Azure installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Microsoft Azure user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

## Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned Azure infrastructure.
- Install the **oc** CLI and log in.

## Procedure

- Complete the cluster installation:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

## Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 5.11.25. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

## Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

## 5.12. INSTALLING A CLUSTER ON AZURE IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.14, you can install a cluster on Microsoft Azure in a restricted network by creating an internal mirror of the installation release content on an existing Azure Virtual Network (VNet).

### IMPORTANT

You can install an OpenShift Container Platform cluster by using mirrored installation release content, but your cluster requires internet access to use the Azure APIs.

#### 5.12.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure account](#) to host the cluster and determined the tested and validated region to deploy the cluster.
- You [mirrored the images for a disconnected installation](#) to your registry and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

### IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have an existing VNet in Azure. While installing a cluster in a restricted network that uses installer-provisioned infrastructure, you cannot use the installer-provisioned VNet. You must use a user-provisioned VNet that satisfies one of the following requirements:
  - The VNet contains the mirror registry
  - The VNet has firewall rules or a peering connection to access the mirror registry hosted elsewhere
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- If you use customer-managed encryption keys, you [prepared your Azure environment for encryption](#).

#### 5.12.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the

OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

#### 5.12.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

#### 5.12.2.2. User-defined outbound routing

In OpenShift Container Platform, you can choose your own outbound routing for a cluster to connect to the internet. This allows you to skip the creation of public IP addresses and the public load balancer.

You can configure user-defined routing by modifying parameters in the **install-config.yaml** file before installing your cluster. A pre-existing VNet is required to use outbound routing when installing a cluster; the installation program is not responsible for configuring this.

When configuring a cluster to use user-defined routing, the installation program does not create the following resources:

- Outbound rules for access to the internet.
- Public IPs for the public load balancer.
- Kubernetes Service object to add the cluster machines to the public load balancer for outbound requests.

You must ensure the following items are available before setting user-defined routing:

- Egress to the internet is possible to pull container images, unless using an OpenShift image registry mirror.
- The cluster can access Azure APIs.
- Various allowlist endpoints are configured. You can reference these endpoints in the *Configuring your firewall* section.

There are several pre-existing networking setups that are supported for internet access using user-defined routing.

#### Restricted cluster with Azure Firewall

You can use Azure Firewall to restrict the outbound routing for the Virtual Network (VNet) that is used to install the OpenShift Container Platform cluster. For more information, see [providing user-defined routing with Azure Firewall](#). You can create a OpenShift Container Platform cluster in a restricted network by using VNet with Azure Firewall and configuring the user-defined routing.

#### IMPORTANT

If you are using Azure Firewall for restricting internet access, you must set the **publish** field to **Internal** in the **install-config.yaml** file. This is because [Azure Firewall does not work properly with Azure public load balancers](#).

### 5.12.3. About reusing a VNet for your OpenShift Container Platform cluster

In OpenShift Container Platform 4.14, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

#### 5.12.3.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups

#### NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet's CIDR block must contain the **Networking.MachineCIDR** range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

NOTE

By default, if you specify availability zones in the **install-config.yaml** file, the installation program distributes the control plane machines and the compute machines across [these availability zones](#) within [a region](#). To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for. If required, the installation program creates public load balancers that manage the control plane and worker nodes, and Azure allocates a public IP address to them.

NOTE

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

5.12.3.1.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

IMPORTANT

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

Table 5.32. Required ports

| Port  | Description                                                                          | Control plane | Compute |
|-------|--------------------------------------------------------------------------------------|---------------|---------|
| 80    | Allows HTTP traffic                                                                  |               | x       |
| 443   | Allows HTTPS traffic                                                                 |               | x       |
| 6443  | Allows communication to the control plane machines                                   | x             |         |
| 22623 | Allows internal communication to the machine config server for provisioning machines | x             |         |

| Port | Description                                                                                                    | Control plane | Compute |
|------|----------------------------------------------------------------------------------------------------------------|---------------|---------|
| *    | Allows connections to Azure APIs. You must set a Destination Service Tag to <b>AzureCloud</b> . <sup>[1]</sup> | x             | x       |
| *    | Denies connections to the internet. You must set a Destination Service Tag to <b>Internet</b> . <sup>[1]</sup> | x             | x       |

1. If you are using Azure Firewall to restrict the internet access, then [you can configure Azure Firewall to allow the Azure APIs](#). A network security group rule is not needed.

## IMPORTANT

Currently, there is no supported way to block or restrict the machine config server endpoint. The machine config server must be exposed to the network so that newly-provisioned machines, which have no existing configuration or state, are able to fetch their configuration. In this model, the root of trust is the certificate signing requests (CSR) endpoint, which is where the kubelet sends its certificate signing request for approval to join the cluster. Because of this, machine configs should not be used to distribute sensitive information, such as secrets and certificates.

To ensure that the machine config server endpoints, ports 22623 and 22624, are secured in bare metal scenarios, customers must configure proper network policies.

Because cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

**Table 5.33. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                       |
|----------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                        |
| TCP      | <b>1936</b>        | Metrics                                                                                                                           |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> . |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                        |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                             |
|          | <b>6081</b>        | Geneve                                                                                                                            |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                      |

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If you configure an external NTP time server, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000–32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

**Table 5.34. Ports used for control plane machine to control plane machine communications**

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379–2380</b> | etcd server and peer ports |

**Additional resources**

- [About the OpenShift SDN network plugin](#)
- [Configuring your firewall](#)

**5.12.3.2. Division of permissions**

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as VNets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make VNets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

**5.12.3.3. Isolation between clusters**

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

**5.12.4. Internet access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

### 5.12.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 5.12.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the **imageContentSources** values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.
- You have retrieved a Red Hat Enterprise Linux CoreOS (RHCOS) image and uploaded it to an accessible location.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

#### Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the **~/.azure/** directory and delete the **osServicePrincipal.json** configuration file.  
Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.
2. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
- i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **azure** as the platform to target.  
If the installation program cannot locate the **osServicePrincipal.json** configuration file from a previous installation, you are prompted for Azure subscription and authentication values.
- iii. Enter the following Azure parameter values for your subscription:
- **azure subscription id** Enter the subscription ID to use for the cluster.
  - **azure tenant id** Enter the tenant ID.
- iv. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client id**
- If you are using a service principal, enter its application ID.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, specify its client ID.
- v. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**
- If you are using a service principal, enter its password.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, leave this value blank.

-  **IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

secret from Red Hat OpenShift Cluster Manager .

- ```
pullSecret: '{"auths":{"<mirror_host_name>:5000":{"auth":"<credentials>","email":
"you@example.com"}}}'
```

b. Add the **additionalTrustBundle** parameter and value.

The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority, or the self-signed certificate that you generated for the mirror registry.

- ```
networkResourceGroupName: <vnet_resource_group> 1
virtualNetwork: <vnet> 2
controlPlaneSubnet: <control_plane_subnet> 3
computeSubnet: <compute_subnet> 4
```

- 1235

- 4 Replace **<compute\_subnet>** with the existing subnet name to deploy compute machines.

- d. Add the image content resources, which resemble the following YAML excerpt:

```
imageContentSources:
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
 source: quay.io/openshift-release-dev/ocp-release
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
 source: registry.redhat.io/ocp/release
```

For these values, use the **imageContentSources** that you recorded during mirror registry creation.

- e. Optional: Set the publishing strategy to **Internal**:

```
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

### IMPORTANT

Azure Firewall [does not work seamlessly](#) with Azure Public Load balancers. Thus, when using Azure Firewall for restricting internet access, the **publish** field in **install-config.yaml** should be set to **Internal**.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

If previously not detected, the installation program creates an **osServicePrincipal.json** configuration file and stores this file in the **~/.azure/** directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

### Additional resources

- [Installation configuration parameters for Azure](#)

#### 5.12.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 5.35. Minimum resource requirements

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

## IMPORTANT

You are required to use Azure virtual machines that have the **premiumIO** parameter set to **true**.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### 5.12.6.2. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

**Example 5.90. Machine types based on 64-bit x86 architecture**

- **c4.\***
- **c5.\***
- **c5a.\***
- **i3.\***
- **m4.\***
- **m5.\***
- **m5a.\***
- **m6a.\***
- **m6i.\***
- **r4.\***
- **r5.\***
- **r5a.\***
- **r6i.\***
- **t3.\***
- **t3a.\***

### 5.12.6.3. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

**Example 5.91. Machine types based on 64-bit ARM architecture**

- **c6g.\***
- **c7g.\***
- **m6g.\***
- **m7g.\***
- **r8g.\***

### 5.12.6.4. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: [secure boot](#) and [virtualized Trusted Platform Modules](#).

See the Azure documentation about [virtual machine sizes](#) to learn what sizes of virtual machines support these features.

## IMPORTANT

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

## Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add the following stanza:

```
controlPlane: ❶
 platform:
 azure:
 settings:
 securityType: TrustedLaunch ❷
 trustedLaunch:
 uefiSettings:
 secureBoot: Enabled ❸
 virtualizedTrustedPlatformModule: Enabled ❹
```

- ❶ Specify **controlPlane.platform.azure** or **compute.platform.azure** to enable trusted launch on only control plane or compute nodes respectively. Specify **platform.azure.defaultMachinePlatform** to enable trusted launch on all nodes.
- ❷ Enable trusted launch features.
- ❸ Enable secure boot. For more information, see the Azure documentation about [secure boot](#).
- ❹ Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about [virtualized Trusted Platform Modules](#).

### 5.12.6.5. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.

## IMPORTANT

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

## IMPORTANT

Confidential VMs are currently not supported on 64-bit ARM architectures.

### Prerequisites

- You have created an **install-config.yaml** file.

### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add the following stanza:

```
controlPlane: ❶
 platform:
 azure:
 settings:
 securityType: ConfidentialVM ❷
 confidentialVM:
 uefiSettings:
 secureBoot: Enabled ❸
 virtualizedTrustedPlatformModule: Enabled ❹
 osDisk:
 securityProfile:
 securityEncryptionType: VMGuestStateOnly ❺
```

- ❶ Specify **controlPlane.platform.azure** or **compute.platform.azure** to deploy confidential VMs on only control plane or compute nodes respectively. Specify **platform.azure.defaultMachinePlatform** to deploy confidential VMs on all nodes.
- ❷ Enable confidential VMs.
- ❸ Enable secure boot. For more information, see the Azure documentation about [secure boot](#).

- 4 Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about [virtualized Trusted Platform Modules](#).
- 5 Specify **VMGuestStateOnly** to encrypt the VM guest state.

#### 5.12.6.6. Sample customized install-config.yaml file for Azure

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com 1
controlPlane: 2
 hyperthreading: Enabled 3 4

 publish: Internal 26

```

- 
- 1 10 14 21 Required. The installation program prompts you for this value.
- 2 6 If you do not provide these parameters and values, the installation program provides the default value.
- 3 7 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 4 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as **Standard\_D8s\_v3**, for your machines if you disable simultaneous multithreading.

- 5 8 You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.
- 9 Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.
- 11 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 12 Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The **publisher**, **offer**, **sku**, and **version** parameters under **platform.azure.defaultMachinePlatform.osImage** apply to both control plane and compute machines. If the parameters under **controlPlane.platform.azure.osImage** or **compute.platform.azure.osImage** are set, they override the **platform.azure.defaultMachinePlatform.osImage** parameters.
- 13 Specify the name of the resource group that contains the DNS zone for your base domain.
- 15 Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
- 16 If you use an existing VNet, specify the name of the resource group that contains it.
- 17 If you use an existing VNet, specify its name.
- 18 If you use an existing VNet, specify the name of the subnet to host the control plane machines.
- 19 If you use an existing VNet, specify the name of the subnet to host the compute machines.
- 20 When using Azure Firewall to restrict Internet access, you must configure outbound routing to send traffic through the Azure Firewall. Configuring user-defined routing prevents exposing external endpoints in your cluster.
- 22 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). The use of FIPS validated or Modules In Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86\_64**, **ppc64le**, and **s390x** architectures.

**23**

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

**24**

Provide the contents of the certificate file that you used for your mirror registry.

**25**

Provide the **imageContentSources** section from the output of the command to mirror the repository.

**26**

How to publish the user-facing endpoints of your cluster. When using Azure Firewall to restrict Internet access, set **publish** to **Internal** to deploy a private cluster. The user-facing endpoints then cannot be accessed from the internet. The default value is **External**.

### 5.12.6.7. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 5.12.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

##### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 5.12.8. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring an Azure cluster to use short-term credentials](#).

### 5.12.8.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \ 1 \
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 2 \
 --to=<path_to_directory_for_credentials_requests> \ 3
```

- 1** The **--included** parameter includes only the manifests that your specific cluster configuration requires.

- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...
```

### Sample **Secret** object

```
apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
```

data:

```
azure_subscription_id: <base64_encoded_azure_subscription_id>
azure_client_id: <base64_encoded_azure_client_id>
azure_client_secret: <base64_encoded_azure_client_secret>
azure_tenant_id: <base64_encoded_azure_tenant_id>
azure_resource_prefix: <base64_encoded_azure_resource_prefix>
azure_resourcegroup: <base64_encoded_azure_resourcegroup>
azure_region: <base64_encoded_azure_region>
```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

## 5.12.8.2. Configuring an Azure cluster to use short-term credentials

To install a cluster that uses Microsoft Entra Workload ID, you must configure the Cloud Credential Operator utility and create the required Azure resources for your cluster.

### 5.12.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccctl**) binary.

### NOTE

The **ccctl** utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).
- You have created a global Microsoft Azure account for the **ccctl** utility to use with the following permissions:

#### Example 5.92. Required Azure permissions

- Microsoft.Resources/subscriptions/resourceGroups/read
- Microsoft.Resources/subscriptions/resourceGroups/write
- Microsoft.Resources/subscriptions/resourceGroups/delete
- Microsoft.Authorization/roleAssignments/read
- Microsoft.Authorization/roleAssignments/delete
- Microsoft.Authorization/roleAssignments/write
- Microsoft.Authorization/roleDefinitions/read
- Microsoft.Authorization/roleDefinitions/write
- Microsoft.Authorization/roleDefinitions/delete

- Microsoft.Storage/storageAccounts/listkeys/action
- Microsoft.Storage/storageAccounts/delete
- Microsoft.Storage/storageAccounts/read
- Microsoft.Storage/storageAccounts/write
- Microsoft.Storage/storageAccounts/blobServices/containers/write
- Microsoft.Storage/storageAccounts/blobServices/containers/delete
- Microsoft.Storage/storageAccounts/blobServices/containers/read
- Microsoft.ManagedIdentity/userAssignedIdentities/delete
- Microsoft.ManagedIdentity/userAssignedIdentities/read
- Microsoft.ManagedIdentity/userAssignedIdentities/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/read
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/delete
- Microsoft.Storage/register/action
- Microsoft.ManagedIdentity/register/action

## Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

### Verification

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccoctl.rhel9
```

### Example output

```
OpenShift credentials provisioning tool

Usage:
 ccoctl [command]

Available Commands:
 alibabacloud Manage credentials objects for alibaba cloud
 aws Manage credentials objects for AWS cloud
 azure Manage credentials objects for Azure
 gcp Manage credentials objects for Google cloud
 help Help about any command
 ibmcloud Manage credentials objects for IBM Cloud
 nutanix Manage credentials objects for Nutanix

Flags:
 -h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.
```

#### 5.12.8.2.2. Creating Azure resources with the Cloud Credential Operator utility

You can use the **ccoctl azure create-all** command to automate the creation of Azure resources.

### NOTE

By default, **ccoctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccoctl\_output\_dir>** to refer to this directory.

### Prerequisites

You must have:

- Extracted and prepared the **ccoctl** binary.
- Access to your Microsoft Azure account by using the Azure CLI.

### Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

#### NOTE

This command might take a few moments to run.

3. To enable the **ccoctl** utility to detect your Azure credentials automatically, log in to the Azure CLI by running the following command:

```
$ az login
```

4. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl azure create-all \
 --name=<azure_infra_name> \1
 --output-dir=<ccoctl_output_dir> \2
 --region=<azure_region> \3
 --subscription-id=<azure_subscription_id> \4
 --credentials-requests-dir=<path_to_credentials_requests_directory> \5
 --dnszone-resource-group-name=<azure_dns_zone_resource_group_name> \6
 --tenant-id=<azure_tenant_id> \7
```

- 1 Specify the user-defined name for all created Azure resources used for tracking.
- 2 Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 3 Specify the Azure region in which cloud resources will be created.
- 4 Specify the Azure subscription ID to use.
- 5 Specify the directory containing the files for the component **CredentialsRequest** objects.

- 6 Specify the name of the resource group containing the cluster's base domain Azure DNS zone.
- 7 Specify the Azure tenant ID to use.

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

To see additional optional parameters and explanations of how to use them, run the **azure create-all --help** command.

#### Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

#### Example output

```
azure-ad-pod-identity-webhook-config.yaml
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-azure-cloud-credentials-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capz-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-disk-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-file-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-azure-cloud-credentials-credentials.yaml
```

You can verify that the Microsoft Entra ID service accounts are created by querying Azure. For more information, refer to Azure documentation on listing Entra ID service accounts.

#### 5.12.8.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccoctl**) created to the correct directories for the installation program.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccoctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccoctl** utility.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you used the **ccoctl** utility to create a new Azure resource group instead of using an existing resource group, modify the **resourceGroupName** parameter in the **install-config.yaml** as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
...
platform:
 azure:
 resourceGroupName: <azure_infra_name> 1
...
```

- 1** This value must match the user-defined name for Azure resources that was specified with the **--name** argument of the **ccoctl azure create-all** command.

3. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

4. Copy the manifests that the **ccoctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

5. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

### 5.12.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

## Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 5.12.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

### 5.12.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 5.12.12. Next steps

- [Customize your cluster.](#)
- If necessary, you can [opt out of remote health reporting](#).

## 5.13. INSTALLING A THREE-NODE CLUSTER ON AZURE

In OpenShift Container Platform version 4.14, you can install a three-node cluster on Microsoft Azure. A three-node cluster consists of three control plane machines, which also act as compute machines. This type of cluster provides a smaller, more resource efficient cluster, for cluster administrators and developers to use for testing, development, and production.

You can install a three-node cluster using either installer-provisioned or user-provisioned infrastructure.

### NOTE

Deploying a three-node cluster using an Azure Marketplace image is not supported.

### 5.13.1. Configuring a three-node cluster

You configure a three-node cluster by setting the number of worker nodes to **0** in the **install-config.yaml** file before deploying the cluster. Setting the number of worker nodes to **0** ensures that the control plane machines are schedulable. This allows application workloads to be scheduled to run from the control plane nodes.

### NOTE

Because application workloads run from control plane nodes, additional subscriptions are required, as the control plane nodes are considered to be compute nodes.

### Prerequisites

- You have an existing **install-config.yaml** file.

### Procedure

1. Set the number of compute replicas to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

#### Example **install-config.yaml** file for a three-node cluster

```
apiVersion: v1
baseDomain: example.com
compute:
```

```
- name: worker
 platform: {}
 replicas: 0
...
```

2. If you are deploying a cluster with user-provisioned infrastructure:

- After you create the Kubernetes manifest files, make sure that the **spec.mastersSchedulable** parameter is set to **true** in **cluster-scheduler-02-config.yml** file. You can locate this file in **<installation\_directory>/manifests**. For more information, see "Creating the Kubernetes manifest and Ignition config files" in "Installing a cluster on Azure using ARM templates".
- Do not create additional worker nodes.

### Example cluster-scheduler-02-config.yml file for a three-node cluster

```
apiVersion: config.openshift.io/v1
kind: Scheduler
metadata:
 creationTimestamp: null
 name: cluster
spec:
 mastersSchedulable: true
 policy:
 name: ""
status: {}
```

### 5.13.2. Next steps

- [Installing a cluster on Azure with customizations](#)
- [Installing a cluster on Azure using ARM templates](#)

## 5.14. UNINSTALLING A CLUSTER ON AZURE

You can remove a cluster that you deployed to Microsoft Azure.

### 5.14.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

#### NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

#### Prerequisites

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

## Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$./openshift-install destroy cluster \
--dir <installation_directory> --log-level info 1 2
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2** To view different details, specify **warn**, **debug**, or **error** instead of **info**.

### NOTE

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the **metadata.json** file in this directory to delete the cluster.

2. Optional: Delete the **<installation\_directory>** directory and the OpenShift Container Platform installation program.

## 5.14.2. Deleting Microsoft Azure resources with the Cloud Credential Operator utility

After uninstalling an OpenShift Container Platform cluster that uses short-term credentials managed outside the cluster, you can use the CCO utility (**ccctl**) to remove the Microsoft Azure (Azure) resources that **ccctl** created during installation.

### Prerequisites

- Extract and prepare the **ccctl** binary.
- Uninstall an OpenShift Container Platform cluster on Azure that uses short-term credentials.

## Procedure

- Delete the Azure resources that **ccctl** created by running the following command:

```
$ ccctl azure delete \
--name=<name> 1
--region=<azure_region> 2
--subscription-id=<azure_subscription_id> 3
--delete-oidc-resource-group
```

- 1** **<name>** matches the name that was originally used to create and tag the cloud resources.
- 2** **<azure\_region>** is the Azure region in which to delete cloud resources.
- 3** **<azure\_subscription\_id>** is the Azure subscription ID for which to delete cloud resources.

## Verification

- To verify that the resources are deleted, query Azure. For more information, refer to Azure documentation.

## 5.15. INSTALLATION CONFIGURATION PARAMETERS FOR AZURE

Before you deploy an OpenShift Container Platform cluster on Microsoft Azure, you provide parameters to customize your cluster and the platform that hosts it. When you create the **install-config.yaml** file, you provide values for the required parameters through the command line. You can then modify the **install-config.yaml** file to customize your cluster further.

### 5.15.1. Available installation configuration parameters for Azure

The following tables specify the required, optional, and Azure-specific installation configuration parameters that you can set as part of the installation process.

#### NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

#### 5.15.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 5.36. Required parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                     | Values                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| <b>apiVersion:</b> | The API version for the <b>install-config.yaml</b> content. The current version is <b>v1</b> . The installation program may also support older API versions.                                                                                                                                                                                    | String                                                                   |
| <b>baseDomain:</b> | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <b>baseDomain</b> and <b>metadata.name</b> parameter values that uses the <b>&lt;metadata.name&gt;</b> . <b>&lt;baseDomain&gt;</b> format. | A fully-qualified domain or subdomain name, such as <b>example.com</b> . |

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                                                                                                                                                                |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>metadata:</code>           | Kubernetes resource <b>ObjectMeta</b> , from which only the <b>name</b> parameter is consumed.                                                                                                                                                                                                                                                                                                                                 | Object                                                                                                                                                                                                |
| <code>metadata:<br/>name:</code> | The name of the cluster. DNS records for the cluster are all subdomains of <b>{{.metadata.name}}.{{.baseDomain}}</b> .                                                                                                                                                                                                                                                                                                         | String of lowercase letters, hyphens (-), and periods (.), such as <b>dev</b> .                                                                                                                       |
| <code>platform:</code>           | The configuration for the specific platform upon which to perform the installation: <b>alibabacloud</b> , <b>aws</b> , <b>baremetal</b> , <b>azure</b> , <b>gcp</b> , <b>ibmcloud</b> , <b>nutanix</b> , <b>openstack</b> , <b>powervs</b> , <b>vsphere</b> , or <b>{}</b> . For additional information about <b>platform</b> . <b>&lt;platform&gt;</b> parameters, consult the table for your specific platform that follows. | Object                                                                                                                                                                                                |
| <code>pullSecret:</code>         | Get a <a href="#">pull secret from Red Hat OpenShift Cluster Manager</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.                                                                                                                                                                                                                               | <pre>{   "auths":{     "cloud.openshift.com":{       "auth":"b3Blb=",       "email":"you@example.com"     },     "quay.io":{       "auth":"b3Blb=",       "email":"you@example.com"     }   } }</pre> |

### 5.15.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

**Table 5.37. Network parameters**

| Parameter                                                          | Description                                                                                                                                                                                                                                                                                   | Values                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>networking:</b>                                                 | The configuration for the cluster network.                                                                                                                                                                                                                                                    | Object<br><br> <b>NOTE</b><br>You cannot modify parameters specified by the <b>networking</b> object after installation.                                                                            |
| <b>networking:</b><br><b>networkType:</b>                          | The Red Hat OpenShift Networking network plugin to install.                                                                                                                                                                                                                                   | Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b> . <b>OpenShiftSDN</b> is a CNI plugin for all-Linux networks. <b>OVNKubernetes</b> is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is <b>OVNKubernetes</b> . |
| <b>networking:</b><br><b>clusterNetwork:</b>                       | The IP address blocks for pods.<br><br>The default value is <b>10.128.0.0/14</b> with a host prefix of <b>/23</b> .<br><br>If you specify multiple IP address blocks, the blocks must not overlap.                                                                                            | An array of objects. For example:<br><br><b>networking:</b><br><b>clusterNetwork:</b><br>- cidr: <b>10.128.0.0/14</b><br>hostPrefix: <b>23</b>                                                                                                                                        |
| <b>networking:</b><br><b>clusterNetwork:</b><br><b>cidr:</b>       | Required if you use <b>networking.clusterNetwork</b> . An IP address block.<br><br>An IPv4 network.                                                                                                                                                                                           | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between <b>0</b> and <b>32</b> .                                                                                                                                        |
| <b>networking:</b><br><b>clusterNetwork:</b><br><b>hostPrefix:</b> | The subnet prefix length to assign to each individual node. For example, if <b>hostPrefix</b> is set to <b>23</b> then each node is assigned a <b>/23</b> subnet out of the given <b>cidr</b> . A <b>hostPrefix</b> value of <b>23</b> provides 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. | A subnet prefix.<br><br>The default value is <b>23</b> .                                                                                                                                                                                                                              |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                         | Values                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:<br/>serviceNetwork:</code>           | <p>The IP address block for services. The default value is <b>172.30.0.0/16</b>.</p> <p>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.</p>                                                                                                                    | <p>An array with an IP address block in CIDR format. For example:</p> <pre>networking:   serviceNetwork:     - 172.30.0.0/16</pre>                                                                                                                                                                            |
| <code>networking:<br/>machineNetwork:</code>           | <p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>                                                                                                                                                                                                           | <p>An array of objects. For example:</p> <pre>networking:   machineNetwork:     - cidr: 10.0.0.0/16</pre>                                                                                                                                                                                                     |
| <code>networking:<br/>machineNetwork:<br/>cidr:</code> | <p>Required if you use <b>networking.machineNetwork</b>. An IP address block. The default value is <b>10.0.0.0/16</b> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <b>192.168.126.0/24</b>. For IBM Power® Virtual Server, the default value is <b>192.168.0.0/24</b>.</p> | <p>An IP network block in CIDR notation.</p> <p>For example, <b>10.0.0.0/16</b>.</p> <div>  <p><b>NOTE</b></p> <p>Set the <b>networking.machineNetwork</b> to match the CIDR that the preferred NIC resides in.</p> </div> |

### 5.15.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 5.38. Optional parameters**

| Parameter                           | Description                                                                                                                                                                                                                                                 | Values       |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <code>additionalTrustBundle:</code> | A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.                                                                                          | String       |
| <code>capabilities:</code>          | Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the "Cluster capabilities" page in <i>Installing</i> . | String array |

| Parameter                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Values                                                             |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| capabilities:<br>baselineCapabilitySet:         | Selects an initial set of optional capabilities to enable. Valid values are <b>None</b> , <b>v4.11</b> , <b>v4.12</b> and <b>vCurrent</b> . The default value is <b>vCurrent</b> .                                                                                                                                                                                                                                                                                                                                               | String                                                             |
| capabilities:<br>additionalEnabledCapabilities: | Extends the set of optional capabilities beyond what you specify in <b>baselineCapabilitySet</b> . You may specify multiple capabilities in this parameter.                                                                                                                                                                                                                                                                                                                                                                      | String array                                                       |
| cpuPartitioningMode:                            | Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <i>Workload partitioning</i> page in the <i>Scalability and Performance</i> section.                   | <b>None</b> or <b>AllNodes</b> . <b>None</b> is the default value. |
| compute:                                        | The configuration for the machines that comprise the compute nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Array of <b>MachinePool</b> objects.                               |
| compute:<br>architecture:                       | Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <b>amd64</b> and <b>arm64</b> . Not all installation options support the 64-bit ARM architecture. To verify if your installation option is supported on your platform, see <i>Supported installation methods for different platforms</i> in <i>Selecting a cluster installation method and preparing it for users</i> . | String                                                             |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Values                                                                                              |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>compute:<br/>hyperthreading:</code> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div> | <b>Enabled</b> or <b>Disabled</b>                                                                   |
| <code>compute:<br/>name:</code>           | Required if you use <b>compute</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                | <b>worker</b>                                                                                       |
| <code>compute:<br/>platform:</code>       | Required if you use <b>compute</b> . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <b>controlPlane.platform</b> parameter value.                                                                                                                                                                                                                                                                                              | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere</b> , or <b>{}</b> |
| <code>compute:<br/>replicas:</code>       | The number of compute machines, which are also known as worker machines, to provision.                                                                                                                                                                                                                                                                                                                                                                                                            | A positive integer greater than or equal to <b>2</b> . The default value is <b>3</b> .              |
| <code>featureSet:</code>                  | Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see "Enabling features using feature gates".                                                                                                                                                                                                                                | String. The name of the feature set to enable, such as <b>TechPreviewNoUpgrade</b> .                |
| <code>controlPlane:</code>                | The configuration for the machines that comprise the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                               | Array of <b>MachinePool</b> objects.                                                                |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Values                                                                                              |

| <b>controlPlane:</b><br><b>platform:</b>       | Required if you use <b>controlPlane</b> . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <b>compute.platform</b> parameter value.                                                                                                                                                                                                                                                                                                                   | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere</b> , or <b>{}</b> |
| <b>controlPlane:</b><br><b>replicas:</b>       | The number of control plane machines to provision.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Supported values are <b>3</b> , or <b>1</b> when deploying single-node OpenShift.                   |

| Parameter               | Description                                                                                                                                                                                                                                  | Values                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <b>credentialsMode:</b> | The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported. | <b>Mint, Passthrough, Manual</b> or an empty string ( <code>""</code> ). <sup>[1]</sup> |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Values        |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| fips:     | <p>Enable or disable FIPS mode. The default is <b>false</b> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p> <div><div></div><div><p><b>IMPORTANT</b></p><p>To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see <a href="#">Installing the system in FIPS mode</a>. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.</p></div></div> <div><div></div><div><p><b>NOTE</b></p><p>If you are using Azure File storage, you cannot enable FIPS mode.</p></div></div> | false or true |

| Parameter                                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                               | Values                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  <b>imageContentSources:</b>                    | Sources and repositories for the release-image content.                                                                                                                                                                                                                                                                                                                                   | Array of objects. Includes a <b>source</b> and, optionally, <b>mirrors</b> , as described in the following rows of this table.                                                               |
|  <b>imageContentSources:</b><br><b>source:</b>  | Required if you use <b>imageContentSources</b> . Specify the repository that users refer to, for example, in image pull specifications.                                                                                                                                                                                                                                                   | String                                                                                                                                                                                       |
|  <b>imageContentSources:</b><br><b>mirrors:</b> | Specify one or more repositories that may also contain the same images.                                                                                                                                                                                                                                                                                                                   | Array of strings                                                                                                                                                                             |
|  <b>publish:</b>                                | How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.                                                                                                                                                                                                                                                                         | <b>Internal</b> or <b>External</b> . To deploy a private cluster, which cannot be accessed from the internet, set <b>publish</b> to <b>Internal</b> . The default value is <b>External</b> . |
|  <b>sshKey:</b>                               | <p>The SSH key to authenticate access to your cluster machines.</p> <div>  <p><b>NOTE</b></p> <p>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <b>ssh-agent</b> process uses.</p> </div> | For example, <b>sshKey: ssh-ed25519 AAAA...</b>                                                                                                                                              |

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.

### IMPORTANT

Setting this parameter to **Manual** enables alternatives to storing administrator-level secrets in the **kube-system** project, which require additional configuration steps. For more information, see "Alternatives to storing administrator-level secrets in the kube-system project".

#### 5.15.1.4. Additional Azure configuration parameters

Additional Azure configuration parameters are described in the following table.

**NOTE**

By default, if you specify availability zones in the **install-config.yaml** file, the installation program distributes the control plane machines and the compute machines across [these availability zones](#) within [a region](#). To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.

**Table 5.39. Additional Azure parameters**

| Parameter                                                                                                         | Description                                                                                                                                                                                                                                                                                   | Values                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <div> <div>compute:</div> <div>platform:</div> <div>azure:</div> <div>encryptionAtHost:</div> </div>              | Enables host-level encryption for compute machines. You can enable this encryption alongside user-managed server-side encryption. This feature encrypts temporary, ephemeral, cached and un-managed disks on the VM host. This is not a prerequisite for user-managed server-side encryption. | <b>true</b> or <b>false</b> . The default is <b>false</b> .                                                |
| <div> <div>compute:</div> <div>platform:</div> <div>azure:</div> <div>osDisk:</div> <div>diskSizeGB:</div> </div> | The Azure disk size for the VM.                                                                                                                                                                                                                                                               | Integer that represents the size of the disk in GB. The default is <b>128</b> .                            |
| <div> <div>compute:</div> <div>platform:</div> <div>azure:</div> <div>osDisk:</div> <div>diskType:</div> </div>   | Defines the type of disk.                                                                                                                                                                                                                                                                     | <b>standard_LRS</b> , <b>premium_LRS</b> , or <b>standardSSD_LRS</b> . The default is <b>premium_LRS</b> . |
| <div> <div>compute:</div> <div>platform:</div> <div>azure:</div> <div>ultraSSDCapability:</div> </div>            | Enables the use of Azure ultra disks for persistent storage on compute nodes. This requires that your Azure region and zone have ultra disks available.                                                                                                                                       | <b>Enabled</b> , <b>Disabled</b> . The default is <b>Disabled</b> .                                        |

| Parameter                                                                                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                   | Values                                                              |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| <code>compute:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskEncryptionSet:</code><br><code>resourceGroup:</code>  | The name of the Azure resource group that contains the disk encryption set from the installation prerequisites. This resource group should be different from the resource group where you install the cluster to avoid deleting your Azure encryption key when the cluster is destroyed. This value is only necessary if you intend to install the cluster with user-managed disk encryption. | String, for example <b>production_encryption_resource_group</b> .   |
| <code>compute:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskEncryptionSet:</code><br><code>name:</code>           | The name of the disk encryption set that contains the encryption key from the installation prerequisites.                                                                                                                                                                                                                                                                                     | String, for example <b>production_disk_encryption_set</b> .         |
| <code>compute:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskEncryptionSet:</code><br><code>subscriptionId:</code> | Defines the Azure subscription of the disk encryption set where the disk encryption set resides. This secondary disk encryption set is used to encrypt compute machines.                                                                                                                                                                                                                      | String, in the format <b>00000000-0000-0000-0000-000000000000</b> . |
| <code>compute:</code><br><code>platform:</code><br><code>azure:</code><br><code>osImage:</code><br><code>publisher:</code>                                        | Optional. By default, the installation program downloads and installs the Red Hat Enterprise Linux CoreOS (RHCOS) image that is used to boot compute machines. You can override the default behavior by using a custom RHCOS image that is available from the Azure Marketplace. The installation program uses this image for compute machines only.                                          | String. The name of the image publisher.                            |
| <code>compute:</code><br><code>platform:</code><br><code>azure:</code><br><code>osImage:</code><br><code>offer:</code>                                            | The name of Azure Marketplace offer that is associated with the custom RHCOS image. If you use <b>compute.platform.azure.osImage.publisher</b> , this field is required.                                                                                                                                                                                                                      | String. The name of the image offer.                                |

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                                                                                | Values                                          |
|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| <pre>compute: platform: azure: osImage: sku:</pre>           | An instance of the Azure Marketplace offer. If you use <b>compute.platform.azure.osImage.publisher</b> , this field is required.                                                                                                                                                                                                                           | String. The SKU of the image offer.             |
| <pre>compute: platform: azure: osImage: version:</pre>       | The version number of the image SKU. If you use <b>compute.platform.azure.osImage.publisher</b> , this field is required.                                                                                                                                                                                                                                  | String. The version of the image to use.        |
| <pre>compute: platform: azure:  vmNetworkingType :</pre>     | Enables accelerated networking. Accelerated networking enables single root I/O virtualization (SR-IOV) to a VM, improving its networking performance. If instance type of compute machines support <b>Accelerated</b> networking, by default, the installer enables <b>Accelerated</b> networking, otherwise the default networking type is <b>Basic</b> . | <b>Accelerated</b> or <b>Basic</b> .            |
| <pre>compute: platform: azure: type:</pre>                   | Defines the Azure instance type for compute machines.                                                                                                                                                                                                                                                                                                      | String                                          |
| <pre>compute: platform: azure: zones:</pre>                  | The availability zones where the installation program creates compute machines.                                                                                                                                                                                                                                                                            | String list                                     |
| <pre>compute: platform: azure: settings: securityType:</pre> | Enables confidential VMs or trusted launch for compute nodes. This option is not enabled by default.                                                                                                                                                                                                                                                       | <b>ConfidentialVM</b> or <b>TrustedLaunch</b> . |

| Parameter                                                                                                                        | Description                                                                                                        | Values                                                               |
|----------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <pre> compute:   platform:     azure:       settings:  confidentialVM:   uefiSettings:  secureBoot: </pre>                       | Enables secure boot on compute nodes if you are using confidential VMs.                                            | <b>Enabled</b> or <b>Disabled</b> . The default is <b>Disabled</b> . |
| <pre> compute:   platform:     azure:       settings:  confidentialVM:   uefiSettings:  virtualizedTrustedPlatformModule: </pre> | Enables the virtualized Trusted Platform Module (vTPM) feature on compute nodes if you are using confidential VMs. | <b>Enabled</b> or <b>Disabled</b> . The default is <b>Disabled</b> . |
| <pre> compute:   platform:     azure:       settings:  trustedLaunch:   uefiSettings:  secureBoot: </pre>                        | Enables secure boot on compute nodes if you are using trusted launch.                                              | <b>Enabled</b> or <b>Disabled</b> . The default is <b>Disabled</b> . |
| <pre> compute:   platform:     azure:       settings:  trustedLaunch:   uefiSettings:  virtualizedTrustedPlatformModule: </pre>  | Enables the vTPM feature on compute nodes if you are using trusted launch.                                         | <b>Enabled</b> or <b>Disabled</b> . The default is <b>Disabled</b> . |

| Parameter                                                                                                                             | Description                                                                                                                               | Values                                                               |
|---------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <pre> compute:   platform:     azure:       osDisk:  securityProfile:  securityEncryptionType: </pre>                                 | Enables the encryption of the virtual machine guest state for compute nodes. This parameter can only be used if you use Confidential VMs. | <b>VMGuestStateOnly</b> is the only supported value.                 |
| <pre> controlPlane:   platform:     azure:       settings:         securityType: </pre>                                               | Enables confidential VMs or trusted launch for control plane nodes. This option is not enabled by default.                                | <b>ConfidentialVM</b> or <b>TrustedLaunch</b> .                      |
| <pre> controlPlane:   platform:     azure:       settings:  confidentialVM:   uefiSettings:  secureBoot: </pre>                       | Enables secure boot on control plane nodes if you are using confidential VMs.                                                             | <b>Enabled</b> or <b>Disabled</b> . The default is <b>Disabled</b> . |
| <pre> controlPlane:   platform:     azure:       settings:  confidentialVM:   uefiSettings:  virtualizedTrustedPlatformModule: </pre> | Enables the vTPM feature on control plane nodes if you are using confidential VMs.                                                        | <b>Enabled</b> or <b>Disabled</b> . The default is <b>Disabled</b> . |

| Parameter                                                                                                                                                                                                                            | Description                                                                                                                                     | Values                                                               |

| Parameter                                                                                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                   | Values                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| <code>platform:</code><br><code>azure:</code><br><br><code>defaultMachinePlatform:</code><br><code>zones:</code>                                                           | The availability zones where the installation program creates compute and control plane machines.                                                                                                                                                                                                                                                                                             | String list.                                                        |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><br><code>encryptionAtHost:</code>                                                          | Enables host-level encryption for control plane machines. You can enable this encryption alongside user-managed server-side encryption. This feature encrypts temporary, ephemeral, cached and un-managed disks on the VM host. This is not a prerequisite for user-managed server-side encryption.                                                                                           | <b>true</b> or <b>false</b> . The default is <b>false</b> .         |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><br><code>diskEncryptionSet:</code><br><code>resourceGroup:</code>  | The name of the Azure resource group that contains the disk encryption set from the installation prerequisites. This resource group should be different from the resource group where you install the cluster to avoid deleting your Azure encryption key when the cluster is destroyed. This value is only necessary if you intend to install the cluster with user-managed disk encryption. | String, for example <b>production_encryption_resource_group</b> .   |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><br><code>diskEncryptionSet:</code><br><code>name:</code>           | The name of the disk encryption set that contains the encryption key from the installation prerequisites.                                                                                                                                                                                                                                                                                     | String, for example <b>production_disk_encryption_set</b> .         |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><br><code>diskEncryptionSet:</code><br><code>subscriptionId:</code> | Defines the Azure subscription of the disk encryption set where the disk encryption set resides. This secondary disk encryption set is used to encrypt control plane machines.                                                                                                                                                                                                                | String, in the format <b>00000000-0000-0000-0000-000000000000</b> . |

| Parameter                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                      | Values                                                                             |
|---------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskSizeGB:</code> | The Azure disk size for the VM.                                                                                                                                                                                                                                                                                                                                  | Integer that represents the size of the disk in GB. The default is <b>1024</b> .   |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskType:</code>   | Defines the type of disk.                                                                                                                                                                                                                                                                                                                                        | <b>premium_LRS</b> or <b>standardSSD_LRS</b> . The default is <b>premium_LRS</b> . |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osImage:</code><br><code>publisher:</code> | Optional. By default, the installation program downloads and installs the Red Hat Enterprise Linux CoreOS (RHCOS) image that is used to boot control plane machines. You can override the default behavior by using a custom RHCOS image that is available from the Azure Marketplace. The installation program uses this image for control plane machines only. | String. The name of the image publisher.                                           |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osImage:</code><br><code>offer:</code>     | The name of Azure Marketplace offer that is associated with the custom RHCOS image. If you use <b>controlPlane.platform.azure.osImage.publisher</b> , this field is required.                                                                                                                                                                                    | String. The name of the image offer.                                               |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osImage:</code><br><code>sku:</code>       | An instance of the Azure Marketplace offer. If you use <b>controlPlane.platform.azure.osImage.publisher</b> , this field is required.                                                                                                                                                                                                                            | String. The SKU of the image offer.                                                |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osImage:</code><br><code>version:</code>   | The version number of the image SKU. If you use <b>controlPlane.platform.azure.osImage.publisher</b> , this field is required.                                                                                                                                                                                                                                   | String. The version of the image to use.                                           |

| Parameter                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Values                                                                                       |
|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| <b>controlPlane:</b><br><b>platform:</b><br><b>azure:</b><br><br><b>ultraSSDCapability:</b>          | Enables the use of Azure ultra disks for persistent storage on control plane machines. This requires that your Azure region and zone have ultra disks available.                                                                                                                                                                                                                                                                                                                                                                                                                                   | <b>Enabled, Disabled.</b> The default is <b>Disabled</b> .                                   |
| <b>controlPlane:</b><br><b>platform:</b><br><b>azure:</b><br><br><b>vmNetworkingType</b><br><b>:</b> | Enables accelerated networking. Accelerated networking enables single root I/O virtualization (SR-IOV) to a VM, improving its networking performance. If instance type of control plane machines support <b>Accelerated</b> networking, by default, the installer enables <b>Accelerated</b> networking, otherwise the default networking type is <b>Basic</b> .                                                                                                                                                                                                                                   | <b>Accelerated</b> or <b>Basic</b> .                                                         |
| <b>platform:</b><br><b>azure:</b><br><br><b>baseDomainResourceGroupName:</b>                         | The name of the resource group that contains the DNS zone for your base domain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | String, for example <b>production_cluster</b> .                                              |
| <b>platform:</b><br><b>azure:</b><br><br><b>resourceGroupName:</b>                                   | The name of an already existing resource group to install your cluster to. This resource group must be empty and only used for this specific cluster; the cluster components assume ownership of all resources in the resource group. If you limit the service principal scope of the installation program to this resource group, you must ensure all other resources used by the installation program in your environment have the necessary permissions, such as the public DNS zone and virtual network. Destroying the cluster by using the installation program deletes this resource group. | String, for example <b>existing_resource_group</b> .                                         |
| <b>platform:</b><br><b>azure:</b><br><br><b>outboundType:</b>                                        | The outbound routing strategy used to connect your cluster to the internet. If you are using user-defined routing, you must have pre-existing networking available where the outbound routing has already been configured prior to installing a cluster. The installation program is not responsible for configuring user-defined routing. If                                                                                                                                                                                                                                                      | <b>LoadBalancer, UserDefinedRouting, or NatGateway.</b> The default is <b>LoadBalancer</b> . |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Values |

|           | <p>you specify the <b>NatGateway</b> routing strategy, the installation program will only create one NAT gateway. If you specify the <b>NatGateway</b> routing strategy, your account must have the <b>Microsoft.Network/natGateways/read</b> and <b>Microsoft.Network/natGateways/write</b> permissions.</p> <div><div><p><b>IMPORTANT</b></p><p><b>NatGateway</b> is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.</p><p>For more information about the support scope of Red Hat Technology Preview features, see <a href="#">Technology Preview Features Support Scope</a>.</p></div></div> |        |

| Parameter                                                                     | Description                                                                                                                                                                                     | Values                                                      |
|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| platform:<br>azure:<br>region:                                                | The name of the Azure region that hosts your cluster.                                                                                                                                           | Any valid region name, such as <b>centralus</b> .           |
| platform:<br>azure:<br>zone:                                                  | List of availability zones to place machines in. For high availability, specify at least two zones.                                                                                             | List of zones, for example <b>["1", "2", "3"]</b> .         |
| platform:<br>azure:<br><br>defaultMachinePlatform:<br><br>ultraSSDCapability: | Enables the use of Azure ultra disks for persistent storage on control plane and compute machines. This requires that your Azure region and zone have ultra disks available.                    | <b>Enabled, Disabled</b> . The default is <b>Disabled</b> . |
| platform:<br>azure:<br><br>networkResourceGroupName:                          | The name of the resource group that contains the existing VNet that you want to deploy your cluster to. This name cannot be the same as the <b>platform.azure.baseDomainResourceGroupName</b> . | String.                                                     |
| platform:<br>azure:<br>virtualNetwork:                                        | The name of the existing VNet that you want to deploy your cluster to.                                                                                                                          | String.                                                     |
| platform:<br>azure:<br><br>controlPlaneSubnet:                                | The name of the existing subnet in your VNet that you want to deploy your control plane machines to.                                                                                            | Valid CIDR, for example <b>10.0.0.0/16</b> .                |
| platform:<br>azure:<br>computeSubnet:                                         | The name of the existing subnet in your VNet that you want to deploy your compute machines to.                                                                                                  | Valid CIDR, for example <b>10.0.0.0/16</b> .                |

| Parameter                                                               | Description                                                                                                                                                                            | Values                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform: azure: cloudName:</code>                                | The name of the Azure cloud environment that is used to configure the Azure SDK with the appropriate Azure API endpoints. If empty, the default value <b>AzurePublicCloud</b> is used. | Any valid cloud environment, such as <b>AzurePublicCloud</b> or <b>AzureUSGovernmentCloud</b> .                                                                                                                                                             |
| <code>platform: azure: defaultMachinePlatform: vmNetworkingType:</code> | Enables accelerated networking. Accelerated networking enables single root I/O virtualization (SR-IOV) to a VM, improving its networking performance.                                  | <b>Accelerated</b> or <b>Basic</b> . If instance type of control plane and compute machines support <b>Accelerated</b> networking, by default, the installer enables <b>Accelerated</b> networking, otherwise the default networking type is <b>Basic</b> . |

NOTE

You cannot customize [Azure Availability Zones](#) or [Use tags to organize your Azure resources](#) with an Azure cluster.

## CHAPTER 6. INSTALLING ON AZURE STACK HUB

### 6.1. PREPARING TO INSTALL ON AZURE STACK HUB

#### 6.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You have installed Azure Stack Hub version 2008 or later.

#### 6.1.2. Requirements for installing OpenShift Container Platform on Azure Stack Hub

Before installing OpenShift Container Platform on Microsoft Azure Stack Hub, you must configure an Azure account.

See [Configuring an Azure Stack Hub account](#) for details about account configuration, account limits, DNS zone configuration, required roles, and creating service principals.

#### 6.1.3. Choosing a method to install OpenShift Container Platform on Azure Stack Hub

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See [Installation process](#) for more information about installer-provisioned and user-provisioned installation processes.

##### 6.1.3.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on Azure Stack Hub infrastructure that is provisioned by the OpenShift Container Platform installation program, by using the following method:

- [Installing a cluster on Azure Stack Hub with an installer-provisioned infrastructure](#) You can install OpenShift Container Platform on Azure Stack Hub infrastructure that is provisioned by the OpenShift Container Platform installation program.

##### 6.1.3.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on Azure Stack Hub infrastructure that you provision, by using the following method:

- [Installing a cluster on Azure Stack Hub using ARM templates](#) You can install OpenShift Container Platform on Azure Stack Hub by using infrastructure that you provide. You can use the provided Azure Resource Manager (ARM) templates to assist with an installation.

#### 6.1.4. Next steps

- [Configuring an Azure Stack Hub account](#)

## 6.2. CONFIGURING AN AZURE STACK HUB ACCOUNT

Before you can install OpenShift Container Platform, you must configure a Microsoft Azure account.

### IMPORTANT

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

### 6.2.1. Azure Stack Hub account limits

The OpenShift Container Platform cluster uses a number of Microsoft Azure Stack Hub components, and the default [Quota types in Azure Stack Hub](#) affect your ability to install OpenShift Container Platform clusters.

The following table summarizes the Azure Stack Hub components whose limits can impact your ability to install and run OpenShift Container Platform clusters.

| Component          | Number of components required by default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vCPU               | 56                                       | <p>A default cluster requires 56 vCPUs, so you must increase the account limit.</p> <p>By default, each cluster creates the following instances:</p> <ul style="list-style-type: none"> <li>• One bootstrap machine, which is removed after installation</li> <li>• Three control plane machines</li> <li>• Three compute machines</li> </ul> <p>Because the bootstrap, control plane, and worker machines use <b>Standard_DS4_v2</b> virtual machines, which use 8 vCPUs, a default cluster requires 56 vCPUs. The bootstrap node VM is used only during installation.</p> <p>To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, you must further increase the vCPU limit for your account to ensure that your cluster can deploy the machines that you require.</p> |
| VNet               | 1                                        | Each default cluster requires one Virtual Network (VNet), which contains two subnets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Network interfaces | 7                                        | Each default cluster requires seven network interfaces. If you create more machines or your deployed workloads create load balancers, your cluster uses more network interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Component               | Number of components required by default                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                      |                                                                                          |                 |                                                                                                      |                 |                                                                                          |

| Public IP addresses     | 2                                                                                                    | The public load balancer uses a public IP address. The bootstrap machine also uses a public IP address so that you can SSH into the machine to troubleshoot issues during installation. The IP address for the bootstrap node is used only during installation.                                                                                                                                                                                                                                                                                                                                                                                   |                      |                                                                                          |                 |                                                                                                      |                 |                                                                                          |
| Private IP addresses    | 7                                                                                                    | The internal load balancer, each of the three control plane machines, and each of the three worker machines each use a private IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                      |                                                                                          |                 |                                                                                                      |                 |                                                                                          |

#### Additional resources

- [Optimizing storage](#).

### 6.2.2. Configuring a DNS zone in Azure Stack Hub

To successfully install OpenShift Container Platform on Azure Stack Hub, you must create DNS records in an Azure Stack Hub DNS zone. The DNS zone must be authoritative for the domain. To delegate a registrar's DNS zone to Azure Stack Hub, see Microsoft's documentation for [Azure Stack Hub datacenter DNS integration](#).

### 6.2.3. Required Azure Stack Hub roles

Your Microsoft Azure Stack Hub account must have the following roles for the subscription that you use:

- **Owner**

To set roles on the Azure portal, see the [Manage access to resources in Azure Stack Hub with role-based access control](#) in the Microsoft documentation.

### 6.2.4. Creating a service principal

Because OpenShift Container Platform and its installation program create Microsoft Azure resources by using the Azure Resource Manager, you must create a service principal to represent it.

#### Prerequisites

- Install or update the [Azure CLI](#).
- Your Azure account has the required roles for the subscription that you use.

#### Procedure

1. Register your environment:

```
$ az cloud register -n AzureStackCloud --endpoint-resource-manager <endpoint> 1
```

- 1 Specify the Azure Resource Manager endpoint, ``https://management.<region>.<fqdn>/'`.

See the [Microsoft documentation](#) for details.

2. Set the active environment:

```
$ az cloud set -n AzureStackCloud
```

3. Update your environment configuration to use the specific API version for Azure Stack Hub:

```
$ az cloud update --profile 2019-03-01-hybrid
```

4. Log in to the Azure CLI:

```
$ az login
```

If you are in a multitenant environment, you must also supply the tenant ID.

5. If your Azure account uses subscriptions, ensure that you are using the right subscription:

- a. View the list of available accounts and record the **tenantId** value for the subscription you want to use for your cluster:

```
$ az account list --refresh
```

#### Example output

```
[
 {
 "cloudName": AzureStackCloud",
 "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
 "isDefault": true,
 "name": "Subscription Name",
 "state": "Enabled",
 "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee",
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
 }
]
```

- b. View your active account details and confirm that the **tenantId** value matches the subscription you want to use:

```
$ az account show
```

### Example output

```
{
 "environmentName": AzureStackCloud",
 "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
 "isDefault": true,
 "name": "Subscription Name",
 "state": "Enabled",
 "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee", ❶
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
}
```

- ❶ Ensure that the value of the **tenantId** parameter is the correct subscription ID.

- c. If you are not using the right subscription, change the active subscription:

```
$ az account set -s <subscription_id> ❶
```

- ❶ Specify the subscription ID.

- d. Verify the subscription ID update:

```
$ az account show
```

### Example output

```
{
 "environmentName": AzureStackCloud",
```

```

 "id": "33212d16-bdf6-45cb-b038-f6565b61edda",
 "isDefault": true,
 "name": "Subscription Name",
 "state": "Enabled",
 "tenantId": "8049c7e9-c3de-762d-a54e-dc3f6be6a7ee",
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
 }
}

```

6. Record the **tenantId** and **id** parameter values from the output. You need these values during the OpenShift Container Platform installation.
7. Create the service principal for your account:

```

$ az ad sp create-for-rbac --role Contributor --name <service_principal> \ 1
--scopes /subscriptions/<subscription_id> 2
--years <years> 3

```

- 1 Specify the service principal name.
- 2 Specify the subscription ID.
- 3 Specify the number of years. By default, a service principal expires in one year. By using the **--years** option you can extend the validity of your service principal.

### Example output

```

Creating 'Contributor' role assignment under scope '/subscriptions/<subscription_id>'
The output includes credentials that you must protect. Be sure that you do not
include these credentials in your code or check the credentials into your source
control. For more information, see https://aka.ms/azadsp-cli
{
 "appId": "ac461d78-bf4b-4387-ad16-7e32e328aec6",
 "displayName": <service_principal>,
 "password": "000000000-0000-0000-0000-000000000000",
 "tenantId": "8049c7e9-c3de-762d-a54e-dc3f6be6a7ee"
}

```

8. Record the values of the **appId** and **password** parameters from the previous output. You need these values during OpenShift Container Platform installation.

### Additional resources

- For more information about CCO modes, see [About the Cloud Credential Operator](#).

## 6.2.5. Next steps

- Install an OpenShift Container Platform cluster:
  - [Installing a cluster quickly on Azure Stack Hub](#) .

- Install an OpenShift Container Platform cluster on Azure Stack Hub with user-provisioned infrastructure by following [Installing a cluster on Azure Stack Hub using ARM templates](#) .

## 6.3. INSTALLING A CLUSTER ON AZURE STACK HUB WITH AN INSTALLER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.14, you can install a cluster on Microsoft Azure Stack Hub with an installer-provisioned infrastructure. However, you must manually configure the **install-config.yaml** file to specify values that are specific to Azure Stack Hub.

### NOTE

While you can select **azure** when using the installation program to deploy a cluster using installer-provisioned infrastructure, this option is only supported for the Azure Public Cloud.

### 6.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure Stack Hub account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You verified that you have approximately 16 GB of local disk space. Installing the cluster requires that you download the RHCOS virtual hard disk (VHD) cluster image and upload it to your Azure Stack Hub environment so that it is accessible during deployment. Decompressing the VHD files requires this amount of local disk space.

### 6.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 6.3.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 6.3.4. Uploading the RHCOS cluster image

You must download the RHCOS virtual hard disk (VHD) cluster image and upload it to your Azure Stack Hub environment so that it is accessible during deployment.

#### Prerequisites

- Configure an Azure account.

#### Procedure

1. Obtain the RHCOS VHD cluster image:

- a. Export the URL of the RHCOS VHD to an environment variable.

```
$ export COMPRESSED_VHD_URL=$(openshift-install coreos print-stream-json | jq -r
'.architectures.x86_64.artifacts.azurestack.formats."vhd.gz".disk.location')
```

- b. Download the compressed RHCOS VHD file locally.

```
$ curl -O -L ${COMPRESSED_VHD_URL}
```

2. Decompress the VHD file.

#### NOTE

The decompressed VHD file is approximately 16 GB, so be sure that your host system has 16 GB of free space available. The VHD file can be deleted once you have uploaded it.

3. Upload the local VHD to the Azure Stack Hub environment, making sure that the blob is publicly available. For example, you can upload the VHD to a blob using the **az** cli or the web portal.

### 6.3.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select **Azure** as the cloud provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 6.3.6. Manually creating the installation configuration file

When installing OpenShift Container Platform on Microsoft Azure Stack Hub, you must manually create your installation configuration file.

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

#### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

#### NOTE

You must name this configuration file **install-config.yaml**.

Make the following modifications:

- a. Specify the required installation parameters.
- b. Update the **platform.azure** section to specify the parameters that are specific to Azure Stack Hub.

- c. Optional: Update one or more of the default configuration parameters to customize the installation.

For more information about the parameters, see "Installation configuration parameters".

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

### Additional resources

- [Installation configuration parameters for Azure Stack Hub](#)

#### 6.3.6.1. Sample customized install-config.yaml file for Azure Stack Hub

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

### IMPORTANT

This sample YAML file is provided for reference only. Use it as a resource to enter parameter values into the installation configuration file that you created manually.

```
apiVersion: v1
baseDomain: example.com 1
credentialsMode: Manual
controlPlane: 2 3
 name: master
 platform:
 azure:
 osDisk:
 diskSizeGB: 1024 4
 diskType: premium_LRS
 replicas: 3
compute: 5
 - name: worker
 platform:
 azure:
 osDisk:
 diskSizeGB: 512 6
 diskType: premium_LRS
 replicas: 3
metadata:
 name: test-cluster 7 8

 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes 9
```

```

serviceNetwork:
- 172.30.0.0/16
platform:
 azure:
 armEndpoint: azurestack_arm_endpoint 10 11
 baseDomainResourceGroupName: resource_group 12 13
 region: azure_stack_local_region 14 15
 resourceGroupName: existing_resource_group 16
 outboundType: Loadbalancer
 cloudName: AzureStackCloud 17
 clusterOSImage: https://vhdsa.blob.example.example.com/vhd/rhcos-410.84.202112040202-0-
azurestack.x86_64.vhd 18 19
pullSecret: '{"auths": ...}' 20 21
fips: false 22
sshKey: ssh-ed25519 AAAA... 23
additionalTrustBundle: | 24
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----

```

1 7 10 12 14 17 18 20 Required.

2 5 If you do not provide these parameters and values, the installation program provides the default value.

3 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

4 6 You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

8 The name of the cluster.

9 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

11 The Azure Resource Manager endpoint that your Azure Stack Hub operator provides.

13 The name of the resource group that contains the DNS zone for your base domain.

15 The name of your Azure Stack Hub local region.

16 The name of an existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.

19 The URL of a storage blob in the Azure Stack environment that contains an RHCOS VHD.

21 The pull secret required to authenticate your cluster.

22 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography

modules that are provided with RHCOS instead.

### IMPORTANT

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

23

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

24

If the Azure Stack Hub environment is using an internal Certificate Authority (CA), adding the CA certificate is required.

## 6.3.7. Manually manage cloud credentials

The Cloud Credential Operator (CCO) only supports your cloud provider in manual mode. As a result, you must specify the identity and access management (IAM) secrets for your cloud provider.

### Procedure

1. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

2. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

3. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

1

The **--included** parameter includes only the manifests that your specific cluster configuration requires.

- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
```

4. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...
```

### Sample **Secret** object

```
apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
```

```
data:
 azure_subscription_id: <base64_encoded_azure_subscription_id>
 azure_client_id: <base64_encoded_azure_client_id>
 azure_client_secret: <base64_encoded_azure_client_secret>
 azure_tenant_id: <base64_encoded_azure_tenant_id>
 azure_resource_prefix: <base64_encoded_azure_resource_prefix>
 azure_resourcegroup: <base64_encoded_azure_resourcegroup>
 azure_region: <base64_encoded_azure_region>
```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

#### Additional resources

- [Updating cloud provider resources with manually maintained credentials](#)

### 6.3.8. Configuring the cluster to use an internal CA

If the Azure Stack Hub environment is using an internal Certificate Authority (CA), update the **cluster-proxy-01-config.yaml** file to configure the cluster to use the internal CA.

#### Prerequisites

- Create the **install-config.yaml** file and specify the certificate trust bundle in **.pem** format.
- Create the cluster manifests.

#### Procedure

1. From the directory in which the installation program creates files, go to the **manifests** directory.
2. Add **user-ca-bundle** to the **spec.trustedCA.name** field.

#### Example cluster-proxy-01-config.yaml file

```
apiVersion: config.openshift.io/v1
kind: Proxy
metadata:
 creationTimestamp: null
 name: cluster
spec:
 trustedCA:
 name: user-ca-bundle
 status: {}
```

3. Optional: Back up the **manifests/ cluster-proxy-01-config.yaml** file. The installation program consumes the **manifests/** directory when you deploy the cluster.

### 6.3.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

## IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

### Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

### Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/./openshift\_install.log**.

## IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 6.3.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

## IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

#### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

## Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 6.3.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

/validating-an-installation.adoc

### 6.3.12. Logging in to the cluster by using the web console

The **kubeadmin** user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the **kubeadmin** user by using the OpenShift Container Platform web console.

#### Prerequisites

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

#### Procedure

1. Obtain the password for the **kubeadmin** user from the **kubeadmin-password** file on the installation host:

```
$ cat <installation_directory>/auth/kubeadmin-password
```

**NOTE**

Alternatively, you can obtain the **kubeadmin** password from the **<installation\_directory>/openshift\_install.log** log file on the installation host.

2. List the OpenShift Container Platform web console route:

```
$ oc get routes -n openshift-console | grep 'console-openshift'
```

**NOTE**

Alternatively, you can obtain the OpenShift Container Platform route from the **<installation\_directory>/openshift\_install.log** log file on the installation host.

**Example output**

```
console console-openshift-console.apps.<cluster_name>.<base_domain> console
https reencrypt/Redirect None
```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

**Additional resources**

- [Accessing the web console](#)

**6.3.13. Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- [About remote health monitoring](#)

**6.3.14. Next steps**

- [Validating an installation.](#)
- [Customize your cluster.](#)
- If necessary, you can [opt out of remote health reporting](#) .
- If necessary, you can [remove cloud provider credentials](#).

**6.4. INSTALLING A CLUSTER ON AZURE STACK HUB WITH NETWORK CUSTOMIZATIONS**

In OpenShift Container Platform version 4.14, you can install a cluster with a customized network configuration on infrastructure that the installation program provisions on Azure Stack Hub. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

#### NOTE

While you can select **azure** when using the installation program to deploy a cluster using installer-provisioned infrastructure, this option is only supported for the Azure Public Cloud.

### 6.4.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure Stack Hub account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You verified that you have approximately 16 GB of local disk space. Installing the cluster requires that you download the RHCOS virtual hard disk (VHD) cluster image and upload it to your Azure Stack Hub environment so that it is accessible during deployment. Decompressing the VHD files requires this amount of local disk space.

### 6.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 6.4.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes

through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**6.4.4. Uploading the RHCOS cluster image**

You must download the RHCOS virtual hard disk (VHD) cluster image and upload it to your Azure Stack Hub environment so that it is accessible during deployment.

**Prerequisites**

- Configure an Azure account.

**Procedure**

1. Obtain the RHCOS VHD cluster image:
  - a. Export the URL of the RHCOS VHD to an environment variable.

```
$ export COMPRESSED_VHD_URL=$(openshift-install coreos print-stream-json | jq -r
'.architectures.x86_64.artifacts.azurestack.formats."vhd.gz".disk.location')
```

- b. Download the compressed RHCOS VHD file locally.

```
$ curl -O -L ${COMPRESSED_VHD_URL}
```

2. Decompress the VHD file.

#### NOTE

The decompressed VHD file is approximately 16 GB, so be sure that your host system has 16 GB of free space available. The VHD file can be deleted once you have uploaded it.

3. Upload the local VHD to the Azure Stack Hub environment, making sure that the blob is publicly available. For example, you can upload the VHD to a blob using the **az** cli or the web portal.

### 6.4.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select **Azure** as the cloud provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 6.4.6. Manually creating the installation configuration file

When installing OpenShift Container Platform on Microsoft Azure Stack Hub, you must manually create your installation configuration file.

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

#### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

#### NOTE

You must name this configuration file **install-config.yaml**.

Make the following modifications:

- a. Specify the required installation parameters.
  - b. Update the **platform.azure** section to specify the parameters that are specific to Azure Stack Hub.
  - c. Optional: Update one or more of the default configuration parameters to customize the installation.  
For more information about the parameters, see "Installation configuration parameters".
3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

**Additional resources**

- [Installation configuration parameters for Azure Stack Hub](#)

**6.4.6.1. Sample customized install-config.yaml file for Azure Stack Hub**

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. Use it as a resource to enter parameter values into the installation configuration file that you created manually.

```

apiVersion: v1
baseDomain: example.com 1
credentialsMode: Manual
controlPlane: 2 3
 name: master
 platform:
 azure:
 osDisk:
 diskSizeGB: 1024 4
 diskType: premium_LRS
 replicas: 3
compute: 5
 - name: worker
 platform:
 azure:
 osDisk:
 diskSizeGB: 512 6
 diskType: premium_LRS
 replicas: 3
metadata:
 name: test-cluster 7 8
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes 9
 serviceNetwork:
 - 172.30.0.0/16
platform:
 azure:
 armEndpoint: azurestack_arm_endpoint 10 11
 baseDomainResourceGroupName: resource_group 12 13

```

```

region: azure_stack_local_region 14 15
resourceGroupName: existing_resource_group 16
outboundType: Loadbalancer
cloudName: AzureStackCloud 17
clusterOSImage: https://vhdsa.blob.example.example.com/vhd/rhcos-410.84.202112040202-0-
azurestack.x86_64.vhd 18 19
pullSecret: '{"auths": ...}' 20 21
fips: false 22
sshKey: ssh-ed25519 AAAA... 23
additionalTrustBundle: | 24
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----

```

1 7 10 12 14 17 18 20 Required.

2 5 If you do not provide these parameters and values, the installation program provides the default value.

3 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

4 6 You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

8 The name of the cluster.

9 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

11 The Azure Resource Manager endpoint that your Azure Stack Hub operator provides.

13 The name of the resource group that contains the DNS zone for your base domain.

15 The name of your Azure Stack Hub local region.

16 The name of an existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.

19 The URL of a storage blob in the Azure Stack environment that contains an RHCOS VHD.

21 The pull secret required to authenticate your cluster.

22 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

23

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

## NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

24

If the Azure Stack Hub environment is using an internal Certificate Authority (CA), adding the CA certificate is required.

### 6.4.7. Manually manage cloud credentials

The Cloud Credential Operator (CCO) only supports your cloud provider in manual mode. As a result, you must specify the identity and access management (IAM) secrets for your cloud provider.

#### Procedure

1. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

2. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

3. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

1

The **--included** parameter includes only the manifests that your specific cluster configuration requires.

2

Specify the location of the **install-config.yaml** file.

- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
```

4. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...
```

### Sample **Secret** object

```
apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 azure_subscription_id: <base64_encoded_azure_subscription_id>
```

```

azure_client_id: <base64_encoded_azure_client_id>
azure_client_secret: <base64_encoded_azure_client_secret>
azure_tenant_id: <base64_encoded_azure_tenant_id>
azure_resource_prefix: <base64_encoded_azure_resource_prefix>
azure_resourcegroup: <base64_encoded_azure_resourcegroup>
azure_region: <base64_encoded_azure_region>

```

## IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### Additional resources

- [Updating a cluster using the web console](#)
- [Updating a cluster using the CLI](#)

### 6.4.8. Configuring the cluster to use an internal CA

If the Azure Stack Hub environment is using an internal Certificate Authority (CA), update the **cluster-proxy-01-config.yaml** file to configure the cluster to use the internal CA.

#### Prerequisites

- Create the **install-config.yaml** file and specify the certificate trust bundle in **.pem** format.
- Create the cluster manifests.

#### Procedure

1. From the directory in which the installation program creates files, go to the **manifests** directory.
2. Add **user-ca-bundle** to the **spec.trustedCA.name** field.

#### Example cluster-proxy-01-config.yaml file

```

apiVersion: config.openshift.io/v1
kind: Proxy
metadata:
 creationTimestamp: null
 name: cluster
spec:
 trustedCA:
 name: user-ca-bundle
status: {}

```

3. Optional: Back up the **manifests/ cluster-proxy-01-config.yaml** file. The installation program consumes the **manifests/** directory when you deploy the cluster.

### 6.4.9. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

## Phase 1

You can customize the following network-related fields in the **install-config.yaml** file before you create the manifest files:

- **networking.networkType**
- **networking.clusterNetwork**
- **networking.serviceNetwork**
- **networking.machineNetwork**

For more information on these fields, refer to *Installation configuration parameters*.

### NOTE

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

### IMPORTANT

The CIDR range **172.17.0.0/16** is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

## Phase 2

After creating the manifest files by running **openshift-install create manifests**, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the **install-config.yaml** file during phase 2. However, you can further customize the network plugin during phase 2.

### 6.4.10. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

### IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

## Prerequisites

- You have created the **install-config.yaml** file and completed any modifications to it.

## Procedure

1. Change to the directory that contains the installation program and create the manifests:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 **<installation\_directory>** specifies the name of the directory that contains the **install-config.yaml** file for your cluster.
2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yaml** in the **<installation\_directory>/manifests/** directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
```

3. Specify the advanced network configuration for your cluster in the **cluster-network-03-config.yaml** file, such as in the following examples:

#### Specify a different VXLAN port for the OpenShift SDN network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 openshiftSDNConfig:
 vxlanPort: 4800
```

#### Enable IPsec for the OVN-Kubernetes network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 ovnKubernetesConfig:
 ipsecConfig: {}
```

4. Optional: Back up the **manifests/cluster-network-03-config.yaml** file. The installation program consumes the **manifests/** directory when you create the Ignition config files.

### 6.4.11. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group:

#### **clusterNetwork**

IP address pools from which pod IP addresses are allocated.

#### **serviceNetwork**

IP address pool for services.

### **defaultNetwork.type**

Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

#### 6.4.11.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 6.1. Cluster Network Operator configuration object**

| Field                       | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metadata.name</b>        | <b>string</b> | The name of the CNO object. This name is always <b>cluster</b> .                                                                                                                                                                                                                                                                                                                                    |
| <b>spec.clusterNetwork</b>  | <b>array</b>  | <p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec:   clusterNetwork:     - cidr: 10.128.0.0/19       hostPrefix: 23     - cidr: 10.128.32.0/19       hostPrefix: 23</pre>                                                                          |
| <b>spec.serviceNetwork</b>  | <b>array</b>  | <p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</p> <pre>spec:   serviceNetwork:     - 172.30.0.0/14</pre> <p>You can customize this field only in the <b>install-config.yaml</b> file before you create the manifests. The value is read-only in the manifest file.</p> |
| <b>spec.defaultNetwork</b>  | <b>object</b> | Configures the network plugin for the cluster network.                                                                                                                                                                                                                                                                                                                                              |
| <b>spec.kubeProxyConfig</b> | <b>object</b> | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.                                                                                                                                                                                                                            |

### **defaultNetwork object configuration**

The values for the **defaultNetwork** object are defined in the following table:

**Table 6.2. defaultNetwork object**

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>type</b>                | <b>string</b> | <p>Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b>. The Red Hat OpenShift Networking network plugin is selected during installation. You can change this value by migrating from OpenShift SDN to OVN-Kubernetes.</p> <div>  <div> <b>NOTE</b><br/> OpenShift Container Platform uses the OVN-Kubernetes network plugin by default. </div> </div> |
| <b>openshiftSDNConfig</b>  | <b>object</b> | This object is only valid for the OpenShift SDN network plugin.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ovnKubernetesConfig</b> | <b>object</b> | This object is only valid for the OVN-Kubernetes network plugin.                                                                                                                                                                                                                                                                                                                                                                      |

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

**Table 6.3. openshiftSDNConfig object**

| Field       | Type          | Description                                                                                                                                                                                                                                                                                                                         |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b> | <b>string</b> | <p>Configures the network isolation mode for OpenShift SDN. The default value is <b>NetworkPolicy</b>.</p> <p>The values <b>Multitenant</b> and <b>Subnet</b> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p> |

| Field            | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>       | <b>integer</b> | <p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>50</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1450</b>.</p> <p>This value cannot be changed after cluster installation.</p> |
| <b>vxlanPort</b> | <b>integer</b> | <p>The port to use for all VXLAN packets. The default value is <b>4789</b>. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port <b>9000</b> and port <b>9999</b>.</p>                                                                                                                                                                                                                            |

## Example OpenShift SDN configuration

```
defaultNetwork:
 type: OpenShiftSDN
 openshiftSDNConfig:
 mode: NetworkPolicy
 mtu: 1450
 vxlanPort: 4789
```

## Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

**Table 6.4. ovnKubernetesConfig object**

| Field | Type | Description |
|-------|------|-------------|
|-------|------|-------------|

| Field                    | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>               | <b>integer</b> | <p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>100</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1400</b>.</p> |
| <b>genevePort</b>        | <b>integer</b> | The port to use for all Geneve packets. The default value is <b>6081</b> . This value cannot be changed after cluster installation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipsecConfig</b>       | <b>object</b>  | Specify an empty object to enable IPsec encryption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>policyAuditConfig</b> | <b>object</b>  | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>gatewayConfig</b>     | <b>object</b>  | <p>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</p> <div>  <div> <p><b>NOTE</b></p> <p>While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.</p> </div> </div>                                                                                                                                                                                                                                                                                                                                                                                                        |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <b>v4InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>100.64.0.0/16</b> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <b>clusterNetwork.cidr</b> value is <b>10.128.0.0/14</b> and the <b>clusterNetwork.hostPrefix</b> value is <b>/23</b>, then the maximum number of nodes is <b><math>2^{(23-14)}=512</math></b>.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>100.64.0.0/16</b> . |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| <b>v6InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>fd98::/48</b> IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>fd98::/48</b> . |

Table 6.5. **policyAuditConfig** object

| Field              | Type    | Description                                                                                                           |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------|
| <b>rateLimit</b>   | integer | The maximum number of messages to generate every second per node. The default value is <b>20</b> messages per second. |
| <b>maxFileSize</b> | integer | The maximum size for the audit log in bytes. The default value is <b>50000000</b> or 50 MB.                           |
| <b>maxLogFiles</b> | integer | The maximum number of log files that are retained.                                                                    |

| Field                 | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination</b>    | string | <p>One of the following additional audit log targets:</p> <p><b>libc</b><br/>The libc <b>syslog()</b> function of the journald process on the host.</p> <p><b>udp:&lt;host&gt;:&lt;port&gt;</b><br/>A syslog server. Replace <b>&lt;host&gt;:&lt;port&gt;</b> with the host and port of the syslog server.</p> <p><b>unix:&lt;file&gt;</b><br/>A Unix Domain Socket file specified by <b>&lt;file&gt;</b>.</p> <p><b>null</b><br/>Do not send the audit logs to any additional target.</p> |
| <b>syslogFacility</b> | string | The syslog facility, such as <b>kern</b> , as defined by RFC5424. The default value is <b>local0</b> .                                                                                                                                                                                                                                                                                                                                                                                     |

Table 6.6. gatewayConfig object

| Field                 | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>routingViaHost</b> | <b>boolean</b> | <p>Set this field to <b>true</b> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <b>false</b>.</p> <p>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <b>true</b>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</p> |
| <b>ipForwarding</b>   | <b>object</b>  | You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <b>ipForwarding</b> specification in the <b>Network</b> resource. Specify <b>Restricted</b> to only allow IP forwarding for Kubernetes related traffic. Specify <b>Global</b> to allow forwarding of all IP traffic. For new installations, the default is <b>Restricted</b> . For updates to OpenShift Container Platform 4.14, the default is <b>Global</b> .                                                                                                                                                                                                                                                                                |

### Example OVN-Kubernetes configuration with IPsec enabled

```
defaultNetwork:
 type: OVNKubernetes
 ovnKubernetesConfig:
 mtu: 1400
 genevePort: 6081
 ipsecConfig: {}
```

**kubeProxyConfig object configuration (OpenShiftSDN container network interface only)**

The values for the **kubeProxyConfig** object are defined in the following table:

Table 6.7. **kubeProxyConfig** object

| Field                                          | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>iptablesSyncPeriod</b>                      | <b>string</b> | <p>The refresh period for <b>iptables</b> rules. The default value is <b>30s</b>. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a> documentation.</p> <div>  <div> <p><b>NOTE</b></p> <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the <b>iptablesSyncPeriod</b> parameter is no longer necessary.</p> </div> </div> |
| <b>proxyArguments.iptables-min-sync-period</b> | <b>array</b>  | <p>The minimum duration before refreshing <b>iptables</b> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a>. The default value is:</p> <div>  <pre>kubeProxyConfig:   proxyArguments:     iptables-min-sync-period:       - 0s</pre> </div>                                                              |

### 6.4.12. Configuring hybrid networking with OVN-Kubernetes

You can configure your cluster to use hybrid networking with the OVN-Kubernetes network plugin. This allows a hybrid cluster that supports different node networking configurations.

**NOTE**

This configuration is necessary to run both Linux and Windows nodes in the same cluster.

#### Prerequisites

- You defined **OVNKubernetes** for the **networking.networkType** parameter in the **install-config.yaml** file. See the installation documentation for configuring OpenShift Container Platform network customizations on your chosen cloud provider for more information.

#### Procedure

1. Change to the directory that contains the installation program and create the manifests:

```
$./openshift-install create manifests --dir <installation_directory>
```

where:

**<installation\_directory>**

Specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yml** in the **<installation\_directory>/manifests/** directory:

```
$ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
EOF
```

where:

**<installation\_directory>**

Specifies the directory name that contains the **manifests/** directory for your cluster.

3. Open the **cluster-network-03-config.yml** file in an editor and configure OVN-Kubernetes with hybrid networking, such as in the following example:

### Specify a hybrid networking configuration

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 ovnKubernetesConfig:
 hybridOverlayConfig:
 hybridClusterNetwork: 1
 - cidr: 10.132.0.0/14
 hostPrefix: 23
 hybridOverlayVXLANPort: 9898 2
```

- 1 Specify the CIDR configuration used for nodes on the additional overlay network. The **hybridClusterNetwork** CIDR cannot overlap with the **clusterNetwork** CIDR.
- 2 Specify a custom VXLAN port for the additional overlay network. This is required for running Windows nodes in a cluster installed on vSphere, and must not be configured for any other cloud provider. The custom port can be any open port excluding the default **4789** port. For more information on this requirement, see the Microsoft documentation on [Pod-to-pod connectivity between hosts is broken](#).

**NOTE**

Windows Server Long-Term Servicing Channel (LTSC): Windows Server 2019 is not supported on clusters with a custom **hybridOverlayVXLANPort** value because this Windows server version does not support selecting a custom VXLAN port.

4. Save the **cluster-network-03-config.yml** file and quit the text editor.
5. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program deletes the **manifests/** directory when creating the cluster.

**NOTE**

For more information on using Linux and Windows nodes in the same cluster, see [Understanding Windows container workloads](#).

### 6.4.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

#### Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

#### Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 6.4.14. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

**NOTE**

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

**Verification**

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

**6.4.15. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

**Example output**

```
■
```

```
system:admin
```

```
/validating-an-installation.adoc
```

### 6.4.16. Logging in to the cluster by using the web console

The **kubeadmin** user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the **kubeadmin** user by using the OpenShift Container Platform web console.

#### Prerequisites

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

#### Procedure

1. Obtain the password for the **kubeadmin** user from the **kubeadmin-password** file on the installation host:

```
$ cat <installation_directory>/auth/kubeadmin-password
```

#### NOTE

Alternatively, you can obtain the **kubeadmin** password from the **<installation\_directory>/openshift\_install.log** log file on the installation host.

2. List the OpenShift Container Platform web console route:

```
$ oc get routes -n openshift-console | grep 'console-openshift'
```

#### NOTE

Alternatively, you can obtain the OpenShift Container Platform route from the **<installation\_directory>/openshift\_install.log** log file on the installation host.

#### Example output

```
console console-openshift-console.apps.<cluster_name>.<base_domain> console
https reencrypt/Redirect None
```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

#### Additional resources

- [Accessing the web console.](#)

### 6.4.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- [About remote health monitoring](#)

#### 6.4.18. Next steps

- [Validating an installation.](#)
- [Customize your cluster.](#)
- If necessary, you can [opt out of remote health reporting](#) .
- If necessary, you can [remove cloud provider credentials](#).

## 6.5. INSTALLING A CLUSTER ON AZURE STACK HUB USING ARM TEMPLATES

In OpenShift Container Platform version 4.14, you can install a cluster on Microsoft Azure Stack Hub by using infrastructure that you provide.

Several [Azure Resource Manager](#) (ARM) templates are provided to assist in completing these steps or to help model your own.

### IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several ARM templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

#### 6.5.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an Azure Stack Hub account](#) to host the cluster.
- You downloaded the Azure CLI and installed it on your computer. See [Install the Azure CLI](#) in the Azure documentation. The documentation below was tested using version **2.28.0** of the Azure CLI. Azure CLI commands might perform differently based on the version you use.

- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

## 6.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

## 6.5.3. Configuring your Azure Stack Hub project

Before you can install OpenShift Container Platform, you must configure an Azure project to host it.

**IMPORTANT**

All Azure Stack Hub resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure Stack Hub restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

### 6.5.3.1. Azure Stack Hub account limits

The OpenShift Container Platform cluster uses a number of Microsoft Azure Stack Hub components, and the default [Quota types in Azure Stack Hub](#) affect your ability to install OpenShift Container Platform clusters.

The following table summarizes the Azure Stack Hub components whose limits can impact your ability to install and run OpenShift Container Platform clusters.

| Component               | Number of components required by default                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                      |                                                                            |             |                                                                         |
|-------------------------|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|----------------------------------------------------------------------------|-------------|-------------------------------------------------------------------------|
| vCPU                    | 56                                                                         | <p>A default cluster requires 56 vCPUs, so you must increase the account limit.</p> <p>By default, each cluster creates the following instances:</p> <ul style="list-style-type: none"><li>● One bootstrap machine, which is removed after installation</li><li>● Three control plane machines</li><li>● Three compute machines</li></ul> <p>Because the bootstrap, control plane, and worker machines use <b>Standard_DS4_v2</b> virtual machines, which use 8 vCPUs, a default cluster requires 56 vCPUs. The bootstrap node VM is used only during installation.</p> <p>To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, you must further increase the vCPU limit for your account to ensure that your cluster can deploy the machines that you require.</p> |                      |                                                                            |             |                                                                         |
| VNet                    | 1                                                                          | Each default cluster requires one Virtual Network (VNet), which contains two subnets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                      |                                                                            |             |                                                                         |
| Network interfaces      | 7                                                                          | Each default cluster requires seven network interfaces. If you create more machines or your deployed workloads create load balancers, your cluster uses more network interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                      |                                                                            |             |                                                                         |
| Network security groups | 2                                                                          | <p>Each cluster creates network security groups for each subnet in the VNet. | Public IP addresses    | 2                                                                                                    | The public load balancer uses a public IP address. The bootstrap machine also uses a public IP address so that you can SSH into the machine to troubleshoot issues during installation. The IP address for the bootstrap node is used only during installation.                                                                                                                                                                                                                                                                                                                                                                           |                |                                                                                          |                 |                                                                                                      |                 |                                                                                          |
| Private IP addresses   | 7                                                                                                    | The internal load balancer, each of the three control plane machines, and each of the three worker machines each use a private IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                                                                                          |                 |                                                                                                      |                 |                                                                                          |

### Additional resources

- [Optimizing storage](#).

#### 6.5.3.2. Configuring a DNS zone in Azure Stack Hub

To successfully install OpenShift Container Platform on Azure Stack Hub, you must create DNS records in an Azure Stack Hub DNS zone. The DNS zone must be authoritative for the domain. To delegate a registrar's DNS zone to Azure Stack Hub, see Microsoft's documentation for [Azure Stack Hub datacenter DNS integration](#).

You can view Azure's DNS solution by visiting this [example for creating DNS zones](#).

#### 6.5.3.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

#### 6.5.3.4. Required Azure Stack Hub roles

Your Microsoft Azure Stack Hub account must have the following roles for the subscription that you use:

- **Owner**

To set roles on the Azure portal, see the [Manage access to resources in Azure Stack Hub with role-based access control](#) in the Microsoft documentation.

### 6.5.3.5. Creating a service principal

Because OpenShift Container Platform and its installation program create Microsoft Azure resources by using the Azure Resource Manager, you must create a service principal to represent it.

#### Prerequisites

- Install or update the [Azure CLI](#).
- Your Azure account has the required roles for the subscription that you use.

#### Procedure

1. Register your environment:

```
$ az cloud register -n AzureStackCloud --endpoint-resource-manager <endpoint> 1
```

- 1** Specify the Azure Resource Manager endpoint, ``https://management.<region>.<fqdn>/``.

See the [Microsoft documentation](#) for details.

2. Set the active environment:

```
$ az cloud set -n AzureStackCloud
```

3. Update your environment configuration to use the specific API version for Azure Stack Hub:

```
$ az cloud update --profile 2019-03-01-hybrid
```

4. Log in to the Azure CLI:

```
$ az login
```

If you are in a multitenant environment, you must also supply the tenant ID.

5. If your Azure account uses subscriptions, ensure that you are using the right subscription:

- a. View the list of available accounts and record the **tenantId** value for the subscription you want to use for your cluster:

```
$ az account list --refresh
```

#### Example output

```
[
{
```

```

 "cloudName": AzureStackCloud",
 "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
 "isDefault": true,
 "name": "Subscription Name",
 "state": "Enabled",
 "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee",
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
 }
]

```

- b. View your active account details and confirm that the **tenantId** value matches the subscription you want to use:

```
$ az account show
```

### Example output

```

{
 "environmentName": AzureStackCloud",
 "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
 "isDefault": true,
 "name": "Subscription Name",
 "state": "Enabled",
 "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee", ❶
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
}

```

- ❶ Ensure that the value of the **tenantId** parameter is the correct subscription ID.

- c. If you are not using the right subscription, change the active subscription:

```
$ az account set -s <subscription_id> ❶
```

- ❶ Specify the subscription ID.

- d. Verify the subscription ID update:

```
$ az account show
```

### Example output

```

{
 "environmentName": AzureStackCloud",
 "id": "33212d16-bdf6-45cb-b038-f6565b61edda",
 "isDefault": true,
 "name": "Subscription Name",

```

```

 "state": "Enabled",
 "tenantId": "8049c7e9-c3de-762d-a54e-dc3f6be6a7ee",
 "user": {
 "name": "you@example.com",
 "type": "user"
 }
 }
}

```

6. Record the **tenantId** and **id** parameter values from the output. You need these values during the OpenShift Container Platform installation.
7. Create the service principal for your account:

```

$ az ad sp create-for-rbac --role Contributor --name <service_principal> \
 --scopes /subscriptions/<subscription_id>
 --years <years>

```

- 1 Specify the service principal name.
- 2 Specify the subscription ID.
- 3 Specify the number of years. By default, a service principal expires in one year. By using the **--years** option you can extend the validity of your service principal.

### Example output

```

Creating 'Contributor' role assignment under scope '/subscriptions/<subscription_id>'
The output includes credentials that you must protect. Be sure that you do not
include these credentials in your code or check the credentials into your source
control. For more information, see https://aka.ms/azadsp-cli
{
 "appId": "ac461d78-bf4b-4387-ad16-7e32e328aec6",
 "displayName": <service_principal>,
 "password": "00000000-0000-0000-0000-000000000000",
 "tenantId": "8049c7e9-c3de-762d-a54e-dc3f6be6a7ee"
}

```

8. Record the values of the **appId** and **password** parameters from the previous output. You need these values during OpenShift Container Platform installation.

### Additional resources

- For more information about CCO modes, see [About the Cloud Credential Operator](#).

## 6.5.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

## Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select **Azure** as the cloud provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 6.5.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**6.5.6. Creating the installation files for Azure Stack Hub**

To install OpenShift Container Platform on Microsoft Azure Stack Hub using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You manually create the **install-config.yaml** file, and then generate and customize the Kubernetes manifests and Ignition config files. You also have the option to first set up a separate **var** partition during the preparation phases of installation.

**6.5.6.1. Manually creating the installation configuration file****Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

## IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

## NOTE

You must name this configuration file **install-config.yaml**.

Make the following modifications for Azure Stack Hub:

- a. Set the **replicas** parameter to **0** for the **compute** pool:

```
compute:
- hyperthreading: Enabled
 name: worker
 platform: {}
 replicas: 0 1
```

- 1** Set to **0**.

The compute machines will be provisioned manually later.

- b. Update the **platform.azure** section of the **install-config.yaml** file to configure your Azure Stack Hub configuration:

```
platform:
 azure:
 armEndpoint: <azurestack_arm_endpoint> 1
 baseDomainResourceGroupName: <resource_group> 2
 cloudName: AzureStackCloud 3
 region: <azurestack_region> 4
```

- 1** Specify the Azure Resource Manager endpoint of your Azure Stack Hub environment, like **https://management.local.azurestack.external**.
- 2** Specify the name of the resource group that contains the DNS zone for your base domain.
- 3** Specify the Azure Stack Hub environment, which is used to configure the Azure SDK with the appropriate Azure API endpoints.
- 4** Specify the name of your Azure Stack Hub region.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

**Additional resources**

- [Installation configuration parameters for Azure Stack Hub](#)

**6.5.6.2. Sample customized install-config.yaml file for Azure Stack Hub**

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. Use it as a resource to enter parameter values into the installation configuration file that you created manually.

```

apiVersion: v1
baseDomain: example.com
controlPlane: ❶
 name: master
 platform:
 azure:
 osDisk:
 diskSizeGB: 1024 ❷
 diskType: premium_LRS
 replicas: 3
compute: ❸
- name: worker
 platform:
 azure:
 osDisk:
 diskSizeGB: 512 ❹
 diskType: premium_LRS
 replicas: 0
metadata:
 name: test-cluster ❺
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes ❻
 serviceNetwork:
 - 172.30.0.0/16
platform:
 azure:
 armEndpoint: azurestack_arm_endpoint ❼
 baseDomainResourceGroupName: resource_group ❽
 region: azure_stack_local_region ❾

```

```

resourceGroupName: existing_resource_group 10
outboundType: Loadbalancer
cloudName: AzureStackCloud 11
pullSecret: '{"auths": ...}' 12
fips: false 13
additionalTrustBundle: | 14
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
sshKey: ssh-ed25519 AAAA... 15

```

- 1 3 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 2 4 You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.
- 5 Specify the name of the cluster.
- 6 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 7 Specify the Azure Resource Manager endpoint that your Azure Stack Hub operator provides.
- 8 Specify the name of the resource group that contains the DNS zone for your base domain.
- 9 Specify the name of your Azure Stack Hub local region.
- 10 Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
- 11 Specify the Azure Stack Hub environment as your target platform.
- 12 Specify the pull secret required to authenticate your cluster.
- 13 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 14 If your Azure Stack Hub environment uses an internal certificate authority (CA), add the necessary certificate bundle in **.pem** format.

- 15 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 6.5.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

#### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.

- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 6.5.6.4. Exporting common variables for ARM templates

You must export a common set of variables that are used with the provided Azure Resource Manager (ARM) templates used to assist in completing a user-provided infrastructure install on Microsoft Azure Stack Hub.

**NOTE**

Specific ARM templates can also require additional exported variables, which are detailed in their related procedures.

## Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

## Procedure

1. Export common variables found in the **install-config.yaml** to be used by the provided ARM templates:

```
$ export CLUSTER_NAME=<cluster_name> 1
$ export AZURE_REGION=<azure_region> 2
$ export SSH_KEY=<ssh_key> 3
$ export BASE_DOMAIN=<base_domain> 4
$ export BASE_DOMAIN_RESOURCE_GROUP=<base_domain_resource_group> 5
```

- 1 The value of the **.metadata.name** attribute from the **install-config.yaml** file.
- 2 The region to deploy the cluster into. This is the value of the **.platform.azure.region** attribute from the **install-config.yaml** file.
- 3 The SSH RSA public key file as a string. You must enclose the SSH key in quotes since it contains spaces. This is the value of the **.sshKey** attribute from the **install-config.yaml** file.
- 4 The base domain to deploy the cluster to. The base domain corresponds to the DNS zone that you created for your cluster. This is the value of the **.baseDomain** attribute from the **install-config.yaml** file.
- 5 The resource group where the DNS zone exists. This is the value of the **.platform.azure.baseDomainResourceGroupName** attribute from the **install-config.yaml** file.

For example:

```
$ export CLUSTER_NAME=test-cluster
$ export AZURE_REGION=centralus
$ export SSH_KEY="ssh-rsa xxx/xxx/xxx= user@email.com"
$ export BASE_DOMAIN=example.com
$ export BASE_DOMAIN_RESOURCE_GROUP=ocp-cluster
```

2. Export the kubeadmin credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

### 6.5.6.5. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

## IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

## Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

## IMPORTANT

If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

5. Check that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
  - a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
  - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
6. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
 privateZone: ❶
 id: mycluster-100419-private-zone
 publicZone: ❷
 id: example.openshift.com
status: {}
```

- ❶ ❷ Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

7. Optional: If your Azure Stack Hub environment uses an internal certificate authority (CA), you must update the **.spec.trustedCA.name** field in the `<installation_directory>/manifests/cluster-proxy-01-config.yaml` file to use **user-ca-bundle**:

```
...
spec:
 trustedCA:
 name: user-ca-bundle
...
```

Later, you must update your bootstrap ignition to include the CA.

8. When configuring Azure on user-provisioned infrastructure, you must export some common variables defined in the manifest files to use later in the Azure Resource Manager (ARM) templates:

- a. Export the infrastructure ID by using the following command:

```
$ export INFRA_ID=<infra_id> 1
```

- 1 The OpenShift Container Platform cluster has been assigned an identifier (**INFRA\_ID**) in the form of **<cluster\_name>-<random\_string>**. This will be used as the base name for most resources created using the provided ARM templates. This is the value of the **.status.infrastructureName** attribute from the **manifests/cluster-infrastructure-02-config.yml** file.

- b. Export the resource group by using the following command:

```
$ export RESOURCE_GROUP=<resource_group> 1
```

- 1 All resources created in this Azure deployment exists as part of a [resource group](#). The resource group name is also based on the **INFRA\_ID**, in the form of **<cluster\_name>-<random\_string>-rg**. This is the value of the **.status.platformStatus.azure.resourceGroupName** attribute from the **manifests/cluster-infrastructure-02-config.yml** file.

9. Manually create your cloud credentials.

- a. From the directory that contains the installation program, obtain details of the OpenShift Container Platform release image that your **openshift-install** binary is built to use:

```
$ openshift-install version
```

### Example output

```
release image quay.io/openshift-release-dev/ocp-release:4.y.z-x86_64
```

- b. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

- c. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included 1 \
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
 2 --to=<path_to_directory_for_credentials_requests> 3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 labels:
 controller-tools.k8s.io: "1.0"
 name: openshift-image-registry-azure
 namespace: openshift-cloud-credential-operator
spec:
 secretRef:
 name: installer-cloud-credentials
 namespace: openshift-image-registry
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: AzureProviderSpec
 roleBindings:
 - role: Contributor
```

- d. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object. The format for the secret data varies for each cloud provider.

### Sample **secrets.yaml** file:

```
apiVersion: v1
kind: Secret
metadata:
 name: ${secret_name}
 namespace: ${secret_namespace}
stringData:
 azure_subscription_id: ${subscription_id}
 azure_client_id: ${app_id}
 azure_client_secret: ${client_secret}
 azure_tenant_id: ${tenant_id}
 azure_resource_prefix: ${cluster_name}
 azure_resourcegroup: ${resource_group}
 azure_region: ${azure_region}
```

- e. Create a **cco-configmap.yaml** file in the manifests directory with the Cloud Credential Operator (CCO) disabled:

### Sample **ConfigMap** object

```

apiVersion: v1
kind: ConfigMap
metadata:
 name: cloud-credential-operator-config
 namespace: openshift-cloud-credential-operator
 annotations:
 release.openshift.io/create-only: "true"
data:
 disabled: "true"

```

10. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

```

.
├── auth
│ ├── kubeadmin-password
│ └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign

```

### Additional resources

- [Manually manage cloud credentials](#)

#### 6.5.6.6. Optional: Creating a separate **/var** partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files

when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

## IMPORTANT

If you follow the steps to create a separate **/var** partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

## Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
```

## Example output

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and
$HOME/clusterconfig/openshift
```

3. Optional: Confirm that the installation program created manifests in the **clusterconfig/openshift** directory:

```
$ ls $HOME/clusterconfig/openshift/
```

## Example output

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

4. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
```

```

labels:
 machineconfiguration.openshift.io/role: worker
name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> ❶
 partitions:
 - label: var
 start_mib: <partition_start_offset> ❷
 size_mib: <partition_size> ❸
 number: 5
 filesystems:
 - device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] ❹
 with_mount_unit: true

```

- ❶ The storage device name of the disk that you want to partition.
- ❷ When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ❸ The size of the data partition in mebibytes.
- ❹ The **prjquota** mount option must be enabled for filesystems used for container storage.

#### NOTE

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

6. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 6.5.7. Creating the Azure resource group

You must create a Microsoft Azure [resource group](#). This is used during the installation of your OpenShift Container Platform cluster on Azure Stack Hub.

### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

### Procedure

- Create the resource group in a supported Azure region:

```
$ az group create --name ${RESOURCE_GROUP} --location ${AZURE_REGION}
```

## 6.5.8. Uploading the RHCOS cluster image and bootstrap Ignition config file

The Azure client does not support deployments based on files existing locally. You must copy and store the RHCOS virtual hard disk (VHD) cluster image and bootstrap Ignition config file in a storage container so they are accessible during deployment.

### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

### Procedure

1. Create an Azure storage account to store the VHD cluster image:

```
$ az storage account create -g ${RESOURCE_GROUP} --location ${AZURE_REGION} --name ${CLUSTER_NAME}sa --kind Storage --sku Standard_LRS
```

#### WARNING

The Azure storage account name must be between 3 and 24 characters in length and use numbers and lower-case letters only. If your **CLUSTER\_NAME** variable does not follow these restrictions, you must manually define the Azure storage account name. For more information on Azure storage account name restrictions, see [Resolve errors for storage account names](#) in the Azure documentation.

2. Export the storage account key as an environment variable:

```
$ export ACCOUNT_KEY=`az storage account keys list -g ${RESOURCE_GROUP} --account-name ${CLUSTER_NAME}sa --query "[0].value" -o tsv`
```

- Export the URL of the RHCOS VHD to an environment variable:

```
$ export COMPRESSED_VHD_URL=$(openshift-install coreos print-stream-json | jq -r
'.architectures.x86_64.artifacts.azurestack.formats."vhd.gz".disk.location')
```

### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must specify an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

- Create the storage container for the VHD:

```
$ az storage container create --name vhd --account-name ${CLUSTER_NAME}sa --account-
key ${ACCOUNT_KEY}
```

- Download the compressed RHCOS VHD file locally:

```
$ curl -O -L ${COMPRESSED_VHD_URL}
```

- Decompress the VHD file.

### NOTE

The decompressed VHD file is approximately 16 GB, so be sure that your host system has 16 GB of free space available. You can delete the VHD file after you upload it.

- Copy the local VHD to a blob:

```
$ az storage blob upload --account-name ${CLUSTER_NAME}sa --account-key
${ACCOUNT_KEY} -c vhd -n "rhcos.vhd" -f rhcos-<rhcos_version>-azurestack.x86_64.vhd
```

- Create a blob storage container and upload the generated **bootstrap.ign** file:

```
$ az storage container create --name files --account-name ${CLUSTER_NAME}sa --
account-key ${ACCOUNT_KEY}
```

```
$ az storage blob upload --account-name ${CLUSTER_NAME}sa --account-key
${ACCOUNT_KEY} -c "files" -f "<installation_directory>/bootstrap.ign" -n "bootstrap.ign"
```

## 6.5.9. Example for creating DNS zones

DNS records are required for clusters that use user-provisioned infrastructure. You should choose the DNS strategy that fits your scenario.

For this example, [Azure Stack Hub's datacenter DNS integration](#) is used, so you will create a DNS zone.

## NOTE

The DNS zone is not required to exist in the same resource group as the cluster deployment and might already exist in your organization for the desired base domain. If that is the case, you can skip creating the DNS zone; be sure the installation config you generated earlier reflects that scenario.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

## Procedure

- Create the new DNS zone in the resource group exported in the **BASE\_DOMAIN\_RESOURCE\_GROUP** environment variable:

```
$ az network dns zone create -g ${BASE_DOMAIN_RESOURCE_GROUP} -n
${CLUSTER_NAME}.${BASE_DOMAIN}
```

You can skip this step if you are using a DNS zone that already exists.

You can learn more about [configuring a DNS zone in Azure Stack Hub](#) by visiting that section.

## 6.5.10. Creating a VNet in Azure Stack Hub

You must create a virtual network (VNet) in Microsoft Azure Stack Hub for your OpenShift Container Platform cluster to use. You can customize the VNet to meet your requirements. One way to create the VNet is to modify the provided Azure Resource Manager (ARM) template.

## NOTE

If you do not use the provided ARM template to create your Azure Stack Hub infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

## Procedure

1. Copy the template from the **ARM template for the VNet** section of this topic and save it as **01\_vnet.json** in your cluster's installation directory. This template describes the VNet that your cluster requires.
2. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/01_vnet.json" \
 --parameters baseName="${INFRA_ID}" 1
```

- 1** The base name to be used in resource names; this is usually the cluster's infrastructure ID.

### 6.5.10.1. ARM template for the VNet

You can use the following Azure Resource Manager (ARM) template to deploy the VNet that you need for your OpenShift Container Platform cluster:

#### Example 6.1. 01\_vnet.json ARM template

link:[https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/01\\_vnet.json](https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/01_vnet.json)

### 6.5.11. Deploying the RHCOS cluster image for the Azure Stack Hub infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Microsoft Azure Stack Hub for your OpenShift Container Platform nodes.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Store the RHCOS virtual hard disk (VHD) cluster image in an Azure storage container.
- Store the bootstrap Ignition config file in an Azure storage container.

#### Procedure

1. Copy the template from the **ARM template for image storage** section of this topic and save it as **02\_storage.json** in your cluster's installation directory. This template describes the image storage that your cluster requires.
2. Export the RHCOS VHD blob URL as a variable:

```
$ export VHD_BLOB_URL=`az storage blob url --account-name ${CLUSTER_NAME}sa --
account-key ${ACCOUNT_KEY} -c vhd -n "rhcos.vhd" -o tsv`
```

3. Deploy the cluster image:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/02_storage.json" \
 --parameters vhdBlobURL="${VHD_BLOB_URL}" 1 \
 --parameters baseName="${INFRA_ID}" 2 \
 --parameters storageAccount="${CLUSTER_NAME}sa" 3 \
 --parameters architecture="<architecture>" 4
```

- 1 The blob URL of the RHCOS VHD to be used to create master and worker machines.
- 2 The base name to be used in resource names; this is usually the cluster's infrastructure ID.
- 3 The name of your Azure storage account.
- 4 Specify the system architecture. Valid values are **x64** (default) or **Arm64**.

### 6.5.11.1. ARM template for image storage

You can use the following Azure Resource Manager (ARM) template to deploy the stored Red Hat Enterprise Linux CoreOS (RHCOS) image that you need for your OpenShift Container Platform cluster:

#### Example 6.2. 02\_storage.json ARM template

link:[https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/02\\_storage.json](https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/02_storage.json)

### 6.5.12. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

#### 6.5.12.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

#### IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 6.8. Ports used for all-machine to all-machine communications

| Protocol | Port               | Description                                                                                                                       |
|----------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                        |
| TCP      | <b>1936</b>        | Metrics                                                                                                                           |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> . |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                        |

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|          | <b>10256</b>       | openshift-sdn                                                                                                                               |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |

| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

Table 6.9. Ports used for all-machine to control plane communications

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

Table 6.10. Ports used for control plane machine to control plane machine communications

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

### 6.5.13. Creating networking and load balancing components in Azure Stack Hub

You must configure networking and load balancing in Microsoft Azure Stack Hub for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Azure Resource Manager (ARM) template.

Load balancing requires the following DNS records:

- An **api** DNS record for the API public load balancer in the DNS zone.
- An **api-int** DNS record for the API internal load balancer in the DNS zone.

## NOTE

If you do not use the provided ARM template to create your Azure Stack Hub infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure Stack Hub.

## Procedure

1. Copy the template from the **ARM template for the network and load balancers** section of this topic and save it as **03\_infra.json** in your cluster's installation directory. This template describes the networking and load balancing objects that your cluster requires.
2. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/03_infra.json" \
 --parameters baseName="${INFRA_ID}" 1
```

- 1** The base name to be used in resource names; this is usually the cluster's infrastructure ID.

3. Create an **api** DNS record and an **api-int** DNS record. When creating the API DNS records, the **\${BASE\_DOMAIN\_RESOURCE\_GROUP}** variable must point to the resource group where the DNS zone exists.

- a. Export the following variable:

```
$ export PUBLIC_IP=`az network public-ip list -g ${RESOURCE_GROUP} --query "[?name=='${INFRA_ID}-master-pip'] | [0].ipAddress" -o tsv`
```

- b. Export the following variable:

```
$ export PRIVATE_IP=`az network lb frontend-ip show -g "$RESOURCE_GROUP" --lb-name "${INFRA_ID}-internal" -n internal-lb-ip --query "privateIpAddress" -o tsv`
```

- c. Create the **api** DNS record in a new DNS zone:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n api -a ${PUBLIC_IP} --ttl 60
```

If you are adding the cluster to an existing DNS zone, you can create the **api** DNS record in it instead:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${BASE_DOMAIN} -n api.${CLUSTER_NAME} -a ${PUBLIC_IP} --ttl 60
```

d. Create the **api-int** DNS record in a new DNS zone:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -
z "${CLUSTER_NAME}.${BASE_DOMAIN}" -n api-int -a ${PRIVATE_IP} --ttl 60
```

If you are adding the cluster to an existing DNS zone, you can create the **api-int** DNS record in it instead:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -
z ${BASE_DOMAIN} -n api-int.${CLUSTER_NAME} -a ${PRIVATE_IP} --ttl 60
```

### 6.5.13.1. ARM template for the network and load balancers

You can use the following Azure Resource Manager (ARM) template to deploy the networking objects and load balancers that you need for your OpenShift Container Platform cluster:

#### Example 6.3. 03\_infra.json ARM template

link:[https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/03\\_infra.json](https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/03_infra.json)

### 6.5.14. Creating the bootstrap machine in Azure Stack Hub

You must create the bootstrap machine in Microsoft Azure Stack Hub to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Azure Resource Manager (ARM) template.

#### NOTE

If you do not use the provided ARM template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure Stack Hub.
- Create and configure networking and load balancers in Azure Stack Hub.
- Create control plane and compute roles.

#### Procedure

1. Copy the template from the **ARM template for the bootstrap machine** section of this topic and save it as **04\_bootstrap.json** in your cluster's installation directory. This template describes the bootstrap machine that your cluster requires.

2. Export the bootstrap URL variable:

```
$ bootstrap_url_expiry=`date -u -d "10 hours" '+%Y-%m-%dT%H:%MZ'`
```

```
$ export BOOTSTRAP_URL=`az storage blob generate-sas -c 'files' -n 'bootstrap.ign' --https-only --full-uri --permissions r --expiry $bootstrap_url_expiry --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} -o tsv`
```

3. Export the bootstrap ignition variable:

- a. If your environment uses a public certificate authority (CA), run this command:

```
$ export BOOTSTRAP_IGNITION=`jq -rcnM --arg v "3.2.0" --arg url ${BOOTSTRAP_URL} '{ignition:{version:$v,config:{replace:{source:$url}}}}' | base64 | tr -d '\n'`
```

- b. If your environment uses an internal CA, you must add your PEM encoded bundle to the bootstrap ignition stub so that your bootstrap virtual machine can pull the bootstrap ignition from the storage account. Run the following commands, which assume your CA is in a file called **CA.pem**:

```
$ export CA="data:text/plain;charset=utf-8;base64,$(cat CA.pem |base64 |tr -d '\n')"
```

```
$ export BOOTSTRAP_IGNITION=`jq -rcnM --arg v "3.2.0" --arg url "$BOOTSTRAP_URL" --arg cert "$CA" '{ignition:{version:$v,security:{tls:{certificateAuthorities:[{source:$cert}]},config:{replace:{source:$url}}}}' | base64 | tr -d '\n'`
```

4. Create the deployment by using the **az** CLI:

```
$ az deployment group create --verbose -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/04_bootstrap.json" \
 --parameters bootstrapIgnition="${BOOTSTRAP_IGNITION}" \ 1
 --parameters baseName="${INFRA_ID}" \ 2
 --parameters diagnosticsStorageAccountName="${CLUSTER_NAME}sa" 3
```

- 1** The bootstrap Ignition content for the bootstrap cluster.
- 2** The base name to be used in resource names; this is usually the cluster's infrastructure ID.
- 3** The name of the storage account for your cluster.

#### 6.5.14.1. ARM template for the bootstrap machine

You can use the following Azure Resource Manager (ARM) template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

##### Example 6.4. 04\_bootstrap.json ARM template

link:[https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/04\\_bootstrap.json](https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/04_bootstrap.json)

### 6.5.15. Creating the control plane machines in Azure Stack Hub

You must create the control plane machines in Microsoft Azure Stack Hub for your cluster to use. One way to create these machines is to modify the provided Azure Resource Manager (ARM) template.

If you do not use the provided ARM template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, consider contacting Red Hat support with your installation logs.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure Stack Hub.
- Create and configure networking and load balancers in Azure Stack Hub.
- Create control plane and compute roles.
- Create the bootstrap machine.

#### Procedure

1. Copy the template from the **ARM template for control plane machines** section of this topic and save it as **05\_masters.json** in your cluster's installation directory. This template describes the control plane machines that your cluster requires.
2. Export the following variable needed by the control plane machine deployment:

```
$ export MASTER_IGNITION=`cat <installation_directory>/master.ign | base64 | tr -d '\n'`
```

3. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
 --template-file "<installation_directory>/05_masters.json" \
 --parameters masterIgnition="${MASTER_IGNITION}" ❶ \
 --parameters baseName="${INFRA_ID}" ❷ \
 --parameters diagnosticsStorageAccountName="${CLUSTER_NAME}sa" ❸
```

- ❶ The Ignition content for the control plane nodes (also known as the master nodes).
- ❷ The base name to be used in resource names; this is usually the cluster's infrastructure ID.
- ❸ The name of the storage account for your cluster.

#### 6.5.15.1. ARM template for control plane machines

You can use the following Azure Resource Manager (ARM) template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

### Example 6.5. 05\_masters.json ARM template

link:[https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/05\\_masters.json](https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/05_masters.json)

## 6.5.16. Wait for bootstrap completion and remove bootstrap resources in Azure Stack Hub

After you create all of the required infrastructure in Microsoft Azure Stack Hub, wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure Stack Hub.
- Create and configure networking and load balancers in Azure Stack Hub.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

### Procedure

1. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install wait-for bootstrap-complete --dir <installation_directory> \ 1
--log-level info 2
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the command exits without a **FATAL** warning, your production control plane has initialized.

2. Delete the bootstrap resources:

```
$ az network nsg rule delete -g ${RESOURCE_GROUP} --nsg-name ${INFRA_ID}-nsg --
name bootstrap_ssh_in
$ az vm stop -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap
$ az vm deallocate -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap
$ az vm delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap --yes
$ az disk delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap_OSDisk --no-
wait --yes
$ az network nic delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap-nic --no-
```

```
wait
$ az storage blob delete --account-key ${ACCOUNT_KEY} --account-name
${CLUSTER_NAME}sa --container-name files --name bootstrap.ign
$ az network public-ip delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap-
ssh-pip
```

## NOTE

If you do not delete the bootstrap server, installation may not succeed due to API traffic being routed to the bootstrap server.

### 6.5.17. Creating additional worker machines in Azure Stack Hub

You can create worker machines in Microsoft Azure Stack Hub for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Azure Resource Manager (ARM) template. Additional instances can be launched by including additional resources of type **06\_workers.json** in the file.

If you do not use the provided ARM template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, consider contacting Red Hat support with your installation logs.

#### Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure Stack Hub.
- Create and configure networking and load balancers in Azure Stack Hub.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

#### Procedure

1. Copy the template from the **ARM template for worker machines** section of this topic and save it as **06\_workers.json** in your cluster's installation directory. This template describes the worker machines that your cluster requires.
2. Export the following variable needed by the worker machine deployment:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign | base64 | tr -d "\n"
```

3. Create the deployment by using the **az** CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
```

```
--template-file "<installation_directory>/06_workers.json" \
--parameters workerIgnition="{WORKER_IGNITION}" \ ❶
--parameters baseName="{INFRA_ID}" ❷
--parameters diagnosticsStorageAccountName="{CLUSTER_NAME}sa" ❸
```

- ❶ The Ignition content for the worker nodes.
- ❷ The base name to be used in resource names; this is usually the cluster's infrastructure ID.
- ❸ The name of the storage account for your cluster.

### 6.5.17.1. ARM template for worker machines

You can use the following Azure Resource Manager (ARM) template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

#### Example 6.6. 06\_workers.json ARM template

link:[https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/06\\_workers.json](https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/azurestack/06_workers.json)

### 6.5.18. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

## Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 6.5.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

## Example output

```
system:admin
```

### 6.5.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

## Prerequisites

- You added machines to your cluster.

## Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

### Example output

| NAME     | STATUS | ROLES  | AGE | VERSION |
|----------|--------|--------|-----|---------|
| master-0 | Ready  | master | 63m | v1.27.3 |
| master-1 | Ready  | master | 63m | v1.27.3 |
| master-2 | Ready  | master | 64m | v1.27.3 |

The output lists all of the machines that you created.

### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

| NAME      | AGE | REQUESTOR                                                                     | CONDITION |
|-----------|-----|-------------------------------------------------------------------------------|-----------|
| csr-8b2br | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstraptrapper | Pending   |
| csr-8vnps | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstraptrapper | Pending   |
| ...       |     |                                                                               |           |

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

### NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

## NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrap** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

## NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

## 6.5.21. Adding the Ingress DNS records

If you removed the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the Ingress load balancer. You can create either a wildcard **\*.apps.{baseDomain}**, or specific records. You can use A, CNAME, and other records per your requirements.

### Prerequisites

- You deployed an OpenShift Container Platform cluster on Microsoft Azure Stack Hub by using infrastructure that you provisioned.
- Install the OpenShift CLI (**oc**).
- Install or update the [Azure CLI](#).

### Procedure

1. Confirm the Ingress router has created a load balancer and populated the **EXTERNAL-IP** field:

```
$ oc -n openshift-ingress get service router-default
```

### Example output

| NAME           | TYPE         | CLUSTER-IP   | EXTERNAL-IP    | PORT(S)                    | AGE |
|----------------|--------------|--------------|----------------|----------------------------|-----|
| router-default | LoadBalancer | 172.30.20.10 | 35.130.120.110 | 80:32288/TCP,443:31215/TCP | 20  |

2. Export the Ingress router IP as a variable:

```
$ export PUBLIC_IP_ROUTER=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
```

3. Add a **\*.apps** record to the DNS zone.

- a. If you are adding this cluster to a new DNS zone, run:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps -a ${PUBLIC_IP_ROUTER} --ttl 300
```

- b. If you are adding this cluster to an already existing DNS zone, run:

```
$ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${BASE_DOMAIN} -n *.apps.${CLUSTER_NAME} -a ${PUBLIC_IP_ROUTER} --ttl 300
```

If you prefer to add explicit domains instead of using a wildcard, you can create entries for each of the cluster's current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}{"\n"}{end}{end}' routes
```

### Example output

```
oauth-openshift.apps.cluster.basedomain.com
console-openshift-console.apps.cluster.basedomain.com
downloads-openshift-console.apps.cluster.basedomain.com
alertmanager-main-openshift-monitoring.apps.cluster.basedomain.com
prometheus-k8s-openshift-monitoring.apps.cluster.basedomain.com
```

## 6.5.22. Completing an Azure Stack Hub installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Microsoft Azure Stack Hub user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

### Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned Azure Stack Hub infrastructure.
- Install the **oc** CLI and log in.

### Procedure

- Complete the cluster installation:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service.

## 6.6. INSTALLATION CONFIGURATION PARAMETERS FOR AZURE STACK HUB

Before you deploy an OpenShift Container Platform cluster on Azure Stack Hub, you provide a customized **install-config.yaml** installation configuration file that describes the details for your environment.

### 6.6.1. Available installation configuration parameters for Azure Stack Hub

The following tables specify the required, optional, and Azure Stack Hub-specific installation configuration parameters that you can set as part of the installation process.

### NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

#### 6.6.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 6.11. Required parameters

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>apiVersion:</b>         | The API version for the <b>install-config.yaml</b> content. The current version is <b>v1</b> . The installation program may also support older API versions.                                                                                                                                                                                                                                                                   | String                                                                          |
| <b>baseDomain:</b>         | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <b>baseDomain</b> and <b>metadata.name</b> parameter values that uses the <b>&lt;metadata.name&gt;.&lt;baseDomain&gt;</b> format.                                                                                         | A fully-qualified domain or subdomain name, such as <b>example.com</b> .        |
| <b>metadata:</b>           | Kubernetes resource <b>ObjectMeta</b> , from which only the <b>name</b> parameter is consumed.                                                                                                                                                                                                                                                                                                                                 | Object                                                                          |
| <b>metadata:<br/>name:</b> | The name of the cluster. DNS records for the cluster are all subdomains of <b>{{.metadata.name}}.{{.baseDomain}}</b> .                                                                                                                                                                                                                                                                                                         | String of lowercase letters, hyphens (-), and periods (.), such as <b>dev</b> . |
| <b>platform:</b>           | The configuration for the specific platform upon which to perform the installation: <b>alibabacloud</b> , <b>aws</b> , <b>baremetal</b> , <b>azure</b> , <b>gcp</b> , <b>ibmcloud</b> , <b>nutanix</b> , <b>openstack</b> , <b>powervs</b> , <b>vsphere</b> , or <b>{}</b> . For additional information about <b>platform</b> . <b>&lt;platform&gt;</b> parameters, consult the table for your specific platform that follows. | Object                                                                          |

| Parameter                                                                                     | Description                                                                                                                                                                                      | Values                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  pullSecret: | Get a <a href="#">pull secret from Red Hat OpenShift Cluster Manager</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io. |  <pre>{   "auths":{     "cloud.openshift.com":{       "auth":"b3Blb=",       "email":"you@example.com"     },     "quay.io":{       "auth":"b3Blb=",       "email":"you@example.com"     }   } }</pre> |

6.6.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

Table 6.12. Network parameters

| Parameter                                                                                       | Description                                | Values                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  networking: | The configuration for the cluster network. | <div>Object</div> <div></div> <div><b>NOTE</b><br/>You cannot modify parameters specified by the <b>networking</b> object after installation.</div> |

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                                  | Values                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:<br/>networkType:</code>                    | The Red Hat OpenShift Networking network plugin to install.                                                                                                                                                                                                                                                  | Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b> . <b>OpenShiftSDN</b> is a CNI plugin for all-Linux networks. <b>OVNKubernetes</b> is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is <b>OVNKubernetes</b> . |
| <code>networking:<br/>clusterNetwork:</code>                 | <p>The IP address blocks for pods.</p> <p>The default value is <b>10.128.0.0/14</b> with a host prefix of <b>/23</b>.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>                                                                                                     | <p>An array of objects. For example:</p> <pre>networking:   clusterNetwork:     - cidr: 10.128.0.0/14       hostPrefix: 23</pre>                                                                                                                                                      |
| <code>networking:<br/>clusterNetwork:<br/>cidr:</code>       | <p>Required if you use <b>networking.clusterNetwork</b>. An IP address block.</p> <p>An IPv4 network.</p>                                                                                                                                                                                                    | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between <b>0</b> and <b>32</b> .                                                                                                                                        |
| <code>networking:<br/>clusterNetwork:<br/>hostPrefix:</code> | <p>The subnet prefix length to assign to each individual node. For example, if <b>hostPrefix</b> is set to <b>23</b> then each node is assigned a <b>/23</b> subnet out of the given <b>cidr</b>. A <b>hostPrefix</b> value of <b>23</b> provides 510 (<math>2^{(32 - 23)} - 2</math>) pod IP addresses.</p> | <p>A subnet prefix.</p> <p>The default value is <b>23</b>.</p>                                                                                                                                                                                                                        |
| <code>networking:<br/>serviceNetwork:</code>                 | <p>The IP address block for services. The default value is <b>172.30.0.0/16</b>.</p> <p>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.</p>                                                                                             | <p>An array with an IP address block in CIDR format. For example:</p> <pre>networking:   serviceNetwork:     - 172.30.0.0/16</pre>                                                                                                                                                    |
| <code>networking:<br/>machineNetwork:</code>                 | <p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>                                                                                                                                                                                    | <p>An array of objects. For example:</p> <pre>networking:   machineNetwork:     - cidr: 10.0.0.0/16</pre>                                                                                                                                                                             |

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                                                     | Values                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>networking:</b><br><b>machineNetwork:</b><br><b>cidr:</b> | Required if you use <b>networking.machineNetwork</b> . An IP address block. The default value is <b>10.0.0.0/16</b> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <b>192.168.126.0/24</b> . For IBM Power® Virtual Server, the default value is <b>192.168.0.0/24</b> . | An IP network block in CIDR notation.<br><br>For example, <b>10.0.0.0/16</b> .<br><br> <div> <b>NOTE</b><br/><br/>           Set the <b>networking.machineNetwork</b> to match the CIDR that the preferred NIC resides in.         </div> |

### 6.6.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 6.13. Optional parameters**

| Parameter                                                     | Description                                                                                                                                                                                                                                                 | Values       |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <b>additionalTrustBundle:</b>                                 | A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.                                                                                          | String       |
| <b>capabilities:</b>                                          | Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the "Cluster capabilities" page in <i>Installing</i> . | String array |
| <b>capabilities:</b><br><b>baselineCapabilitySet:</b>         | Selects an initial set of optional capabilities to enable. Valid values are <b>None</b> , <b>v4.11</b> , <b>v4.12</b> and <b>vCurrent</b> . The default value is <b>vCurrent</b> .                                                                          | String       |
| <b>capabilities:</b><br><b>additionalEnabledCapabilities:</b> | Extends the set of optional capabilities beyond what you specify in <b>baselineCapabilitySet</b> . You may specify multiple capabilities in this parameter.                                                                                                 | String array |

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                             |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| <b>cpuPartitioningMode:</b>     | Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <i>Workload partitioning</i> page in the <i>Scalability and Performance</i> section. | <b>None</b> or <b>AllNodes</b> . <b>None</b> is the default value. |
| <b>compute:</b>                 | The configuration for the machines that comprise the compute nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                            | Array of <b>MachinePool</b> objects.                               |
| <b>compute: architecture:</b>   | Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <b>amd64</b> (the default).                                                                                                                                                                                                                                                                           | String                                                             |
| <b>compute: hyperthreading:</b> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div>            | <b>Enabled</b> or <b>Disabled</b>                                  |

| Parameter                                    | Description                                                                                                                                                                                                                                                        | Values                                                                                              |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <b>compute:</b><br><b>name:</b>              | Required if you use <b>compute</b> . The name of the machine pool.                                                                                                                                                                                                 | <b>worker</b>                                                                                       |
| <b>compute:</b><br><b>platform:</b>          | Required if you use <b>compute</b> . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <b>controlPlane.platform</b> parameter value.                                                               | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere</b> , or <b>{}</b> |
| <b>compute:</b><br><b>replicas:</b>          | The number of compute machines, which are also known as worker machines, to provision.                                                                                                                                                                             | A positive integer greater than or equal to <b>2</b> . The default value is <b>3</b> .              |
| <b>featureSet:</b>                           | Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see "Enabling features using feature gates". | String. The name of the feature set to enable, such as <b>TechPreviewNoUpgrade</b> .                |
| <b>controlPlane:</b>                         | The configuration for the machines that comprise the control plane.                                                                                                                                                                                                | Array of <b>MachinePool</b> objects.                                                                |
| <b>controlPlane:</b><br><b>architecture:</b> | Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <b>amd64</b> (the default).                               | String                                                                                              |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Values                                                                                      |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>controlPlane:</b><br><b>hyperthreading:</b> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div> | <b>Enabled</b> or <b>Disabled</b>                                                           |
| <b>controlPlane:</b><br><b>name:</b>           | Required if you use <b>controlPlane</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                 | <b>master</b>                                                                               |
| <b>controlPlane:</b><br><b>platform:</b>       | Required if you use <b>controlPlane</b> . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <b>compute.platform</b> parameter value.                                                                                                                                                                                                                                                                                          | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |
| <b>controlPlane:</b><br><b>replicas:</b>       | The number of control plane machines to provision.                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Supported values are <b>3</b> , or <b>1</b> when deploying single-node OpenShift.           |
| <b>credentialsMode:</b>                        | The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.                                                                                                                                                                                                                                                            | <b>Mint, Passthrough, Manual</b> or an empty string (""). <sup>[1]</sup>                    |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Values        |

| <b>imageContentSources:</b>              | Sources and repositories for the release-image content.                                                                                                                                                                                                                                                                                                                                   | Array of objects. Includes a <b>source</b> and, optionally, <b>mirrors</b> , as described in the following rows of this table.                                                                                                                                                                                                                                                                                                                                  |
| <b>imageContentSources:<br/>source:</b>  | Required if you use <b>imageContentSources</b> . Specify the repository that users refer to, for example, in image pull specifications.                                                                                                                                                                                                                                                   | String                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>imageContentSources:<br/>mirrors:</b> | Specify one or more repositories that may also contain the same images.                                                                                                                                                                                                                                                                                                                   | Array of strings                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>publish:</b>                          | How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.                                                                                                                                                                                                                                                                         | <p><b>Internal</b> or <b>External</b>. The default value is <b>External</b>.</p> <p>Setting this field to <b>Internal</b> is not supported on non-cloud platforms.</p> <div>  <p><b>IMPORTANT</b></p> <p>If the value of the field is set to <b>Internal</b>, the cluster will become non-functional. For more information, refer to <a href="#">BZ#1953035</a>.</p> </div> |
| <b>sshKey:</b>                           | <p>The SSH key to authenticate access to your cluster machines.</p> <div>  <p><b>NOTE</b></p> <p>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <b>ssh-agent</b> process uses.</p> </div> | For example, <b>sshKey: ssh-ed25519 AAAA...</b>                                                                                                                                                                                                                                                                                                                                                                                                                 |

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.

### 6.6.1.4. Additional Azure Stack Hub configuration parameters

Additional Azure configuration parameters are described in the following table:

**Table 6.14. Additional Azure Stack Hub parameters**

| Parameter                                                                                                                       | Description                                                 | Values                                                                             |
|---------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|------------------------------------------------------------------------------------|
| <code>compute:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskSizeGB:</code>      | The Azure disk size for the VM.                             | Integer that represents the size of the disk in GB. The default is <b>128</b> .    |
| <code>compute:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskType:</code>        | Defines the type of disk.                                   | <b>standard_LRS</b> or <b>premium_LRS</b> .<br>The default is <b>premium_LRS</b> . |
| <code>compute:</code><br><code>platform:</code><br><code>azure:</code><br><code>type:</code>                                    | Defines the azure instance type for compute machines.       | String                                                                             |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskSizeGB:</code> | The Azure disk size for the VM.                             | Integer that represents the size of the disk in GB. The default is <b>1024</b> .   |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>osDisk:</code><br><code>diskType:</code>   | Defines the type of disk.                                   | <b>premium_LRS</b> .                                                               |
| <code>controlPlane:</code><br><code>platform:</code><br><code>azure:</code><br><code>type:</code>                               | Defines the azure instance type for control plane machines. | String                                                                             |

| Parameter                                                                        | Description                                                                                 | Values                                                                             |
|----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <pre>platform:   azure:  defaultMachinePlatform:   osDisk:     diskSizeGB:</pre> | The Azure disk size for the VM.                                                             | Integer that represents the size of the disk in GB. The default is <b>128</b> .    |
| <pre>platform:   azure:  defaultMachinePlatform:   osDisk:     diskType:</pre>   | Defines the type of disk.                                                                   | <b>standard_LRS</b> or <b>premium_LRS</b> .<br>The default is <b>premium_LRS</b> . |
| <pre>platform:   azure:  defaultMachinePlatform:   type:</pre>                   | The Azure instance type for control plane and compute machines.                             | The Azure instance type.                                                           |
| <pre>platform:   azure:     armEndpoint:</pre>                                   | The URL of the Azure Resource Manager endpoint that your Azure Stack Hub operator provides. | String                                                                             |
| <pre>platform:   azure:  baseDomainResourceGroupName:</pre>                      | The name of the resource group that contains the DNS zone for your base domain.             | String, for example <b>production_cluster</b> .                                    |
| <pre>platform:   azure:     region:</pre>                                        | The name of your Azure Stack Hub local region.                                              | String                                                                             |

| Parameter                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Values                                                                                                                                |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>platform:</b><br><b>azure:</b><br><b>resourceGroupName:</b> | <p>The name of an already existing resource group to install your cluster to. This resource group must be empty and only used for this specific cluster; the cluster components assume ownership of all resources in the resource group. If you limit the service principal scope of the installation program to this resource group, you must ensure all other resources used by the installation program in your environment have the necessary permissions, such as the public DNS zone and virtual network. Destroying the cluster by using the installation program deletes this resource group.</p> | <p>String, for example <b>existing_resource_group</b>.</p>                                                                            |
| <b>platform:</b><br><b>azure:</b><br><b>outboundType:</b>      | <p>The outbound routing strategy used to connect your cluster to the internet. If you are using user-defined routing, you must have pre-existing networking available where the outbound routing has already been configured prior to installing a cluster. The installation program is not responsible for configuring user-defined routing.</p>                                                                                                                                                                                                                                                         | <p><b>LoadBalancer</b> or <b>UserDefinedRouting</b>. The default is <b>LoadBalancer</b>.</p>                                          |
| <b>platform:</b><br><b>azure:</b><br><b>cloudName:</b>         | <p>The name of the Azure cloud environment that is used to configure the Azure SDK with the appropriate Azure API endpoints.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <p><b>AzureStackCloud</b></p>                                                                                                         |
| <b>clusterOSImage:</b>                                         | <p>The URL of a storage blob in the Azure Stack environment that contains an RHCOS VHD.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <p>String, for example, <code>https://vhdsa.blob.example.example.com/vhd/rhcos-410.84.202112040202-0-azurestack.x86_64.vhd</code></p> |

## 6.7. UNINSTALLING A CLUSTER ON AZURE STACK HUB

You can remove a cluster that you deployed to Azure Stack Hub.

### 6.7.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

## NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

## Prerequisites

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

## Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$./openshift-install destroy cluster \
--dir <installation_directory> --log-level info 1 2
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2** To view different details, specify **warn**, **debug**, or **error** instead of **info**.

## NOTE

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the **metadata.json** file in this directory to delete the cluster.

2. Optional: Delete the **<installation\_directory>** directory and the OpenShift Container Platform installation program.

## CHAPTER 7. INSTALLING ON GCP

### 7.1. PREPARING TO INSTALL ON GCP

#### 7.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

#### 7.1.2. Requirements for installing OpenShift Container Platform on GCP

Before installing OpenShift Container Platform on Google Cloud Platform (GCP), you must create a service account and configure a GCP project. See [Configuring a GCP project](#) for details about creating a project, enabling API services, configuring DNS, GCP account limits, and supported GCP regions.

If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the **kube-system** namespace, see [Manually creating long-term credentials for GCP](#) for other options.

#### 7.1.3. Choosing a method to install OpenShift Container Platform on GCP

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See [Installation process](#) for more information about installer-provisioned and user-provisioned installation processes.

##### 7.1.3.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on GCP infrastructure that is provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- [Installing a cluster quickly on GCP](#) You can install OpenShift Container Platform on GCP infrastructure that is provisioned by the OpenShift Container Platform installation program. You can install a cluster quickly by using the default configuration options.
- [Installing a customized cluster on GCP](#) You can install a customized cluster on GCP infrastructure that the installation program provisions. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available [post-installation](#).
- [Installing a cluster on GCP with network customizations](#) You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.
- [Installing a cluster on GCP in a restricted network](#) You can install OpenShift Container Platform on GCP on installer-provisioned infrastructure by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an

active internet connection to obtain the software components. While you can install OpenShift Container Platform by using the mirrored content, your cluster still requires internet access to use the GCP APIs.

- **Installing a cluster into an existing Virtual Private Cloud** You can install OpenShift Container Platform on an existing GCP Virtual Private Cloud (VPC). You can use this installation method if you have constraints set by the guidelines of your company, such as limits on creating new accounts or infrastructure.
- **Installing a private cluster on an existing VPC** You can install a private cluster on an existing GCP VPC. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

### 7.1.3.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on GCP infrastructure that you provision, by using one of the following methods:

- **Installing a cluster on GCP with user-provisioned infrastructure** You can install OpenShift Container Platform on GCP infrastructure that you provide. You can use the provided Deployment Manager templates to assist with the installation.
- **Installing a cluster with shared VPC on user-provisioned infrastructure in GCP** You can use the provided Deployment Manager templates to create GCP resources in a shared VPC infrastructure.
- **Installing a cluster on GCP in a restricted network with user-provisioned infrastructure** You can install OpenShift Container Platform on GCP in a restricted network with user-provisioned infrastructure. By creating an internal mirror of the installation release content, you can install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

### 7.1.4. Next steps

- [Configuring a GCP project](#)

## 7.2. CONFIGURING A GCP PROJECT

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

### 7.2.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.

#### Procedure

- Create a project to host your OpenShift Container Platform cluster. See [Creating and Managing Projects](#) in the GCP documentation.

## IMPORTANT

Your GCP project must use the Premium Network Service Tier if you are using installer-provisioned infrastructure. The Standard Network Service Tier is not supported for clusters installed using the installation program. The installation program configures internal load balancing for the **api-int.<cluster\_name>.<base\_domain>** URL; the Premium Tier is required for internal load balancing.

### 7.2.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

#### Prerequisites

- You created a project to host your cluster.

#### Procedure

- Enable the following required API services in the project that hosts your cluster. You may also enable optional API services which are not required for installation. See [Enabling services](#) in the GCP documentation.

**Table 7.1. Required API services**

| API service                              | Console service name                       |
|------------------------------------------|--------------------------------------------|
| Compute Engine API                       | <b>compute.googleapis.com</b>              |
| Cloud Resource Manager API               | <b>cloudresourcemanager.googleapis.com</b> |
| Google DNS API                           | <b>dns.googleapis.com</b>                  |
| IAM Service Account Credentials API      | <b>iamcredentials.googleapis.com</b>       |
| Identity and Access Management (IAM) API | <b>iam.googleapis.com</b>                  |
| Service Usage API                        | <b>serviceusage.googleapis.com</b>         |

**Table 7.2. Optional API services**

| API service                   | Console service name                    |
|-------------------------------|-----------------------------------------|
| Google Cloud APIs             | <b>cloudapis.googleapis.com</b>         |
| Service Management API        | <b>servicemanagement.googleapis.com</b> |
| Google Cloud Storage JSON API | <b>storage-api.googleapis.com</b>       |

| API service   | Console service name                    |
|---------------|-----------------------------------------|
| Cloud Storage | <b>storage-component.googleapis.com</b> |

### 7.2.3. Configuring DNS for GCP

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the same project that you host the OpenShift Container Platform cluster. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

#### Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

#### NOTE

If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see [Google Domains](#).

2. Create a public hosted zone for your domain or subdomain in your GCP project. See [Creating public zones](#) in the GCP documentation.  
Use an appropriate root domain, such as **openshiftcorp.com**, or subdomain, such as **clusters.openshiftcorp.com**.
3. Extract the new authoritative name servers from the hosted zone records. See [Look up your Cloud DNS name servers](#) in the GCP documentation.  
You typically have four name servers.
4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: [How to switch to custom name servers](#).
5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See [Migrating to Cloud DNS](#) in the GCP documentation.
6. If you use a subdomain, follow your company's procedures to add its delegation records to the parent domain. This process might include a request to your company's IT department or the division that controls the root domain and DNS services for your company.

### 7.2.4. GCP account limits

The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default [Quotas](#) do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

**Table 7.3. GCP resources used in a default cluster**

| Service                    | Component | Location | Total resources required | Resources removed after bootstrap |
|----------------------------|-----------|----------|--------------------------|-----------------------------------|
| Service account            | IAM       | Global   | 6                        | 1                                 |
| Firewall rules             | Compute   | Global   | 11                       | 1                                 |
| Forwarding rules           | Compute   | Global   | 2                        | 0                                 |
| In-use global IP addresses | Compute   | Global   | 4                        | 1                                 |
| Health checks              | Compute   | Global   | 3                        | 0                                 |
| Images                     | Compute   | Global   | 1                        | 0                                 |
| Networks                   | Compute   | Global   | 2                        | 0                                 |
| Static IP addresses        | Compute   | Region   | 4                        | 1                                 |
| Routers                    | Compute   | Global   | 1                        | 0                                 |
| Routes                     | Compute   | Global   | 2                        | 0                                 |
| Subnetworks                | Compute   | Global   | 2                        | 0                                 |
| Target pools               | Compute   | Global   | 3                        | 0                                 |
| CPUs                       | Compute   | Region   | 28                       | 4                                 |
| Persistent disk SSD (GB)   | Compute   | Region   | 896                      | 128                               |

**NOTE**

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- **asia-east2**
- **asia-northeast2**

- **asia-south1**
- **australia-southeast1**
- **europa-north1**
- **europa-west2**
- **europa-west3**
- **europa-west6**
- **northamerica-northeast1**
- **southamerica-east1**
- **us-west2**

You can increase resource quotas from the [GCP console](#), but you might need to file a support ticket. Be sure to plan your cluster size early so that you can allow time to resolve the support ticket before you install your OpenShift Container Platform cluster.

### 7.2.5. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

#### Prerequisites

- You created a project to host your cluster.

#### Procedure

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See [Creating a service account](#) in the GCP documentation.
2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the **Owner** role to it. See [Granting roles to a service account for specific resources](#).

#### NOTE

While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. You can create the service account key in JSON format, or attach the service account to a GCP virtual machine. See [Creating service account keys](#) and [Creating and enabling service accounts for instances](#) in the GCP documentation.  
You must have a service account key or a virtual machine with an attached service account to create the cluster.

**NOTE**

If you use a virtual machine with an attached service account to create your cluster, you must set **credentialsMode: Manual** in the **install-config.yaml** file before installation.

**7.2.5.1. Required GCP roles**

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. If the security policies for your organization require a more restrictive set of permissions, you can create a service account with the following permissions.

**IMPORTANT**

If you configure the Cloud Credential Operator to operate in passthrough mode, you must use roles rather than granular permissions.

If you deploy your cluster into an existing virtual private cloud (VPC), the service account does not require certain networking permissions, which are noted in the following lists:

**Required roles for the installation program**

- Compute Admin
- IAM Security Admin
- Service Account Admin
- Service Account Key Admin
- Service Account User
- Storage Admin

**Required roles for creating network resources during installation**

- DNS Administrator

**Required roles for using passthrough credentials mode**

- Compute Load Balancer Admin
- IAM Role Viewer

The roles are applied to the service accounts that the control plane and compute machines use:

**Table 7.4. GCP service account permissions**

| Account       | Roles                              |
|---------------|------------------------------------|
| Control Plane | <b>roles/compute.instanceAdmin</b> |
|               | <b>roles/compute.networkAdmin</b>  |

| Account | Roles                               |
|---------|-------------------------------------|
|         | <b>roles/compute.securityAdmin</b>  |
|         | <b>roles/storage.admin</b>          |
|         | <b>roles/iam.serviceAccountUser</b> |
| Compute | <b>roles/compute.viewer</b>         |
|         | <b>roles/storage.admin</b>          |

### 7.2.5.2. Required GCP permissions for installer-provisioned infrastructure

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform.

If the security policies for your organization require a more restrictive set of permissions, you can create [custom roles](#) with the necessary permissions. The following permissions are required for the installer-provisioned infrastructure for creating and deleting the OpenShift Container Platform cluster.

#### IMPORTANT

If you configure the Cloud Credential Operator to operate in passthrough mode, you must use roles rather than granular permissions. For more information, see "Required roles for using passthrough credentials mode" in the "Required GCP roles" section.

#### Example 7.1. Required permissions for creating network resources

- **compute.addresses.create**
- **compute.addresses.createInternal**
- **compute.addresses.delete**
- **compute.addresses.get**
- **compute.addresses.list**
- **compute.addresses.use**
- **compute.addresses.useInternal**
- **compute.firewalls.create**
- **compute.firewalls.delete**
- **compute.firewalls.get**
- **compute.firewalls.list**
- **compute.forwardingRules.create**

- `compute.forwardingRules.get`
- `compute.forwardingRules.list`
- `compute.forwardingRules.setLabels`
- `compute.networks.create`
- `compute.networks.get`
- `compute.networks.list`
- `compute.networks.updatePolicy`
- `compute.routers.create`
- `compute.routers.get`
- `compute.routers.list`
- `compute.routers.update`
- `compute.routes.list`
- `compute.subnetworks.create`
- `compute.subnetworks.get`
- `compute.subnetworks.list`
- `compute.subnetworks.use`
- `compute.subnetworks.useExternallp`

Example 7.2. Required permissions for creating load balancer resources

- `compute.regionBackendServices.create`
- `compute.regionBackendServices.get`
- `compute.regionBackendServices.list`
- `compute.regionBackendServices.update`
- `compute.regionBackendServices.use`
- `compute.targetPools.addInstance`
- `compute.targetPools.create`
- `compute.targetPools.get`
- `compute.targetPools.list`
- `compute.targetPools.removeInstance`
- `compute.targetPools.use`

**Example 7.3. Required permissions for creating DNS resources**

- **dns.changes.create**
- **dns.changes.get**
- **dns.managedZones.create**
- **dns.managedZones.get**
- **dns.managedZones.list**
- **dns.networks.bindPrivateDNSZone**
- **dns.resourceRecordSets.create**
- **dns.resourceRecordSets.list**

**Example 7.4. Required permissions for creating Service Account resources**

- **iam.serviceAccountKeys.create**
- **iam.serviceAccountKeys.delete**
- **iam.serviceAccountKeys.get**
- **iam.serviceAccountKeys.list**
- **iam.serviceAccounts.actAs**
- **iam.serviceAccounts.create**
- **iam.serviceAccounts.delete**
- **iam.serviceAccounts.get**
- **iam.serviceAccounts.list**
- **resourcemanager.projects.get**
- **resourcemanager.projects.getIamPolicy**
- **resourcemanager.projects.setIamPolicy**

**Example 7.5. Required permissions for creating compute resources**

- **compute.disks.create**
- **compute.disks.get**
- **compute.disks.list**
- **compute.disks.setLabels**

- `compute.instanceGroups.create`
- `compute.instanceGroups.delete`
- `compute.instanceGroups.get`
- `compute.instanceGroups.list`
- `compute.instanceGroups.update`
- `compute.instanceGroups.use`
- `compute.instances.create`
- `compute.instances.delete`
- `compute.instances.get`
- `compute.instances.list`
- `compute.instances.setLabels`
- `compute.instances.setMetadata`
- `compute.instances.setServiceAccount`
- `compute.instances.setTags`
- `compute.instances.use`
- `compute.machineTypes.get`
- `compute.machineTypes.list`

Example 7.6. Required for creating storage resources

- `storage.buckets.create`
- `storage.buckets.delete`
- `storage.buckets.get`
- `storage.buckets.list`
- `storage.objects.create`
- `storage.objects.delete`
- `storage.objects.get`
- `storage.objects.list`

Example 7.7. Required permissions for creating health check resources

- `compute.healthChecks.create`

- `compute.healthChecks.get`
- `compute.healthChecks.list`
- `compute.healthChecks.useReadOnly`
- `compute.httpHealthChecks.create`
- `compute.httpHealthChecks.get`
- `compute.httpHealthChecks.list`
- `compute.httpHealthChecks.useReadOnly`

Example 7.8. Required permissions to get GCP zone and region related information

- `compute.globalOperations.get`
- `compute.regionOperations.get`
- `compute.regions.list`
- `compute.zoneOperations.get`
- `compute.zones.get`
- `compute.zones.list`

Example 7.9. Required permissions for checking services and quotas

- `monitoring.timeSeries.list`
- `serviceusage.quotas.get`
- `serviceusage.services.list`

Example 7.10. Required IAM permissions for installation

- `iam.roles.get`

Example 7.11. Optional Images permissions for installation

- `compute.images.list`

Example 7.12. Optional permission for running gather bootstrap

- `compute.instances.getSerialPortOutput`

Example 7.13. Required permissions for deleting network resources

- `compute.addresses.delete`
- `compute.addresses.deleteInternal`
- `compute.addresses.list`
- `compute.firewalls.delete`
- `compute.firewalls.list`
- `compute.forwardingRules.delete`
- `compute.forwardingRules.list`
- `compute.networks.delete`
- `compute.networks.list`
- `compute.networks.updatePolicy`
- `compute.routers.delete`
- `compute.routers.list`
- `compute.routes.list`
- `compute.subnetworks.delete`
- `compute.subnetworks.list`

Example 7.14. Required permissions for deleting load balancer resources

- `compute.regionBackendServices.delete`
- `compute.regionBackendServices.list`
- `compute.targetPools.delete`
- `compute.targetPools.list`

Example 7.15. Required permissions for deleting DNS resources

- `dns.changes.create`
- `dns.managedZones.delete`
- `dns.managedZones.get`
- `dns.managedZones.list`
- `dns.resourceRecordSets.delete`
- `dns.resourceRecordSets.list`

**Example 7.16. Required permissions for deleting Service Account resources**

- **iam.serviceAccounts.delete**
- **iam.serviceAccounts.get**
- **iam.serviceAccounts.list**
- **resourcemanager.projects.getIamPolicy**
- **resourcemanager.projects.setIamPolicy**

**Example 7.17. Required permissions for deleting compute resources**

- **compute.disks.delete**
- **compute.disks.list**
- **compute.instanceGroups.delete**
- **compute.instanceGroups.list**
- **compute.instances.delete**
- **compute.instances.list**
- **compute.instances.stop**
- **compute.machineTypes.list**

**Example 7.18. Required for deleting storage resources**

- **storage.buckets.delete**
- **storage.buckets.getIamPolicy**
- **storage.buckets.list**
- **storage.objects.delete**
- **storage.objects.list**

**Example 7.19. Required permissions for deleting health check resources**

- **compute.healthChecks.delete**
- **compute.healthChecks.list**
- **compute.httpHealthChecks.delete**
- **compute.httpHealthChecks.list**

**Example 7.20. Required Images permissions for deletion**

- **compute.images.list**

**7.2.5.3. Required GCP permissions for shared VPC installations**

When you are installing a cluster to a [shared VPC](#), you must configure the service account for both the host project and the service project. If you are not installing to a shared VPC, you can skip this section.

You must apply the minimum roles required for a standard installation as listed above, to the service project.

**IMPORTANT**

You can use granular permissions for a Cloud Credential Operator that operates in either manual or mint credentials mode. You cannot use granular permissions in passthrough credentials mode.

Ensure that the host project applies one of the following configurations to the service account:

**Example 7.21. Required permissions for creating firewalls in the host project**

- **projects/<host-project>/roles/dns.networks.bindPrivateDNSZone**
- **roles/compute.networkAdmin**
- **roles/compute.securityAdmin**

**Example 7.22. Required minimal permissions**

- **projects/<host-project>/roles/dns.networks.bindPrivateDNSZone**
- **roles/compute.networkUser**

**7.2.6. Supported GCP regions**

You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
- **asia-northeast3** (Seoul, South Korea)
- **asia-south1** (Mumbai, India)

- **asia-south2** (Delhi, India)
- **asia-southeast1** (Jurong West, Singapore)
- **asia-southeast2** (Jakarta, Indonesia)
- **australia-southeast1** (Sydney, Australia)
- **australia-southeast2** (Melbourne, Australia)
- **europa-central2** (Warsaw, Poland)
- **europa-north1** (Hamina, Finland)
- **europa-southwest1** (Madrid, Spain)
- **europa-west1** (St. Ghislain, Belgium)
- **europa-west2** (London, England, UK)
- **europa-west3** (Frankfurt, Germany)
- **europa-west4** (Eemshaven, Netherlands)
- **europa-west6** (Zürich, Switzerland)
- **europa-west8** (Milan, Italy)
- **europa-west9** (Paris, France)
- **europa-west12** (Turin, Italy)
- **me-central1** (Doha, Qatar, Middle East)
- **me-west1** (Tel Aviv, Israel)
- **northamerica-northeast1** (Montréal, Québec, Canada)
- **northamerica-northeast2** (Toronto, Ontario, Canada)
- **southamerica-east1** (São Paulo, Brazil)
- **southamerica-west1** (Santiago, Chile)
- **us-central1** (Council Bluffs, Iowa, USA)
- **us-east1** (Moncks Corner, South Carolina, USA)
- **us-east4** (Ashburn, Northern Virginia, USA)
- **us-east5** (Columbus, Ohio)
- **us-south1** (Dallas, Texas)
- **us-west1** (The Dalles, Oregon, USA)
- **us-west2** (Los Angeles, California, USA)

- **us-west3** (Salt Lake City, Utah, USA)
- **us-west4** (Las Vegas, Nevada, USA)

**NOTE**

To determine which machine type instances are available by region and zone, see the Google [documentation](#).

### 7.2.7. Next steps

- Install an OpenShift Container Platform cluster on GCP. You can [install a customized cluster](#) or [quickly install a cluster](#) with default options.

## 7.3. INSTALLING A CLUSTER QUICKLY ON GCP

In OpenShift Container Platform version 4.14, you can install a cluster on Google Cloud Platform (GCP) that uses the default configuration options.

### 7.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured a GCP project](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

### 7.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.3.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**7.3.4. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 7.3.5. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

### Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
  - The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GCLOUD\_KEYFILE\_JSON** environment variables
  - The `~/gcp/osServiceAccount.json` file
  - The **gcloud cli** default credentials
2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

3. Provide values at the prompts:

- a. Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- b. Select **gcp** as the platform to target.
- c. If you have not configured the service account key for your GCP account on your host, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
- d. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
- e. Select the region to deploy the cluster to.
- f. Select the base domain to deploy the cluster to. The base domain corresponds to the

- i. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - g. Enter a descriptive name for your cluster. If you provide a name that is longer than 6 characters, only the first 6 characters will be used in the infrastructure ID that is generated from the cluster name.
  - h. Paste the [pull secret from Red Hat OpenShift Cluster Manager](#) .
4. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
- If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 7.3.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

## IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

#### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

## Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 7.3.7. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.3.8. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 7.3.9. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

## 7.4. INSTALLING A CLUSTER ON GCP WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a customized cluster on infrastructure that the installation program provisions on Google Cloud Platform (GCP). To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### 7.4.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured a GCP project](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

### 7.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.4.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**7.4.4. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 7.4.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **gcp** as the platform to target.
  - iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
  - iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
  - v. Select the region to deploy the cluster to.
  - vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - vii. Enter a descriptive name for your cluster.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.

**NOTE**

If you are installing a three-node cluster, be sure to set the **compute.replicas** parameter to **0**. This ensures that the cluster's control planes are schedulable. For more information, see "Installing a three-node cluster on GCP".

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- [Installation configuration parameters for GCP](#)

**7.4.5.1. Minimum resource requirements for cluster installation**

Each cluster machine must meet the following minimum requirements:

**Table 7.5. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### Additional resources

- [Optimizing storage](#)

### 7.4.5.2. Tested instance types for GCP

The following Google Cloud Platform instance types have been tested with OpenShift Container Platform.

#### Example 7.23. Machine series

- **A2**
- **A3**
- **C2**
- **C2D**
- **C3**
- **C3D**
- **E2**
- **M1**
- **N1**
- **N2**
- **N2D**
- **N4**
- **Tau T2D**

### 7.4.5.3. Tested instance types for GCP on 64-bit ARM infrastructures

The following Google Cloud Platform (GCP) 64-bit ARM instance types have been tested with OpenShift Container Platform.

#### Example 7.24. Machine series for 64-bit ARM machines

- **Tau T2A**

### 7.4.5.4. Using custom machine types

Using a custom machine type to install a OpenShift Container Platform cluster is supported.

Consider the following when using a custom machine type:

- Similar to predefined instance types, custom machine types must meet the minimum resource requirements for control plane and compute machines. For more information, see "Minimum resource requirements for cluster installation".
- The name of the custom machine type must adhere to the following syntax:  
**custom-`<number_of_cpus>-<amount_of_memory_in_mb>`**

For example, **custom-6-20480**.

As part of the installation process, you specify the custom machine type in the **install-config.yaml** file.

#### Sample install-config.yaml file with a custom machine type

```
compute:
- architecture: amd64
 hyperthreading: Enabled
 name: worker
 platform:
 gcp:
 type: custom-6-20480
 replicas: 2
controlPlane:
 architecture: amd64
 hyperthreading: Enabled
 name: master
 platform:
 gcp:
 type: custom-6-20480
 replicas: 3
```

### 7.4.5.5. Enabling Shielded VMs

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

#### NOTE

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

## Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
 secureBoot: Enabled
```

- To use shielded VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

### 7.4.5.6. Enabling Confidential VMs

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

#### NOTE

Confidential VMs are currently not supported on 64-bit ARM architectures.

## Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
```

```
gcp:
 confidentialCompute: Enabled ❶
 type: n2d-standard-8 ❷
 onHostMaintenance: Terminate ❸
```

- ❶ Enable confidential VMs.
- ❷ Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- ❸ Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

b. To use confidential VMs for only compute machines:

```
compute:
- platform:
 gcp:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

c. To use confidential VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

#### 7.4.5.7. Sample customized install-config.yaml file for GCP

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com ❶
credentialsMode: Mint ❷
controlPlane: ❸ ❹
 hyperthreading: Enabled ❺
 name: master
 platform:
 gcp:
 type: n2-standard-4
```

```

 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes 16
 serviceNetwork:
 - 172.30.0.0/16

```

```
platform:
 gcp:
 projectID: openshift-production 17
 region: us-central1 18
 defaultMachinePlatform:
 tags: 19
 - global-tag1
 - global-tag2
 osImage: 20
 project: example-project-name
 name: example-image-name
 pullSecret: '{"auths": ...}' 21
 fips: false 22
 sshKey: ssh-ed25519 AAAA... 23
```

1 15 17 18 21 Required. The installation program prompts you for this value.

2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the **kube-system** namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the *Authentication and authorization* guide.

3 9 If you do not provide these parameters and values, the installation program provides the default value.

4 10 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

5 11 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

6 12 Optional: The custom encryption key section to encrypt both virtual machines and persistent volumes. Your default compute service account must have the permissions granted to use your KMS key and have the correct IAM role assigned. The default service account name follows the **service-`<project_number>`@compute-system.iam.gserviceaccount.com** pattern. For more information about granting the correct permissions for your service account, see "Machine management" → "Creating compute machine sets" → "Creating a compute machine set on GCP".

7 13 19 Optional: A set of network tags to apply to the control plane or compute machine sets. The **platform.gcp.defaultMachinePlatform.tags** parameter will apply to both control plane and compute machines. If the **compute.platform.gcp.tags** or **controlPlane.platform.gcp.tags** parameters are set, they override the **platform.gcp.defaultMachinePlatform.tags** parameter.

- 8 14 20 Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) that should be used to boot control plane and compute machines. The **project** and **name** parameters under
- 16 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 22 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 23 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### Additional resources

- [Enabling customer-managed encryption keys for a compute machine set](#)

### 7.4.5.8. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

## NOTE

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 7.4.6. Managing user-defined labels and tags for GCP

**IMPORTANT**

Support for user-defined labels and tags for GCP is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Google Cloud Platform (GCP) provides labels and tags that help to identify and organize the resources created for a specific OpenShift Container Platform cluster, making them easier to manage.

You can define labels and tags for each GCP resource only during OpenShift Container Platform cluster installation.

**IMPORTANT**

User-defined labels and tags are not supported for OpenShift Container Platform clusters upgraded to OpenShift Container Platform 4.14 version.

#### User-defined labels

User-defined labels and OpenShift Container Platform specific labels are applied only to resources created by OpenShift Container Platform installation program and its core components such as:

- GCP filestore CSI Driver Operator
- GCP PD CSI Driver Operator
- Image Registry Operator

- Machine API provider for GCP

User-defined labels and OpenShift Container Platform specific labels are not applied on the resources created by any other operators or the Kubernetes in-tree components that create resources, for example, the Ingress load balancers.

User-defined labels and OpenShift Container Platform labels are available on the following GCP resources:

- Compute disk
- Compute instance
- Compute image
- Compute forwarding rule
- DNS managed zone
- Filestore instance
- Storage bucket

#### Limitations to user-defined labels

- Labels for **ComputeAddress** are supported in the GCP beta version. OpenShift Container Platform does not add labels to the resource.

#### User-defined tags

User-defined tags are attached to resources created by the OpenShift Container Platform Image Registry Operator and not on the resources created by any other Operators or the Kubernetes in-tree components.

User-defined tags are available on the following GCP resources: \* Storage bucket

#### Limitations to the user-defined tags

- Tags will not be attached to the following items:
  - Control plane instances and storage buckets created by the installation program
  - Compute instances created by the Machine API provider for GCP
  - Filestore instance resources created by the GCP filestore CSI driver Operator
  - Compute disk and compute image resources created by the GCP PD CSI driver Operator
- Tags are not supported for buckets located in the following regions:
  - **us-east2**
  - **us-east3**
- Image Registry Operator does not throw any error but skips processing tags when the buckets are created in the tags unsupported region.

- Tags must not be restricted to particular service accounts, because Operators create and use service accounts with minimal roles.
- OpenShift Container Platform does not create any key and value resources of the tag.
- OpenShift Container Platform specific tags are not added to any resource.

#### Additional resources

- For more information about identifying the **OrganizationID**, see: [OrganizationID](#)
- For more information about identifying the **ProjectID**, see: [ProjectID](#)
- For more information about labels, see [Labels Overview](#).
- For more information about tags, see [Tags Overview](#).

#### 7.4.6.1. Configuring user-defined labels and tags for GCP

##### Prerequisites

- The installation program requires that a service account includes a **TagUser** role, so that the program can create the OpenShift Container Platform cluster with defined tags at both organization and project levels.

##### Procedure

- Update the **install-config.yaml** file to define the list of desired labels and tags.

#### NOTE

Labels and tags are defined during the **install-config.yaml** creation phase, and cannot be modified or updated with new labels and tags after cluster creation.

#### Sample install-config.yaml file

```
apiVersion: v1
featureSet: TechPreviewNoUpgrade
platform:
 gcp:
 userLabels: ❶
 - key: <label_key> ❷
 value: <label_value> ❸
 userTags: ❹
 - parentID: <OrganizationID/ProjectID> ❺
 key: <tag_key_short_name>
 value: <tag_value_short_name>
```

- ❶ Adds keys and values as labels to the resources created on GCP.
- ❷ Defines the label name.
- ❸ Defines the label content.

- 4 Adds keys and values as tags to the resources created on GCP.
- 5 The ID of the hierarchical resource where the tags are defined, at the organization or the project level.

The following are the requirements for user-defined labels:

- A label key and value must have a minimum of 1 character and can have a maximum of 63 characters.
- A label key and value must contain only lowercase letters, numeric characters, underscore (`_`), and dash (`-`).
- A label key must start with a lowercase letter.
- You can configure a maximum of 32 labels per resource. Each resource can have a maximum of 64 labels, and 32 labels are reserved for internal use by OpenShift Container Platform.

The following are the requirements for user-defined tags:

- Tag key and tag value must already exist. OpenShift Container Platform does not create the key and the value.
- A tag **parentID** can be either **OrganizationID** or **ProjectID**:
  - **OrganizationID** must consist of decimal numbers without leading zeros.
  - **ProjectID** must be 6 to 30 characters in length, that includes only lowercase letters, numbers, and hyphens.
  - **ProjectID** must start with a letter, and cannot end with a hyphen.
- A tag key must contain only uppercase and lowercase alphanumeric characters, hyphen (`-`), underscore (`_`), and period (`.`).
- A tag value must contain only uppercase and lowercase alphanumeric characters, hyphen (`-`), underscore (`_`), period (`.`), at sign (`@`), percent sign (`%`), equals sign (`=`), plus (`+`), colon (`:`), comma (`,`), asterisk (`*`), pound sign (`$`), ampersand (`&`), parentheses (`()`), square braces (`[]`), curly braces (`{}`), and space.
- A tag key and value must begin and end with an alphanumeric character.
- Tag value must be one of the pre-defined values for the key.
- You can configure a maximum of 50 tags.
- There should be no tag key defined with the same value as any of the existing tag keys that will be inherited from the parent resource.

#### 7.4.6.2. Querying user-defined labels and tags for GCP

After creating the OpenShift Container Platform cluster, you can access the list of the labels and tags defined for the GCP resources in the **infrastructures.config.openshift.io/cluster** object as shown in the following sample **infrastructure.yaml** file.

##### Sample **infrastructure.yaml** file

```

apiVersion: config.openshift.io/v1
kind: Infrastructure
metadata:
 name: cluster
spec:
 platformSpec:
 type: GCP
status:
 infrastructureName: <cluster_id> 1
 platform: GCP
 platformStatus:
 gcp:
 resourceLabels:
 - key: <label_key>
 value: <label_value>
 resourceTags:
 - key: <tag_key_short_name>
 parentID: <OrganizationID/ProjectID>
 value: <tag_value_short_name>
 type: GCP

```

**1** The cluster ID that is generated during cluster installation.

Along with the user-defined labels, resources have a label defined by the OpenShift Container Platform. The format of the OpenShift Container Platform labels is **kubernetes-io-cluster-<cluster\_id>:owned**.

### 7.4.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

## 7.4.8. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring a GCP cluster to use short-term credentials](#).

### 7.4.8.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \ ❶
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ ❷
 --to=<path_to_directory_for_credentials_requests> ❸
```

- ❶ The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- ❷ Specify the location of the **install-config.yaml** file.
- ❸ Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: GCPProviderSpec
 predefinedRoles:
 - roles/storage.admin
 - roles/iam.serviceAccountUser
 skipServiceCheck: true
...
```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 ...
```

```
secretRef:
 name: <component_secret>
 namespace: <component_namespace>
...
```

### Sample Secret object

```
apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 service_account.json: <base64_encoded_gcp_service_account_file>
```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

## 7.4.8.2. Configuring a GCP cluster to use short-term credentials

To install a cluster that is configured to use GCP Workload Identity, you must configure the CCO utility and create the required GCP resources for your cluster.

### 7.4.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccctl**) binary.

### NOTE

The **ccctl** utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

### Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

**NOTE**

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

**Verification**

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccoctl.rhel9
```

**Example output**

```
OpenShift credentials provisioning tool
```

```
Usage:
```

```
ccoctl [command]
```

```
Available Commands:
```

```
alibabacloud Manage credentials objects for alibaba cloud
aws Manage credentials objects for AWS cloud
azure Manage credentials objects for Azure
gcp Manage credentials objects for Google cloud
help Help about any command
ibmcloud Manage credentials objects for IBM Cloud
nutanix Manage credentials objects for Nutanix
```

```
Flags:
```

```
-h, --help help for ccoctl
```

```
Use "ccoctl [command] --help" for more information about a command.
```

**7.4.8.2.2. Creating GCP resources with the Cloud Credential Operator utility**

You can use the **ccoctl gcp create-all** command to automate the creation of GCP resources.

**NOTE**

By default, **ccoctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccoctl\_output\_dir>** to refer to this directory.

## Prerequisites

You must have:

- Extracted and prepared the **ccoctl** binary.

## Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

### NOTE

This command might take a few moments to run.

3. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl gcp create-all \
 --name=<name> \1
 --region=<gcp_region> \2
 --project=<gcp_project_id> \3
 --credentials-requests-dir=<path_to_credentials_requests_directory> \4
```

- 1 Specify the user-defined name for all created GCP resources used for tracking.
- 2 Specify the GCP region in which cloud resources will be created.
- 3 Specify the GCP project ID in which cloud resources will be created.
- 4 Specify the directory containing the files of **CredentialsRequest** manifests to create GCP service accounts.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-gcp-ccm-cloud-credentials-credentials.yaml
openshift-cloud-credential-operator-cloud-credential-operator-gcp-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capg-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-gcp-pd-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-gcp-cloud-credentials-credentials.yaml
```

You can verify that the IAM service accounts are created by querying GCP. For more information, refer to GCP documentation on listing IAM service accounts.

**7.4.8.2.3. Incorporating the Cloud Credential Operator utility manifests**

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccoctl**) created to the correct directories for the installation program.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccoctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccoctl** utility.

**Procedure**

- If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

**Sample configuration file snippet**

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Copy the manifests that the **ccocctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccocctl_output_dir>/manifests/* ./manifests/
```

4. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccocctl_output_dir>/tls .
```

### 7.4.9. Using the GCP Marketplace offering

Using the GCP Marketplace offering lets you deploy an OpenShift Container Platform cluster, which is billed on pay-per-use basis (hourly, per core) through GCP, while still being supported directly by Red Hat.

By default, the installation program downloads and installs the Red Hat Enterprise Linux CoreOS (RHCOS) image that is used to deploy compute machines. To deploy an OpenShift Container Platform cluster using an RHCOS image from the GCP Marketplace, override the default behavior by modifying the **install-config.yaml** file to reference the location of GCP Marketplace offer.

#### Prerequisites

- You have an existing **install-config.yaml** file.

#### Procedure

1. Edit the **compute.platform.gcp.osImage** parameters to specify the location of the GCP Marketplace image:

- Set the **project** parameter to **redhat-marketplace-public**
- Set the **name** parameter to one of the following offers:

OpenShift Container Platform

**redhat-coreos-ocp-413-x86-64-202305021736**

OpenShift Platform Plus

**redhat-coreos-opp-413-x86-64-202305021736**

OpenShift Kubernetes Engine

**redhat-coreos-oke-413-x86-64-202305021736**

2. Save the file and reference it when deploying the cluster.

**Sample install-config.yaml file that specifies a GCP Marketplace image for compute machines**

```
apiVersion: v1
```

```
baseDomain: example.com
controlPlane:
...
compute:
 platform:
 gcp:
 osImage:
 project: redhat-marketplace-public
 name: redhat-coreos-ocp-413-x86-64-202305021736
...
```

### 7.4.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

#### Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
  - The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GCPLOUD\_KEYFILE\_JSON** environment variables
  - The **~/gcp/osServiceAccount.json** file
  - The **gcloud cli** default credentials
2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
  - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 7.4.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

### Example output

```
system:admin
```

## Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

## 7.4.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

## Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

## 7.4.13. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#) .

## 7.5. INSTALLING A CLUSTER ON GCP WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a cluster with a customized network

configuration on infrastructure that the installation program provisions on Google Cloud Platform (GCP). By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

You must set most of the network configuration parameters during installation, and you can modify only **kubeProxy** configuration parameters in a running cluster.

### 7.5.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured a GCP project](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

### 7.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.5.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 7.5.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 7.5.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If

you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the `~/powers` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powers
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **gcp** as the platform to target.
  - iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
  - iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
  - v. Select the region to deploy the cluster to.
  - vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - vii. Enter a descriptive name for your cluster.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

#### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

#### Additional resources

- [Installation configuration parameters for GCP](#)

#### 7.5.5.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 7.6. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 7.5.5.2. Tested instance types for GCP

The following Google Cloud Platform instance types have been tested with OpenShift Container Platform.

#### Example 7.25. Machine series

- **A2**
- **A3**
- **C2**
- **C2D**
- **C3**
- **C3D**
- **E2**
- **M1**
- **N1**
- **N2**
- **N2D**
- **N4**
- **Tau T2D**

### 7.5.5.3. Tested instance types for GCP on 64-bit ARM infrastructures

The following Google Cloud Platform (GCP) 64-bit ARM instance types have been tested with OpenShift Container Platform.

#### Example 7.26. Machine series for 64-bit ARM machines

- **Tau T2A**

### 7.5.5.4. Using custom machine types

Using a custom machine type to install a OpenShift Container Platform cluster is supported.

Consider the following when using a custom machine type:

- Similar to predefined instance types, custom machine types must meet the minimum resource requirements for control plane and compute machines. For more information, see "Minimum resource requirements for cluster installation".
- The name of the custom machine type must adhere to the following syntax:  
**custom-`<number_of_cpus>-<amount_of_memory_in_mb>`**

For example, **custom-6-20480**.

As part of the installation process, you specify the custom machine type in the **install-config.yaml** file.

### Sample **install-config.yaml** file with a custom machine type

```
compute:
- architecture: amd64
 hyperthreading: Enabled
 name: worker
 platform:
 gcp:
 type: custom-6-20480
 replicas: 2
controlPlane:
 architecture: amd64
 hyperthreading: Enabled
 name: master
 platform:
 gcp:
 type: custom-6-20480
 replicas: 3
```

#### 7.5.5.5. Enabling Shielded VMs

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

#### NOTE

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:
  - To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
```

```
secureBoot: Enabled
```

- c. To use shielded VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

### 7.5.5.6. Enabling Confidential VMs

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

#### NOTE

Confidential VMs are currently not supported on 64-bit ARM architectures.

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 confidentialCompute: Enabled ❶
 type: n2d-standard-8 ❷
 onHostMaintenance: Terminate ❸
```

- ❶ Enable confidential VMs.
- ❷ Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- ❸ Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

- b. To use confidential VMs for only compute machines:

```
compute:
 - platform:
 gcp:
```

```
confidentialCompute: Enabled
type: n2d-standard-8
onHostMaintenance: Terminate
```

- c. To use confidential VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

### 7.5.5.7. Sample customized install-config.yaml file for GCP

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com 1
credentialsMode: Mint 2
controlPlane: 3 4
 hyperthreading: Enabled 5
 name: master
 platform:
 gcp:
 type: n2-standard-4
 zones:
 - us-central1-a
 - us-central1-c
 osDisk:
 diskType: pd-ssd
 diskSizeGB: 1024
 encryptionKey: 6
 kmsKey:
 name: worker-key
 keyRing: test-machine-keys
 location: global
 projectID: project-id
 tags: 7
 - control-plane-tag1
 - control-plane-tag2
 osImage: 8
 project: example-project-name
 name: example-image-name
 replicas: 3
compute: 9 10
 - hyperthreading: Enabled 11
```

```

name: worker
platform:
 gcp:
 type: n2-standard-4
 zones:
 - us-central1-a
 - us-central1-c
 osDisk:
 diskType: pd-standard
 diskSizeGB: 128
 encryptionKey: 12
 kmsKey:
 name: worker-key
 keyRing: test-machine-keys
 location: global
 projectID: project-id
 tags: 13
 - compute-tag1
 - compute-tag2
 osImage: 14
 project: example-project-name
 name: example-image-name
 replicas: 3
metadata:
 name: test-cluster 15
networking: 16
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes 17
 serviceNetwork:
 - 172.30.0.0/16
platform:
 gcp:
 projectID: openshift-production 18
 region: us-central1 19
 defaultMachinePlatform:
 tags: 20
 - global-tag1
 - global-tag2
 osImage: 21
 project: example-project-name
 name: example-image-name
 pullSecret: '{"auths": ...}' 22
 fips: false 23
 sshKey: ssh-ed25519 AAAA... 24

```

1 15 18 19 22 Required. The installation program prompts you for this value.

2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the **kube-system** namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see

the "About the Cloud Credential Operator" section in the *Authentication and authorization* guide.

- 3 9 16** If you do not provide these parameters and values, the installation program provides the default value.
- 4 10** The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 5 11** Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

- 6 12** Optional: The custom encryption key section to encrypt both virtual machines and persistent volumes. Your default compute service account must have the permissions granted to use your KMS key and have the correct IAM role assigned. The default service account name follows the **service-<project\_number>@compute-system.iam.gserviceaccount.com** pattern. For more information about granting the correct permissions for your service account, see "Machine management" → "Creating compute machine sets" → "Creating a compute machine set on GCP".
- 7 13 20** Optional: A set of network tags to apply to the control plane or compute machine sets. The **platform.gcp.defaultMachinePlatform.tags** parameter will apply to both control plane and compute machines. If the **compute.platform.gcp.tags** or **controlPlane.platform.gcp.tags** parameters are set, they override the **platform.gcp.defaultMachinePlatform.tags** parameter.
- 8 14 21** Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) that should be used to boot control plane and compute machines. The **project** and **name** parameters under **platform.gcp.defaultMachinePlatform.osImage** apply to both control plane and compute machines. If the **project** and **name** parameters under **controlPlane.platform.gcp.osImage** or **compute.platform.gcp.osImage** are set, they override the **platform.gcp.defaultMachinePlatform.osImage** parameters.
- 17** The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 23** Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

24

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

## NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

## Additional resources

- [Enabling customer-managed encryption keys for a compute machine set](#)

### 7.5.5.8. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

## Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
```

```

httpProxy: http://<username>:<pswd>@<ip>:<port> 1
httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
noProxy: example.com 3
additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5

```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 7.5.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

##### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

## 7.5.7. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring a GCP cluster to use short-term credentials](#).

### 7.5.7.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \ ❶
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ ❷
 --to=<path_to_directory_for_credentials_requests> ❸
```

- ❶ The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- ❷ Specify the location of the **install-config.yaml** file.
- ❸ Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```

apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: GCPPProviderSpec
 predefinedRoles:
 - roles/storage.admin
 - roles/iam.serviceAccountUser
 skipServiceCheck: true
 ...

```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```

apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...

```

### Sample **Secret** object

```

apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 service_account.json: <base64_encoded_gcp_service_account_file>

```

#### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### 7.5.7.2. Configuring a GCP cluster to use short-term credentials

To install a cluster that is configured to use GCP Workload Identity, you must configure the CCO utility and create the required GCP resources for your cluster.

#### 7.5.7.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

#### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

#### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

#### Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

#### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

#### Verification

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccocctl.rhel9
```

### Example output

OpenShift credentials provisioning tool

Usage:

```
ccocctl [command]
```

Available Commands:

```
alibabacloud Manage credentials objects for alibaba cloud
aws Manage credentials objects for AWS cloud
azure Manage credentials objects for Azure
gcp Manage credentials objects for Google cloud
help Help about any command
ibmcloud Manage credentials objects for IBM Cloud
nutanix Manage credentials objects for Nutanix
```

Flags:

```
-h, --help help for ccocctl
```

Use "ccocctl [command] --help" for more information about a command.

#### 7.5.7.2.2. Creating GCP resources with the Cloud Credential Operator utility

You can use the **ccocctl gcp create-all** command to automate the creation of GCP resources.

#### NOTE

By default, **ccocctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccocctl\_output\_dir>** to refer to this directory.

### Prerequisites

You must have:

- Extracted and prepared the **ccocctl** binary.

### Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
```

```
--included \1
--install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
--to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

#### NOTE

This command might take a few moments to run.

3. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl gcp create-all \
 --name=<name> \1
 --region=<gcp_region> \2
 --project=<gcp_project_id> \3
 --credentials-requests-dir=<path_to_credentials_requests_directory> \4
```

- 1 Specify the user-defined name for all created GCP resources used for tracking.
- 2 Specify the GCP region in which cloud resources will be created.
- 3 Specify the GCP project ID in which cloud resources will be created.
- 4 Specify the directory containing the files of **CredentialsRequest** manifests to create GCP service accounts.

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

#### Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

#### Example output

```
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-gcp-ccm-cloud-credentials-credentials.yaml
```

```

openshift-cloud-credential-operator-cloud-credential-operator-gcp-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capg-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-gcp-pd-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-gcp-cloud-credentials-credentials.yaml

```

You can verify that the IAM service accounts are created by querying GCP. For more information, refer to GCP documentation on listing IAM service accounts.

### 7.5.7.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccctl**) created to the correct directories for the installation program.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccctl** utility.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```

apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...

```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Copy the manifests that the **ccctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccctl_output_dir>/manifests/* ./manifests/
```

4. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccctl_output_dir>/tls .
```

### 7.5.8. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

#### Phase 1

You can customize the following network-related fields in the **install-config.yaml** file before you create the manifest files:

- **networking.networkType**
- **networking.clusterNetwork**
- **networking.serviceNetwork**
- **networking.machineNetwork**

For more information on these fields, refer to *Installation configuration parameters*.

#### NOTE

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

#### IMPORTANT

The CIDR range **172.17.0.0/16** is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

#### Phase 2

After creating the manifest files by running **openshift-install create manifests**, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the **install-config.yaml** file during phase 2. However, you can further customize the network plugin during phase 2.

### 7.5.9. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

#### IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

#### Prerequisites

- You have created the **install-config.yaml** file and completed any modifications to it.

## Procedure

1. Change to the directory that contains the installation program and create the manifests:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 **<installation\_directory>** specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yml** in the **<installation\_directory>/manifests/** directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
```

3. Specify the advanced network configuration for your cluster in the **cluster-network-03-config.yml** file, such as in the following examples:

### Specify a different VXLAN port for the OpenShift SDN network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 openshiftSDNConfig:
 vxlanPort: 4800
```

### Enable IPsec for the OVN-Kubernetes network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 ovnKubernetesConfig:
 ipsecConfig: {}
```

4. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program consumes the **manifests/** directory when you create the Ignition config files.

## 7.5.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group:

#### **clusterNetwork**

IP address pools from which pod IP addresses are allocated.

#### **serviceNetwork**

IP address pool for services.

#### **defaultNetwork.type**

Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

### 7.5.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 7.7. Cluster Network Operator configuration object**

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metadata.name</b>       | <b>string</b> | The name of the CNO object. This name is always <b>cluster</b> .                                                                                                                                                                                                                                                                                                                                    |
| <b>spec.clusterNetwork</b> | <b>array</b>  | <p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec:   clusterNetwork:     - cidr: 10.128.0.0/19       hostPrefix: 23     - cidr: 10.128.32.0/19       hostPrefix: 23</pre>                                                                          |
| <b>spec.serviceNetwork</b> | <b>array</b>  | <p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</p> <pre>spec:   serviceNetwork:     - 172.30.0.0/14</pre> <p>You can customize this field only in the <b>install-config.yaml</b> file before you create the manifests. The value is read-only in the manifest file.</p> |
| <b>spec.defaultNetwork</b> | <b>object</b> | Configures the network plugin for the cluster network.                                                                                                                                                                                                                                                                                                                                              |

| Field                        | Type          | Description                                                                                                                                                              |
|------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>spec.kubeProxy Config</b> | <b>object</b> | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect. |

### defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

**Table 7.8. defaultNetwork object**

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>type</b>                | <b>string</b> | <p>Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b>. The Red Hat OpenShift Networking network plugin is selected during installation. You can change this value by migrating from OpenShift SDN to OVN-Kubernetes.</p> <div>  <div> <p><b>NOTE</b></p> <p>OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.</p> </div> </div> |
| <b>openshiftSDNConfig</b>  | <b>object</b> | This object is only valid for the OpenShift SDN network plugin.                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ovnKubernetesConfig</b> | <b>object</b> | This object is only valid for the OVN-Kubernetes network plugin.                                                                                                                                                                                                                                                                                                                                                                                |

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

**Table 7.9. openshiftSDNConfig object**

| Field       | Type          | Description                                                                                                                                                                                                                                                                                                                         |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b> | <b>string</b> | <p>Configures the network isolation mode for OpenShift SDN. The default value is <b>NetworkPolicy</b>.</p> <p>The values <b>Multitenant</b> and <b>Subnet</b> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p> |

| Field            | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>       | <b>integer</b> | <p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>50</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1450</b>.</p> <p>This value cannot be changed after cluster installation.</p> |
| <b>vxlanPort</b> | <b>integer</b> | <p>The port to use for all VXLAN packets. The default value is <b>4789</b>. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port <b>9000</b> and port <b>9999</b>.</p>                                                                                                                                                                                                                            |

### Example OpenShift SDN configuration

```
defaultNetwork:
 type: OpenShiftSDN
 openshiftSDNConfig:
 mode: NetworkPolicy
 mtu: 1450
 vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

**Table 7.10. ovnKubernetesConfig object**

| Field | Type | Description |
|-------|------|-------------|
|-------|------|-------------|

| Field                    | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>               | <b>integer</b> | <p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>100</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1400</b>.</p> |
| <b>genevePort</b>        | <b>integer</b> | The port to use for all Geneve packets. The default value is <b>6081</b> . This value cannot be changed after cluster installation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipsecConfig</b>       | <b>object</b>  | Specify an empty object to enable IPsec encryption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>policyAuditConfig</b> | <b>object</b>  | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>gatewayConfig</b>     | <b>object</b>  | <p>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</p> <div>  <div> <p><b>NOTE</b></p> <p>While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.</p> </div> </div>                                                                                                                                                                                                                                                                                                                                                                                                        |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <b>v4InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>100.64.0.0/16</b> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <b>clusterNetwork.cidr</b> value is <b>10.128.0.0/14</b> and the <b>clusterNetwork.hostPrefix</b> value is <b>/23</b>, then the maximum number of nodes is <b><math>2^{(23-14)}=512</math></b>.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>100.64.0.0/16</b> . |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| <b>v6InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>fd98::/48</b> IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>fd98::/48</b> . |

Table 7.11. **policyAuditConfig** object

| Field              | Type    | Description                                                                                                           |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------|
| <b>rateLimit</b>   | integer | The maximum number of messages to generate every second per node. The default value is <b>20</b> messages per second. |
| <b>maxFileSize</b> | integer | The maximum size for the audit log in bytes. The default value is <b>50000000</b> or 50 MB.                           |
| <b>maxLogFiles</b> | integer | The maximum number of log files that are retained.                                                                    |

| Field                 | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination</b>    | string | <p>One of the following additional audit log targets:</p> <p><b>libc</b><br/>The libc <b>syslog()</b> function of the journald process on the host.</p> <p><b>udp:&lt;host&gt;:&lt;port&gt;</b><br/>A syslog server. Replace <b>&lt;host&gt;:&lt;port&gt;</b> with the host and port of the syslog server.</p> <p><b>unix:&lt;file&gt;</b><br/>A Unix Domain Socket file specified by <b>&lt;file&gt;</b>.</p> <p><b>null</b><br/>Do not send the audit logs to any additional target.</p> |
| <b>syslogFacility</b> | string | The syslog facility, such as <b>kern</b> , as defined by RFC5424. The default value is <b>local0</b> .                                                                                                                                                                                                                                                                                                                                                                                     |

Table 7.12. gatewayConfig object

| Field                 | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>routingViaHost</b> | <b>boolean</b> | <p>Set this field to <b>true</b> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <b>false</b>.</p> <p>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <b>true</b>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</p> |
| <b>ipForwarding</b>   | <b>object</b>  | You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <b>ipForwarding</b> specification in the <b>Network</b> resource. Specify <b>Restricted</b> to only allow IP forwarding for Kubernetes related traffic. Specify <b>Global</b> to allow forwarding of all IP traffic. For new installations, the default is <b>Restricted</b> . For updates to OpenShift Container Platform 4.14, the default is <b>Global</b> .                                                                                                                                                                                                                                                                                |

### Example OVN-Kubernetes configuration with IPsec enabled

```
defaultNetwork:
 type: OVNKubernetes
 ovnKubernetesConfig:
 mtu: 1400
 genevePort: 6081
 ipsecConfig: {}
```

**kubeProxyConfig** object configuration (OpenShiftSDN container network interface only)

The values for the **kubeProxyConfig** object are defined in the following table:

Table 7.13. **kubeProxyConfig** object

| Field                                          | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>iptablesSyncPeriod</b>                      | <b>string</b> | <p>The refresh period for <b>iptables</b> rules. The default value is <b>30s</b>. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a> documentation.</p> <div>  <div> <b>NOTE</b> <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the <b>iptablesSyncPeriod</b> parameter is no longer necessary.</p> </div> </div> |
| <b>proxyArguments.iptables-min-sync-period</b> | <b>array</b>  | <p>The minimum duration before refreshing <b>iptables</b> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a>. The default value is:</p> <pre>kubeProxyConfig:   proxyArguments:     iptables-min-sync-period:       - 0s</pre>                                                                                                                                                        |

## 7.5.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
  - The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GCPLOUD\_KEYFILE\_JSON** environment variables
  - The `~/.gcp/osServiceAccount.json` file
  - The **gcloud cli** default credentials
2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

**1** For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

**2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
  - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 7.5.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.5.13. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 7.5.14. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

## 7.6. INSTALLING A CLUSTER ON GCP IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.14, you can install a cluster on Google Cloud Platform (GCP) in a restricted network by creating an internal mirror of the installation release content on an existing Google Virtual Private Cloud (VPC).

### IMPORTANT

You can install an OpenShift Container Platform cluster by using mirrored installation release content, but your cluster will require internet access to use the GCP APIs.

### 7.6.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured a GCP project](#) to host the cluster.
- You [mirrored the images for a disconnected installation](#) to your registry and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

### IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have an existing VPC in GCP. While installing a cluster in a restricted network that uses installer-provisioned infrastructure, you cannot use the installer-provisioned VPC. You must use a user-provisioned VPC that satisfies one of the following requirements:
  - Contains the mirror registry
  - Has firewall rules or a peering connection to access the mirror registry hosted elsewhere

- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to. While you might need to grant access to more sites, you must grant access to **\*.googleapis.com** and **accounts.google.com**.

## 7.6.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

### 7.6.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

## 7.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

## 7.6.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the **~/.ssh/authorized\_keys** list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**7.6.5. Creating the installation configuration file**

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the **imageContentSources** values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.

**Procedure**

1. Create the **install-config.yaml** file.

- a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the **~/.powervs** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:

- i. Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **gcp** as the platform to target.
- iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
- iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
- v. Select the region to deploy the cluster to.
- vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
- vii. Enter a descriptive name for your cluster.

3. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
4. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### Additional resources

- [Installation configuration parameters for GCP](#)

### 7.6.5.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 7.14. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### Additional resources

- [Optimizing storage](#)

### 7.6.5.2. Tested instance types for GCP

The following Google Cloud Platform instance types have been tested with OpenShift Container Platform.

#### Example 7.27. Machine series

- **A2**
- **A3**
- **C2**
- **C2D**
- **C3**
- **C3D**
- **E2**
- **M1**
- **N1**
- **N2**
- **N2D**
- **N4**
- **Tau T2D**

### 7.6.5.3. Tested instance types for GCP on 64-bit ARM infrastructures

The following Google Cloud Platform (GCP) 64-bit ARM instance types have been tested with OpenShift Container Platform.

#### Example 7.28. Machine series for 64-bit ARM machines

- **Tau T2A**

### 7.6.5.4. Using custom machine types

Using a custom machine type to install a OpenShift Container Platform cluster is supported.

Consider the following when using a custom machine type:

- Similar to predefined instance types, custom machine types must meet the minimum resource requirements for control plane and compute machines. For more information, see "Minimum resource requirements for cluster installation".
- The name of the custom machine type must adhere to the following syntax:  
**custom-<number\_of\_cpus>-<amount\_of\_memory\_in\_mb>**

For example, **custom-6-20480**.

As part of the installation process, you specify the custom machine type in the **install-config.yaml** file.

#### Sample install-config.yaml file with a custom machine type

```
compute:
- architecture: amd64
 hyperthreading: Enabled
 name: worker
 platform:
 gcp:
 type: custom-6-20480
 replicas: 2
controlPlane:
 architecture: amd64
 hyperthreading: Enabled
 name: master
 platform:
 gcp:
 type: custom-6-20480
 replicas: 3
```

### 7.6.5.5. Enabling Shielded VMs

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

#### NOTE

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

## Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- b. To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
 secureBoot: Enabled
```

- c. To use shielded VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

### 7.6.5.6. Enabling Confidential VMs

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

#### NOTE

Confidential VMs are currently not supported on 64-bit ARM architectures.

## Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
```

```

gcp:
 confidentialCompute: Enabled ❶
 type: n2d-standard-8 ❷
 onHostMaintenance: Terminate ❸

```

- ❶ Enable confidential VMs.
- ❷ Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- ❸ Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

- b. To use confidential VMs for only compute machines:

```

compute:
- platform:
 gcp:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate

```

- c. To use confidential VMs for all machines:

```

platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate

```

### 7.6.5.7. Sample customized install-config.yaml file for GCP

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```

apiVersion: v1
baseDomain: example.com ❶
credentialsMode: Mint ❷
controlPlane: ❸ ❹
 hyperthreading: Enabled ❺
 name: master
 platform:
 gcp:
 type: n2-standard-4

```

```

 - mirrors:
 - <local_registry>/<local_repository_name>/release
 source: quay.io/openshift-release-dev/ocp-release
 - mirrors:
 - <local_registry>/<local_repository_name>/release
 source: quay.io/openshift-release-dev/ocp-v4.0-art-dev

```

- 1 15 17 18 Required. The installation program prompts you for this value.
- 2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the **kube-system** namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the *Authentication and authorization* guide.
- 3 9 If you do not provide these parameters and values, the installation program provides the default value.
- 4 10 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 5 11 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

## IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

- 6 12** Optional: The custom encryption key section to encrypt both virtual machines and persistent volumes. Your default compute service account must have the permissions granted to use your KMS key and have the correct IAM role assigned. The default service account name follows the **service-`<project_number>`@compute-system.iam.gserviceaccount.com** pattern. For more information about granting the correct permissions for your service account, see "Machine management" → "Creating compute machine sets" → "Creating a compute machine set on GCP".
- 7 13 19** Optional: A set of network tags to apply to the control plane or compute machine sets. The **platform.gcp.defaultMachinePlatform.tags** parameter will apply to both control plane and compute machines. If the **compute.platform.gcp.tags** or **controlPlane.platform.gcp.tags** parameters are set, they override the **platform.gcp.defaultMachinePlatform.tags** parameter.
- 8 14 20** Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) that should be used to boot control plane and compute machines. The **project** and **name** parameters under **platform.gcp.defaultMachinePlatform.osImage** apply to both control plane and compute machines. If the **project** and **name** parameters under **controlPlane.platform.gcp.osImage** or **compute.platform.gcp.osImage** are set, they override the **platform.gcp.defaultMachinePlatform.osImage** parameters.
- 16** The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 21** Specify the name of an existing VPC.
- 22** Specify the name of the existing subnet to deploy the control plane machines to. The subnet must belong to the VPC that you specified.
- 23** Specify the name of the existing subnet to deploy the compute machines to. The subnet must belong to the VPC that you specified.
- 24** For **<local\_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, **registry.example.com** or **registry.example.com:5000**. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.
- 25** Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 26 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- 27 Provide the contents of the certificate file that you used for your mirror registry.
- 28 Provide the **imageContentSources** section from the output of the command to mirror the repository.

### 7.6.5.8. Create an Ingress Controller with global access on GCP

You can create an Ingress Controller that has global access to a Google Cloud Platform (GCP) cluster. Global access is only available to Ingress Controllers using internal load balancers.

#### Prerequisites

- You created the **install-config.yaml** and complete any modifications to it.

#### Procedure

Create an Ingress Controller with global access on a new GCP cluster.

1. Change to the directory that contains the installation program and create a manifest file:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a file that is named **cluster-ingress-default-ingresscontroller.yaml** in the **<installation\_directory>/manifests/** directory:

```
$ touch <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml 1
```

- 1 For **<installation\_directory>**, specify the directory name that contains the **manifests/** directory for your cluster.

After creating the file, several network configuration files are in the **manifests/** directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml
```

#### Example output

```
cluster-ingress-default-ingresscontroller.yaml
```

3. Open the **cluster-ingress-default-ingresscontroller.yaml** file in an editor and enter a custom resource (CR) that describes the Operator configuration you want:

### Sample **clientAccess** configuration to Global

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
 name: default
 namespace: openshift-ingress-operator
spec:
 endpointPublishingStrategy:
 loadBalancer:
 providerParameters:
 gcp:
 clientAccess: Global 1
 type: GCP
 scope: Internal 2
 type: LoadBalancerService
```

- 1 Set **gcp.clientAccess** to **Global**.
- 2 Global access is only available to Ingress Controllers using internal load balancers.

#### 7.6.5.9. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

#### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```

apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5

```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 7.6.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 7.6.7. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring a GCP cluster to use short-term credentials](#).

### 7.6.7.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \ ❶
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ ❷
 --to=<path_to_directory_for_credentials_requests> ❸
```

- ❶ The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- ❷ Specify the location of the **install-config.yaml** file.
- ❸ Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample `CredentialsRequest` object

```

apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: GCPPProviderSpec
 predefinedRoles:
 - roles/storage.admin
 - roles/iam.serviceAccountUser
 skipServiceCheck: true
 ...

```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample `CredentialsRequest` object with secrets

```

apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...

```

### Sample `Secret` object

```

apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 service_account.json: <base64_encoded_gcp_service_account_file>

```

#### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### 7.6.7.2. Configuring a GCP cluster to use short-term credentials

To install a cluster that is configured to use GCP Workload Identity, you must configure the CCO utility and create the required GCP resources for your cluster.

#### 7.6.7.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

#### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

#### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

#### Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

#### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

#### Verification

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccocctl.rhel9
```

### Example output

OpenShift credentials provisioning tool

Usage:

```
ccocctl [command]
```

Available Commands:

```
alibabacloud Manage credentials objects for alibaba cloud
aws Manage credentials objects for AWS cloud
azure Manage credentials objects for Azure
gcp Manage credentials objects for Google cloud
help Help about any command
ibmcloud Manage credentials objects for IBM Cloud
nutanix Manage credentials objects for Nutanix
```

Flags:

```
-h, --help help for ccocctl
```

Use "ccocctl [command] --help" for more information about a command.

#### 7.6.7.2.2. Creating GCP resources with the Cloud Credential Operator utility

You can use the **ccocctl gcp create-all** command to automate the creation of GCP resources.

#### NOTE

By default, **ccocctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccocctl\_output\_dir>** to refer to this directory.

### Prerequisites

You must have:

- Extracted and prepared the **ccocctl** binary.

### Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
```

```
--included \1
--install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
--to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

#### NOTE

This command might take a few moments to run.

3. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl gcp create-all \
 --name=<name> \1
 --region=<gcp_region> \2
 --project=<gcp_project_id> \3
 --credentials-requests-dir=<path_to_credentials_requests_directory> \4
```

- 1 Specify the user-defined name for all created GCP resources used for tracking.
- 2 Specify the GCP region in which cloud resources will be created.
- 3 Specify the GCP project ID in which cloud resources will be created.
- 4 Specify the directory containing the files of **CredentialsRequest** manifests to create GCP service accounts.

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

### Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

### Example output

```
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-gcp-ccm-cloud-credentials-credentials.yaml
```

```

openshift-cloud-credential-operator-cloud-credential-operator-gcp-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capg-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-gcp-pd-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-gcp-cloud-credentials-credentials.yaml

```

You can verify that the IAM service accounts are created by querying GCP. For more information, refer to GCP documentation on listing IAM service accounts.

### 7.6.7.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccctl**) created to the correct directories for the installation program.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccctl** utility.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```

apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...

```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Copy the manifests that the **ccctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccctl_output_dir>/manifests/* ./manifests/
```

4. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccctl_output_dir>/tls .
```

## 7.6.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

### Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:

- The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GCPLOUD\_KEYFILE\_JSON** environment variables
- The `~/.gcp/osServiceAccount.json` file
- The **gcloud cli** default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
  - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

### Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 7.6.9. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

### 7.6.10. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

#### Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
 -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

#### TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Configuration → OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

### 7.6.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 7.6.12. Next steps

- [Validate an installation](#).

- [Customize your cluster](#).
- [Configure image streams](#) for the Cluster Samples Operator and the **must-gather** tool.
- Learn how to [use Operator Lifecycle Manager \(OLM\) on restricted networks](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).
- If necessary, you can [opt out of remote health reporting](#).
- If necessary, see [Registering your disconnected cluster](#)

## 7.7. INSTALLING A CLUSTER ON GCP INTO AN EXISTING VPC

In OpenShift Container Platform version 4.14, you can install a cluster into an existing Virtual Private Cloud (VPC) on Google Cloud Platform (GCP). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### 7.7.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured a GCP project](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

### 7.7.2. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into existing subnets in an existing Virtual Private Cloud (VPC) in Google Cloud Platform (GCP). By deploying OpenShift Container Platform into an existing GCP VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option. You must configure networking for the subnets.

#### 7.7.2.1. Requirements for using your VPC

The union of the VPC CIDR block and the machine network CIDR must be non-empty. The subnets must be within the machine network.

The installation program does not create the following components:

- NAT gateways
- Subnets
- Route tables
- VPC network

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

**7.7.2.2. VPC validation**

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide one subnet for control-plane machines and one subnet for compute machines.
- The subnet's CIDRs belong to the machine CIDR that you specified.

**7.7.2.3. Division of permissions**

Some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

**7.7.2.4. Isolation between clusters**

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed to the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

**7.7.3. Internet access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

## IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.7.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

## IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

## NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

## NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 7.7.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

## Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

## Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 7.7.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

## Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

## Procedure

1. Create the **install-config.yaml** file.

- a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the **~/.powervs** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
- Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- Select **gcp** as the platform to target.
- If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
- Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
- Select the region to deploy the cluster to.
- Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
- Enter a descriptive name for your cluster.

2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

#### Additional resources

- [Installation configuration parameters for GCP](#)

#### 7.7.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 7.15. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### Additional resources

- [Optimizing storage](#)

### 7.7.6.2. Tested instance types for GCP

The following Google Cloud Platform instance types have been tested with OpenShift Container Platform.

#### Example 7.29. Machine series

- **A2**
- **A3**
- **C2**
- **C2D**
- **C3**
- **C3D**
- **E2**
- **M1**
- **N1**
- **N2**
- **N2D**
- **N4**
- **Tau T2D**

### 7.7.6.3. Tested instance types for GCP on 64-bit ARM infrastructures

The following Google Cloud Platform (GCP) 64-bit ARM instance types have been tested with OpenShift Container Platform.

#### Example 7.30. Machine series for 64-bit ARM machines

- **Tau T2A**

### 7.7.6.4. Using custom machine types

Using a custom machine type to install a OpenShift Container Platform cluster is supported.

Consider the following when using a custom machine type:

- Similar to predefined instance types, custom machine types must meet the minimum resource requirements for control plane and compute machines. For more information, see "Minimum resource requirements for cluster installation".
- The name of the custom machine type must adhere to the following syntax:  
**custom-`<number_of_cpus>-<amount_of_memory_in_mb>`**

For example, **custom-6-20480**.

As part of the installation process, you specify the custom machine type in the **install-config.yaml** file.

#### Sample install-config.yaml file with a custom machine type

```
compute:
- architecture: amd64
 hyperthreading: Enabled
 name: worker
 platform:
 gcp:
 type: custom-6-20480
 replicas: 2
controlPlane:
 architecture: amd64
 hyperthreading: Enabled
 name: master
 platform:
 gcp:
 type: custom-6-20480
 replicas: 3
```

### 7.7.6.5. Enabling Shielded VMs

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

#### NOTE

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

## Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- b. To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
 secureBoot: Enabled
```

- c. To use shielded VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

### 7.7.6.6. Enabling Confidential VMs

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

#### NOTE

Confidential VMs are currently not supported on 64-bit ARM architectures.

## Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
```

```

gcp:
 confidentialCompute: Enabled ❶
 type: n2d-standard-8 ❷
 onHostMaintenance: Terminate ❸

```

- ❶ Enable confidential VMs.
- ❷ Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- ❸ Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

b. To use confidential VMs for only compute machines:

```

compute:
- platform:
 gcp:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate

```

c. To use confidential VMs for all machines:

```

platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate

```

#### 7.7.6.7. Sample customized install-config.yaml file for GCP

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```

apiVersion: v1
baseDomain: example.com ❶
credentialsMode: Mint ❷
controlPlane: ❸ ❹
 hyperthreading: Enabled ❺
 name: master
 platform:
 gcp:
 type: n2-standard-4

```

```

 fips: false 25
 sshKey: ssh-ed25519 AAAA... 26

```

- 1 15 17 18 24 Required. The installation program prompts you for this value.
- 2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the **kube-system** namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the *Authentication and authorization* guide.
- 3 9 If you do not provide these parameters and values, the installation program provides the default value.
- 4 10 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 5 11 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

## IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

- 6 12 Optional: The custom encryption key section to encrypt both virtual machines and persistent volumes. Your default compute service account must have the permissions granted to use your KMS key and have the correct IAM role assigned. The default service account name follows the **service-<project\_number>@compute-system.iam.gserviceaccount.com** pattern. For more information about granting the correct permissions for your service account, see "Machine management" → "Creating compute machine sets" → "Creating a compute machine set on GCP".
- 7 13 19 Optional: A set of network tags to apply to the control plane or compute machine sets. The

- 8 14 20 Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) that should be used to boot control plane and compute machines. The **project** and **name** parameters under
- 16 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 21 Specify the name of an existing VPC.
- 22 Specify the name of the existing subnet to deploy the control plane machines to. The subnet must belong to the VPC that you specified.
- 23 Specify the name of the existing subnet to deploy the compute machines to. The subnet must belong to the VPC that you specified.
- 25 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 26 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### Additional resources

- [Enabling customer-managed encryption keys for a compute machine set](#)

### 7.7.6.8. Create an Ingress Controller with global access on GCP

You can create an Ingress Controller that has global access to a Google Cloud Platform (GCP) cluster. Global access is only available to Ingress Controllers using internal load balancers.

### Prerequisites

- You created the **install-config.yaml** and complete any modifications to it.

### Procedure

Create an Ingress Controller with global access on a new GCP cluster.

1. Change to the directory that contains the installation program and create a manifest file:

```
$./openshift-install create manifests --dir <installation_directory> ❶
```

- ❶ For **<installation\_directory>**, specify the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a file that is named **cluster-ingress-default-ingresscontroller.yaml** in the **<installation\_directory>/manifests/** directory:

```
$ touch <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml ❶
```

- ❶ For **<installation\_directory>**, specify the directory name that contains the **manifests/** directory for your cluster.

After creating the file, several network configuration files are in the **manifests/** directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml
```

### Example output

```
cluster-ingress-default-ingresscontroller.yaml
```

3. Open the **cluster-ingress-default-ingresscontroller.yaml** file in an editor and enter a custom resource (CR) that describes the Operator configuration you want:

### Sample clientAccess configuration to Global

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
 name: default
 namespace: openshift-ingress-operator
spec:
 endpointPublishingStrategy:
 loadBalancer:
 providerParameters:
 gcp:
 clientAccess: Global ❶
 type: GCP
 scope: Internal ❷
 type: LoadBalancerService
```

- ❶ Set **gcp.clientAccess** to **Global**.
- ❷ Global access is only available to Ingress Controllers using internal load balancers.

#### 7.7.6.9. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

## Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the

**trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.

- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 7.7.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.

To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

**NOTE**

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

**Verification**

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

**7.7.8. Alternatives to storing administrator-level secrets in the kube-system project**

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring a GCP cluster to use short-term credentials](#).

**7.7.8.1. Manually creating long-term credentials**

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

**Procedure**

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

**Sample configuration file snippet**

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: GCPPProviderSpec
 predefinedRoles:
 - roles/storage.admin
 - roles/iam.serviceAccountUser
 skipServiceCheck: true
...
```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
```

```

metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...

```

### Sample Secret object

```

apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 service_account.json: <base64_encoded_gcp_service_account_file>

```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

## 7.7.8.2. Configuring a GCP cluster to use short-term credentials

To install a cluster that is configured to use GCP Workload Identity, you must configure the CCO utility and create the required GCP resources for your cluster.

### 7.7.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

### Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

- Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

#### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

- Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

- Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

#### Verification

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccoctl.rhel9
```

#### Example output

OpenShift credentials provisioning tool

Usage:

ccoctl [command]

Available Commands:

|              |                                              |
|--------------|----------------------------------------------|
| alibabacloud | Manage credentials objects for alibaba cloud |
| aws          | Manage credentials objects for AWS cloud     |
| azure        | Manage credentials objects for Azure         |
| gcp          | Manage credentials objects for Google cloud  |
| help         | Help about any command                       |
| ibmcloud     | Manage credentials objects for IBM Cloud     |
| nutanix      | Manage credentials objects for Nutanix       |

Flags:

-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

#### 7.7.8.2.2. Creating GCP resources with the Cloud Credential Operator utility

You can use the **ccoctl gcp create-all** command to automate the creation of GCP resources.

## NOTE

By default, **ccoctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccoctl\_output\_dir>** to refer to this directory.

## Prerequisites

You must have:

- Extracted and prepared the **ccoctl** binary.

## Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

## NOTE

This command might take a few moments to run.

3. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl gcp create-all \
 --name=<name> \1
 --region=<gcp_region> \2
 --project=<gcp_project_id> \3
 --credentials-requests-dir=<path_to_credentials_requests_directory> \4
```

- 1 Specify the user-defined name for all created GCP resources used for tracking.
- 2 Specify the GCP region in which cloud resources will be created.
- 3 Specify the GCP project ID in which cloud resources will be created.
- 4 Specify the directory containing the files of **CredentialsRequest** manifests to create GCP service accounts.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-gcp-ccm-cloud-credentials-credentials.yaml
openshift-cloud-credential-operator-cloud-credential-operator-gcp-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capg-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-gcp-pd-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-gcp-cloud-credentials-credentials.yaml
```

You can verify that the IAM service accounts are created by querying GCP. For more information, refer to GCP documentation on listing IAM service accounts.

**7.7.8.2.3. Incorporating the Cloud Credential Operator utility manifests**

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccctl**) created to the correct directories for the installation program.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccctl** utility.

**Procedure**

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Copy the manifests that the **ccoctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

4. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

## 7.7.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

### Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
  - The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GKLOUD\_KEYFILE\_JSON** environment variables

- The `~/gcp/osServiceAccount.json` file
  - The `gcloud cli` default credentials
2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

**1** For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

**2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
  - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 7.7.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.7.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 7.7.12. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#) .

## 7.8. INSTALLING A CLUSTER ON GCP INTO A SHARED VPC

In OpenShift Container Platform version 4.14, you can install a cluster into a shared Virtual Private Cloud (VPC) on Google Cloud Platform (GCP). In this installation method, the cluster is configured to use a VPC from a different GCP project. A shared VPC enables an organization to connect resources from multiple projects to a common VPC network. You can communicate within the organization securely and efficiently by using internal IP addresses from that network. For more information about shared VPC, see [Shared VPC overview in the GCP documentation](#) .

The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### 7.8.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You have a GCP host project which contains a shared VPC network.
- You [configured a GCP project](#) to host the cluster. This project, known as the service project, must be attached to the host project. For more information, see [Attaching service projects in the GCP documentation](#).
- You have a GCP service account that has the [required GCP permissions](#) in both the host and service projects.

### 7.8.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

## 7.8.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 7.8.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 7.8.5. Creating the installation files for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) into a shared VPC, you must generate the **install-config.yaml** file and modify it so that the cluster uses the correct VPC networks, DNS zones, and project names.

### 7.8.5.1. Manually creating the installation configuration file

You must manually create your installation configuration file when installing OpenShift Container Platform on GCP into a shared VPC using installer-provisioned infrastructure.

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

#### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

#### NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

#### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

#### Additional resources

- [Installation configuration parameters for GCP](#)

### 7.8.5.2. Enabling Shielded VMs

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

**NOTE**

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

**Prerequisites**

- You have created an **install-config.yaml** file.

**Procedure**

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
 secureBoot: Enabled
```

- To use shielded VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

**7.8.5.3. Enabling Confidential VMs**

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

**NOTE**

Confidential VMs are currently not supported on 64-bit ARM architectures.

**Prerequisites**

- You have created an **install-config.yaml** file.

**Procedure**

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 confidentialCompute: Enabled 1
 type: n2d-standard-8 2
 onHostMaintenance: Terminate 3
```

- 1** Enable confidential VMs.
- 2** Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- 3** Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

- b. To use confidential VMs for only compute machines:

```
compute:
 - platform:
 gcp:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

- c. To use confidential VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

#### 7.8.5.4. Sample customized install-config.yaml file for shared VPC installation

There are several configuration parameters which are required to install OpenShift Container Platform on GCP using a shared VPC. The following is a sample **install-config.yaml** file which demonstrates these fields.

#### IMPORTANT

This sample YAML file is provided for reference only. You must modify this file with the correct values for your environment and cluster.

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Passthrough 1
metadata:
```

```

name: cluster_name
platform:
 gcp:
 computeSubnet: shared-vpc-subnet-1 ❷
 controlPlaneSubnet: shared-vpc-subnet-2 ❸
 network: shared-vpc ❹
 networkProjectID: host-project-name ❺
 projectID: service-project-name ❻
 region: us-east1
 defaultMachinePlatform:
 tags: ❼
 - global-tag1
controlPlane:
 name: master
 platform:
 gcp:
 tags: ❽
 - control-plane-tag1
 type: n2-standard-4
 zones:
 - us-central1-a
 - us-central1-c
 replicas: 3
compute:
- name: worker
 platform:
 gcp:
 tags: ❾
 - compute-tag1
 type: n2-standard-4
 zones:
 - us-central1-a
 - us-central1-c
 replicas: 3
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA... ❿

```

- ❶ **credentialsMode** must be set to **Passthrough** or **Manual**. See the "Prerequisites" section for the required GCP permissions that your service account must have.
- ❷ The name of the subnet in the shared VPC for compute machines to use.
- ❸ The name of the subnet in the shared VPC for control plane machines to use.
- ❹ The name of the shared VPC.
- ❺ The name of the host project where the shared VPC exists.
- ❻ The name of the GCP project where you want to install the cluster.

- 7 8 9 Optional. One or more network tags to apply to compute machines, control plane machines, or all machines.
- 10 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

### 7.8.5.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

#### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

- Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network

- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 7.8.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.

To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

**NOTE**

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

**Verification**

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

**7.8.7. Alternatives to storing administrator-level secrets in the kube-system project**

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring a GCP cluster to use short-term credentials](#).

**7.8.7.1. Manually creating long-term credentials**

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

**Procedure**

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

**Sample configuration file snippet**

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: GCPPProviderSpec
 predefinedRoles:
 - roles/storage.admin
 - roles/iam.serviceAccountUser
 skipServiceCheck: true
...
```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
```

```

metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
 ...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
 ...

```

### Sample Secret object

```

apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 service_account.json: <base64_encoded_gcp_service_account_file>

```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

## 7.8.7.2. Configuring a GCP cluster to use short-term credentials

To install a cluster that is configured to use GCP Workload Identity, you must configure the CCO utility and create the required GCP resources for your cluster.

### 7.8.7.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

### Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

- Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

#### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

- Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

- Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

#### Verification

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccoctl.rhel9
```

#### Example output

OpenShift credentials provisioning tool

Usage:

ccoctl [command]

Available Commands:

|              |                                              |
|--------------|----------------------------------------------|
| alibabacloud | Manage credentials objects for alibaba cloud |
| aws          | Manage credentials objects for AWS cloud     |
| azure        | Manage credentials objects for Azure         |
| gcp          | Manage credentials objects for Google cloud  |
| help         | Help about any command                       |
| ibmcloud     | Manage credentials objects for IBM Cloud     |
| nutanix      | Manage credentials objects for Nutanix       |

Flags:

-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

#### 7.8.7.2.2. Creating GCP resources with the Cloud Credential Operator utility

You can use the **ccoctl gcp create-all** command to automate the creation of GCP resources.

## NOTE

By default, **ccoctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccoctl\_output\_dir>** to refer to this directory.

## Prerequisites

You must have:

- Extracted and prepared the **ccoctl** binary.

## Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \ 1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 2
 --to=<path_to_directory_for_credentials_requests> \ 3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

## NOTE

This command might take a few moments to run.

3. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl gcp create-all \
 --name=<name> \ 1
 --region=<gcp_region> \ 2
 --project=<gcp_project_id> \ 3
 --credentials-requests-dir=<path_to_credentials_requests_directory> \ 4
```

- 1 Specify the user-defined name for all created GCP resources used for tracking.
- 2 Specify the GCP region in which cloud resources will be created.
- 3 Specify the GCP project ID in which cloud resources will be created.
- 4 Specify the directory containing the files of **CredentialsRequest** manifests to create GCP service accounts.

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

#### Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

#### Example output

```
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-gcp-ccm-cloud-credentials-credentials.yaml
openshift-cloud-credential-operator-cloud-credential-operator-gcp-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capg-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-gcp-pd-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-gcp-cloud-credentials-credentials.yaml
```

You can verify that the IAM service accounts are created by querying GCP. For more information, refer to GCP documentation on listing IAM service accounts.

#### 7.8.7.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccctl**) created to the correct directories for the installation program.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccctl** utility.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Copy the manifests that the **ccocctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccocctl_output_dir>/manifests/* ./manifests/
```

4. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccocctl_output_dir>/tls .
```

## 7.8.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

### Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
  - The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GCPLOUD\_KEYFILE\_JSON** environment variables

- The `~/gcp/osServiceAccount.json` file
  - The `gcloud cli` default credentials
2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

**1** For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

**2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
  - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 7.8.9. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.8.10. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

#### 7.8.11. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#) .

### 7.9. INSTALLING A PRIVATE CLUSTER ON GCP

In OpenShift Container Platform version 4.14, you can install a private cluster into an existing VPC on Google Cloud Platform (GCP). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

#### 7.9.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured a GCP project](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

#### 7.9.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

#### IMPORTANT

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.
- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company's guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

### 7.9.2.1. Private clusters in GCP

To create a private cluster on Google Cloud Platform (GCP), you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

The cluster still requires access to internet to access the GCP APIs.

The following items are not required or created when you install a private cluster:

- Public subnets
- Public network load balancers, which support public ingress
- A public DNS zone that matches the **baseDomain** for the cluster

The installation program does use the **baseDomain** that you specify to create a private DNS zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

Because it is not possible to limit access to external load balancers based on source tags, the private cluster uses only internal load balancers to allow access to internal instances.

The internal load balancer relies on instance groups rather than the target pools that the network load balancers use. The installation program creates instance groups for each zone, even if there is no instance in that group.

- The cluster IP address is internal only.
- One forwarding rule manages both the Kubernetes API and machine config server ports.
- The backend service is comprised of each zone's instance group and, while it exists, the bootstrap instance group.
- The firewall uses a single rule that is based on only internal source ranges.

#### 7.9.2.1.1. Limitations

No health check for the Machine config server, **/healthz**, runs because of a difference in load balancer

functionality. Two internal load balancers cannot share a single IP address, but two network load balancers can share a single external IP address. Instead, the health of an instance is determined entirely by the **/readyz** check on port 6443.

### 7.9.3. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into an existing VPC in Google Cloud Platform (GCP). If you do, you must also use existing subnets within the VPC and routing rules.

By deploying OpenShift Container Platform into an existing GCP VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself.

#### 7.9.3.1. Requirements for using your VPC

The installation program will no longer create the following components:

- VPC
- Subnets
- Cloud router
- Cloud NAT
- NAT IP addresses

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VPC options like DHCP, so you must do so before you install the cluster.

Your VPC and subnets must meet the following characteristics:

- The VPC must be in the same GCP project that you deploy the OpenShift Container Platform cluster to.
- To allow access to the internet from the control plane and compute machines, you must configure cloud NAT on the subnets to allow egress to it. These machines do not have a public address. Even if you do not require access to the internet, you must allow egress to the VPC network to obtain the installation program and images. Because multiple cloud NATs cannot be configured on the shared subnets, the installation program cannot configure it.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist and belong to the VPC that you specified.
- The subnet CIDRs belong to the machine CIDR.
- You must provide a subnet to deploy the cluster control plane and compute machines to. You can use the same subnet for both machine types.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted.

### 7.9.3.2. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or Ingress rules.

The GCP credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage, and nodes.

### 7.9.3.3. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is preserved by firewall rules that reference the machines in your cluster by the cluster's infrastructure ID. Only traffic within the cluster is allowed.

If you deploy multiple clusters to the same VPC, the following components might share access between clusters:

- The API, which is globally available with an external publishing strategy or available throughout the network in an internal publishing strategy
- Debugging tools, such as ports on VM instances that are open to the machine CIDR for SSH and ICMP access

### 7.9.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.9.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **`./openshift-install gather`** command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **`ssh-agent`** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **`ssh-agent`**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 7.9.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 7.9.7. Manually creating the installation configuration file

When installing a private OpenShift Container Platform cluster, you must manually generate the installation configuration file.

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

### NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

#### Additional resources

- [Installation configuration parameters for GCP](#)

#### 7.9.7.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 7.16. Minimum resource requirements

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so

you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 7.9.7.2. Tested instance types for GCP

The following Google Cloud Platform instance types have been tested with OpenShift Container Platform.

#### Example 7.31. Machine series

- **A2**
- **A3**
- **C2**
- **C2D**
- **C3**
- **C3D**
- **E2**
- **M1**
- **N1**

- N2
- N2D
- N4
- Tau T2D

### 7.9.7.3. Tested instance types for GCP on 64-bit ARM infrastructures

The following Google Cloud Platform (GCP) 64-bit ARM instance types have been tested with OpenShift Container Platform.

#### Example 7.32. Machine series for 64-bit ARM machines

- Tau T2A

### 7.9.7.4. Using custom machine types

Using a custom machine type to install a OpenShift Container Platform cluster is supported.

Consider the following when using a custom machine type:

- Similar to predefined instance types, custom machine types must meet the minimum resource requirements for control plane and compute machines. For more information, see "Minimum resource requirements for cluster installation".
- The name of the custom machine type must adhere to the following syntax:  
**custom-<number\_of\_cpus>-<amount\_of\_memory\_in\_mb>**

For example, **custom-6-20480**.

As part of the installation process, you specify the custom machine type in the **install-config.yaml** file.

#### Sample install-config.yaml file with a custom machine type

```
compute:
- architecture: amd64
 hyperthreading: Enabled
 name: worker
 platform:
 gcp:
 type: custom-6-20480
 replicas: 2
controlPlane:
 architecture: amd64
 hyperthreading: Enabled
 name: master
 platform:
 gcp:
 type: custom-6-20480
 replicas: 3
```

### 7.9.7.5. Enabling Shielded VMs

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

#### NOTE

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
 secureBoot: Enabled
```

- To use shielded VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

### 7.9.7.6. Enabling Confidential VMs

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

#### NOTE

Confidential VMs are currently not supported on 64-bit ARM architectures.

#### Prerequisites

- You have created an **install-config.yaml** file.

## Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 confidentialCompute: Enabled 1
 type: n2d-standard-8 2
 onHostMaintenance: Terminate 3
```

- 1** Enable confidential VMs.
- 2** Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- 3** Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

- To use confidential VMs for only compute machines:

```
compute:
- platform:
 gcp:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

- To use confidential VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

### 7.9.7.7. Sample customized install-config.yaml file for GCP

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

## IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```

apiVersion: v1
baseDomain: example.com 1
credentialsMode: Mint 2
controlPlane: 3 4
hyperthreading: Enabled 5
name: master
platform:
 gcp:
 type: n2-standard-4
 zones:

 tags: 19
 - global-tag1
 - global-tag2
 osImage: 20
 project: example-project-name
 name: example-image-name
 network: existing_vpc 21
 controlPlaneSubnet: control_plane_subnet 22
 computeSubnet: compute_subnet 23
 pullSecret: '{"auths": ...}' 24
 fips: false 25
 sshKey: ssh-ed25519 AAAA... 26
 publish: Internal 27

```

- 1 15 17 18 24 Required. The installation program prompts you for this value.
- 2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the **kube-system** namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the *Authentication and authorization* guide.
- 3 9 If you do not provide these parameters and values, the installation program provides the default value.
- 4 10 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 5 11 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

## IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

- 6 12** Optional: The custom encryption key section to encrypt both virtual machines and persistent volumes. Your default compute service account must have the permissions granted to use your KMS key and have the correct IAM role assigned. The default service account name follows the **service-`<project_number>`@compute-system.iam.gserviceaccount.com** pattern. For more information about granting the correct permissions for your service account, see "Machine management" → "Creating compute machine sets" → "Creating a compute machine set on GCP".
- 7 13 19** Optional: A set of network tags to apply to the control plane or compute machine sets. The **platform.gcp.defaultMachinePlatform.tags** parameter will apply to both control plane and compute machines. If the **compute.platform.gcp.tags** or **controlPlane.platform.gcp.tags** parameters are set, they override the **platform.gcp.defaultMachinePlatform.tags** parameter.
- 8 14 20** Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) that should be used to boot control plane and compute machines. The **project** and **name** parameters under **platform.gcp.defaultMachinePlatform.osImage** apply to both control plane and compute machines. If the **project** and **name** parameters under **controlPlane.platform.gcp.osImage** or **compute.platform.gcp.osImage** are set, they override the **platform.gcp.defaultMachinePlatform.osImage** parameters.
- 16** The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 21** Specify the name of an existing VPC.
- 22** Specify the name of the existing subnet to deploy the control plane machines to. The subnet must belong to the VPC that you specified.
- 23** Specify the name of the existing subnet to deploy the compute machines to. The subnet must belong to the VPC that you specified.
- 25** Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 26** You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

## NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- 27** How to publish the user-facing endpoints of your cluster. Set **publish** to **Internal** to deploy a private cluster, which cannot be accessed from the internet. The default value is **External**.

## Additional resources

- [Enabling customer-managed encryption keys for a compute machine set](#)

### 7.9.7.8. Create an Ingress Controller with global access on GCP

You can create an Ingress Controller that has global access to a Google Cloud Platform (GCP) cluster. Global access is only available to Ingress Controllers using internal load balancers.

## Prerequisites

- You created the **install-config.yaml** and complete any modifications to it.

## Procedure

Create an Ingress Controller with global access on a new GCP cluster.

1. Change to the directory that contains the installation program and create a manifest file:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a file that is named **cluster-ingress-default-ingresscontroller.yaml** in the **<installation\_directory>/manifests/** directory:

```
$ touch <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml 1
```

- 1** For **<installation\_directory>**, specify the directory name that contains the **manifests/** directory for your cluster.

After creating the file, several network configuration files are in the **manifests/** directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml
```

## Example output

```
cluster-ingress-default-ingresscontroller.yaml
```

- Open the **cluster-ingress-default-ingresscontroller.yaml** file in an editor and enter a custom resource (CR) that describes the Operator configuration you want:

### Sample **clientAccess** configuration to Global

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
 name: default
 namespace: openshift-ingress-operator
spec:
 endpointPublishingStrategy:
 loadBalancer:
 providerParameters:
 gcp:
 clientAccess: Global ❶
 type: GCP
 scope: Internal ❷
 type: LoadBalancerService
```

- ❶ Set **gcp.clientAccess** to **Global**.
- ❷ Global access is only available to Ingress Controllers using internal load balancers.

#### 7.9.7.9. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

#### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

- Edit your **install-config.yaml** file and add the proxy settings. For example:

```

apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5

```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 7.9.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

##### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 7.9.9. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring a GCP cluster to use short-term credentials](#).

### 7.9.9.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample `CredentialsRequest` object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: GCPPProviderSpec
 predefinedRoles:
 - roles/storage.admin
 - roles/iam.serviceAccountUser
 skipServiceCheck: true
...
```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample `CredentialsRequest` object with secrets

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 name: <component_credentials_request>
 namespace: openshift-cloud-credential-operator
...
spec:
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 ...
 secretRef:
 name: <component_secret>
 namespace: <component_namespace>
...
```

### Sample `Secret` object

```
apiVersion: v1
kind: Secret
metadata:
 name: <component_secret>
 namespace: <component_namespace>
data:
 service_account.json: <base64_encoded_gcp_service_account_file>
```

#### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### 7.9.9.2. Configuring a GCP cluster to use short-term credentials

To install a cluster that is configured to use GCP Workload Identity, you must configure the CCO utility and create the required GCP resources for your cluster.

#### 7.9.9.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

#### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

#### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

#### Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

#### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

#### Verification

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccocctl.rhel9
```

### Example output

OpenShift credentials provisioning tool

Usage:

ccocctl [command]

Available Commands:

alibabacloud Manage credentials objects for alibaba cloud

aws Manage credentials objects for AWS cloud

azure Manage credentials objects for Azure

gcp Manage credentials objects for Google cloud

help Help about any command

ibmcloud Manage credentials objects for IBM Cloud

nutanix Manage credentials objects for Nutanix

Flags:

-h, --help help for ccocctl

Use "ccocctl [command] --help" for more information about a command.

#### 7.9.9.2.2. Creating GCP resources with the Cloud Credential Operator utility

You can use the **ccocctl gcp create-all** command to automate the creation of GCP resources.

#### NOTE

By default, **ccocctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses **<path\_to\_ccocctl\_output\_dir>** to refer to this directory.

### Prerequisites

You must have:

- Extracted and prepared the **ccocctl** binary.

### Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
```

```
--included \1
--install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
--to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

#### NOTE

This command might take a few moments to run.

3. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:

```
$ ccoctl gcp create-all \
 --name=<name> \1
 --region=<gcp_region> \2
 --project=<gcp_project_id> \3
 --credentials-requests-dir=<path_to_credentials_requests_directory> \4
```

- 1 Specify the user-defined name for all created GCP resources used for tracking.
- 2 Specify the GCP region in which cloud resources will be created.
- 3 Specify the GCP project ID in which cloud resources will be created.
- 4 Specify the directory containing the files of **CredentialsRequest** manifests to create GCP service accounts.

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

### Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the **<path\_to\_ccoctl\_output\_dir>/manifests** directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

### Example output

```
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-gcp-ccm-cloud-credentials-credentials.yaml
```

```

openshift-cloud-credential-operator-cloud-credential-operator-gcp-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capg-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-gcp-pd-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-gcp-cloud-credentials-credentials.yaml

```

You can verify that the IAM service accounts are created by querying GCP. For more information, refer to GCP documentation on listing IAM service accounts.

### 7.9.9.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (**ccoctl**) created to the correct directories for the installation program.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (**ccoctl**).
- You have created the cloud provider resources that are required for your cluster with the **ccoctl** utility.

#### Procedure

1. If you did not set the **credentialsMode** parameter in the **install-config.yaml** configuration file to **Manual**, modify the value as shown:

#### Sample configuration file snippet

```

apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
...

```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where **<installation\_directory>** is the directory in which the installation program creates files.

3. Copy the manifests that the **ccoctl** utility generated to the **manifests** directory that the installation program created by running the following command:

```
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

4. Copy the **tls** directory that contains the private key to the installation directory:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

## 7.9.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

### Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:

- The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GCPLOUD\_KEYFILE\_JSON** environment variables
- The `~/.gcp/osServiceAccount.json` file
- The **gcloud cli** default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the location of your customized `./install-config.yaml` file.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
  - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

### Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 7.9.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.9.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 7.9.13. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#) .

## 7.10. INSTALLING A CLUSTER ON USER-PROVISIONED INFRASTRUCTURE IN GCP BY USING DEPLOYMENT MANAGER TEMPLATES

In OpenShift Container Platform version 4.14, you can install a cluster on Google Cloud Platform (GCP) that uses infrastructure that you provide.

The steps for performing a user-provided infrastructure install are outlined here. Several [Deployment Manager](#) templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.

## IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

### 7.10.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.
- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the **kube-system** namespace, you can [manually create and maintain long-term credentials](#).

## NOTE

Be sure to also review this site list if you are configuring a proxy.

### 7.10.2. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 7.10.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

## IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.10.4. Configuring your GCP project

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

#### 7.10.4.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.

#### Procedure

- Create a project to host your OpenShift Container Platform cluster. See [Creating and Managing Projects](#) in the GCP documentation.

## IMPORTANT

Your GCP project must use the Premium Network Service Tier if you are using installer-provisioned infrastructure. The Standard Network Service Tier is not supported for clusters installed using the installation program. The installation program configures internal load balancing for the **api-int.<cluster\_name>.<base\_domain>** URL; the Premium Tier is required for internal load balancing.

#### 7.10.4.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

#### Prerequisites

- You created a project to host your cluster.

#### Procedure

- Enable the following required API services in the project that hosts your cluster. You may also enable optional API services which are not required for installation. See [Enabling services](#) in the GCP documentation.

**Table 7.17. Required API services**

| API service        | Console service name          |
|--------------------|-------------------------------|
| Compute Engine API | <b>compute.googleapis.com</b> |

| API service                              | Console service name                       |
|------------------------------------------|--------------------------------------------|
| Cloud Resource Manager API               | <b>cloudresourcemanager.googleapis.com</b> |
| Google DNS API                           | <b>dns.googleapis.com</b>                  |
| IAM Service Account Credentials API      | <b>iamcredentials.googleapis.com</b>       |
| Identity and Access Management (IAM) API | <b>iam.googleapis.com</b>                  |
| Service Usage API                        | <b>serviceusage.googleapis.com</b>         |

Table 7.18. Optional API services

| API service                     | Console service name                    |
|---------------------------------|-----------------------------------------|
| Cloud Deployment Manager V2 API | <b>deploymentmanager.googleapis.com</b> |
| Google Cloud APIs               | <b>cloudapis.googleapis.com</b>         |
| Service Management API          | <b>servicemanagement.googleapis.com</b> |
| Google Cloud Storage JSON API   | <b>storage-api.googleapis.com</b>       |
| Cloud Storage                   | <b>storage-component.googleapis.com</b> |

### 7.10.4.3. Configuring DNS for GCP

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the same project that you host the OpenShift Container Platform cluster. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

#### Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

#### NOTE

If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see [Google Domains](#).

2. Create a public hosted zone for your domain or subdomain in your GCP project. See [Creating public zones](#) in the GCP documentation.  
Use an appropriate root domain, such as **openshiftcorp.com**, or subdomain, such as **clusters.openshiftcorp.com**.

3. Extract the new authoritative name servers from the hosted zone records. See [Look up your Cloud DNS name servers](#) in the GCP documentation.  
You typically have four name servers.
4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: [How to switch to custom name servers](#).
5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See [Migrating to Cloud DNS](#) in the GCP documentation.
6. If you use a subdomain, follow your company's procedures to add its delegation records to the parent domain. This process might include a request to your company's IT department or the division that controls the root domain and DNS services for your company.

#### 7.10.4.4. GCP account limits

The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default [Quotas](#) do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

**Table 7.19. GCP resources used in a default cluster**

| Service          | Component  | Location | Total resources required | Resources removed after bootstrap |
|------------------|------------|----------|--------------------------|-----------------------------------|
| Service account  | IAM        | Global   | 6                        | 1                                 |
| Firewall rules   | Networking | Global   | 11                       | 1                                 |
| Forwarding rules | Compute    | Global   | 2                        | 0                                 |
| Health checks    | Compute    | Global   | 2                        | 0                                 |
| Images           | Compute    | Global   | 1                        | 0                                 |
| Networks         | Networking | Global   | 1                        | 0                                 |
| Routers          | Networking | Global   | 1                        | 0                                 |
| Routes           | Networking | Global   | 2                        | 0                                 |
| Subnetworks      | Compute    | Global   | 2                        | 0                                 |
| Target pools     | Networking | Global   | 2                        | 0                                 |

**NOTE**

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- **asia-east2**
- **asia-northeast2**
- **asia-south1**
- **australia-southeast1**
- **europa-north1**
- **europa-west2**
- **europa-west3**
- **europa-west6**
- **northamerica-northeast1**
- **southamerica-east1**
- **us-west2**

You can increase resource quotas from the [GCP console](#), but you might need to file a support ticket. Be sure to plan your cluster size early so that you can allow time to resolve the support ticket before you install your OpenShift Container Platform cluster.

#### 7.10.4.5. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

#### Prerequisites

- You created a project to host your cluster.

#### Procedure

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See [Creating a service account](#) in the GCP documentation.
2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the **Owner** role to it. See [Granting roles to a service account for specific resources](#).

**NOTE**

While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. You can create the service account key in JSON format, or attach the service account to a GCP virtual machine. See [Creating service account keys](#) and [Creating and enabling service accounts for instances](#) in the GCP documentation.

You must have a service account key or a virtual machine with an attached service account to create the cluster.

**NOTE**

If you use a virtual machine with an attached service account to create your cluster, you must set **credentialsMode: Manual** in the **install-config.yaml** file before installation.

#### 7.10.4.6. Required GCP roles

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. If the security policies for your organization require a more restrictive set of permissions, you can create a service account with the following permissions.

**IMPORTANT**

If you configure the Cloud Credential Operator to operate in passthrough mode, you must use roles rather than granular permissions.

If you deploy your cluster into an existing virtual private cloud (VPC), the service account does not require certain networking permissions, which are noted in the following lists:

#### Required roles for the installation program

- Compute Admin
- IAM Security Admin
- Service Account Admin
- Service Account Key Admin
- Service Account User
- Storage Admin

#### Required roles for creating network resources during installation

- DNS Administrator

#### Required roles for using passthrough credentials mode

- Compute Load Balancer Admin
- IAM Role Viewer

#### Required roles for user-provisioned GCP infrastructure

- Deployment Manager Editor

The roles are applied to the service accounts that the control plane and compute machines use:

**Table 7.20. GCP service account permissions**

| Account       | Roles                               |
|---------------|-------------------------------------|
| Control Plane | <b>roles/compute.instanceAdmin</b>  |
|               | <b>roles/compute.networkAdmin</b>   |
|               | <b>roles/compute.securityAdmin</b>  |
|               | <b>roles/storage.admin</b>          |
|               | <b>roles/iam.serviceAccountUser</b> |
| Compute       | <b>roles/compute.viewer</b>         |
|               | <b>roles/storage.admin</b>          |

#### 7.10.4.7. Required GCP permissions for user-provisioned infrastructure

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform.

If the security policies for your organization require a more restrictive set of permissions, you can create [custom roles](#) with the necessary permissions. The following permissions are required for the user-provisioned infrastructure for creating and deleting the OpenShift Container Platform cluster.

#### IMPORTANT

If you configure the Cloud Credential Operator to operate in passthrough mode, you must use roles rather than granular permissions. For more information, see "Required roles for using passthrough credentials mode" in the "Required GCP roles" section.

#### Example 7.33. Required permissions for creating network resources

- **compute.addresses.create**
- **compute.addresses.createInternal**
- **compute.addresses.delete**
- **compute.addresses.get**

- `compute.addresses.list`
- `compute.addresses.use`
- `compute.addresses.useInternal`
- `compute.firewalls.create`
- `compute.firewalls.delete`
- `compute.firewalls.get`
- `compute.firewalls.list`
- `compute.forwardingRules.create`
- `compute.forwardingRules.get`
- `compute.forwardingRules.list`
- `compute.forwardingRules.setLabels`
- `compute.networks.create`
- `compute.networks.get`
- `compute.networks.list`
- `compute.networks.updatePolicy`
- `compute.routers.create`
- `compute.routers.get`
- `compute.routers.list`
- `compute.routers.update`
- `compute.routes.list`
- `compute.subnetworks.create`
- `compute.subnetworks.get`
- `compute.subnetworks.list`
- `compute.subnetworks.use`
- `compute.subnetworks.useExternalIp`

Example 7.34. Required permissions for creating load balancer resources

- `compute.regionBackendServices.create`
- `compute.regionBackendServices.get`
- `compute.regionBackendServices.list`

- `compute.regionBackendServices.update`
- `compute.regionBackendServices.use`
- `compute.targetPools.addInstance`
- `compute.targetPools.create`
- `compute.targetPools.get`
- `compute.targetPools.list`
- `compute.targetPools.removeInstance`
- `compute.targetPools.use`

Example 7.35. Required permissions for creating DNS resources

- `dns.changes.create`
- `dns.changes.get`
- `dns.managedZones.create`
- `dns.managedZones.get`
- `dns.managedZones.list`
- `dns.networks.bindPrivateDNSZone`
- `dns.resourceRecordSets.create`
- `dns.resourceRecordSets.list`
- `dns.resourceRecordSets.update`

Example 7.36. Required permissions for creating Service Account resources

- `iam.serviceAccountKeys.create`
- `iam.serviceAccountKeys.delete`
- `iam.serviceAccountKeys.get`
- `iam.serviceAccountKeys.list`
- `iam.serviceAccounts.actAs`
- `iam.serviceAccounts.create`
- `iam.serviceAccounts.delete`
- `iam.serviceAccounts.get`
- `iam.serviceAccounts.list`

- `resourcemanager.projects.get`
- `resourcemanager.projects.getIamPolicy`
- `resourcemanager.projects.setIamPolicy`

Example 7.37. Required permissions for creating compute resources

- `compute.disks.create`
- `compute.disks.get`
- `compute.disks.list`
- `compute.instanceGroups.create`
- `compute.instanceGroups.delete`
- `compute.instanceGroups.get`
- `compute.instanceGroups.list`
- `compute.instanceGroups.update`
- `compute.instanceGroups.use`
- `compute.instances.create`
- `compute.instances.delete`
- `compute.instances.get`
- `compute.instances.list`
- `compute.instances.setLabels`
- `compute.instances.setMetadata`
- `compute.instances.setServiceAccount`
- `compute.instances.setTags`
- `compute.instances.use`
- `compute.machineTypes.get`
- `compute.machineTypes.list`

Example 7.38. Required for creating storage resources

- `storage.buckets.create`
- `storage.buckets.delete`
- `storage.buckets.get`

- `storage.buckets.list`
- `storage.objects.create`
- `storage.objects.delete`
- `storage.objects.get`
- `storage.objects.list`

Example 7.39. Required permissions for creating health check resources

- `compute.healthChecks.create`
- `compute.healthChecks.get`
- `compute.healthChecks.list`
- `compute.healthChecks.useReadOnly`
- `compute.httpHealthChecks.create`
- `compute.httpHealthChecks.get`
- `compute.httpHealthChecks.list`
- `compute.httpHealthChecks.useReadOnly`

Example 7.40. Required permissions to get GCP zone and region related information

- `compute.globalOperations.get`
- `compute.regionOperations.get`
- `compute.regions.list`
- `compute.zoneOperations.get`
- `compute.zones.get`
- `compute.zones.list`

Example 7.41. Required permissions for checking services and quotas

- `monitoring.timeSeries.list`
- `serviceusage.quotas.get`
- `serviceusage.services.list`

Example 7.42. Required IAM permissions for installation

- `iam.roles.get`

Example 7.43. Required Images permissions for installation

- `compute.images.create`
- `compute.images.delete`
- `compute.images.get`
- `compute.images.list`

Example 7.44. Optional permission for running gather bootstrap

- `compute.instances.getSerialPortOutput`

Example 7.45. Required permissions for deleting network resources

- `compute.addresses.delete`
- `compute.addresses.deleteInternal`
- `compute.addresses.list`
- `compute.firewalls.delete`
- `compute.firewalls.list`
- `compute.forwardingRules.delete`
- `compute.forwardingRules.list`
- `compute.networks.delete`
- `compute.networks.list`
- `compute.networks.updatePolicy`
- `compute.routers.delete`
- `compute.routers.list`
- `compute.routes.list`
- `compute.subnetworks.delete`
- `compute.subnetworks.list`

Example 7.46. Required permissions for deleting load balancer resources

- `compute.regionBackendServices.delete`

- `compute.regionBackendServices.list`
- `compute.targetPools.delete`
- `compute.targetPools.list`

Example 7.47. Required permissions for deleting DNS resources

- `dns.changes.create`
- `dns.managedZones.delete`
- `dns.managedZones.get`
- `dns.managedZones.list`
- `dns.resourceRecordSets.delete`
- `dns.resourceRecordSets.list`

Example 7.48. Required permissions for deleting Service Account resources

- `iam.serviceAccounts.delete`
- `iam.serviceAccounts.get`
- `iam.serviceAccounts.list`
- `resourcemanager.projects.getIamPolicy`
- `resourcemanager.projects.setIamPolicy`

Example 7.49. Required permissions for deleting compute resources

- `compute.disks.delete`
- `compute.disks.list`
- `compute.instanceGroups.delete`
- `compute.instanceGroups.list`
- `compute.instances.delete`
- `compute.instances.list`
- `compute.instances.stop`
- `compute.machineTypes.list`

Example 7.50. Required for deleting storage resources

- `storage.buckets.delete`
- `storage.buckets.getIamPolicy`
- `storage.buckets.list`
- `storage.objects.delete`
- `storage.objects.list`

Example 7.51. Required permissions for deleting health check resources

- `compute.healthChecks.delete`
- `compute.healthChecks.list`
- `compute.httpHealthChecks.delete`
- `compute.httpHealthChecks.list`

Example 7.52. Required Images permissions for deletion

- `compute.images.delete`
- `compute.images.list`

Example 7.53. Required permissions to get Region related information

- `compute.regions.get`

Example 7.54. Required Deployment Manager permissions

- `deploymentmanager.deployments.create`
- `deploymentmanager.deployments.delete`
- `deploymentmanager.deployments.get`
- `deploymentmanager.deployments.list`
- `deploymentmanager.manifests.get`
- `deploymentmanager.operations.get`
- `deploymentmanager.resources.list`

Additional resources

- [Optimizing storage](#)

#### 7.10.4.8. Supported GCP regions

You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
- **asia-northeast3** (Seoul, South Korea)
- **asia-south1** (Mumbai, India)
- **asia-south2** (Delhi, India)
- **asia-southeast1** (Jurong West, Singapore)
- **asia-southeast2** (Jakarta, Indonesia)
- **australia-southeast1** (Sydney, Australia)
- **australia-southeast2** (Melbourne, Australia)
- **europa-central2** (Warsaw, Poland)
- **europa-north1** (Hamina, Finland)
- **europa-southwest1** (Madrid, Spain)
- **europa-west1** (St. Ghislain, Belgium)
- **europa-west2** (London, England, UK)
- **europa-west3** (Frankfurt, Germany)
- **europa-west4** (Eemshaven, Netherlands)
- **europa-west6** (Zürich, Switzerland)
- **europa-west8** (Milan, Italy)
- **europa-west9** (Paris, France)
- **europa-west12** (Turin, Italy)
- **me-central1** (Doha, Qatar, Middle East)
- **me-west1** (Tel Aviv, Israel)
- **northamerica-northeast1** (Montréal, Québec, Canada)
- **northamerica-northeast2** (Toronto, Ontario, Canada)
- **southamerica-east1** (São Paulo, Brazil)

- **southamerica-west1** (Santiago, Chile)
- **us-central1** (Council Bluffs, Iowa, USA)
- **us-east1** (Moncks Corner, South Carolina, USA)
- **us-east4** (Ashburn, Northern Virginia, USA)
- **us-east5** (Columbus, Ohio)
- **us-south1** (Dallas, Texas)
- **us-west1** (The Dalles, Oregon, USA)
- **us-west2** (Los Angeles, California, USA)
- **us-west3** (Salt Lake City, Utah, USA)
- **us-west4** (Las Vegas, Nevada, USA)

**NOTE**

To determine which machine type instances are available by region and zone, see the Google [documentation](#).

#### 7.10.4.9. Installing and configuring CLI tools for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must install and configure the CLI tools for GCP.

**Prerequisites**

- You created a project to host your cluster.
- You created a service account and granted it the required permissions.

**Procedure**

1. Install the following binaries in **\$PATH**:

- **gcloud**
- **gsutil**

See [Install the latest Cloud SDK version](#) in the GCP documentation.

2. Authenticate using the **gcloud** tool with your configured service account.  
See [Authorizing with a service account](#) in the GCP documentation.

#### 7.10.5. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

### 7.10.5.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 7.21. Minimum required hosts**

| Hosts                                                                   | Description                                                                                                                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine                                         | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines                                            | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.                                                                                                             |

#### IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

### 7.10.5.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 7.22. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio:  $(\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}$ .
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 7.10.5.3. Tested instance types for GCP

The following Google Cloud Platform instance types have been tested with OpenShift Container Platform.

#### Example 7.55. Machine series

- **A2**
- **A3**
- **C2**
- **C2D**
- **C3**
- **C3D**

- E2
- M1
- N1
- N2
- N2D
- N4
- Tau T2D

#### 7.10.5.4. Tested instance types for GCP on 64-bit ARM infrastructures

The following Google Cloud Platform (GCP) 64-bit ARM instance types have been tested with OpenShift Container Platform.

##### Example 7.56. Machine series for 64-bit ARM machines

- Tau T2A

#### 7.10.5.5. Using custom machine types

Using a custom machine type to install a OpenShift Container Platform cluster is supported.

Consider the following when using a custom machine type:

- Similar to predefined instance types, custom machine types must meet the minimum resource requirements for control plane and compute machines. For more information, see "Minimum resource requirements for cluster installation".
- The name of the custom machine type must adhere to the following syntax:  
**custom-`<number_of_cpus>-<amount_of_memory_in_mb>`**

For example, **custom-6-20480**.

#### 7.10.6. Creating the installation files for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the **install-config.yaml** file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate **var** partition during the preparation phases of installation.

##### 7.10.6.1. Optional: Creating a separate `/var` partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

### IMPORTANT

If you follow the steps to create a separate **/var** partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

### Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
```

### Example output

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and
$HOME/clusterconfig/openshift
```

3. Optional: Confirm that the installation program created manifests in the **clusterconfig/openshift** directory:

```
$ ls $HOME/clusterconfig/openshift/
```

### Example output

```
99_kubeadmin-password-secret.yaml
```

```

99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...

```

4. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```

variant: openshift
version: 4.14.0
metadata:
 labels:
 machineconfiguration.openshift.io/role: worker
 name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> ❶
 partitions:
 - label: var
 start_mib: <partition_start_offset> ❷
 size_mib: <partition_size> ❸
 number: 5
 filesystems:
 - device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] ❹
 with_mount_unit: true

```

- ❶ The storage device name of the disk that you want to partition.
- ❷ When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ❸ The size of the data partition in mebibytes.
- ❹ The **prjquota** mount option must be enabled for filesystems used for container storage.

## NOTE

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

6. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 7.10.6.2. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the **~/.powervs** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **gcp** as the platform to target.
  - iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
  - iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
  - v. Select the region to deploy the cluster to.
  - vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - vii. Enter a descriptive name for your cluster.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.

**NOTE**

If you are installing a three-node cluster, be sure to set the **compute.replicas** parameter to **0**. This ensures that the cluster's control planes are schedulable. For more information, see "Installing a three-node cluster on GCP".

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- [Installation configuration parameters for GCP](#)

**7.10.6.3. Enabling Shielded VMs**

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

**NOTE**

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

**Prerequisites**

- You have created an **install-config.yaml** file.

**Procedure**

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- b. To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
 secureBoot: Enabled
```

- c. To use shielded VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

**7.10.6.4. Enabling Confidential VMs**

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

**NOTE**

Confidential VMs are currently not supported on 64-bit ARM architectures.

**Prerequisites**

- You have created an **install-config.yaml** file.

**Procedure**

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 confidentialCompute: Enabled ❶
 type: n2d-standard-8 ❷
 onHostMaintenance: Terminate ❸
```

- ❶ Enable confidential VMs.
- ❷ Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- ❸ Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

- b. To use confidential VMs for only compute machines:

```
compute:
- platform:
 gcp:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

- c. To use confidential VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

#### 7.10.6.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

## NOTE

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 7.10.6.6. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

### IMPORTANT

If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

### WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

### IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

5. Check that the **mastersSchedulable** parameter in the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
- Open the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** file.

- b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
6. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the **<installation\_directory>/manifests/cluster-dns-02-config.yml** DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
 privateZone: ❶
 id: mycluster-100419-private-zone
 publicZone: ❷
 id: example.openshift.com
status: {}
```

- ❶ ❷ Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

7. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> ❶
```

- ❶ For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

```
.
├── auth
│ ├── kubeadmin-password
│ └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

#### Additional resources

- [Optional: Adding the ingress DNS records](#)

#### 7.10.7. Exporting common variables

### 7.10.7.1. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Google Cloud Platform (GCP). The infrastructure name is also used to locate the appropriate GCP resources during an OpenShift Container Platform installation. The provided Deployment Manager templates contain references to this infrastructure name, so you must extract it.

#### Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

#### Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

#### Example output

```
openshift-vw9j6 1
```

- 1 The output of this command is your cluster name and a random string.

### 7.10.7.2. Exporting common variables for Deployment Manager templates

You must export a common set of variables that are used with the provided Deployment Manager templates used to assist in completing a user-provided infrastructure install on Google Cloud Platform (GCP).

#### NOTE

Specific Deployment Manager templates can also require additional exported variables, which are detailed in their related procedures.

#### Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Generate the Ignition config files for your cluster.
- Install the **jq** package.

#### Procedure

## Procedure

1. Export the following common variables to be used by the provided Deployment Manager templates:

```
$ export BASE_DOMAIN='<base_domain>'
$ export BASE_DOMAIN_ZONE_NAME='<base_domain_zone_name>'
$ export NETWORK_CIDR='10.0.0.0/16'
$ export MASTER_SUBNET_CIDR='10.0.0.0/17'
$ export WORKER_SUBNET_CIDR='10.0.128.0/17'

$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
$ export CLUSTER_NAME=`jq -r .clusterName <installation_directory>/metadata.json`
$ export INFRA_ID=`jq -r .infraID <installation_directory>/metadata.json`
$ export PROJECT_NAME=`jq -r .gcp.projectID <installation_directory>/metadata.json`
$ export REGION=`jq -r .gcp.region <installation_directory>/metadata.json`
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

### 7.10.8. Creating a VPC in GCP

You must create a VPC in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements. One way to create the VPC is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.

## Procedure

1. Copy the template from the **Deployment Manager template for the VPC** section of this topic and save it as **01\_vpc.py** on your computer. This template describes the VPC that your cluster requires.
2. Create a **01\_vpc.yaml** resource definition file:

```
$ cat <<EOF >01_vpc.yaml
imports:
- path: 01_vpc.py

resources:
- name: cluster-vpc
 type: 01_vpc.py
```

```

properties:
 infra_id: '${INFRA_ID}' 1
 region: '${REGION}' 2
 master_subnet_cidr: '${MASTER_SUBNET_CIDR}' 3
 worker_subnet_cidr: '${WORKER_SUBNET_CIDR}' 4
EOF

```

- 1** **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- 2** **region** is the region to deploy the cluster into, for example **us-central1**.
- 3** **master\_subnet\_cidr** is the CIDR for the master subnet, for example **10.0.0.0/17**.
- 4** **worker\_subnet\_cidr** is the CIDR for the worker subnet, for example **10.0.128.0/17**.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-vpc --config 01_vpc.yaml
```

### 7.10.8.1. Deployment Manager template for the VPC

You can use the following Deployment Manager template to deploy the VPC that you need for your OpenShift Container Platform cluster:

#### Example 7.57. 01\_vpc.py Deployment Manager template

```

def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-network',
 'type': 'compute.v1.network',
 'properties': {
 'region': context.properties['region'],
 'autoCreateSubnetworks': False
 }
 }, {
 'name': context.properties['infra_id'] + '-master-subnet',
 'type': 'compute.v1.subnetwork',
 'properties': {
 'region': context.properties['region'],
 'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
 'ipCidrRange': context.properties['master_subnet_cidr']
 }
 }, {
 'name': context.properties['infra_id'] + '-worker-subnet',
 'type': 'compute.v1.subnetwork',
 'properties': {
 'region': context.properties['region'],
 'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
 'ipCidrRange': context.properties['worker_subnet_cidr']
 }
 }, {
 'name': context.properties['infra_id'] + '-router',
 'type': 'compute.v1.router',

```

```

'properties': {
 'region': context.properties['region'],
 'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
 'nats': [{
 'name': context.properties['infra_id'] + '-nat-master',
 'natIpAllocateOption': 'AUTO_ONLY',
 'minPortsPerVm': 7168,
 'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
 'subnetworks': [{
 'name': '${ref.' + context.properties['infra_id'] + '-master-subnet.selfLink}',
 'sourceIpRangesToNat': ['ALL_IP_RANGES']
 }]
 }],
 {
 'name': context.properties['infra_id'] + '-nat-worker',
 'natIpAllocateOption': 'AUTO_ONLY',
 'minPortsPerVm': 512,
 'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
 'subnetworks': [{
 'name': '${ref.' + context.properties['infra_id'] + '-worker-subnet.selfLink}',
 'sourceIpRangesToNat': ['ALL_IP_RANGES']
 }]
 }
]
}
}

return {'resources': resources}

```

### 7.10.9. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

#### 7.10.9.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

#### 7.10.9.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

## IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

**Table 7.23. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
|          | <b>10256</b>       | openshift-sdn                                                                                                                               |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

**Table 7.24. Ports used for all-machine to control plane communications**

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

**Table 7.25. Ports used for control plane machine to control plane machine communications**

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

### 7.10.10. Creating load balancers in GCP

You must configure load balancers in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

#### Procedure

1. Copy the template from the **Deployment Manager template for the internal load balancer** section of this topic and save it as **02\_lb\_int.py** on your computer. This template describes the internal load balancing objects that your cluster requires.
2. For an external cluster, also copy the template from the **Deployment Manager template for the external load balancer** section of this topic and save it as **02\_lb\_ext.py** on your computer. This template describes the external load balancing objects that your cluster requires.
3. Export the variables that the deployment template uses:

- a. Export the cluster network location:

```
$ export CLUSTER_NETWORK=(`gcloud compute networks describe ${INFRA_ID}-network --format json | jq -r .selfLink`)
```

- b. Export the control plane subnet location:

```
$ export CONTROL_SUBNET=(`gcloud compute networks subnets describe ${INFRA_ID}-master-subnet --region=${REGION} --format json | jq -r .selfLink`)
```

- c. Export the three zones that the cluster uses:

```
$ export ZONE_0=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "/" -f9`)
```

```
$ export ZONE_1=('gcloud compute regions describe ${REGION} --format=json | jq -r
.zones[1] | cut -d "/" -f9')
```

```
$ export ZONE_2=('gcloud compute regions describe ${REGION} --format=json | jq -r
.zones[2] | cut -d "/" -f9')
```

4. Create a **02\_infra.yaml** resource definition file:

```
$ cat <<EOF >02_infra.yaml
imports:
- path: 02_lb_ext.py
- path: 02_lb_int.py ❶
resources:
- name: cluster-lb-ext ❷
 type: 02_lb_ext.py
 properties:
 infra_id: '${INFRA_ID}' ❸
 region: '${REGION}' ❹
- name: cluster-lb-int
 type: 02_lb_int.py
 properties:
 cluster_network: '${CLUSTER_NETWORK}'
 control_subnet: '${CONTROL_SUBNET}' ❺
 infra_id: '${INFRA_ID}'
 region: '${REGION}'
 zones: ❻
 - '${ZONE_0}'
 - '${ZONE_1}'
 - '${ZONE_2}'
EOF
```

❶ ❷ Required only when deploying an external cluster.

❸ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.

❹ **region** is the region to deploy the cluster into, for example **us-central1**.

❺ **control\_subnet** is the URI to the control subnet.

❻ **zones** are the zones to deploy the control plane instances into, like **us-east1-b**, **us-east1-c**, and **us-east1-d**.

5. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:

```
$ export CLUSTER_IP=('gcloud compute addresses describe ${INFRA_ID}-cluster-ip --
region=${REGION} --format json | jq -r .address')
```

7. For an external cluster, also export the cluster public IP address:

■

```
$ export CLUSTER_PUBLIC_IP=$(gcloud compute addresses describe ${INFRA_ID}-cluster-public-ip --region=${REGION} --format json | jq -r .address)
```

### 7.10.10.1. Deployment Manager template for the external load balancer

You can use the following Deployment Manager template to deploy the external load balancer that you need for your OpenShift Container Platform cluster:

#### Example 7.58. 02\_lb\_ext.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-cluster-public-ip',
 'type': 'compute.v1.address',
 'properties': {
 'region': context.properties['region']
 }
 }, {
 # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
 probe for kube-apiserver
 'name': context.properties['infra_id'] + '-api-http-health-check',
 'type': 'compute.v1.httpHealthCheck',
 'properties': {
 'port': 6080,
 'requestPath': '/readyz'
 }
 }, {
 'name': context.properties['infra_id'] + '-api-target-pool',
 'type': 'compute.v1.targetPool',
 'properties': {
 'region': context.properties['region'],
 'healthChecks': ['$(ref.' + context.properties['infra_id'] + '-api-http-health-check.selfLink)'],
 'instances': []
 }
 }, {
 'name': context.properties['infra_id'] + '-api-forwarding-rule',
 'type': 'compute.v1.forwardingRule',
 'properties': {
 'region': context.properties['region'],
 'IPAddress': '$(ref.' + context.properties['infra_id'] + '-cluster-public-ip.selfLink)',
 'target': '$(ref.' + context.properties['infra_id'] + '-api-target-pool.selfLink)',
 'portRange': '6443'
 }
 }
]

 return {'resources': resources}
```

### 7.10.10.2. Deployment Manager template for the internal load balancer

You can use the following Deployment Manager template to deploy the internal load balancer that you need for your OpenShift Container Platform cluster:

## Example 7.59. 02\_lb\_int.py Deployment Manager template

```
def GenerateConfig(context):

 backends = []
 for zone in context.properties['zones']:
 backends.append({
 'group': '$(ref.' + context.properties['infra_id'] + '-master-' + zone + '-ig' + '.selfLink)'
 })

 resources = [{
 'name': context.properties['infra_id'] + '-cluster-ip',
 'type': 'compute.v1.address',
 'properties': {
 'addressType': 'INTERNAL',
 'region': context.properties['region'],
 'subnetwork': context.properties['control_subnet']
 }
 }, {
 # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
probe for kube-apiserver
 'name': context.properties['infra_id'] + '-api-internal-health-check',
 'type': 'compute.v1.healthCheck',
 'properties': {
 'httpsHealthCheck': {
 'port': 6443,
 'requestPath': '/readyz'
 },
 'type': "HTTPS"
 }
 }, {
 'name': context.properties['infra_id'] + '-api-internal-backend-service',
 'type': 'compute.v1.regionBackendService',
 'properties': {
 'backends': backends,
 'healthChecks': ['$(ref.' + context.properties['infra_id'] + '-api-internal-health-
check.selfLink)'],
 'loadBalancingScheme': 'INTERNAL',
 'region': context.properties['region'],
 'protocol': 'TCP',
 'timeoutSec': 120
 }
 }, {
 'name': context.properties['infra_id'] + '-api-internal-forwarding-rule',
 'type': 'compute.v1.forwardingRule',
 'properties': {
 'backendService': '$(ref.' + context.properties['infra_id'] + '-api-internal-backend-
service.selfLink)',
 'IPAddress': '$(ref.' + context.properties['infra_id'] + '-cluster-ip.selfLink)',
 'loadBalancingScheme': 'INTERNAL',
 'ports': ['6443','22623'],
 'region': context.properties['region'],
 'subnetwork': context.properties['control_subnet']
 }
 }
]
```

```

for zone in context.properties['zones']:
 resources.append({
 'name': context.properties['infra_id'] + '-master-' + zone + '-ig',
 'type': 'compute.v1.instanceGroup',
 'properties': {
 'namedPorts': [
 {
 'name': 'ignition',
 'port': 22623
 }, {
 'name': 'https',
 'port': 6443
 }
],
 'network': context.properties['cluster_network'],
 'zone': zone
 }
 })

return {'resources': resources}

```

You will need this template in addition to the **02\_lb\_ext.py** template when you create an external cluster.

### 7.10.11. Creating a private DNS zone in GCP

You must configure a private DNS zone in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create this component is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

#### Procedure

1. Copy the template from the **Deployment Manager template for the private DNS** section of this topic and save it as **02\_dns.py** on your computer. This template describes the private DNS objects that your cluster requires.
2. Create a **02\_dns.yaml** resource definition file:

```
$ cat <<EOF >02_dns.yaml
```

```

imports:
- path: 02_dns.py

resources:
- name: cluster-dns
 type: 02_dns.py
 properties:
 infra_id: '${INFRA_ID}' 1
 cluster_domain: '${CLUSTER_NAME}.${BASE_DOMAIN}' 2
 cluster_network: '${CLUSTER_NETWORK}' 3
EOF

```

- 1** **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- 2** **cluster\_domain** is the domain for the cluster, for example **openshift.example.com**.
- 3** **cluster\_network** is the **selfLink** URL to the cluster network.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-dns --config 02_dns.yaml
```

4. The templates do not create DNS entries due to limitations of Deployment Manager, so you must create them manually:

- a. Add the internal DNS entries:

```

$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name
api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-
private-zone
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-
int.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-
private-zone
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone

```

- b. For an external cluster, also add the external DNS entries:

```

$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction add ${CLUSTER_PUBLIC_IP} --name
api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone
${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}

```

### 7.10.11.1. Deployment Manager template for the private DNS

You can use the following Deployment Manager template to deploy the private DNS that you need for your OpenShift Container Platform cluster:

#### Example 7.60. 02\_dns.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-private-zone',
 'type': 'dns.v1.managedZone',
 'properties': {
 'description': "",
 'dnsName': context.properties['cluster_domain'] + '.',
 'visibility': 'private',
 'privateVisibilityConfig': {
 'networks': [{
 'networkUrl': context.properties['cluster_network']
 }]
 }
 }
 }]

 return {'resources': resources}
```

### 7.10.12. Creating firewall rules in GCP

You must create firewall rules in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

#### Procedure

1. Copy the template from the **Deployment Manager template for firewall rules** section of this topic and save it as **03\_firewall.py** on your computer. This template describes the security groups that your cluster requires.
2. Create a **03\_firewall.yaml** resource definition file:

```
$ cat <<EOF >03_firewall.yaml
imports:
- path: 03_firewall.py

resources:
```

```
- name: cluster-firewall
 type: 03_firewall.py
 properties:
 allowed_external_cidr: '0.0.0.0/0' ❶
 infra_id: '${INFRA_ID}' ❷
 cluster_network: '${CLUSTER_NETWORK}' ❸
 network_cidr: '${NETWORK_CIDR}' ❹
EOF
```

- ❶ **allowed\_external\_cidr** is the CIDR range that can access the cluster API and SSH to the bootstrap host. For an internal cluster, set this value to **\${NETWORK\_CIDR}**.
- ❷ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❸ **cluster\_network** is the **selfLink** URL to the cluster network.
- ❹ **network\_cidr** is the CIDR of the VPC network, for example **10.0.0.0/16**.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-firewall --config
03_firewall.yaml
```

### 7.10.12.1. Deployment Manager template for firewall rules

You can use the following Deployment Manager template to deploy the firewall rules that you need for your OpenShift Container Platform cluster:

#### Example 7.61. 03\_firewall.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-bootstrap-in-ssh',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['22']
 }],
 'sourceRanges': [context.properties['allowed_external_cidr']],
 'targetTags': [context.properties['infra_id'] + '-bootstrap']
 }
], {
 'name': context.properties['infra_id'] + '-api',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['6443']
 }],
 'sourceRanges': [context.properties['allowed_external_cidr']],
```

```

 'targetTags': [context.properties['infra_id'] + '-master']
 }, {
 }, {
 'name': context.properties['infra_id'] + '-health-checks',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['6080', '6443', '22624']
 }],
 'sourceRanges': ['35.191.0.0/16', '130.211.0.0/22', '209.85.152.0/22', '209.85.204.0/22'],
 'targetTags': [context.properties['infra_id'] + '-master']
 }, {
 }, {
 'name': context.properties['infra_id'] + '-etcd',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['2379-2380']
 }],
 'sourceTags': [context.properties['infra_id'] + '-master'],
 'targetTags': [context.properties['infra_id'] + '-master']
 }, {
 }, {
 'name': context.properties['infra_id'] + '-control-plane',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['10257']
 }], {
 'IPProtocol': 'tcp',
 'ports': ['10259']
 }, {
 'IPProtocol': 'tcp',
 'ports': ['22623']
 }],
 'sourceTags': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-worker'
],
 'targetTags': [context.properties['infra_id'] + '-master']
 }, {
 }, {
 'name': context.properties['infra_id'] + '-internal-network',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'icmp'
 }], {
 'IPProtocol': 'tcp',

```

```

 'ports': ['22']
 }},
 'sourceRanges': [context.properties['network_cidr']],
 'targetTags': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-worker'
]
}
}, {
 'name': context.properties['infra_id'] + '-internal-cluster',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'udp',
 'ports': ['4789', '6081']
 }, {
 'IPProtocol': 'udp',
 'ports': ['500', '4500']
 }, {
 'IPProtocol': 'esp',
 }, {
 'IPProtocol': 'tcp',
 'ports': ['9000-9999']
 }, {
 'IPProtocol': 'udp',
 'ports': ['9000-9999']
 }, {
 'IPProtocol': 'tcp',
 'ports': ['10250']
 }, {
 'IPProtocol': 'tcp',
 'ports': ['30000-32767']
 }, {
 'IPProtocol': 'udp',
 'ports': ['30000-32767']
 }
],
 'sourceTags': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-worker'
],
 'targetTags': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-worker'
]
}
}]

return {'resources': resources}

```

### 7.10.13. Creating IAM roles in GCP

You must create IAM roles in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

## NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

## Procedure

1. Copy the template from the **Deployment Manager template for IAM roles** section of this topic and save it as **03\_iam.py** on your computer. This template describes the IAM roles that your cluster requires.
2. Create a **03\_iam.yaml** resource definition file:

```
$ cat <<EOF >03_iam.yaml
imports:
- path: 03_iam.py
resources:
- name: cluster-iam
 type: 03_iam.py
 properties:
 infra_id: '${INFRA_ID}' 1
EOF
```

- 1** **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-iam --config 03_iam.yaml
```

4. Export the variable for the master service account:

```
$ export MASTER_SERVICE_ACCOUNT=$(gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-m@${PROJECT_NAME}." --format json | jq -r '[0].email')
```

5. Export the variable for the worker service account:

```
$ export WORKER_SERVICE_ACCOUNT=$(gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '[0].email')
```

6. Export the variable for the subnet that hosts the compute machines:

```
$ export COMPUTE_SUBNET=('gcloud compute networks subnets describe ${INFRA_ID}-worker-subnet --region=${REGION} --format json | jq -r .selfLink')
```

7. The templates do not create the policy bindings due to limitations of Deployment Manager, so you must create them manually:

```
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.instanceAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.securityAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/iam.serviceAccountUser"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/storage.admin"

$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/compute.viewer"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
```

8. Create a service account key and store it locally for later use:

```
$ gcloud iam service-accounts keys create service-account-key.json --iam-
account=${MASTER_SERVICE_ACCOUNT}
```

### 7.10.13.1. Deployment Manager template for IAM roles

You can use the following Deployment Manager template to deploy the IAM roles that you need for your OpenShift Container Platform cluster:

#### Example 7.62. 03\_iam.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-master-node-sa',
 'type': 'iam.v1.serviceAccount',
 'properties': {
 'accountId': context.properties['infra_id'] + '-m',
 'displayName': context.properties['infra_id'] + '-master-node'
 }
 }, {
 'name': context.properties['infra_id'] + '-worker-node-sa',
 'type': 'iam.v1.serviceAccount',
 'properties': {
 'accountId': context.properties['infra_id'] + '-w',
 'displayName': context.properties['infra_id'] + '-worker-node'
 }
 }]
```

```

}}
return {'resources': resources}

```

### 7.10.14. Creating the RHCOS cluster image for the GCP infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Google Cloud Platform (GCP) for your OpenShift Container Platform nodes.

#### Procedure

1. Obtain the RHCOS image from the [RHCOS image mirror](#) page.

#### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The file name contains the OpenShift Container Platform version number in the format **rhcos-  
<version>-<arch>-gcp.<arch>.tar.gz**.

2. Create the Google storage bucket:

```
$ gsutil mb gs://<bucket_name>
```

3. Upload the RHCOS image to the Google storage bucket:

```
$ gsutil cp <downloaded_image_file_path>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz
gs://<bucket_name>
```

4. Export the uploaded RHCOS image location as a variable:

```
$ export IMAGE_SOURCE=gs://<bucket_name>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz
```

5. Create the cluster image:

```
$ gcloud compute images create "${INFRA_ID}-rhcos-image" \
--source-uri="${IMAGE_SOURCE}"
```

### 7.10.15. Creating the bootstrap machine in GCP

You must create the bootstrap machine in Google Cloud Platform (GCP) to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Deployment Manager template.

## NOTE

If you do not use the provided Deployment Manager template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Ensure pyOpenSSL is installed.

## Procedure

1. Copy the template from the **Deployment Manager template for the bootstrap machine** section of this topic and save it as **04\_bootstrap.py** on your computer. This template describes the bootstrap machine that your cluster requires.
2. Export the location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that the installation program requires:

```
$ export CLUSTER_IMAGE=(`gcloud compute images describe ${INFRA_ID}-rhcos-image --
format json | jq -r .selfLink`)
```

3. Create a bucket and upload the **bootstrap.ign** file:

```
$ gsutil mb gs://${INFRA_ID}-bootstrap-ignition
```

```
$ gsutil cp <installation_directory>/bootstrap.ign gs://${INFRA_ID}-bootstrap-ignition/
```

4. Create a signed URL for the bootstrap instance to use to access the Ignition config. Export the URL from the output as a variable:

```
$ export BOOTSTRAP_IGN=`gsutil signurl -d 1h service-account-key.json gs://${INFRA_ID}-
bootstrap-ignition/bootstrap.ign | grep "^gs:" | awk '{print $5}'`
```

5. Create a **04\_bootstrap.yaml** resource definition file:

```
$ cat <<EOF >04_bootstrap.yaml
imports:
- path: 04_bootstrap.py

resources:
- name: cluster-bootstrap
 type: 04_bootstrap.py
```

```

properties:
 infra_id: '${INFRA_ID}' ❶
 region: '${REGION}' ❷
 zone: '${ZONE_0}' ❸

 cluster_network: '${CLUSTER_NETWORK}' ❹
 control_subnet: '${CONTROL_SUBNET}' ❺
 image: '${CLUSTER_IMAGE}' ❻
 machine_type: 'n1-standard-4' ❼
 root_volume_size: '128' ❽

 bootstrap_ign: '${BOOTSTRAP_IGN}' ❾
EOF

```

- ❶ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❷ **region** is the region to deploy the cluster into, for example **us-central1**.
- ❸ **zone** is the zone to deploy the bootstrap instance into, for example **us-central1-b**.
- ❹ **cluster\_network** is the **selfLink** URL to the cluster network.
- ❺ **control\_subnet** is the **selfLink** URL to the control subnet.
- ❻ **image** is the **selfLink** URL to the RHCOS image.
- ❼ **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- ❽ **root\_volume\_size** is the boot disk size for the bootstrap machine.
- ❾ **bootstrap\_ign** is the URL output when creating a signed URL.

6. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-bootstrap --config
04_bootstrap.yaml
```

7. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the bootstrap machine manually.

a. Add the bootstrap instance to the internal load balancer instance group:

```
$ gcloud compute instance-groups unmanaged add-instances \
 ${INFRA_ID}-bootstrap-ig --zone=${ZONE_0} --instances=${INFRA_ID}-bootstrap
```

b. Add the bootstrap instance group to the internal load balancer backend service:

```
$ gcloud compute backend-services add-backend \
 ${INFRA_ID}-api-internal-backend-service --region=${REGION} --instance-
 group=${INFRA_ID}-bootstrap-ig --instance-group-zone=${ZONE_0}
```

#### 7.10.15.1. Deployment Manager template for the bootstrap machine

You can use the following Deployment Manager template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

#### Example 7.63. 04\_bootstrap.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-bootstrap-public-ip',
 'type': 'compute.v1.address',
 'properties': {
 'region': context.properties['region']
 }
 }, {
 'name': context.properties['infra_id'] + '-bootstrap',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': '{"ignition":{"config":{"replace":{"source":"' + context.properties['bootstrap_ign']
+ '"},"version":"3.2.0"}}}',
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet'],
 'accessConfigs': [{
 'natIP': '${ref.' + context.properties['infra_id'] + '-bootstrap-public-ip.address}'
 }]
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-bootstrap'
]
 },
 'zone': context.properties['zone']
 }
 }, {
 'name': context.properties['infra_id'] + '-bootstrap-ig',
 'type': 'compute.v1.instanceGroup',
 'properties': {

}
}}

return {'resources': resources}

```

### 7.10.16. Creating the control plane machines in GCP

You must create the control plane machines in Google Cloud Platform (GCP) for your cluster to use. One way to create these machines is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

#### Procedure

1. Copy the template from the **Deployment Manager template for control plane machines** section of this topic and save it as **05\_control\_plane.py** on your computer. This template describes the control plane machines that your cluster requires.
2. Export the following variable required by the resource definition:

```
$ export MASTER_IGNITION=`cat <installation_directory>/master.ign`
```

3. Create a **05\_control\_plane.yaml** resource definition file:

```
$ cat <<EOF >05_control_plane.yaml
imports:
- path: 05_control_plane.py
```

```

resources:
- name: cluster-control-plane
 type: 05_control_plane.py
 properties:
 infra_id: '${INFRA_ID}' ❶
 zones: ❷
 - '${ZONE_0}'
 - '${ZONE_1}'
 - '${ZONE_2}'

 control_subnet: '${CONTROL_SUBNET}' ❸
 image: '${CLUSTER_IMAGE}' ❹
 machine_type: 'n1-standard-4' ❺
 root_volume_size: '128'
 service_account_email: '${MASTER_SERVICE_ACCOUNT}' ❻

 ignition: '${MASTER_IGNITION}' ❼
EOF

```

- ❶ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❷ **zones** are the zones to deploy the control plane instances into, for example **us-central1-a**, **us-central1-b**, and **us-central1-c**.
- ❸ **control\_subnet** is the **selfLink** URL to the control subnet.
- ❹ **image** is the **selfLink** URL to the RHCOS image.
- ❺ **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- ❻ **service\_account\_email** is the email address for the master service account that you created.
- ❼ **ignition** is the contents of the **master.ign** file.

4. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-control-plane --config 05_control_plane.yaml
```

5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

- Run the following commands to add the control plane machines to the appropriate instance groups:

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-${ZONE_0}-ig --zone=${ZONE_0} --instances=${INFRA_ID}-master-0
```

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-${ZONE_1}-ig --zone=${ZONE_1} --instances=${INFRA_ID}-master-1
```

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_2}-ig --zone=${ZONE_2} --instances=${INFRA_ID}-master-2
```

- For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_0}" --instances=${INFRA_ID}-master-0
```

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_1}" --instances=${INFRA_ID}-master-1
```

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_2}" --instances=${INFRA_ID}-master-2
```

### 7.10.16.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

#### Example 7.64. `05_control_plane.py` Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-master-0',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][0] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zones'][0] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
```

```

 'items': [
 context.properties['infra_id'] + '-master',
]
 },
 'zone': context.properties['zones'][0]
}
}, {
 'name': context.properties['infra_id'] + '-master-1',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][1] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zones'][1] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
]
 },
 'zone': context.properties['zones'][1]
 }
}, {
 'name': context.properties['infra_id'] + '-master-2',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][2] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zones'][2] + '/machineTypes/' +
context.properties['machine_type'],

```

```

 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
]
 },
 'zone': context.properties['zones'][2]
 }
}

return {'resources': resources}

```

### 7.10.17. Wait for bootstrap completion and remove bootstrap resources in GCP

After you create all of the required infrastructure in Google Cloud Platform (GCP), wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

#### Procedure

1. Change to the directory that contains the installation program and run the following command:

```

$./openshift-install wait-for bootstrap-complete --dir <installation_directory> \ 1
--log-level info 2

```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the command exits without a **FATAL** warning, your production control plane has initialized.

2. Delete the bootstrap resources:

```
$ gcloud compute backend-services remove-backend ${INFRA_ID}-api-internal-backend-
service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-ig --instance-group-
zone=${ZONE_0}
```

```
$ gsutil rm gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign
```

```
$ gsutil rb gs://${INFRA_ID}-bootstrap-ignition
```

```
$ gcloud deployment-manager deployments delete ${INFRA_ID}-bootstrap
```

### 7.10.18. Creating additional worker machines in GCP

You can create worker machines in Google Cloud Platform (GCP) for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

#### NOTE

If you are installing a three-node cluster, skip this step. A three-node cluster consists of three control plane machines, which also act as compute machines.

In this example, you manually launch one instance by using the Deployment Manager template. Additional instances can be launched by including additional resources of type **06\_worker.py** in the file.

#### NOTE

If you do not use the provided Deployment Manager template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.

- Create the bootstrap machine.
- Create the control plane machines.

## Procedure

1. Copy the template from the **Deployment Manager template for worker machines** section of this topic and save it as **06\_worker.py** on your computer. This template describes the worker machines that your cluster requires.
2. Export the variables that the resource definition uses.

- a. Export the subnet that hosts the compute machines:

```
$ export COMPUTE_SUBNET=(`gcloud compute networks subnets describe
${INFRA_ID}-worker-subnet --region=${REGION} --format json | jq -r .selfLink`)
```

- b. Export the email address for your service account:

```
$ export WORKER_SERVICE_ACCOUNT=(`gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '[0].email`)
```

- c. Export the location of the compute machine Ignition config file:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign`
```

3. Create a **06\_worker.yaml** resource definition file:

```
$ cat <<EOF >06_worker.yaml
imports:
- path: 06_worker.py

resources:
- name: 'worker-0' 1
 type: 06_worker.py
 properties:
 infra_id: '${INFRA_ID}' 2
 zone: '${ZONE_0}' 3
 compute_subnet: '${COMPUTE_SUBNET}' 4
 image: '${CLUSTER_IMAGE}' 5
 machine_type: 'n1-standard-4' 6
 root_volume_size: '128'
 service_account_email: '${WORKER_SERVICE_ACCOUNT}' 7
 ignition: '${WORKER_IGNITION}' 8
- name: 'worker-1'
 type: 06_worker.py
 properties:
 infra_id: '${INFRA_ID}' 9
 zone: '${ZONE_1}' 10
 compute_subnet: '${COMPUTE_SUBNET}' 11
 image: '${CLUSTER_IMAGE}' 12
 machine_type: 'n1-standard-4' 13
 root_volume_size: '128'
```

```

service_account_email: '${WORKER_SERVICE_ACCOUNT}' 14
ignition: '${WORKER_IGNITION}' 15
EOF

```

- 1 **name** is the name of the worker machine, for example **worker-0**.
- 2 9 **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- 3 10 **zone** is the zone to deploy the worker machine into, for example **us-central1-a**.
- 4 11 **compute\_subnet** is the **selfLink** URL to the compute subnet.
- 5 12 **image** is the **selfLink** URL to the RHCOS image. <sup>1</sup>
- 6 13 **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- 7 14 **service\_account\_email** is the email address for the worker service account that you created.
- 8 15 **ignition** is the contents of the **worker.ign** file.

4. Optional: If you want to launch additional instances, include additional resources of type **06\_worker.py** in your **06\_worker.yaml** resource definition file.
5. Create the deployment by using the **gcloud** CLI:

```

$ gcloud deployment-manager deployments create ${INFRA_ID}-worker --config
06_worker.yaml

```

1. To use a GCP Marketplace image, specify the offer to use:
  - OpenShift Container Platform:  
**<https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-ocp-413-x86-64-202305021736>**
  - OpenShift Platform Plus: **<https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-opp-413-x86-64-202305021736>**
  - OpenShift Kubernetes Engine:  
**<https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-oke-413-x86-64-202305021736>**

### 7.10.18.1. Deployment Manager template for worker machines

You can use the following Deployment Manager template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

#### Example 7.65. 06\_worker.py Deployment Manager template

```

def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-' + context.env['name'],
 'type': 'compute.v1.instance',

```

```

'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['compute_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-worker',
]
 },
 'zone': context.properties['zone']
}
}]

return {'resources': resources}

```

### 7.10.19. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.

2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.

2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

**NOTE**

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

**Verification**

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

**7.10.20. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

**Example output**

```
system:admin
```

## 7.10.21. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

### Prerequisites

- You added machines to your cluster.

### Procedure

- Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

#### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 63m v1.27.3
master-1 Ready master 63m v1.27.3
master-2 Ready master 64m v1.27.3
```

The output lists all of the machines that you created.

#### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

#### Example output

```
NAME AGE REQUESTOR CONDITION
csr-8b2br 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
csr-8vnps 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

## NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

## NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrap** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

## NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

| NAME      | AGE   | REQUESTOR                                             | CONDITION |
|-----------|-------|-------------------------------------------------------|-----------|
| csr-bfd72 | 5m26s | system:node:ip-10-0-50-126.us-east-2.compute.internal | Pending   |
| csr-c57lv | 5m26s | system:node:ip-10-0-95-157.us-east-2.compute.internal | Pending   |
| ...       |       |                                                       |           |

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

## 7.10.22. Optional: Adding the ingress DNS records

If you removed the DNS zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the ingress load balancer. You can create either a wildcard **\*.apps.{baseDomain}**. or specific records. You can use A, CNAME, and other records per your requirements.

### Prerequisites

- Configure a GCP account.
- Remove the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs.
- Create and configure a VPC and associated subnets in GCP.

- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.
- Create the worker machines.

## Procedure

1. Wait for the Ingress router to create a load balancer and populate the **EXTERNAL-IP** field:

```
$ oc -n openshift-ingress get service router-default
```

### Example output

| NAME           | TYPE         | CLUSTER-IP    | EXTERNAL-IP    | PORT(S)                    | AGE |
|----------------|--------------|---------------|----------------|----------------------------|-----|
| router-default | LoadBalancer | 172.30.18.154 | 35.233.157.184 | 80:32288/TCP,443:31215/TCP | 98  |

2. Add the A record to your zones:

- To use A records:

- i. Export the variable for the router IP address:

```
$ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
```

- ii. Add the A record to the private zones:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name
*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
```

- iii. For an external cluster, also add the A record to the public zones:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name
*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction execute --zone
${BASE_DOMAIN_ZONE_NAME}
```

- To add explicit domains instead of using a wildcard, create entries for each of the cluster's current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}
{"\n"}}{end}{end}' routes
```

### Example output

```
oauth-openshift.apps.your.cluster.domain.example.com
console-openshift-console.apps.your.cluster.domain.example.com
downloads-openshift-console.apps.your.cluster.domain.example.com
alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com
prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com
```

## 7.10.23. Completing a GCP installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Google Cloud Platform (GCP) user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

### Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned GCP infrastructure.
- Install the **oc** CLI and log in.

### Procedure

1. Complete the cluster installation:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 2. Observe the running state of your cluster.

- a. Run the following command to view the current cluster version and status:

```
$ oc get clusterversion
```

**Example output**

```
NAME VERSION AVAILABLE PROGRESSING SINCE STATUS
version False True 24m Working towards 4.5.4: 99% complete
```

- b. Run the following command to view the Operators managed on the control plane by the Cluster Version Operator (CVO):

```
$ oc get clusteroperators
```

**Example output**

| NAME                                     | VERSION | AVAILABLE | PROGRESSING | DEGRADED    |
|------------------------------------------|---------|-----------|-------------|-------------|
| SINCE                                    |         |           |             |             |
| authentication                           | 4.5.4   | True      | False       | False 7m56s |
| cloud-credential                         | 4.5.4   | True      | False       | False 31m   |
| cluster-autoscaler                       | 4.5.4   | True      | False       | False 16m   |
| console                                  | 4.5.4   | True      | False       | False 10m   |
| csi-snapshot-controller                  | 4.5.4   | True      | False       | False 16m   |
| dns                                      | 4.5.4   | True      | False       | False 22m   |
| etcd                                     | 4.5.4   | False     | False       | False 25s   |
| image-registry                           | 4.5.4   | True      | False       | False 16m   |
| ingress                                  | 4.5.4   | True      | False       | False 16m   |
| insights                                 | 4.5.4   | True      | False       | False 17m   |
| kube-apiserver                           | 4.5.4   | True      | False       | False 19m   |
| kube-controller-manager                  | 4.5.4   | True      | False       | False 20m   |
| kube-scheduler                           | 4.5.4   | True      | False       | False 20m   |
| kube-storage-version-migrator            | 4.5.4   | True      | False       | False 16m   |
| machine-api                              | 4.5.4   | True      | False       | False 22m   |
| machine-config                           | 4.5.4   | True      | False       | False 22m   |
| marketplace                              | 4.5.4   | True      | False       | False 16m   |
| monitoring                               | 4.5.4   | True      | False       | False 10m   |
| network                                  | 4.5.4   | True      | False       | False 23m   |
| node-tuning                              | 4.5.4   | True      | False       | False 23m   |
| openshift-apiserver                      | 4.5.4   | True      | False       | False 17m   |
| openshift-controller-manager             | 4.5.4   | True      | False       | False 15m   |
| openshift-samples                        | 4.5.4   | True      | False       | False 16m   |
| operator-lifecycle-manager               | 4.5.4   | True      | False       | False 22m   |
| operator-lifecycle-manager-catalog       | 4.5.4   | True      | False       | False 22m   |
| operator-lifecycle-manager-packageserver | 4.5.4   | True      | False       | False 18m   |
| service-ca                               | 4.5.4   | True      | False       | False 23m   |
| service-catalog-apiserver                | 4.5.4   | True      | False       | False 23m   |
| service-catalog-controller-manager       | 4.5.4   | True      | False       | False 23m   |
| storage                                  | 4.5.4   | True      | False       | False 17m   |

- c. Run the following command to view your cluster pods:

```
$ oc get pods --all-namespaces
```

### Example output

```

NAMESPACE NAME
READY STATUS RESTARTS AGE
kube-system etcd-member-ip-10-0-3-111.us-east-
2.compute.internal 1/1 Running 0 35m
kube-system etcd-member-ip-10-0-3-239.us-east-

controller-manager-operator-b78cr2lnm 1/1 Running 0 31m

```

When the current cluster version is **AVAILABLE**, the installation is complete.

### 7.10.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 7.10.25. Next steps

- [Customize your cluster.](#)
- If necessary, you can [opt out of remote health reporting](#) .
- [Configure Global Access for an Ingress Controller on GCP](#) .

## 7.11. INSTALLING A CLUSTER INTO A SHARED VPC ON GCP USING DEPLOYMENT MANAGER TEMPLATES

In OpenShift Container Platform version 4.14, you can install a cluster into a shared Virtual Private Cloud (VPC) on Google Cloud Platform (GCP) that uses infrastructure that you provide. In this context, a cluster installed into a shared VPC is a cluster that is configured to use a VPC from a project different from where the cluster is being deployed.

A shared VPC enables an organization to connect resources from multiple projects to a common VPC network. You can communicate within the organization securely and efficiently by using internal IPs from that network. For more information about shared VPC, see [Shared VPC overview](#) in the GCP documentation.

The steps for performing a user-provided infrastructure installation into a shared VPC are outlined here. Several [Deployment Manager](#) templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.

### IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

### 7.11.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.
- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the **kube-system** namespace, you can [manually create and maintain long-term credentials](#).

### NOTE

Be sure to also review this site list if you are configuring a proxy.

### 7.11.2. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 7.11.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.11.4. Configuring the GCP project that hosts your cluster

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

#### 7.11.4.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.

##### Procedure

- Create a project to host your OpenShift Container Platform cluster. See [Creating and Managing Projects](#) in the GCP documentation.

#### IMPORTANT

Your GCP project must use the Premium Network Service Tier if you are using installer-provisioned infrastructure. The Standard Network Service Tier is not supported for clusters installed using the installation program. The installation program configures internal load balancing for the **api-int.<cluster\_name>.<base\_domain>** URL; the Premium Tier is required for internal load balancing.

#### 7.11.4.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

##### Prerequisites

- You created a project to host your cluster.

## Procedure

- Enable the following required API services in the project that hosts your cluster. You may also enable optional API services which are not required for installation. See [Enabling services](#) in the GCP documentation.

**Table 7.26. Required API services**

| API service                              | Console service name                       |
|------------------------------------------|--------------------------------------------|
| Compute Engine API                       | <b>compute.googleapis.com</b>              |
| Cloud Resource Manager API               | <b>cloudresourcemanager.googleapis.com</b> |
| Google DNS API                           | <b>dns.googleapis.com</b>                  |
| IAM Service Account Credentials API      | <b>iamcredentials.googleapis.com</b>       |
| Identity and Access Management (IAM) API | <b>iam.googleapis.com</b>                  |
| Service Usage API                        | <b>serviceusage.googleapis.com</b>         |

**Table 7.27. Optional API services**

| API service                     | Console service name                    |
|---------------------------------|-----------------------------------------|
| Cloud Deployment Manager V2 API | <b>deploymentmanager.googleapis.com</b> |
| Google Cloud APIs               | <b>cloudapis.googleapis.com</b>         |
| Service Management API          | <b>servicemanagement.googleapis.com</b> |
| Google Cloud Storage JSON API   | <b>storage-api.googleapis.com</b>       |
| Cloud Storage                   | <b>storage-component.googleapis.com</b> |

### 7.11.4.3. GCP account limits

The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default [Quotas](#) do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

**Table 7.28. GCP resources used in a default cluster**

| Service          | Component  | Location | Total resources required | Resources removed after bootstrap |
|------------------|------------|----------|--------------------------|-----------------------------------|
| Service account  | IAM        | Global   | 6                        | 1                                 |
| Firewall rules   | Networking | Global   | 11                       | 1                                 |
| Forwarding rules | Compute    | Global   | 2                        | 0                                 |
| Health checks    | Compute    | Global   | 2                        | 0                                 |
| Images           | Compute    | Global   | 1                        | 0                                 |
| Networks         | Networking | Global   | 1                        | 0                                 |
| Routers          | Networking | Global   | 1                        | 0                                 |
| Routes           | Networking | Global   | 2                        | 0                                 |
| Subnetworks      | Compute    | Global   | 2                        | 0                                 |
| Target pools     | Networking | Global   | 2                        | 0                                 |

**NOTE**

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- **asia-east2**
- **asia-northeast2**
- **asia-south1**
- **australia-southeast1**
- **europa-north1**
- **europa-west2**
- **europa-west3**
- **europa-west6**

- **northamerica-northeast1**
- **southamerica-east1**
- **us-west2**

You can increase resource quotas from the [GCP console](#), but you might need to file a support ticket. Be sure to plan your cluster size early so that you can allow time to resolve the support ticket before you install your OpenShift Container Platform cluster.

#### 7.11.4.4. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

##### Prerequisites

- You created a project to host your cluster.

##### Procedure

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See [Creating a service account](#) in the GCP documentation.
2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the **Owner** role to it. See [Granting roles to a service account for specific resources](#).

##### NOTE

While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. You can create the service account key in JSON format, or attach the service account to a GCP virtual machine. See [Creating service account keys](#) and [Creating and enabling service accounts for instances](#) in the GCP documentation.

You must have a service account key or a virtual machine with an attached service account to create the cluster.

##### NOTE

If you use a virtual machine with an attached service account to create your cluster, you must set **credentialsMode: Manual** in the **install-config.yaml** file before installation.

##### 7.11.4.4.1. Required GCP roles

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. If the security policies for your organization require a more restrictive set of permissions, you can create a service account with the following permissions.

IMPORTANT

If you configure the Cloud Credential Operator to operate in passthrough mode, you must use roles rather than granular permissions.

If you deploy your cluster into an existing virtual private cloud (VPC), the service account does not require certain networking permissions, which are noted in the following lists:

Required roles for the installation program

- Compute Admin
- IAM Security Admin
- Service Account Admin
- Service Account Key Admin
- Service Account User
- Storage Admin

Required roles for creating network resources during installation

- DNS Administrator

Required roles for using passthrough credentials mode

- Compute Load Balancer Admin
- IAM Role Viewer

Required roles for user-provisioned GCP infrastructure

- Deployment Manager Editor

The roles are applied to the service accounts that the control plane and compute machines use:

Table 7.29. GCP service account permissions

| Account       | Roles                        |
|---------------|------------------------------|
| Control Plane | roles/compute.instanceAdmin  |
|               | roles/compute.networkAdmin   |
|               | roles/compute.securityAdmin  |
|               | roles/storage.admin          |
|               | roles/iam.serviceAccountUser |
| Compute       | roles/compute.viewer         |

| Account | Roles                      |
|---------|----------------------------|
|         |                            |
|         | <b>roles/storage.admin</b> |

#### 7.11.4.5. Supported GCP regions

You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
- **asia-northeast3** (Seoul, South Korea)
- **asia-south1** (Mumbai, India)
- **asia-south2** (Delhi, India)
- **asia-southeast1** (Jurong West, Singapore)
- **asia-southeast2** (Jakarta, Indonesia)
- **australia-southeast1** (Sydney, Australia)
- **australia-southeast2** (Melbourne, Australia)
- **europa-central2** (Warsaw, Poland)
- **europa-north1** (Hamina, Finland)
- **europa-southwest1** (Madrid, Spain)
- **europa-west1** (St. Ghislain, Belgium)
- **europa-west2** (London, England, UK)
- **europa-west3** (Frankfurt, Germany)
- **europa-west4** (Eemshaven, Netherlands)
- **europa-west6** (Zürich, Switzerland)
- **europa-west8** (Milan, Italy)
- **europa-west9** (Paris, France)
- **europa-west12** (Turin, Italy)

- **me-central1** (Doha, Qatar, Middle East)
- **me-west1** (Tel Aviv, Israel)
- **northamerica-northeast1** (Montréal, Québec, Canada)
- **northamerica-northeast2** (Toronto, Ontario, Canada)
- **southamerica-east1** (São Paulo, Brazil)
- **southamerica-west1** (Santiago, Chile)
- **us-central1** (Council Bluffs, Iowa, USA)
- **us-east1** (Moncks Corner, South Carolina, USA)
- **us-east4** (Ashburn, Northern Virginia, USA)
- **us-east5** (Columbus, Ohio)
- **us-south1** (Dallas, Texas)
- **us-west1** (The Dalles, Oregon, USA)
- **us-west2** (Los Angeles, California, USA)
- **us-west3** (Salt Lake City, Utah, USA)
- **us-west4** (Las Vegas, Nevada, USA)

**NOTE**

To determine which machine type instances are available by region and zone, see the Google [documentation](#).

#### 7.11.4.6. Installing and configuring CLI tools for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must install and configure the CLI tools for GCP.

##### Prerequisites

- You created a project to host your cluster.
- You created a service account and granted it the required permissions.

##### Procedure

1. Install the following binaries in **\$PATH**:

- **gcloud**
- **gsutil**

See [Install the latest Cloud SDK version](#) in the GCP documentation.

2. Authenticate using the **gcloud** tool with your configured service account.

See [Authorizing with a service account](#) in the GCP documentation.

### 7.11.5. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

#### 7.11.5.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 7.30. Minimum required hosts**

| Hosts                                                                   | Description                                                                                                                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine                                         | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines                                            | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.                                                                                                             |

#### IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

#### 7.11.5.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 7.31. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 7.11.5.3. Tested instance types for GCP

The following Google Cloud Platform instance types have been tested with OpenShift Container Platform.

#### Example 7.66. Machine series

- **A2**
- **A3**
- **C2**
- **C2D**
- **C3**
- **C3D**
- **E2**
- **M1**
- **N1**
- **N2**
- **N2D**
- **N4**
- **Tau T2D**

#### 7.11.5.4. Using custom machine types

Using a custom machine type to install a OpenShift Container Platform cluster is supported.

Consider the following when using a custom machine type:

- Similar to predefined instance types, custom machine types must meet the minimum resource requirements for control plane and compute machines. For more information, see "Minimum resource requirements for cluster installation".
- The name of the custom machine type must adhere to the following syntax:  
**custom-<number\_of\_cpus>-<amount\_of\_memory\_in\_mb>**

For example, **custom-6-20480**.

#### 7.11.6. Configuring the GCP project that hosts your shared VPC network

If you use a shared Virtual Private Cloud (VPC) to host your OpenShift Container Platform cluster in Google Cloud Platform (GCP), you must configure the project that hosts it.

**NOTE**

If you already have a project that hosts the shared VPC network, review this section to ensure that the project meets all of the requirements to install an OpenShift Container Platform cluster.

**Procedure**

1. Create a project to host the shared VPC for your OpenShift Container Platform cluster. See [Creating and Managing Projects](#) in the GCP documentation.
2. Create a service account in the project that hosts your shared VPC. See [Creating a service account](#) in the GCP documentation.
3. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the **Owner** role to it. See [Granting roles to a service account for specific resources](#).

**NOTE**

While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

The service account for the project that hosts the shared VPC network requires the following roles:

- Compute Network User
- Compute Security Admin
- Deployment Manager Editor
- DNS Administrator
- Security Admin
- Network Management Admin

**7.11.6.1. Configuring DNS for GCP**

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the project that hosts the shared VPC that you install the cluster into. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

**Procedure**

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

**NOTE**

If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see [Google Domains](#).

2. Create a public hosted zone for your domain or subdomain in your GCP project. See [Creating public zones](#) in the GCP documentation.  
Use an appropriate root domain, such as **openshiftcorp.com**, or subdomain, such as **clusters.openshiftcorp.com**.
3. Extract the new authoritative name servers from the hosted zone records. See [Look up your Cloud DNS name servers](#) in the GCP documentation.  
You typically have four name servers.
4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: [How to switch to custom name servers](#).
5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See [Migrating to Cloud DNS](#) in the GCP documentation.
6. If you use a subdomain, follow your company's procedures to add its delegation records to the parent domain. This process might include a request to your company's IT department or the division that controls the root domain and DNS services for your company.

**7.11.6.2. Creating a VPC in GCP**

You must create a VPC in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements. One way to create the VPC is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.

**Procedure**

1. Copy the template from the **Deployment Manager template for the VPC** section of this topic and save it as **01\_vpc.py** on your computer. This template describes the VPC that your cluster requires.
2. Export the following variables required by the resource definition:
  - a. Export the control plane CIDR:

```
$ export MASTER_SUBNET_CIDR='10.0.0.0/17'
```

- b. Export the compute CIDR:

```
$ export WORKER_SUBNET_CIDR='10.0.128.0/17'
```

- c. Export the region to deploy the VPC network and cluster to:

```
$ export REGION='<region>'
```

3. Export the variable for the ID of the project that hosts the shared VPC:

```
$ export HOST_PROJECT=<host_project>
```

4. Export the variable for the email of the service account that belongs to host project:

```
$ export HOST_PROJECT_ACCOUNT=<host_service_account_email>
```

5. Create a **01\_vpc.yaml** resource definition file:

```
$ cat <<EOF >01_vpc.yaml
imports:
- path: 01_vpc.py

resources:
- name: cluster-vpc
 type: 01_vpc.py
 properties:
 infra_id: '<prefix>' ❶
 region: '${REGION}' ❷
 master_subnet_cidr: '${MASTER_SUBNET_CIDR}' ❸
 worker_subnet_cidr: '${WORKER_SUBNET_CIDR}' ❹
EOF
```

- ❶ **infra\_id** is the prefix of the network name.
- ❷ **region** is the region to deploy the cluster into, for example **us-central1**.
- ❸ **master\_subnet\_cidr** is the CIDR for the master subnet, for example **10.0.0.0/17**.
- ❹ **worker\_subnet\_cidr** is the CIDR for the worker subnet, for example **10.0.128.0/17**.

6. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create <vpc_deployment_name> --config
01_vpc.yaml --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT} ❶
```

- ❶ For **<vpc\_deployment\_name>**, specify the name of the VPC to deploy.

7. Export the VPC variable that other components require:

- a. Export the name of the host project network:

```
$ export HOST_PROJECT_NETWORK=<vpc_network>
```

- b. Export the name of the host project control plane subnet:

```
$ export HOST_PROJECT_CONTROL_SUBNET=<control_plane_subnet>
```

- c. Export the name of the host project compute subnet:

```
$ export HOST_PROJECT_COMPUTE_SUBNET=<compute_subnet>
```

8. Set up the shared VPC. See [Setting up Shared VPC](#) in the GCP documentation.

#### 7.11.6.2.1. Deployment Manager template for the VPC

You can use the following Deployment Manager template to deploy the VPC that you need for your OpenShift Container Platform cluster:

##### Example 7.67. 01\_vpc.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-network',
 'type': 'compute.v1.network',
 'properties': {
 'region': context.properties['region'],
 'autoCreateSubnetworks': False
 }
 }, {
 'name': context.properties['infra_id'] + '-master-subnet',
 'type': 'compute.v1.subnetwork',
 'properties': {
 'region': context.properties['region'],
 'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
 'ipCidrRange': context.properties['master_subnet_cidr']
 }
 }, {
 'name': context.properties['infra_id'] + '-worker-subnet',
 'type': 'compute.v1.subnetwork',
 'properties': {
 'region': context.properties['region'],
 'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
 'ipCidrRange': context.properties['worker_subnet_cidr']
 }
 }, {
 'name': context.properties['infra_id'] + '-router',
 'type': 'compute.v1.router',
 'properties': {
 'region': context.properties['region'],
 'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
 'nats': [{
 'name': context.properties['infra_id'] + '-nat-master',
 'natIpAllocateOption': 'AUTO_ONLY',
 'minPortsPerVm': 7168,
 'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
 'subnetworks': [{
```

```

 'name': '${ref.' + context.properties['infra_id'] + '-master-subnet.selfLink)',
 'sourceIpRangesToNat': ['ALL_IP_RANGES']
 }], {
 'name': context.properties['infra_id'] + '-nat-worker',
 'natIpAllocateOption': 'AUTO_ONLY',
 'minPortsPerVm': 512,
 'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
 'subnetworks': [{
 'name': '${ref.' + context.properties['infra_id'] + '-worker-subnet.selfLink)',
 'sourceIpRangesToNat': ['ALL_IP_RANGES']
 }]
 }]
}
]]
return {'resources': resources}

```

### 7.11.7. Creating the installation files for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the **install-config.yaml** file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate **var** partition during the preparation phases of installation.

#### 7.11.7.1. Manually creating the installation configuration file

##### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

##### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

#### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

#### NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

#### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

#### Additional resources

- [Installation configuration parameters for GCP](#)

#### 7.11.7.2. Enabling Shielded VMs

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

#### NOTE

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- b. To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
 secureBoot: Enabled
```

- c. To use shielded VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

### 7.11.7.3. Enabling Confidential VMs

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

#### NOTE

Confidential VMs are currently not supported on 64-bit ARM architectures.

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:
  - To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 confidentialCompute: Enabled ❶
 type: n2d-standard-8 ❷
 onHostMaintenance: Terminate ❸
```

- ❶ Enable confidential VMs.
- ❷ Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- ❸ Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

- To use confidential VMs for only compute machines:

```
compute:
- platform:
 gcp:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

- c. To use confidential VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

#### 7.11.7.4. Sample customized install-config.yaml file for GCP

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

#### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com ❶
controlPlane: ❷
 hyperthreading: Enabled ❸ ❹
 name: master
 platform:
 gcp:
 type: n2-standard-4
 zones:
 - us-central1-a
 - us-central1-c
 tags: ❺
 - control-plane-tag1
 - control-plane-tag2
 replicas: 3
compute: ❻
 - hyperthreading: Enabled ❼
 name: worker
 platform:
 gcp:
 type: n2-standard-4
 zones:
 - us-central1-a
 - us-central1-c
 tags: ❽
 - compute-tag1
 - compute-tag2
 replicas: 0
metadata:
 name: test-cluster
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
```

```

machineNetwork:
- cidr: 10.0.0.0/16
networkType: OVNKubernetes 9
serviceNetwork:
- 172.30.0.0/16
platform:
gcp:
defaultMachinePlatform:
tags: 10
- global-tag1
- global-tag2
projectID: openshift-production 11
region: us-central1 12
pullSecret: '{"auths": ...}'
fips: false 13
sshKey: ssh-ed25519 AAAA... 14
publish: Internal 15

```

- 1 Specify the public DNS on the host project.
- 2 6 If you do not provide these parameters and values, the installation program provides the default value.
- 3 7 The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
- 4 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

- 5 8 10 Optional: A set of network tags to apply to the control plane or compute machine sets. The **platform.gcp.defaultMachinePlatform.tags** parameter applies to both control plane and compute machines. If the **compute.platform.gcp.tags** or **controlPlane.platform.gcp.tags** parameters are set, they override the **platform.gcp.defaultMachinePlatform.tags** parameter.
- 9 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 11 Specify the main project where the VM instances reside.
- 12 Specify the region that your VPC network is in.
- 13 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is

enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

14

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

15

How to publish the user-facing endpoints of your cluster. Set **publish** to **Internal** to deploy a private cluster, which cannot be accessed from the internet. The default value is **External**. To use a shared VPC in a cluster that uses infrastructure that you provision, you must set **publish** to **Internal**. The installation program will no longer be able to access the public DNS zone for the base domain in the host project.

#### 7.11.7.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

## NOTE

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 7.11.7.6. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> ❶
```

- ❶ For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

5. Check that the **mastersSchedulable** parameter in the **<installation\_directory>/manifests/cluster-scheduler-02-config.yaml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:

- a. Open the **<installation\_directory>/manifests/cluster-scheduler-02-config.yaml** file.
- b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
- c. Save and exit the file.

6. Remove the **privateZone** sections from the **<installation\_directory>/manifests/cluster-dns-02-config.yaml** DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
 privateZone: ❶
 id: mycluster-100419-private-zone
status: {}
```

- ❶ Remove this section completely.

7. Configure the cloud provider for your VPC.

- a. Open the `<installation_directory>/manifests/cloud-provider-config.yaml` file.
- b. Add the **network-project-id** parameter and set its value to the ID of project that hosts the shared VPC network.
- c. Add the **network-name** parameter and set its value to the name of the shared VPC network that hosts the OpenShift Container Platform cluster.
- d. Replace the value of the **subnetwork-name** parameter with the value of the shared VPC subnet that hosts your compute machines.

The contents of the `<installation_directory>/manifests/cloud-provider-config.yaml` resemble the following example:

```
config: |+
 [global]
 project-id = example-project
 regional = true
 multizone = true
 node-tags = opensh-ptzzx-master
 node-tags = opensh-ptzzx-worker
 node-instance-prefix = opensh-ptzzx
 external-instance-groups-prefix = opensh-ptzzx
 network-project-id = example-shared-vpc
 network-name = example-network
 subnetwork-name = example-worker-subnet
```

8. If you deploy a cluster that is not on a private network, open the `<installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml` file and replace the value of the **scope** parameter with **External**. The contents of the file resemble the following example:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
 creationTimestamp: null
 name: default
 namespace: openshift-ingress-operator
spec:
 endpointPublishingStrategy:
 loadBalancer:
 scope: External
 type: LoadBalancerService
status:
 availableReplicas: 0
 domain: ""
 selector: ""
```

9. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> ❶
```

- ❶ For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

## 7.11.8. Exporting common variables

### 7.11.8.1. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Google Cloud Platform (GCP). The infrastructure name is also used to locate the appropriate GCP resources during an OpenShift Container Platform installation. The provided Deployment Manager templates contain references to this infrastructure name, so you must extract it.

#### Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

#### Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

#### Example output

```
openshift-vw9j6 1
```

- 1 The output of this command is your cluster name and a random string.

### 7.11.8.2. Exporting common variables for Deployment Manager templates

You must export a common set of variables that are used with the provided Deployment Manager templates used to assist in completing a user-provided infrastructure install on Google Cloud Platform (GCP).

## NOTE

Specific Deployment Manager templates can also require additional exported variables, which are detailed in their related procedures.

## Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Generate the Ignition config files for your cluster.
- Install the **jq** package.

## Procedure

1. Export the following common variables to be used by the provided Deployment Manager templates:

```
$ export BASE_DOMAIN='<base_domain>' 1
$ export BASE_DOMAIN_ZONE_NAME='<base_domain_zone_name>' 2
$ export NETWORK_CIDR='10.0.0.0/16'

$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 3
$ export CLUSTER_NAME=`jq -r .clusterName <installation_directory>/metadata.json`
$ export INFRA_ID=`jq -r .infraID <installation_directory>/metadata.json`
$ export PROJECT_NAME=`jq -r .gcp.projectID <installation_directory>/metadata.json`
```

- 1 2 Supply the values for the host project.
- 3 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

## 7.11.9. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **inittamfs** during boot to fetch their Ignition config files.

### 7.11.9.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

### 7.11.9.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

#### IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

**Table 7.32. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
|          | <b>10256</b>       | openshift-sdn                                                                                                                               |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

**Table 7.33. Ports used for all-machine to control plane communications**

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

Table 7.34. Ports used for control plane machine to control plane machine communications

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

### 7.11.10. Creating load balancers in GCP

You must configure load balancers in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

#### Procedure

1. Copy the template from the **Deployment Manager template for the internal load balancer** section of this topic and save it as **02\_lb\_int.py** on your computer. This template describes the internal load balancing objects that your cluster requires.
2. For an external cluster, also copy the template from the **Deployment Manager template for the external load balancer** section of this topic and save it as **02\_lb\_ext.py** on your computer. This template describes the external load balancing objects that your cluster requires.
3. Export the variables that the deployment template uses:
  - a. Export the cluster network location:

```
$ export CLUSTER_NETWORK=(`gcloud compute networks describe
${HOST_PROJECT_NETWORK} --project ${HOST_PROJECT} --account
${HOST_PROJECT_ACCOUNT} --format json | jq -r .selfLink`)
```

- b. Export the control plane subnet location:

```
$ export CONTROL_SUBNET=(`gcloud compute networks subnets describe
```

```
{HOST_PROJECT_CONTROL_SUBNET} --region=${REGION} --project
${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT} --format json | jq -r
.selfLink`)
```

- c. Export the three zones that the cluster uses:

```
$ export ZONE_0=`gcloud compute regions describe ${REGION} --format=json | jq -r
.zones[0] | cut -d "/" -f9`
```

```
$ export ZONE_1=`gcloud compute regions describe ${REGION} --format=json | jq -r
.zones[1] | cut -d "/" -f9`
```

```
$ export ZONE_2=`gcloud compute regions describe ${REGION} --format=json | jq -r
.zones[2] | cut -d "/" -f9`
```

4. Create a **02\_infra.yaml** resource definition file:

```
$ cat <<EOF >02_infra.yaml
imports:
- path: 02_lb_ext.py
- path: 02_lb_int.py ❶
resources:
- name: cluster-lb-ext ❷
 type: 02_lb_ext.py
 properties:
 infra_id: '${INFRA_ID}' ❸
 region: '${REGION}' ❹
- name: cluster-lb-int
 type: 02_lb_int.py
 properties:
 cluster_network: '${CLUSTER_NETWORK}'
 control_subnet: '${CONTROL_SUBNET}' ❺
 infra_id: '${INFRA_ID}'
 region: '${REGION}'
 zones: ❻
 - '${ZONE_0}'
 - '${ZONE_1}'
 - '${ZONE_2}'
EOF
```

❶ ❷ Required only when deploying an external cluster.

❸ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.

❹ **region** is the region to deploy the cluster into, for example **us-central1**.

❺ **control\_subnet** is the URI to the control subnet.

❻ **zones** are the zones to deploy the control plane instances into, like **us-east1-b**, **us-east1-c**, and **us-east1-d**.

5. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:

```
$ export CLUSTER_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-ip --
region=${REGION} --format json | jq -r .address`
```

7. For an external cluster, also export the cluster public IP address:

```
$ export CLUSTER_PUBLIC_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-
public-ip --region=${REGION} --format json | jq -r .address`
```

### 7.11.10.1. Deployment Manager template for the external load balancer

You can use the following Deployment Manager template to deploy the external load balancer that you need for your OpenShift Container Platform cluster:

#### Example 7.68. 02\_lb\_ext.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-cluster-public-ip',
 'type': 'compute.v1.address',
 'properties': {
 'region': context.properties['region']
 }
 }, {
 # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
probe for kube-apiserver
 'name': context.properties['infra_id'] + '-api-http-health-check',
 'type': 'compute.v1.httpHealthCheck',
 'properties': {
 'port': 6080,
 'requestPath': '/readyz'
 }
 }, {
 'name': context.properties['infra_id'] + '-api-target-pool',
 'type': 'compute.v1.targetPool',
 'properties': {
 'region': context.properties['region'],
 'healthChecks': ['$({ref.' + context.properties['infra_id'] + '-api-http-health-check.selfLink})'],
 'instances': []
 }
 }, {
 'name': context.properties['infra_id'] + '-api-forwarding-rule',
 'type': 'compute.v1.forwardingRule',
 'properties': {
 'region': context.properties['region'],
 'IPAddress': '$({ref.' + context.properties['infra_id'] + '-cluster-public-ip.selfLink})',
 'target': '$({ref.' + context.properties['infra_id'] + '-api-target-pool.selfLink})',
 'portRange': '6443'
 }
 }]
```

```

]]

 return {'resources': resources}

```

### 7.11.10.2. Deployment Manager template for the internal load balancer

You can use the following Deployment Manager template to deploy the internal load balancer that you need for your OpenShift Container Platform cluster:

#### Example 7.69. `02_lb_int.py` Deployment Manager template

```

def GenerateConfig(context):

 backends = []
 for zone in context.properties['zones']:
 backends.append({
 'group': '${ref.' + context.properties['infra_id'] + '-master-' + zone + '-ig' + '.selfLink}'
 })

 resources = [{
 'name': context.properties['infra_id'] + '-cluster-ip',
 'type': 'compute.v1.address',
 'properties': {
 'addressType': 'INTERNAL',
 'region': context.properties['region'],
 'subnetwork': context.properties['control_subnet']
 }
 }, {
 # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
probe for kube-apiserver
 'name': context.properties['infra_id'] + '-api-internal-health-check',
 'type': 'compute.v1.healthCheck',
 'properties': {
 'httpsHealthCheck': {
 'port': 6443,
 'requestPath': '/readyz'
 },
 'type': "HTTPS"
 }
 }, {
 'name': context.properties['infra_id'] + '-api-internal-backend-service',
 'type': 'compute.v1.regionBackendService',
 'properties': {
 'backends': backends,
 'healthChecks': ['${ref.' + context.properties['infra_id'] + '-api-internal-health-
check.selfLink}'],
 'loadBalancingScheme': 'INTERNAL',
 'region': context.properties['region'],
 'protocol': 'TCP',
 'timeoutSec': 120
 }
 }, {
 'name': context.properties['infra_id'] + '-api-internal-forwarding-rule',
 'type': 'compute.v1.forwardingRule',

```

```

 'properties': {
 'backendService': '${ref.' + context.properties['infra_id'] + '-api-internal-backend-
service.selfLink}',
 'IPAddress': '${ref.' + context.properties['infra_id'] + '-cluster-ip.selfLink}',
 'loadBalancingScheme': 'INTERNAL',
 'ports': ['6443','22623'],
 'region': context.properties['region'],
 'subnetwork': context.properties['control_subnet']
 }
]
}

for zone in context.properties['zones']:
 resources.append({
 'name': context.properties['infra_id'] + '-master-' + zone + '-ig',
 'type': 'compute.v1.instanceGroup',
 'properties': {
 'namedPorts': [
 {
 'name': 'ignition',
 'port': 22623
 }, {
 'name': 'https',
 'port': 6443
 }
],
 'network': context.properties['cluster_network'],
 'zone': zone
 }
 })

return {'resources': resources}

```

You will need this template in addition to the **02\_lb\_ext.py** template when you create an external cluster.

### 7.11.11. Creating a private DNS zone in GCP

You must configure a private DNS zone in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create this component is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.

- Create and configure a VPC and associated subnets in GCP.

## Procedure

1. Copy the template from the **Deployment Manager template for the private DNS** section of this topic and save it as **02\_dns.py** on your computer. This template describes the private DNS objects that your cluster requires.
2. Create a **02\_dns.yaml** resource definition file:

```
$ cat <<EOF >02_dns.yaml
imports:
- path: 02_dns.py

resources:
- name: cluster-dns
 type: 02_dns.py
 properties:
 infra_id: '${INFRA_ID}' 1
 cluster_domain: '${CLUSTER_NAME}.${BASE_DOMAIN}' 2
 cluster_network: '${CLUSTER_NETWORK}' 3
EOF
```

- 1** **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- 2** **cluster\_domain** is the domain for the cluster, for example **openshift.example.com**.
- 3** **cluster\_network** is the **selfLink** URL to the cluster network.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-dns --config 02_dns.yaml --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

4. The templates do not create DNS entries due to limitations of Deployment Manager, so you must create them manually:

- a. Add the internal DNS entries:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-int.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

- b. For an external cluster, also add the external DNS entries:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
```

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} dns
record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} dns
record-sets transaction add ${CLUSTER_PUBLIC_IP} --name
api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone
${BASE_DOMAIN_ZONE_NAME}
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} dns
record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
```

### 7.11.11.1. Deployment Manager template for the private DNS

You can use the following Deployment Manager template to deploy the private DNS that you need for your OpenShift Container Platform cluster:

#### Example 7.70. `02_dns.py` Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-private-zone',
 'type': 'dns.v1.managedZone',
 'properties': {
 'description': '',
 'dnsName': context.properties['cluster_domain'] + '.',
 'visibility': 'private',
 'privateVisibilityConfig': {
 'networks': [{
 'networkUrl': context.properties['cluster_network']
 }]
 }
 }
 }]

 return {'resources': resources}
```

### 7.11.12. Creating firewall rules in GCP

You must create firewall rules in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.

- Create and configure a VPC and associated subnets in GCP.

## Procedure

1. Copy the template from the **Deployment Manager template for firewall rules** section of this topic and save it as **03\_firewall.py** on your computer. This template describes the security groups that your cluster requires.
2. Create a **03\_firewall.yaml** resource definition file:

```
$ cat <<EOF >03_firewall.yaml
imports:
- path: 03_firewall.py

resources:
- name: cluster-firewall
 type: 03_firewall.py
 properties:
 allowed_external_cidr: '0.0.0.0/0' ❶
 infra_id: '${INFRA_ID}' ❷
 cluster_network: '${CLUSTER_NETWORK}' ❸
 network_cidr: '${NETWORK_CIDR}' ❹
EOF
```

- ❶ **allowed\_external\_cidr** is the CIDR range that can access the cluster API and SSH to the bootstrap host. For an internal cluster, set this value to **\${NETWORK\_CIDR}**.
- ❷ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❸ **cluster\_network** is the **selfLink** URL to the cluster network.
- ❹ **network\_cidr** is the CIDR of the VPC network, for example **10.0.0.0/16**.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-firewall --config
03_firewall.yaml --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

### 7.11.12.1. Deployment Manager template for firewall rules

You can use the following Deployment Manager template to deploy the firewall rules that you need for your OpenShift Container Platform cluster:

#### Example 7.71. 03\_firewall.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-bootstrap-in-ssh',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
```

```

 'IPProtocol': 'tcp',
 'ports': ['22']
 }},
 'sourceRanges': [context.properties['allowed_external_cidr']],
 'targetTags': [context.properties['infra_id'] + '-bootstrap']
}
}, {
 'name': context.properties['infra_id'] + '-api',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['6443']
 }],
 'sourceRanges': [context.properties['allowed_external_cidr']],
 'targetTags': [context.properties['infra_id'] + '-master']
 }
}, {
 'name': context.properties['infra_id'] + '-health-checks',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['6080', '6443', '22624']
 }],
 'sourceRanges': ['35.191.0.0/16', '130.211.0.0/22', '209.85.152.0/22', '209.85.204.0/22'],
 'targetTags': [context.properties['infra_id'] + '-master']
 }
}, {
 'name': context.properties['infra_id'] + '-etcd',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['2379-2380']
 }],
 'sourceTags': [context.properties['infra_id'] + '-master'],
 'targetTags': [context.properties['infra_id'] + '-master']
 }
}, {
 'name': context.properties['infra_id'] + '-control-plane',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['10257']
 }],
 'IPProtocol': 'tcp',
 'ports': ['10259']
 }, {
 'IPProtocol': 'tcp',
 'ports': ['22623']
 }
}

```

```

 }},
 'sourceTags': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-worker'
],
 'targetTags': [context.properties['infra_id'] + '-master']
 }
}, {
 'name': context.properties['infra_id'] + '-internal-network',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'icmp'
 }, {
 'IPProtocol': 'tcp',
 'ports': ['22']
 }],
 'sourceRanges': [context.properties['network_cidr']],
 'targetTags': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-worker'
]
 }
}, {
 'name': context.properties['infra_id'] + '-internal-cluster',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'udp',
 'ports': ['4789', '6081']
 }, {
 'IPProtocol': 'udp',
 'ports': ['500', '4500']
 }, {
 'IPProtocol': 'esp',
 }, {
 'IPProtocol': 'tcp',
 'ports': ['9000-9999']
 }, {
 'IPProtocol': 'udp',
 'ports': ['9000-9999']
 }, {
 'IPProtocol': 'tcp',
 'ports': ['10250']
 }, {
 'IPProtocol': 'tcp',
 'ports': ['30000-32767']
 }, {
 'IPProtocol': 'udp',
 'ports': ['30000-32767']
 }],
 'sourceTags': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-worker'
]
 }
}

```

```

],
 'targetTags': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-worker'
]
}
}}

return {'resources': resources}

```

### 7.11.13. Creating IAM roles in GCP

You must create IAM roles in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

#### Procedure

1. Copy the template from the **Deployment Manager template for IAM roles** section of this topic and save it as **03\_iam.py** on your computer. This template describes the IAM roles that your cluster requires.
2. Create a **03\_iam.yaml** resource definition file:

```

$ cat <<EOF >03_iam.yaml
imports:
- path: 03_iam.py
resources:
- name: cluster-iam
 type: 03_iam.py
 properties:
 infra_id: '${INFRA_ID}' 1
EOF

```

- 1** **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.

3. Create the deployment by using the **gcloud** CLI:

—

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-iam --config 03_iam.yaml
```

4. Export the variable for the master service account:

```
$ export MASTER_SERVICE_ACCOUNT=$(gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-m@${PROJECT_NAME}." --format json | jq -r '[0].email')
```

5. Export the variable for the worker service account:

```
$ export WORKER_SERVICE_ACCOUNT=$(gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '[0].email')
```

6. Assign the permissions that the installation program requires to the service accounts for the subnets that host the control plane and compute subnets:

- a. Grant the **networkViewer** role of the project that hosts your shared VPC to the master service account:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
projects add-iam-policy-binding ${HOST_PROJECT} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role
"roles/compute.networkViewer"
```

- b. Grant the **networkUser** role to the master service account for the control plane subnet:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
compute networks subnets add-iam-policy-binding
"${HOST_PROJECT_CONTROL_SUBNET}" --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkUser"
--region ${REGION}
```

- c. Grant the **networkUser** role to the worker service account for the control plane subnet:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
compute networks subnets add-iam-policy-binding
"${HOST_PROJECT_CONTROL_SUBNET}" --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role
"roles/compute.networkUser" --region ${REGION}
```

- d. Grant the **networkUser** role to the master service account for the compute subnet:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
compute networks subnets add-iam-policy-binding
"${HOST_PROJECT_COMPUTE_SUBNET}" --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkUser"
--region ${REGION}
```

- e. Grant the **networkUser** role to the worker service account for the compute subnet:

```
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
compute networks subnets add-iam-policy-binding
"${HOST_PROJECT_COMPUTE_SUBNET}" --member
```

```
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role
"roles/compute.networkUser" --region ${REGION}
```

7. The templates do not create the policy bindings due to limitations of Deployment Manager, so you must create them manually:

```
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.instanceAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.securityAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/iam.serviceAccountUser"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/storage.admin"

$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/compute.viewer"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
```

8. Create a service account key and store it locally for later use:

```
$ gcloud iam service-accounts keys create service-account-key.json --iam-
account=${MASTER_SERVICE_ACCOUNT}
```

### 7.11.13.1. Deployment Manager template for IAM roles

You can use the following Deployment Manager template to deploy the IAM roles that you need for your OpenShift Container Platform cluster:

#### Example 7.72. 03\_iam.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-master-node-sa',
 'type': 'iam.v1.serviceAccount',
 'properties': {
 'accountId': context.properties['infra_id'] + '-m',
 'displayName': context.properties['infra_id'] + '-master-node'
 }
 }, {
 'name': context.properties['infra_id'] + '-worker-node-sa',
 'type': 'iam.v1.serviceAccount',
 'properties': {
 'accountId': context.properties['infra_id'] + '-w',
 'displayName': context.properties['infra_id'] + '-worker-node'
 }
 }]

 return {'resources': resources}
```

### 7.11.14. Creating the RHCOS cluster image for the GCP infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Google Cloud Platform (GCP) for your OpenShift Container Platform nodes.

#### Procedure

1. Obtain the RHCOS image from the [RHCOS image mirror](#) page.

#### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The file name contains the OpenShift Container Platform version number in the format **rhcos-  
<version>-<arch>-gcp.<arch>.tar.gz**.

2. Create the Google storage bucket:

```
$ gsutil mb gs://<bucket_name>
```

3. Upload the RHCOS image to the Google storage bucket:

```
$ gsutil cp <downloaded_image_file_path>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz
gs://<bucket_name>
```

4. Export the uploaded RHCOS image location as a variable:

```
$ export IMAGE_SOURCE=gs://<bucket_name>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz
```

5. Create the cluster image:

```
$ gcloud compute images create "${INFRA_ID}-rhcos-image" \
--source-uri="${IMAGE_SOURCE}"
```

### 7.11.15. Creating the bootstrap machine in GCP

You must create the bootstrap machine in Google Cloud Platform (GCP) to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Ensure pyOpenSSL is installed.

## Procedure

1. Copy the template from the **Deployment Manager template for the bootstrap machine** section of this topic and save it as **04\_bootstrap.py** on your computer. This template describes the bootstrap machine that your cluster requires.
2. Export the location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that the installation program requires:

```
$ export CLUSTER_IMAGE=`gcloud compute images describe ${INFRA_ID}-rhcos-image --
format json | jq -r .selfLink`
```

3. Create a bucket and upload the **bootstrap.ign** file:

```
$ gsutil mb gs://${INFRA_ID}-bootstrap-ignition
```

```
$ gsutil cp <installation_directory>/bootstrap.ign gs://${INFRA_ID}-bootstrap-ignition/
```

4. Create a signed URL for the bootstrap instance to use to access the Ignition config. Export the URL from the output as a variable:

```
$ export BOOTSTRAP_IGN=`gsutil signurl -d 1h service-account-key.json gs://${INFRA_ID}-
bootstrap-ignition/bootstrap.ign | grep "^gs:" | awk '{print $5}'`
```

5. Create a **04\_bootstrap.yaml** resource definition file:

```
$ cat <<EOF >04_bootstrap.yaml
imports:
- path: 04_bootstrap.py

resources:
- name: cluster-bootstrap
 type: 04_bootstrap.py
 properties:
 infra_id: '${INFRA_ID}' ❶
 region: '${REGION}' ❷
 zone: '${ZONE_0}' ❸

 cluster_network: '${CLUSTER_NETWORK}' ❹
 control_subnet: '${CONTROL_SUBNET}' ❺
 image: '${CLUSTER_IMAGE}' ❻
```

```

machine_type: 'n1-standard-4' 7
root_volume_size: '128' 8

bootstrap_ign: '${BOOTSTRAP_IGN}' 9
EOF

```

- 1 **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- 2 **region** is the region to deploy the cluster into, for example **us-central1**.
- 3 **zone** is the zone to deploy the bootstrap instance into, for example **us-central1-b**.
- 4 **cluster\_network** is the **selfLink** URL to the cluster network.
- 5 **control\_subnet** is the **selfLink** URL to the control subnet.
- 6 **image** is the **selfLink** URL to the RHCOS image.
- 7 **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- 8 **root\_volume\_size** is the boot disk size for the bootstrap machine.
- 9 **bootstrap\_ign** is the URL output when creating a signed URL.

6. Create the deployment by using the **gcloud** CLI:

```

$ gcloud deployment-manager deployments create ${INFRA_ID}-bootstrap --config
04_bootstrap.yaml

```

7. Add the bootstrap instance to the internal load balancer instance group:

```

$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-bootstrap-ig --
zone=${ZONE_0} --instances=${INFRA_ID}-bootstrap

```

8. Add the bootstrap instance group to the internal load balancer backend service:

```

$ gcloud compute backend-services add-backend ${INFRA_ID}-api-internal-backend-service
--region=${REGION} --instance-group=${INFRA_ID}-bootstrap-ig --instance-group-
zone=${ZONE_0}

```

#### 7.11.15.1. Deployment Manager template for the bootstrap machine

You can use the following Deployment Manager template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

##### Example 7.73. 04\_bootstrap.py Deployment Manager template

```

def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-bootstrap-public-ip',
 'type': 'compute.v1.address',
 'properties': {

```

```

 'region': context.properties['region']
 }
}, {
 'name': context.properties['infra_id'] + '-bootstrap',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': '{"ignition":{"config":{"replace":{"source":"' + context.properties['bootstrap_ign']
+ ""}}, "version":"3.2.0"}}',
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet'],
 'accessConfigs': [{
 'natIP': '$(ref.' + context.properties['infra_id'] + '-bootstrap-public-ip.address)'
 }]
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-bootstrap'
]
 },
 'zone': context.properties['zone']
 }
}, {
 'name': context.properties['infra_id'] + '-bootstrap-ig',
 'type': 'compute.v1.instanceGroup',
 'properties': {
 'namedPorts': [
 {
 'name': 'ignition',
 'port': 22623
 }, {
 'name': 'https',
 'port': 6443
 }
],
 'network': context.properties['cluster_network'],
 'zone': context.properties['zone']
 }
}]

return {'resources': resources}

```

### 7.11.16. Creating the control plane machines in GCP

You must create the control plane machines in Google Cloud Platform (GCP) for your cluster to use. One way to create these machines is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

#### Procedure

1. Copy the template from the **Deployment Manager template for control plane machines** section of this topic and save it as **05\_control\_plane.py** on your computer. This template describes the control plane machines that your cluster requires.
2. Export the following variable required by the resource definition:

```
$ export MASTER_IGNITION=`cat <installation_directory>/master.ign`
```

3. Create a **05\_control\_plane.yaml** resource definition file:

```
$ cat <<EOF >05_control_plane.yaml
imports:
- path: 05_control_plane.py

resources:
- name: cluster-control-plane
 type: 05_control_plane.py
 properties:
 infra_id: '${INFRA_ID}' ❶
 zones: ❷
 - '${ZONE_0}'
 - '${ZONE_1}'
 - '${ZONE_2}'

 control_subnet: '${CONTROL_SUBNET}' ❸
```

```

image: '${CLUSTER_IMAGE}' ❹
machine_type: 'n1-standard-4' ❺
root_volume_size: '128'
service_account_email: '${MASTER_SERVICE_ACCOUNT}' ❻

ignition: '${MASTER_IGNITION}' ❼
EOF

```

- ❶ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❷ **zones** are the zones to deploy the control plane instances into, for example **us-central1-a**, **us-central1-b**, and **us-central1-c**.
- ❸ **control\_subnet** is the **selfLink** URL to the control subnet.
- ❹ **image** is the **selfLink** URL to the RHCOS image.
- ❺ **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- ❻ **service\_account\_email** is the email address for the master service account that you created.
- ❼ **ignition** is the contents of the **master.ign** file.

#### 4. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-control-plane --config
05_control_plane.yaml
```

#### 5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

- Run the following commands to add the control plane machines to the appropriate instance groups:

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_0}-ig --zone=${ZONE_0} --instances=${INFRA_ID}-master-0
```

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_1}-ig --zone=${ZONE_1} --instances=${INFRA_ID}-master-1
```

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_2}-ig --zone=${ZONE_2} --instances=${INFRA_ID}-master-2
```

- For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_0}" --instances=${INFRA_ID}-master-0
```

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_1}" --instances=${INFRA_ID}-master-1
```

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_2}" --instances=${INFRA_ID}-master-2
```

### 7.11.16.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

#### Example 7.74. 05\_control\_plane.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-master-0',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][0] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zones'][0] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
]
 },
 'zone': context.properties['zones'][0]
 }
], {
 'name': context.properties['infra_id'] + '-master-1',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
```

```

 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][1] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 },
 'machineType': 'zones/' + context.properties['zones'][1] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
]
 },
 'zone': context.properties['zones'][1]
}
}, {
 'name': context.properties['infra_id'] + '-master-2',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][2] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 }]
 },
 'machineType': 'zones/' + context.properties['zones'][2] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {

```

```

 'items': [
 context.properties['infra_id'] + '-master',
],
 },
 'zone': context.properties['zones'][2]
}
}]

return {'resources': resources}

```

### 7.11.17. Wait for bootstrap completion and remove bootstrap resources in GCP

After you create all of the required infrastructure in Google Cloud Platform (GCP), wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

#### Procedure

1. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install wait-for bootstrap-complete --dir <installation_directory> \ 1
--log-level info 2
```

**1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

**2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the command exits without a **FATAL** warning, your production control plane has initialized.

2. Delete the bootstrap resources:

```
$ gcloud compute backend-services remove-backend ${INFRA_ID}-api-internal-backend-
service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-ig --instance-group-
zone=${ZONE_0}
```

```
$ gsutil rm gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign
```

```
$ gsutil rb gs://${INFRA_ID}-bootstrap-ignition
```

```
$ gcloud deployment-manager deployments delete ${INFRA_ID}-bootstrap
```

### 7.11.18. Creating additional worker machines in GCP

You can create worker machines in Google Cloud Platform (GCP) for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Deployment Manager template. Additional instances can be launched by including additional resources of type **06\_worker.py** in the file.

#### NOTE

If you do not use the provided Deployment Manager template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

#### Procedure

1. Copy the template from the **Deployment Manager template for worker machines** section of this topic and save it as **06\_worker.py** on your computer. This template describes the worker machines that your cluster requires.
2. Export the variables that the resource definition uses.
  - a. Export the subnet that hosts the compute machines:

```
$ export COMPUTE_SUBNET=$(gcloud compute networks subnets describe
${HOST_PROJECT_COMPUTE_SUBNET} --region=${REGION} --project
${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT} --format json | jq -r
.selfLink)
```

- b. Export the email address for your service account:

```
$ export WORKER_SERVICE_ACCOUNT=$(gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '[0].email')
```

- c. Export the location of the compute machine Ignition config file:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign`
```

3. Create a **06\_worker.yaml** resource definition file:

```
$ cat <<EOF >06_worker.yaml
imports:
- path: 06_worker.py

resources:
- name: 'worker-0' ❶
 type: 06_worker.py
 properties:
 infra_id: '${INFRA_ID}' ❷
 zone: '${ZONE_0}' ❸
 compute_subnet: '${COMPUTE_SUBNET}' ❹
 image: '${CLUSTER_IMAGE}' ❺
 machine_type: 'n1-standard-4' ❻
 root_volume_size: '128'
 service_account_email: '${WORKER_SERVICE_ACCOUNT}' ❼
 ignition: '${WORKER_IGNITION}' ❽
- name: 'worker-1'
 type: 06_worker.py
 properties:
 infra_id: '${INFRA_ID}' ❾
 zone: '${ZONE_1}' ❿
 compute_subnet: '${COMPUTE_SUBNET}' ⓫
 image: '${CLUSTER_IMAGE}' ⓬
 machine_type: 'n1-standard-4' ⓭
 root_volume_size: '128'
 service_account_email: '${WORKER_SERVICE_ACCOUNT}' ⓮
 ignition: '${WORKER_IGNITION}' ⓯
EOF
```

- ❶ **name** is the name of the worker machine, for example **worker-0**.
- ❷ ❾ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❸ ❿ **zone** is the zone to deploy the worker machine into, for example **us-central1-a**.
- ❹ ⓫ **compute\_subnet** is the **selfLink** URL to the compute subnet.
- ❺ ⓬ **image** is the **selfLink** URL to the RHCOS image. <sup>1</sup>
- ❻ ⓭ **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- ❼ ⓮ **service\_account\_email** is the email address for the worker service account that you created

created.

**8 15** **ignition** is the contents of the **worker.ign** file.

4. Optional: If you want to launch additional instances, include additional resources of type **06\_worker.py** in your **06\_worker.yaml** resource definition file.
5. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-worker --config
06_worker.yaml
```

1. To use a GCP Marketplace image, specify the offer to use:
  - OpenShift Container Platform:  
**<https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-ocp-413-x86-64-202305021736>**
  - OpenShift Platform Plus: **<https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-opp-413-x86-64-202305021736>**
  - OpenShift Kubernetes Engine:  
**<https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-oke-413-x86-64-202305021736>**

#### 7.11.18.1. Deployment Manager template for worker machines

You can use the following Deployment Manager template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

##### Example 7.75. **06\_worker.py** Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-' + context.env['name'],
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
```

```

 'subnetwork': context.properties['compute_subnet']
 }},
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }},
 'tags': {
 'items': [
 context.properties['infra_id'] + '-worker',
]
 },
 'zone': context.properties['zone']
}
}]

return {'resources': resources}

```

### 7.11.19. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

#### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

#### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your **PATH**.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

#### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 7.11.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

### 7.11.21. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

#### Prerequisites

- You added machines to your cluster.

#### Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

#### Example output

| NAME     | STATUS | ROLES  | AGE | VERSION |
|----------|--------|--------|-----|---------|
| master-0 | Ready  | master | 63m | v1.27.3 |
| master-1 | Ready  | master | 63m | v1.27.3 |
| master-2 | Ready  | master | 64m | v1.27.3 |

The output lists all of the machines that you created.

#### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

#### Example output

| NAME      | AGE | REQUESTOR                                                                 | CONDITION |
|-----------|-----|---------------------------------------------------------------------------|-----------|
| csr-8b2br | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstrapper | Pending   |
| csr-8vnps | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstrapper | Pending   |
| ...       |     |                                                                           |           |

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

#### NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrap** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

## 7.11.22. Adding the ingress DNS records

DNS zone configuration is removed when creating Kubernetes manifests and generating Ignition configs. You must manually create DNS records that point at the ingress load balancer. You can create either a wildcard **\*.apps.{baseDomain}**, or specific records. You can use A, CNAME, and other records per your requirements.

### Prerequisites

- Configure a GCP account.
- Remove the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.
- Create the worker machines.

## Procedure

1. Wait for the Ingress router to create a load balancer and populate the **EXTERNAL-IP** field:

```
$ oc -n openshift-ingress get service router-default
```

### Example output

| NAME           | TYPE         | CLUSTER-IP    | EXTERNAL-IP    | PORT(S)                    | AGE |
|----------------|--------------|---------------|----------------|----------------------------|-----|
| router-default | LoadBalancer | 172.30.18.154 | 35.233.157.184 | 80:32288/TCP,443:31215/TCP | 98  |

2. Add the A record to your zones:

- To use A records:

- i. Export the variable for the router IP address:

```
$ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
```

- ii. Add the A record to the private zones:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name *.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

- iii. For an external cluster, also add the A record to the public zones:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name *.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone ${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

- To add explicit domains instead of using a wildcard, create entries for each of the cluster's current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}\n\n'} routes
```

### Example output

```

oauth-openshift.apps.your.cluster.domain.example.com
console-openshift-console.apps.your.cluster.domain.example.com
downloads-openshift-console.apps.your.cluster.domain.example.com
alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com
prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com

```

### 7.11.23. Adding ingress firewall rules

The cluster requires several firewall rules. If you do not use a shared VPC, these rules are created by the Ingress Controller via the GCP cloud provider. When you use a shared VPC, you can either create cluster-wide firewall rules for all services now or create each rule based on events, when the cluster requests access. By creating each rule when the cluster requests access, you know exactly which firewall rules are required. By creating cluster-wide firewall rules, you can apply the same rule set across multiple clusters.

If you choose to create each rule based on events, you must create firewall rules after you provision the cluster and during the life of the cluster when the console notifies you that rules are missing. Events that are similar to the following event are displayed, and you must add the firewall rules that are required:

```
$ oc get events -n openshift-ingress --field-selector="reason=LoadBalancerManualChange"
```

#### Example output

```

Firewall change required by security admin: `gcloud compute firewall-rules create k8s-fw-
a26e631036a3f46cba28f8df67266d55 --network example-network --description "
{"kubernetes.io/service-name":"openshift-ingress/router-default", "kubernetes.io/service-
ip":"35.237.236.234"}" --allow tcp:443,tcp:80 --source-ranges 0.0.0.0/0 --target-tags exampl-fqzq7-
master,exampl-fqzq7-worker --project example-project`

```

If you encounter issues when creating these rule-based events, you can configure the cluster-wide firewall rules while your cluster is running.

#### 7.11.23.1. Creating cluster-wide firewall rules for a shared VPC in GCP

You can create cluster-wide firewall rules to allow the access that the OpenShift Container Platform cluster requires.

#### WARNING

If you do not choose to create firewall rules based on cluster events, you must create cluster-wide firewall rules.

#### Prerequisites

- You exported the variables that the Deployment Manager templates require to deploy your cluster.
- You created the networking and load balancing components in GCP that your cluster requires.

## Procedure

1. Add a single firewall rule to allow the Google Cloud Engine health checks to access all of the services. This rule enables the ingress load balancers to determine the health status of their instances.

```
$ gcloud compute firewall-rules create --allow='tcp:30000-32767,udp:30000-32767' --
network="${CLUSTER_NETWORK}" --source-
ranges='130.211.0.0/22,35.191.0.0/16,209.85.152.0/22,209.85.204.0/22' --target-
tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress-hc --
account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

2. Add a single firewall rule to allow access to all cluster services:

- For an external cluster:

```
$ gcloud compute firewall-rules create --allow='tcp:80,tcp:443' --
network="${CLUSTER_NETWORK}" --source-ranges="0.0.0.0/0" --target-
tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress --
account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

- For a private cluster:

```
$ gcloud compute firewall-rules create --allow='tcp:80,tcp:443' --
network="${CLUSTER_NETWORK}" --source-ranges=${NETWORK_CIDR} --target-
tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress --
account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

Because this rule only allows traffic on TCP ports **80** and **443**, ensure that you add all the ports that your services use.

## 7.11.24. Completing a GCP installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Google Cloud Platform (GCP) user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

### Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned GCP infrastructure.
- Install the **oc** CLI and log in.

## Procedure

1. Complete the cluster installation:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Observe the running state of your cluster.

- a. Run the following command to view the current cluster version and status:

```
$ oc get clusterversion
```

### Example output

```
NAME VERSION AVAILABLE PROGRESSING SINCE STATUS
version False True 24m Working towards 4.5.4: 99% complete
```

- b. Run the following command to view the Operators managed on the control plane by the Cluster Version Operator (CVO):

```
$ oc get clusteroperators
```

### Example output

| NAME                    | VERSION | AVAILABLE | PROGRESSING | DEGRADED    |
|-------------------------|---------|-----------|-------------|-------------|
| authentication          | 4.5.4   | True      | False       | False 7m56s |
| cloud-credential        | 4.5.4   | True      | False       | False 31m   |
| cluster-autoscaler      | 4.5.4   | True      | False       | False 16m   |
| console                 | 4.5.4   | True      | False       | False 10m   |
| csi-snapshot-controller | 4.5.4   | True      | False       | False 16m   |
| dns                     | 4.5.4   | True      | False       | False 22m   |
| etcd                    | 4.5.4   | False     | False       | False 25s   |
| image-registry          | 4.5.4   | True      | False       | False 16m   |
| ingress                 | 4.5.4   | True      | False       | False 16m   |
| insights                | 4.5.4   | True      | False       | False 17m   |
| kube-apiserver          | 4.5.4   | True      | False       | False 19m   |
| kube-controller-manager | 4.5.4   | True      | False       | False 20m   |
| kube-scheduler          | 4.5.4   | True      | False       | False 20m   |

|                                          |       |      |       |       |     |
|------------------------------------------|-------|------|-------|-------|-----|
| kube-storage-version-migrator            | 4.5.4 | True | False | False | 16m |
| machine-api                              | 4.5.4 | True | False | False | 22m |
| machine-config                           | 4.5.4 | True | False | False | 22m |
| marketplace                              | 4.5.4 | True | False | False | 16m |
| monitoring                               | 4.5.4 | True | False | False | 10m |
| network                                  | 4.5.4 | True | False | False | 23m |

```

When the current cluster version is **AVAILABLE**, the installation is complete.

### 7.11.25. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 7.11.26. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

## 7.12. INSTALLING A CLUSTER ON GCP IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.14, you can install a cluster on Google Cloud Platform (GCP) that uses infrastructure that you provide and an internal mirror of the installation release content.

#### IMPORTANT

While you can install an OpenShift Container Platform cluster by using mirrored installation release content, your cluster still requires internet access to use the GCP APIs.

The steps for performing a user-provided infrastructure install are outlined here. Several [Deployment Manager](#) templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.

#### IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

### 7.12.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

- You [created a registry on your mirror host](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

### IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to. While you might need to grant access to more sites, you must grant access to **\*.googleapis.com** and **accounts.google.com**.
- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the **kube-system** namespace, you can [manually create and maintain long-term credentials](#).

## 7.12.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

### IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

### 7.12.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

## 7.12.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### 7.12.4. Configuring your GCP project

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

##### 7.12.4.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.

##### Procedure

- Create a project to host your OpenShift Container Platform cluster. See [Creating and Managing Projects](#) in the GCP documentation.

#### IMPORTANT

Your GCP project must use the Premium Network Service Tier if you are using installer-provisioned infrastructure. The Standard Network Service Tier is not supported for clusters installed using the installation program. The installation program configures internal load balancing for the **api-int.<cluster\_name>.<base\_domain>** URL; the Premium Tier is required for internal load balancing.

##### 7.12.4.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

##### Prerequisites

- You created a project to host your cluster.

##### Procedure

- Enable the following required API services in the project that hosts your cluster. You may also enable optional API services which are not required for installation. See [Enabling services](#) in the GCP documentation.

**Table 7.35. Required API services**

| API service        | Console service name          |
|--------------------|-------------------------------|
| Compute Engine API | <b>compute.googleapis.com</b> |

| API service                              | Console service name                       |
|------------------------------------------|--------------------------------------------|
| Cloud Resource Manager API               | <b>cloudresourcemanager.googleapis.com</b> |
| Google DNS API                           | <b>dns.googleapis.com</b>                  |
| IAM Service Account Credentials API      | <b>iamcredentials.googleapis.com</b>       |
| Identity and Access Management (IAM) API | <b>iam.googleapis.com</b>                  |
| Service Usage API                        | <b>serviceusage.googleapis.com</b>         |

Table 7.36. Optional API services

| API service                   | Console service name                    |
|-------------------------------|-----------------------------------------|
| Google Cloud APIs             | <b>cloudapis.googleapis.com</b>         |
| Service Management API        | <b>servicemanagement.googleapis.com</b> |
| Google Cloud Storage JSON API | <b>storage-api.googleapis.com</b>       |
| Cloud Storage                 | <b>storage-component.googleapis.com</b> |

### 7.12.4.3. Configuring DNS for GCP

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the same project that you host the OpenShift Container Platform cluster. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

#### Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

#### NOTE

If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see [Google Domains](#).

2. Create a public hosted zone for your domain or subdomain in your GCP project. See [Creating public zones](#) in the GCP documentation. Use an appropriate root domain, such as **openshiftcorp.com**, or subdomain, such as **clusters.openshiftcorp.com**.

3. Extract the new authoritative name servers from the hosted zone records. See [Look up your Cloud DNS name servers](#) in the GCP documentation.  
You typically have four name servers.
4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: [How to switch to custom name servers](#).
5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See [Migrating to Cloud DNS](#) in the GCP documentation.
6. If you use a subdomain, follow your company's procedures to add its delegation records to the parent domain. This process might include a request to your company's IT department or the division that controls the root domain and DNS services for your company.

#### 7.12.4.4. GCP account limits

The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default [Quotas](#) do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

**Table 7.37. GCP resources used in a default cluster**

| Service          | Component  | Location | Total resources required | Resources removed after bootstrap |
|------------------|------------|----------|--------------------------|-----------------------------------|
| Service account  | IAM        | Global   | 6                        | 1                                 |
| Firewall rules   | Networking | Global   | 11                       | 1                                 |
| Forwarding rules | Compute    | Global   | 2                        | 0                                 |
| Health checks    | Compute    | Global   | 2                        | 0                                 |
| Images           | Compute    | Global   | 1                        | 0                                 |
| Networks         | Networking | Global   | 1                        | 0                                 |
| Routers          | Networking | Global   | 1                        | 0                                 |
| Routes           | Networking | Global   | 2                        | 0                                 |
| Subnetworks      | Compute    | Global   | 2                        | 0                                 |
| Target pools     | Networking | Global   | 2                        | 0                                 |

**NOTE**

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- **asia-east2**
- **asia-northeast2**
- **asia-south1**
- **australia-southeast1**
- **europa-north1**
- **europa-west2**
- **europa-west3**
- **europa-west6**
- **northamerica-northeast1**
- **southamerica-east1**
- **us-west2**

You can increase resource quotas from the [GCP console](#), but you might need to file a support ticket. Be sure to plan your cluster size early so that you can allow time to resolve the support ticket before you install your OpenShift Container Platform cluster.

#### 7.12.4.5. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

##### Prerequisites

- You created a project to host your cluster.

##### Procedure

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See [Creating a service account](#) in the GCP documentation.
2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the **Owner** role to it. See [Granting roles to a service account for specific resources](#).

**NOTE**

While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. You can create the service account key in JSON format, or attach the service account to a GCP virtual machine. See [Creating service account keys](#) and [Creating and enabling service accounts for instances](#) in the GCP documentation.

You must have a service account key or a virtual machine with an attached service account to create the cluster.

**NOTE**

If you use a virtual machine with an attached service account to create your cluster, you must set **credentialsMode: Manual** in the **install-config.yaml** file before installation.

#### 7.12.4.6. Required GCP roles

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. If the security policies for your organization require a more restrictive set of permissions, you can create a service account with the following permissions.

**IMPORTANT**

If you configure the Cloud Credential Operator to operate in passthrough mode, you must use roles rather than granular permissions.

If you deploy your cluster into an existing virtual private cloud (VPC), the service account does not require certain networking permissions, which are noted in the following lists:

#### Required roles for the installation program

- Compute Admin
- IAM Security Admin
- Service Account Admin
- Service Account Key Admin
- Service Account User
- Storage Admin

#### Required roles for creating network resources during installation

- DNS Administrator

#### Required roles for using passthrough credentials mode

- Compute Load Balancer Admin
- IAM Role Viewer

Required roles for user-provisioned GCP infrastructure

- Deployment Manager Editor

The roles are applied to the service accounts that the control plane and compute machines use:

Table 7.38. GCP service account permissions

| Account       | Roles                        |
|---------------|------------------------------|
| Control Plane | roles/compute.instanceAdmin  |
|               | roles/compute.networkAdmin   |
|               | roles/compute.securityAdmin  |
|               | roles/storage.admin          |
|               | roles/iam.serviceAccountUser |
| Compute       | roles/compute.viewer         |
|               | roles/storage.admin          |

7.12.4.7. Required GCP permissions for user-provisioned infrastructure

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform.

If the security policies for your organization require a more restrictive set of permissions, you can create [custom roles](#) with the necessary permissions. The following permissions are required for the user-provisioned infrastructure for creating and deleting the OpenShift Container Platform cluster.

IMPORTANT

If you configure the Cloud Credential Operator to operate in passthrough mode, you must use roles rather than granular permissions. For more information, see "Required roles for using passthrough credentials mode" in the "Required GCP roles" section.

Example 7.76. Required permissions for creating network resources

- compute.addresses.create
- compute.addresses.createInternal
- compute.addresses.delete
- compute.addresses.get

- `compute.addresses.list`
- `compute.addresses.use`
- `compute.addresses.useInternal`
- `compute.firewalls.create`
- `compute.firewalls.delete`
- `compute.firewalls.get`
- `compute.firewalls.list`
- `compute.forwardingRules.create`
- `compute.forwardingRules.get`
- `compute.forwardingRules.list`
- `compute.forwardingRules.setLabels`
- `compute.networks.create`
- `compute.networks.get`
- `compute.networks.list`
- `compute.networks.updatePolicy`
- `compute.routers.create`
- `compute.routers.get`
- `compute.routers.list`
- `compute.routers.update`
- `compute.routes.list`
- `compute.subnetworks.create`
- `compute.subnetworks.get`
- `compute.subnetworks.list`
- `compute.subnetworks.use`
- `compute.subnetworks.useExternallp`

Example 7.77. Required permissions for creating load balancer resources

- `compute.regionBackendServices.create`
- `compute.regionBackendServices.get`
- `compute.regionBackendServices.list`

- `compute.regionBackendServices.update`
- `compute.regionBackendServices.use`
- `compute.targetPools.addInstance`
- `compute.targetPools.create`
- `compute.targetPools.get`
- `compute.targetPools.list`
- `compute.targetPools.removeInstance`
- `compute.targetPools.use`

Example 7.78. Required permissions for creating DNS resources

- `dns.changes.create`
- `dns.changes.get`
- `dns.managedZones.create`
- `dns.managedZones.get`
- `dns.managedZones.list`
- `dns.networks.bindPrivateDNSZone`
- `dns.resourceRecordSets.create`
- `dns.resourceRecordSets.list`
- `dns.resourceRecordSets.update`

Example 7.79. Required permissions for creating Service Account resources

- `iam.serviceAccountKeys.create`
- `iam.serviceAccountKeys.delete`
- `iam.serviceAccountKeys.get`
- `iam.serviceAccountKeys.list`
- `iam.serviceAccounts.actAs`
- `iam.serviceAccounts.create`
- `iam.serviceAccounts.delete`
- `iam.serviceAccounts.get`
- `iam.serviceAccounts.list`

- `resourcemanager.projects.get`
- `resourcemanager.projects.getIamPolicy`
- `resourcemanager.projects.setIamPolicy`

Example 7.80. Required permissions for creating compute resources

- `compute.disks.create`
- `compute.disks.get`
- `compute.disks.list`
- `compute.instanceGroups.create`
- `compute.instanceGroups.delete`
- `compute.instanceGroups.get`
- `compute.instanceGroups.list`
- `compute.instanceGroups.update`
- `compute.instanceGroups.use`
- `compute.instances.create`
- `compute.instances.delete`
- `compute.instances.get`
- `compute.instances.list`
- `compute.instances.setLabels`
- `compute.instances.setMetadata`
- `compute.instances.setServiceAccount`
- `compute.instances.setTags`
- `compute.instances.use`
- `compute.machineTypes.get`
- `compute.machineTypes.list`

Example 7.81. Required for creating storage resources

- `storage.buckets.create`
- `storage.buckets.delete`
- `storage.buckets.get`

- `storage.buckets.list`
- `storage.objects.create`
- `storage.objects.delete`
- `storage.objects.get`
- `storage.objects.list`

Example 7.82. Required permissions for creating health check resources

- `compute.healthChecks.create`
- `compute.healthChecks.get`
- `compute.healthChecks.list`
- `compute.healthChecks.useReadOnly`
- `compute.httpHealthChecks.create`
- `compute.httpHealthChecks.get`
- `compute.httpHealthChecks.list`
- `compute.httpHealthChecks.useReadOnly`

Example 7.83. Required permissions to get GCP zone and region related information

- `compute.globalOperations.get`
- `compute.regionOperations.get`
- `compute.regions.list`
- `compute.zoneOperations.get`
- `compute.zones.get`
- `compute.zones.list`

Example 7.84. Required permissions for checking services and quotas

- `monitoring.timeSeries.list`
- `serviceusage.quotas.get`
- `serviceusage.services.list`

Example 7.85. Required IAM permissions for installation

- `iam.roles.get`

Example 7.86. Required Images permissions for installation

- `compute.images.create`
- `compute.images.delete`
- `compute.images.get`
- `compute.images.list`

Example 7.87. Optional permission for running gather bootstrap

- `compute.instances.getSerialPortOutput`

Example 7.88. Required permissions for deleting network resources

- `compute.addresses.delete`
- `compute.addresses.deleteInternal`
- `compute.addresses.list`
- `compute.firewalls.delete`
- `compute.firewalls.list`
- `compute.forwardingRules.delete`
- `compute.forwardingRules.list`
- `compute.networks.delete`
- `compute.networks.list`
- `compute.networks.updatePolicy`
- `compute.routers.delete`
- `compute.routers.list`
- `compute.routes.list`
- `compute.subnetworks.delete`
- `compute.subnetworks.list`

Example 7.89. Required permissions for deleting load balancer resources

- `compute.regionBackendServices.delete`

- `compute.regionBackendServices.list`
- `compute.targetPools.delete`
- `compute.targetPools.list`

Example 7.90. Required permissions for deleting DNS resources

- `dns.changes.create`
- `dns.managedZones.delete`
- `dns.managedZones.get`
- `dns.managedZones.list`
- `dns.resourceRecordSets.delete`
- `dns.resourceRecordSets.list`

Example 7.91. Required permissions for deleting Service Account resources

- `iam.serviceAccounts.delete`
- `iam.serviceAccounts.get`
- `iam.serviceAccounts.list`
- `resourcemanager.projects.getIamPolicy`
- `resourcemanager.projects.setIamPolicy`

Example 7.92. Required permissions for deleting compute resources

- `compute.disks.delete`
- `compute.disks.list`
- `compute.instanceGroups.delete`
- `compute.instanceGroups.list`
- `compute.instances.delete`
- `compute.instances.list`
- `compute.instances.stop`
- `compute.machineTypes.list`

Example 7.93. Required for deleting storage resources

- `storage.buckets.delete`
- `storage.buckets.getIamPolicy`
- `storage.buckets.list`
- `storage.objects.delete`
- `storage.objects.list`

Example 7.94. Required permissions for deleting health check resources

- `compute.healthChecks.delete`
- `compute.healthChecks.list`
- `compute.httpHealthChecks.delete`
- `compute.httpHealthChecks.list`

Example 7.95. Required Images permissions for deletion

- `compute.images.delete`
- `compute.images.list`

Example 7.96. Required permissions to get Region related information

- `compute.regions.get`

Example 7.97. Required Deployment Manager permissions

- `deploymentmanager.deployments.create`
- `deploymentmanager.deployments.delete`
- `deploymentmanager.deployments.get`
- `deploymentmanager.deployments.list`
- `deploymentmanager.manifests.get`
- `deploymentmanager.operations.get`
- `deploymentmanager.resources.list`

#### 7.12.4.8. Supported GCP regions

You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
- **asia-northeast3** (Seoul, South Korea)
- **asia-south1** (Mumbai, India)
- **asia-south2** (Delhi, India)
- **asia-southeast1** (Jurong West, Singapore)
- **asia-southeast2** (Jakarta, Indonesia)
- **australia-southeast1** (Sydney, Australia)
- **australia-southeast2** (Melbourne, Australia)
- **europa-central2** (Warsaw, Poland)
- **europa-north1** (Hamina, Finland)
- **europa-southwest1** (Madrid, Spain)
- **europa-west1** (St. Ghislain, Belgium)
- **europa-west2** (London, England, UK)
- **europa-west3** (Frankfurt, Germany)
- **europa-west4** (Eemshaven, Netherlands)
- **europa-west6** (Zürich, Switzerland)
- **europa-west8** (Milan, Italy)
- **europa-west9** (Paris, France)
- **europa-west12** (Turin, Italy)
- **me-central1** (Doha, Qatar, Middle East)
- **me-west1** (Tel Aviv, Israel)
- **northamerica-northeast1** (Montréal, Québec, Canada)
- **northamerica-northeast2** (Toronto, Ontario, Canada)
- **southamerica-east1** (São Paulo, Brazil)

- **southamerica-west1** (Santiago, Chile)
- **us-central1** (Council Bluffs, Iowa, USA)
- **us-east1** (Moncks Corner, South Carolina, USA)
- **us-east4** (Ashburn, Northern Virginia, USA)
- **us-east5** (Columbus, Ohio)
- **us-south1** (Dallas, Texas)
- **us-west1** (The Dalles, Oregon, USA)
- **us-west2** (Los Angeles, California, USA)
- **us-west3** (Salt Lake City, Utah, USA)
- **us-west4** (Las Vegas, Nevada, USA)

#### NOTE

To determine which machine type instances are available by region and zone, see the Google [documentation](#).

#### 7.12.4.9. Installing and configuring CLI tools for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must install and configure the CLI tools for GCP.

#### Prerequisites

- You created a project to host your cluster.
- You created a service account and granted it the required permissions.

#### Procedure

1. Install the following binaries in **\$PATH**:

- **gcloud**
- **gsutil**

See [Install the latest Cloud SDK version](#) in the GCP documentation.

2. Authenticate using the **gcloud** tool with your configured service account.  
See [Authorizing with a service account](#) in the GCP documentation.

#### 7.12.5. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

7.12.5.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 7.39. Minimum required hosts

| Hosts                                                                   | Description                                                                                                                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine                                         | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines                                            | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.                                                                                                             |

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#) .

7.12.5.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 7.40. Minimum resource requirements

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio:  $(\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}$ .
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### 7.12.5.3. Tested instance types for GCP

The following Google Cloud Platform instance types have been tested with OpenShift Container Platform.

#### Example 7.98. Machine series

- **A2**
- **A3**
- **C2**
- **C2D**
- **C3**
- **C3D**
- **E2**
- **M1**

- N1
- N2
- N2D
- N4
- Tau T2D

#### 7.12.5.4. Using custom machine types

Using a custom machine type to install a OpenShift Container Platform cluster is supported.

Consider the following when using a custom machine type:

- Similar to predefined instance types, custom machine types must meet the minimum resource requirements for control plane and compute machines. For more information, see "Minimum resource requirements for cluster installation".
- The name of the custom machine type must adhere to the following syntax:  
**custom-`<number_of_cpus>-<amount_of_memory_in_mb>`**

For example, **custom-6-20480**.

#### 7.12.6. Creating the installation files for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the **install-config.yaml** file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate **var** partition during the preparation phases of installation.

##### 7.12.6.1. Optional: Creating a separate **/var** partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

## IMPORTANT

If you follow the steps to create a separate **/var** partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

## Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
```

## Example output

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and
$HOME/clusterconfig/openshift
```

3. Optional: Confirm that the installation program created manifests in the **clusterconfig/openshift** directory:

```
$ ls $HOME/clusterconfig/openshift/
```

## Example output

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

4. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
 labels:
 machineconfiguration.openshift.io/role: worker
```

```

name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> ❶
 partitions:
 - label: var
 start_mib: <partition_start_offset> ❷
 size_mib: <partition_size> ❸
 number: 5
 filesystems:
 - device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] ❹
 with_mount_unit: true

```

- ❶ The storage device name of the disk that you want to partition.
- ❷ When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ❸ The size of the data partition in mebibytes.
- ❹ The **prjquota** mount option must be enabled for filesystems used for container storage.

#### NOTE

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

6. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 7.12.6.2. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

## Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the **imageContentSources** values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.

## Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

### NOTE

Always delete the **~/powers** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powers
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

```
source: quay.io/openshift-release-dev/ocp-release
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
source: registry.redhat.io/ocp/release
```

For these values, use the **imageContentSources** that you recorded during mirror registry creation.

- e. Optional: Set the publishing strategy to **Internal**:

```
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

3. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
4. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### Additional resources

- [Installation configuration parameters for GCP](#)

### 7.12.6.3. Enabling Shielded VMs

You can use Shielded VMs when installing your cluster. Shielded VMs have extra security features including secure boot, firmware and integrity monitoring, and rootkit detection. For more information, see Google's documentation on [Shielded VMs](#).

### NOTE

Shielded VMs are currently not supported on clusters with 64-bit ARM infrastructures.

### Prerequisites

- You have created an **install-config.yaml** file.

### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:
  - a. To use shielded VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 secureBoot: Enabled
```

- b. To use shielded VMs for only compute machines:

```
compute:
- platform:
 gcp:
 secureBoot: Enabled
```

- c. To use shielded VMs for all machines:

```
platform:
gcp:
 defaultMachinePlatform:
 secureBoot: Enabled
```

#### 7.12.6.4. Enabling Confidential VMs

You can use Confidential VMs when installing your cluster. Confidential VMs encrypt data while it is being processed. For more information, see Google's documentation on [Confidential Computing](#). You can enable Confidential VMs and Shielded VMs at the same time, although they are not dependent on each other.

#### NOTE

Confidential VMs are currently not supported on 64-bit ARM architectures.

#### Prerequisites

- You have created an **install-config.yaml** file.

#### Procedure

- Use a text editor to edit the **install-config.yaml** file prior to deploying your cluster and add one of the following stanzas:

- a. To use confidential VMs for only control plane machines:

```
controlPlane:
 platform:
 gcp:
 confidentialCompute: Enabled 1
 type: n2d-standard-8 2
 onHostMaintenance: Terminate 3
```

- 1** Enable confidential VMs.
- 2** Specify a machine type that supports Confidential VMs. Confidential VMs require the N2D or C2D series of machine types. For more information on supported machine types, see [Supported operating systems and machine types](#).
- 3** Specify the behavior of the VM during a host maintenance event, such as a hardware or software update. For a machine that uses Confidential VM, this value must be set to **Terminate**, which stops the VM. Confidential VMs do not support live VM migration.

- b. To use confidential VMs for only compute machines:

```
compute:
- platform:
 gcp:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

- c. To use confidential VMs for all machines:

```
platform:
 gcp:
 defaultMachinePlatform:
 confidentialCompute: Enabled
 type: n2d-standard-8
 onHostMaintenance: Terminate
```

### 7.12.6.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

#### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
```

```

additionalTrustBundle: | ❹
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ❺

```

- ❶ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- ❷ A proxy URL to use for creating HTTPS connections outside the cluster.
- ❸ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- ❹ If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- ❺ Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 7.12.6.6. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

## IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

## Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

## IMPORTANT

If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

5. Check that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
  - a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
  - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
6. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
 privateZone: ❶
 id: mycluster-100419-private-zone
 publicZone: ❷
 id: example.openshift.com
status: {}
```

- ❶ ❷ Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

7. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> ❶
```

- ❶ For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the `./<installation_directory>/auth` directory:

## Additional resources

- [Optional: Adding the ingress DNS records](#)

## 7.12.7. Exporting common variables

### 7.12.7.1. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Google Cloud Platform (GCP). The infrastructure name is also used to locate the appropriate GCP resources during an OpenShift Container Platform installation. The provided Deployment Manager templates contain references to this infrastructure name, so you must extract it.

## Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

## Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

## Example output

```
openshift-vw9j6 1
```

- 1 The output of this command is your cluster name and a random string.

### 7.12.7.2. Exporting common variables for Deployment Manager templates

You must export a common set of variables that are used with the provided Deployment Manager templates used to assist in completing a user-provided infrastructure install on Google Cloud Platform (GCP).

## NOTE

Specific Deployment Manager templates can also require additional exported variables, which are detailed in their related procedures.

## Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Generate the Ignition config files for your cluster.
- Install the **jq** package.

## Procedure

1. Export the following common variables to be used by the provided Deployment Manager templates:

```
$ export BASE_DOMAIN='<base_domain>'
$ export BASE_DOMAIN_ZONE_NAME='<base_domain_zone_name>'
$ export NETWORK_CIDR='10.0.0.0/16'
$ export MASTER_SUBNET_CIDR='10.0.0.0/17'
$ export WORKER_SUBNET_CIDR='10.0.128.0/17'

$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
$ export CLUSTER_NAME=`jq -r .clusterName <installation_directory>/metadata.json`
$ export INFRA_ID=`jq -r .infraID <installation_directory>/metadata.json`
$ export PROJECT_NAME=`jq -r .gcp.projectID <installation_directory>/metadata.json`
$ export REGION=`jq -r .gcp.region <installation_directory>/metadata.json`
```

**1**

For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

## 7.12.8. Creating a VPC in GCP

You must create a VPC in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements. One way to create the VPC is to modify the provided Deployment Manager template.

## NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.

## Procedure

1. Copy the template from the **Deployment Manager template for the VPC** section of this topic and save it as **01\_vpc.py** on your computer. This template describes the VPC that your cluster requires.
2. Create a **01\_vpc.yaml** resource definition file:

```
$ cat <<EOF >01_vpc.yaml
imports:
- path: 01_vpc.py

resources:
- name: cluster-vpc
 type: 01_vpc.py
 properties:
 infra_id: '${INFRA_ID}' ❶
 region: '${REGION}' ❷
 master_subnet_cidr: '${MASTER_SUBNET_CIDR}' ❸
 worker_subnet_cidr: '${WORKER_SUBNET_CIDR}' ❹
EOF
```

- ❶ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❷ **region** is the region to deploy the cluster into, for example **us-central1**.
- ❸ **master\_subnet\_cidr** is the CIDR for the master subnet, for example **10.0.0.0/17**.
- ❹ **worker\_subnet\_cidr** is the CIDR for the worker subnet, for example **10.0.128.0/17**.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-vpc --config 01_vpc.yaml
```

### 7.12.8.1. Deployment Manager template for the VPC

You can use the following Deployment Manager template to deploy the VPC that you need for your OpenShift Container Platform cluster:

#### Example 7.99. 01\_vpc.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-network',
 'type': 'compute.v1.network',
 'properties': {
 'region': context.properties['region'],
 'autoCreateSubnetworks': False
```

```

 }
 }, {
 'name': context.properties['infra_id'] + '-master-subnet',
 'type': 'compute.v1.subnetwork',
 'properties': {
 'region': context.properties['region'],
 'network': $(ref.' + context.properties['infra_id'] + '-network.selfLink)',
 'ipCidrRange': context.properties['master_subnet_cidr']
 }
 }, {
 'name': context.properties['infra_id'] + '-worker-subnet',
 'type': 'compute.v1.subnetwork',
 'properties': {
 'region': context.properties['region'],
 'network': $(ref.' + context.properties['infra_id'] + '-network.selfLink)',
 'ipCidrRange': context.properties['worker_subnet_cidr']
 }
 }, {
 'name': context.properties['infra_id'] + '-router',
 'type': 'compute.v1.router',
 'properties': {
 'region': context.properties['region'],
 'network': $(ref.' + context.properties['infra_id'] + '-network.selfLink)',
 'nats': [{
 'name': context.properties['infra_id'] + '-nat-master',
 'natIpAllocateOption': 'AUTO_ONLY',
 'minPortsPerVm': 7168,
 'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
 'subnetworks': [{
 'name': $(ref.' + context.properties['infra_id'] + '-master-subnet.selfLink)',
 'sourceIpRangesToNat': ['ALL_IP_RANGES']
 }]
 }]
 }, {
 'name': context.properties['infra_id'] + '-nat-worker',
 'natIpAllocateOption': 'AUTO_ONLY',
 'minPortsPerVm': 512,
 'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
 'subnetworks': [{
 'name': $(ref.' + context.properties['infra_id'] + '-worker-subnet.selfLink)',
 'sourceIpRangesToNat': ['ALL_IP_RANGES']
 }]
 }
]
}
}
return {'resources': resources}

```

### 7.12.9. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

#### 7.12.9.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

### 7.12.9.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**Table 7.41. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
|          | <b>10256</b>       | openshift-sdn                                                                                                                               |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |

| Protocol | Port | Description                                |
|----------|------|--------------------------------------------|
| ESP      | N/A  | IPsec Encapsulating Security Payload (ESP) |

**Table 7.42. Ports used for all-machine to control plane communications**

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

**Table 7.43. Ports used for control plane machine to control plane machine communications**

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

## 7.12.10. Creating load balancers in GCP

You must configure load balancers in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

### Procedure

1. Copy the template from the **Deployment Manager template for the internal load balancer** section of this topic and save it as **02\_lb\_int.py** on your computer. This template describes the internal load balancing objects that your cluster requires.
2. For an external cluster, also copy the template from the **Deployment Manager template for the external load balancer** section of this topic and save it as **02\_lb\_ext.py** on your computer. This template describes the external load balancing objects that your cluster requires.
3. Export the variables that the deployment template uses:
  - a. Export the cluster network location:

```
$ export CLUSTER_NETWORK=(`gcloud compute networks describe ${INFRA_ID}-
network --format json | jq -r .selfLink`)
```

- b. Export the control plane subnet location:

```
$ export CONTROL_SUBNET=(`gcloud compute networks subnets describe
${INFRA_ID}-master-subnet --region=${REGION} --format json | jq -r .selfLink`)
```

- c. Export the three zones that the cluster uses:

```
$ export ZONE_0=(`gcloud compute regions describe ${REGION} --format=json | jq -r
.zones[0] | cut -d "/" -f9`)
```

```
$ export ZONE_1=(`gcloud compute regions describe ${REGION} --format=json | jq -r
.zones[1] | cut -d "/" -f9`)
```

```
$ export ZONE_2=(`gcloud compute regions describe ${REGION} --format=json | jq -r
.zones[2] | cut -d "/" -f9`)
```

4. Create a **02\_infra.yaml** resource definition file:

```
$ cat <<EOF >02_infra.yaml
imports:
- path: 02_lb_ext.py
- path: 02_lb_int.py ❶
resources:
- name: cluster-lb-ext ❷
 type: 02_lb_ext.py
 properties:
 infra_id: '${INFRA_ID}' ❸
 region: '${REGION}' ❹
- name: cluster-lb-int
 type: 02_lb_int.py
 properties:
 cluster_network: '${CLUSTER_NETWORK}'
 control_subnet: '${CONTROL_SUBNET}' ❺
 infra_id: '${INFRA_ID}'
 region: '${REGION}'
 zones: ❻
 - '${ZONE_0}'
 - '${ZONE_1}'
 - '${ZONE_2}'
EOF
```

❶ ❷ Required only when deploying an external cluster.

❸ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.

❹ **region** is the region to deploy the cluster into, for example **us-central1**.

❺ **control\_subnet** is the URI to the control subnet.

❻ **zones** are the zones to deploy the control plane instances into, like **us-east1-b**, **us-east1-c**,

5. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:

```
$ export CLUSTER_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-ip --region=${REGION} --format json | jq -r .address`
```

7. For an external cluster, also export the cluster public IP address:

```
$ export CLUSTER_PUBLIC_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-public-ip --region=${REGION} --format json | jq -r .address`
```

### 7.12.10.1. Deployment Manager template for the external load balancer

You can use the following Deployment Manager template to deploy the external load balancer that you need for your OpenShift Container Platform cluster:

#### Example 7.100. 02\_lb\_ext.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-cluster-public-ip',
 'type': 'compute.v1.address',
 'properties': {
 'region': context.properties['region']
 }
 }, {
 # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
 # probe for kube-apiserver
 'name': context.properties['infra_id'] + '-api-http-health-check',
 'type': 'compute.v1.httpHealthCheck',
 'properties': {
 'port': 6080,
 'requestPath': '/readyz'
 }
 }, {
 'name': context.properties['infra_id'] + '-api-target-pool',
 'type': 'compute.v1.targetPool',
 'properties': {
 'region': context.properties['region'],
 'healthChecks': ['$(ref.' + context.properties['infra_id'] + '-api-http-health-check.selfLink)'],
 'instances': []
 }
 }, {
 'name': context.properties['infra_id'] + '-api-forwarding-rule',
 'type': 'compute.v1.forwardingRule',
 'properties': {
 'region': context.properties['region'],
 'IPAddress': '$(ref.' + context.properties['infra_id'] + '-cluster-public-ip.selfLink)',
 'target': '$(ref.' + context.properties['infra_id'] + '-api-target-pool.selfLink)',
 'portRange': '6443'
```

```

 }
 }}

 return {'resources': resources}

```

### 7.12.10.2. Deployment Manager template for the internal load balancer

You can use the following Deployment Manager template to deploy the internal load balancer that you need for your OpenShift Container Platform cluster:

#### Example 7.101. **02\_lb\_int.py** Deployment Manager template

```

def GenerateConfig(context):

 backends = []
 for zone in context.properties['zones']:
 backends.append({
 'group': '${ref.' + context.properties['infra_id'] + '-master-' + zone + '-ig' + '.selfLink}'
 })

 resources = [{
 'name': context.properties['infra_id'] + '-cluster-ip',
 'type': 'compute.v1.address',
 'properties': {
 'addressType': 'INTERNAL',
 'region': context.properties['region'],
 'subnetwork': context.properties['control_subnet']
 }
 }, {
 # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
 # probe for kube-apiserver
 'name': context.properties['infra_id'] + '-api-internal-health-check',
 'type': 'compute.v1.healthCheck',
 'properties': {
 'httpsHealthCheck': {
 'port': 6443,
 'requestPath': '/readyz'
 },
 'type': "HTTPS"
 }
 }, {
 'name': context.properties['infra_id'] + '-api-internal-backend-service',
 'type': 'compute.v1.regionBackendService',
 'properties': {
 'backends': backends,
 'healthChecks': ['${ref.' + context.properties['infra_id'] + '-api-internal-health-
check.selfLink}'],
 'loadBalancingScheme': 'INTERNAL',
 'region': context.properties['region'],
 'protocol': 'TCP',
 'timeoutSec': 120
 }
 }, {
 'name': context.properties['infra_id'] + '-api-internal-forwarding-rule',

```

```

 'type': 'compute.v1.forwardingRule',
 'properties': {
 'backendService': '${ref.' + context.properties['infra_id'] + '-api-internal-backend-
service.selfLink}',
 'IPAddress': '${ref.' + context.properties['infra_id'] + '-cluster-ip.selfLink}',
 'loadBalancingScheme': 'INTERNAL',
 'ports': ['6443','22623'],
 'region': context.properties['region'],
 'subnetwork': context.properties['control_subnet']
 }
]
}

for zone in context.properties['zones']:
 resources.append({
 'name': context.properties['infra_id'] + '-master-' + zone + '-ig',
 'type': 'compute.v1.instanceGroup',
 'properties': {
 'namedPorts': [
 {
 'name': 'ignition',
 'port': 22623
 }, {
 'name': 'https',
 'port': 6443
 }
],
 'network': context.properties['cluster_network'],
 'zone': zone
 }
 })

return {'resources': resources}

```

You will need this template in addition to the **02\_lb\_ext.py** template when you create an external cluster.

### 7.12.11. Creating a private DNS zone in GCP

You must configure a private DNS zone in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create this component is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.

- Create and configure a VPC and associated subnets in GCP.

## Procedure

1. Copy the template from the **Deployment Manager template for the private DNS** section of this topic and save it as **02\_dns.py** on your computer. This template describes the private DNS objects that your cluster requires.
2. Create a **02\_dns.yaml** resource definition file:

```
$ cat <<EOF >02_dns.yaml
imports:
- path: 02_dns.py

resources:
- name: cluster-dns
 type: 02_dns.py
 properties:
 infra_id: '${INFRA_ID}' ❶
 cluster_domain: '${CLUSTER_NAME}.${BASE_DOMAIN}' ❷
 cluster_network: '${CLUSTER_NETWORK}' ❸
EOF
```

- ❶ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❷ **cluster\_domain** is the domain for the cluster, for example **openshift.example.com**.
- ❸ **cluster\_network** is the **selfLink** URL to the cluster network.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-dns --config 02_dns.yaml
```

4. The templates do not create DNS entries due to limitations of Deployment Manager, so you must create them manually:
  - a. Add the internal DNS entries:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name
api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-
private-zone
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-
int.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-
private-zone
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
```

- b. For an external cluster, also add the external DNS entries:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction add ${CLUSTER_PUBLIC_IP} --name
```

```
api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone
${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
```

#### 7.12.11.1. Deployment Manager template for the private DNS

You can use the following Deployment Manager template to deploy the private DNS that you need for your OpenShift Container Platform cluster:

##### Example 7.102. 02\_dns.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-private-zone',
 'type': 'dns.v1.managedZone',
 'properties': {
 'description': '',
 'dnsName': context.properties['cluster_domain'] + '.',
 'visibility': 'private',
 'privateVisibilityConfig': {
 'networks': [{
 'networkUrl': context.properties['cluster_network']
 }]
 }
 }
 }]

 return {'resources': resources}
```

#### 7.12.12. Creating firewall rules in GCP

You must create firewall rules in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

#### Procedure

1. Copy the template from the **Deployment Manager template for firewall rules** section of this topic and save it as **03\_firewall.py** on your computer. This template describes the security groups that your cluster requires.
2. Create a **03\_firewall.yaml** resource definition file:

```
$ cat <<EOF >03_firewall.yaml
imports:
- path: 03_firewall.py

resources:
- name: cluster-firewall
 type: 03_firewall.py
 properties:
 allowed_external_cidr: '0.0.0.0/0' ❶
 infra_id: '${INFRA_ID}' ❷
 cluster_network: '${CLUSTER_NETWORK}' ❸
 network_cidr: '${NETWORK_CIDR}' ❹
EOF
```

- ❶ **allowed\_external\_cidr** is the CIDR range that can access the cluster API and SSH to the bootstrap host. For an internal cluster, set this value to **\${NETWORK\_CIDR}**.
- ❷ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❸ **cluster\_network** is the **selfLink** URL to the cluster network.
- ❹ **network\_cidr** is the CIDR of the VPC network, for example **10.0.0.0/16**.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-firewall --config
03_firewall.yaml
```

### 7.12.12.1. Deployment Manager template for firewall rules

You can use the following Deployment Manager template to deploy the firewall rules that you need for your OpenShift Container Platform cluster:

#### Example 7.103. 03\_firewall.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-bootstrap-in-ssh',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['22']
 }],
 'sourceRanges': [context.properties['allowed_external_cidr']],
```

```

 'targetTags': [context.properties['infra_id'] + '-bootstrap']
 }, {
 'name': context.properties['infra_id'] + '-api',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{
 'IPProtocol': 'tcp',
 'ports': ['6443']
 }],
 'sourceRanges': [context.properties['allowed_external_cidr']],
 'targetTags': [context.properties['infra_id'] + '-master']
 }
 }, {
 'name': context.properties['infra_id'] + '-health-checks',
 'type': 'compute.v1.firewall',
 'properties': {
 'network': context.properties['cluster_network'],
 'allowed': [{

]
 }
}

```

```

]
 }
}}

return {'resources': resources}

```

### 7.12.13. Creating IAM roles in GCP

You must create IAM roles in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

#### Procedure

1. Copy the template from the **Deployment Manager template for IAM roles** section of this topic and save it as **03\_iam.py** on your computer. This template describes the IAM roles that your cluster requires.
2. Create a **03\_iam.yaml** resource definition file:

```

$ cat <<EOF >03_iam.yaml
imports:
- path: 03_iam.py
resources:
- name: cluster-iam
 type: 03_iam.py
 properties:
 infra_id: '${INFRA_ID}' 1
EOF

```

- 1** **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.

3. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-iam --config 03_iam.yaml
```

4. Export the variable for the master service account:

```
$ export MASTER_SERVICE_ACCOUNT=$(gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-m@${PROJECT_NAME}." --format json | jq -r '[0].email')
```

5. Export the variable for the worker service account:

```
$ export WORKER_SERVICE_ACCOUNT=$(gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '[0].email')
```

6. Export the variable for the subnet that hosts the compute machines:

```
$ export COMPUTE_SUBNET=$(gcloud compute networks subnets describe ${INFRA_ID}-
worker-subnet --region=${REGION} --format json | jq -r .selfLink)
```

7. The templates do not create the policy bindings due to limitations of Deployment Manager, so you must create them manually:

```
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.instanceAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.securityAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/iam.serviceAccountUser"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/storage.admin"

$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/compute.viewer"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
"serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
```

8. Create a service account key and store it locally for later use:

```
$ gcloud iam service-accounts keys create service-account-key.json --iam-
account=${MASTER_SERVICE_ACCOUNT}
```

### 7.12.13.1. Deployment Manager template for IAM roles

You can use the following Deployment Manager template to deploy the IAM roles that you need for your OpenShift Container Platform cluster:

#### Example 7.104. 03\_iam.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-master-node-sa',
 'type': 'iam.v1.serviceAccount',
 'properties': {
 'accountId': context.properties['infra_id'] + '-m',
 'displayName': context.properties['infra_id'] + '-master-node'
 }
 }]
```

```

 }, {
 'name': context.properties['infra_id'] + '-worker-node-sa',
 'type': 'iam.v1.serviceAccount',
 'properties': {
 'accountId': context.properties['infra_id'] + '-w',
 'displayName': context.properties['infra_id'] + '-worker-node'
 }
 }
]
}

return {'resources': resources}

```

### 7.12.14. Creating the RHCOS cluster image for the GCP infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Google Cloud Platform (GCP) for your OpenShift Container Platform nodes.

#### Procedure

1. Obtain the RHCOS image from the [RHCOS image mirror](#) page.

#### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The file name contains the OpenShift Container Platform version number in the format **rhcos-  
<version>-<arch>-gcp.<arch>.tar.gz**.

2. Create the Google storage bucket:

```
$ gsutil mb gs://<bucket_name>
```

3. Upload the RHCOS image to the Google storage bucket:

```
$ gsutil cp <downloaded_image_file_path>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz
gs://<bucket_name>
```

4. Export the uploaded RHCOS image location as a variable:

```
$ export IMAGE_SOURCE=gs://<bucket_name>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz
```

5. Create the cluster image:

```
$ gcloud compute images create "${INFRA_ID}-rhcos-image" \
 --source-uri="${IMAGE_SOURCE}"
```

### 7.12.15. Creating the bootstrap machine in GCP

You must create the bootstrap machine in Google Cloud Platform (GCP) to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Deployment Manager template.

## NOTE

If you do not use the provided Deployment Manager template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

## Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Ensure pyOpenSSL is installed.

## Procedure

1. Copy the template from the **Deployment Manager template for the bootstrap machine** section of this topic and save it as **04\_bootstrap.py** on your computer. This template describes the bootstrap machine that your cluster requires.
2. Export the location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that the installation program requires:

```
$ export CLUSTER_IMAGE=(`gcloud compute images describe ${INFRA_ID}-rhcos-image --
format json | jq -r .selfLink`)
```

3. Create a bucket and upload the **bootstrap.ign** file:

```
$ gsutil mb gs://${INFRA_ID}-bootstrap-ignition
```

```
$ gsutil cp <installation_directory>/bootstrap.ign gs://${INFRA_ID}-bootstrap-ignition/
```

4. Create a signed URL for the bootstrap instance to use to access the Ignition config. Export the URL from the output as a variable:

```
$ export BOOTSTRAP_IGN=`gsutil signurl -d 1h service-account-key.json gs://${INFRA_ID}-
bootstrap-ignition/bootstrap.ign | grep "^gs:" | awk '{print $5}'`
```

5. Create a **04\_bootstrap.yaml** resource definition file:

```
$ cat <<EOF >04_bootstrap.yaml
imports:
- path: 04_bootstrap.py
```

```
resources:
- name: cluster-bootstrap
 type: 04_bootstrap.py
 properties:
 infra_id: '${INFRA_ID}' ❶
 region: '${REGION}' ❷
 zone: '${ZONE_0}' ❸

 cluster_network: '${CLUSTER_NETWORK}' ❹
 control_subnet: '${CONTROL_SUBNET}' ❺
 image: '${CLUSTER_IMAGE}' ❻
 machine_type: 'n1-standard-4' ❼
 root_volume_size: '128' ❽

 bootstrap_ign: '${BOOTSTRAP_IGN}' ❾
EOF
```

- ❶ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❷ **region** is the region to deploy the cluster into, for example **us-central1**.
- ❸ **zone** is the zone to deploy the bootstrap instance into, for example **us-central1-b**.
- ❹ **cluster\_network** is the **selfLink** URL to the cluster network.
- ❺ **control\_subnet** is the **selfLink** URL to the control subnet.
- ❻ **image** is the **selfLink** URL to the RHCOS image.
- ❼ **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- ❽ **root\_volume\_size** is the boot disk size for the bootstrap machine.
- ❾ **bootstrap\_ign** is the URL output when creating a signed URL.

6. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-bootstrap --config
04_bootstrap.yaml
```

7. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the bootstrap machine manually.

a. Add the bootstrap instance to the internal load balancer instance group:

```
$ gcloud compute instance-groups unmanaged add-instances \
 ${INFRA_ID}-bootstrap-ig --zone=${ZONE_0} --instances=${INFRA_ID}-bootstrap
```

b. Add the bootstrap instance group to the internal load balancer backend service:

```
$ gcloud compute backend-services add-backend \
 ${INFRA_ID}-api-internal-backend-service --region=${REGION} --instance-
group=${INFRA_ID}-bootstrap-ig --instance-group-zone=${ZONE_0}
```

### 7.12.15.1. Deployment Manager template for the bootstrap machine

You can use the following Deployment Manager template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

#### Example 7.105. 04\_bootstrap.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-bootstrap-public-ip',
 'type': 'compute.v1.address',
 'properties': {
 'region': context.properties['region']
 }
 }, {
 'name': context.properties['infra_id'] + '-bootstrap',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': '{"ignition":{"config":{"replace":{"source":"' + context.properties['bootstrap_ign']
+ '"},"version":"3.2.0"}}}',
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet'],
 'accessConfigs': [{
 'natIP': '$(ref.' + context.properties['infra_id'] + '-bootstrap-public-ip.address)'
 }]
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
 context.properties['infra_id'] + '-bootstrap'
]
 },
 'zone': context.properties['zone']
 }
 }, {
 'name': context.properties['infra_id'] + '-bootstrap-ig',
 'type': 'compute.v1.instanceGroup',
 'properties': {
```

```

 'namedPorts': [
 {
 'name': 'ignition',
 'port': 22623
 }, {
 'name': 'https',
 'port': 6443
 }
],
 'network': context.properties['cluster_network'],
 'zone': context.properties['zone']
 }
}
]]

return {'resources': resources}

```

### 7.12.16. Creating the control plane machines in GCP

You must create the control plane machines in Google Cloud Platform (GCP) for your cluster to use. One way to create these machines is to modify the provided Deployment Manager template.

#### NOTE

If you do not use the provided Deployment Manager template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

#### Procedure

1. Copy the template from the **Deployment Manager template for control plane machines** section of this topic and save it as **05\_control\_plane.py** on your computer. This template describes the control plane machines that your cluster requires.
2. Export the following variable required by the resource definition:

```
$ export MASTER_IGNITION=`cat <installation_directory>/master.ign`
```

3. Create a **05\_control\_plane.yaml** resource definition file:

■

```
$ cat <<EOF >05_control_plane.yaml
imports:
- path: 05_control_plane.py

resources:
- name: cluster-control-plane
 type: 05_control_plane.py
 properties:
 infra_id: '${INFRA_ID}' ❶
 zones: ❷
 - '${ZONE_0}'
 - '${ZONE_1}'
 - '${ZONE_2}'

 control_subnet: '${CONTROL_SUBNET}' ❸
 image: '${CLUSTER_IMAGE}' ❹
 machine_type: 'n1-standard-4' ❺
 root_volume_size: '128'
 service_account_email: '${MASTER_SERVICE_ACCOUNT}' ❻

 ignition: '${MASTER_IGNITION}' ❼
EOF
```

- ❶ **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- ❷ **zones** are the zones to deploy the control plane instances into, for example **us-central1-a**, **us-central1-b**, and **us-central1-c**.
- ❸ **control\_subnet** is the **selfLink** URL to the control subnet.
- ❹ **image** is the **selfLink** URL to the RHCOS image.
- ❺ **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- ❻ **service\_account\_email** is the email address for the master service account that you created.
- ❼ **ignition** is the contents of the **master.ign** file.

4. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-control-plane --config
05_control_plane.yaml
```

5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

- Run the following commands to add the control plane machines to the appropriate instance groups:

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_0}-ig --zone=${ZONE_0} --instances=${INFRA_ID}-master-0
```

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_1}-ig --zone=${ZONE_1} --instances=${INFRA_ID}-master-1
```

```
$ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-
${ZONE_2}-ig --zone=${ZONE_2} --instances=${INFRA_ID}-master-2
```

- For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_0}" --instances=${INFRA_ID}-master-0
```

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_1}" --instances=${INFRA_ID}-master-1
```

```
$ gcloud compute target-pools add-instances ${INFRA_ID}-api-target-pool --instances-
zone="${ZONE_2}" --instances=${INFRA_ID}-master-2
```

### 7.12.16.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

#### Example 7.106. 05\_control\_plane.py Deployment Manager template

```
def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-master-0',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][0] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zones'][0] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
```

```

 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 },
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
]
 },
 'zone': context.properties['zones'][0]
}
}, {
 'name': context.properties['infra_id'] + '-master-1',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][1] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zones'][1] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
]
 },
 'zone': context.properties['zones'][1]
 }
}, {
 'name': context.properties['infra_id'] + '-master-2',
 'type': 'compute.v1.instance',
 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'diskType': 'zones/' + context.properties['zones'][2] + '/diskTypes/pd-ssd',
 'sourceImage': context.properties['image']
 }
 }],
 }
}

```

```

 },
 'machineType': 'zones/' + context.properties['zones'][2] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['control_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-master',
]
 },
 'zone': context.properties['zones'][2]
 }
}
}

return {'resources': resources}

```

### 7.12.17. Wait for bootstrap completion and remove bootstrap resources in GCP

After you create all of the required infrastructure in Google Cloud Platform (GCP), wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

#### Procedure

1. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install wait-for bootstrap-complete --dir <installation_directory> \ 1
--log-level info 2
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

If the command exits without a **FATAL** warning, your production control plane has initialized.

2. Delete the bootstrap resources:

```
$ gcloud compute backend-services remove-backend ${INFRA_ID}-api-internal-backend-
service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-ig --instance-group-
zone=${ZONE_0}
```

```
$ gsutil rm gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign
```

```
$ gsutil rb gs://${INFRA_ID}-bootstrap-ignition
```

```
$ gcloud deployment-manager deployments delete ${INFRA_ID}-bootstrap
```

### 7.12.18. Creating additional worker machines in GCP

You can create worker machines in Google Cloud Platform (GCP) for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Deployment Manager template. Additional instances can be launched by including additional resources of type **06\_worker.py** in the file.

#### NOTE

If you do not use the provided Deployment Manager template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

#### Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

- Create the control plane machines.

## Procedure

1. Copy the template from the **Deployment Manager template for worker machines** section of this topic and save it as **06\_worker.py** on your computer. This template describes the worker machines that your cluster requires.
2. Export the variables that the resource definition uses.

- a. Export the subnet that hosts the compute machines:

```
$ export COMPUTE_SUBNET=$(gcloud compute networks subnets describe
${INFRA_ID}-worker-subnet --region=${REGION} --format json | jq -r .selfLink)
```

- b. Export the email address for your service account:

```
$ export WORKER_SERVICE_ACCOUNT=$(gcloud iam service-accounts list --filter
"email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '[0].email')
```

- c. Export the location of the compute machine Ignition config file:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign`
```

3. Create a **06\_worker.yaml** resource definition file:

```
$ cat <<EOF >06_worker.yaml
imports:
- path: 06_worker.py

resources:
- name: 'worker-0' 1
 type: 06_worker.py
 properties:
 infra_id: '${INFRA_ID}' 2
 zone: '${ZONE_0}' 3
 compute_subnet: '${COMPUTE_SUBNET}' 4
 image: '${CLUSTER_IMAGE}' 5
 machine_type: 'n1-standard-4' 6
 root_volume_size: '128'
 service_account_email: '${WORKER_SERVICE_ACCOUNT}' 7
 ignition: '${WORKER_IGNITION}' 8
- name: 'worker-1'
 type: 06_worker.py
 properties:
 infra_id: '${INFRA_ID}' 9
 zone: '${ZONE_1}' 10
 compute_subnet: '${COMPUTE_SUBNET}' 11
 image: '${CLUSTER_IMAGE}' 12
 machine_type: 'n1-standard-4' 13
 root_volume_size: '128'
```

```

 service_account_email: '${WORKER_SERVICE_ACCOUNT}' 14
 ignition: '${WORKER_IGNITION}' 15
EOF

```

- 1 **name** is the name of the worker machine, for example **worker-0**.
- 2 9 **infra\_id** is the **INFRA\_ID** infrastructure name from the extraction step.
- 3 10 **zone** is the zone to deploy the worker machine into, for example **us-central1-a**.
- 4 11 **compute\_subnet** is the **selfLink** URL to the compute subnet.
- 5 12 **image** is the **selfLink** URL to the RHCOS image. <sup>1</sup>
- 6 13 **machine\_type** is the machine type of the instance, for example **n1-standard-4**.
- 7 14 **service\_account\_email** is the email address for the worker service account that you created.
- 8 15 **ignition** is the contents of the **worker.ign** file.

4. Optional: If you want to launch additional instances, include additional resources of type **06\_worker.py** in your **06\_worker.yaml** resource definition file.
5. Create the deployment by using the **gcloud** CLI:

```

$ gcloud deployment-manager deployments create ${INFRA_ID}-worker --config
06_worker.yaml

```

1. To use a GCP Marketplace image, specify the offer to use:
  - OpenShift Container Platform:  
<https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-ocp-413-x86-64-202305021736>
  - OpenShift Platform Plus: <https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-opp-413-x86-64-202305021736>
  - OpenShift Kubernetes Engine:  
<https://www.googleapis.com/compute/v1/projects/redhat-marketplace-public/global/images/redhat-coreos-oke-413-x86-64-202305021736>

### 7.12.18.1. Deployment Manager template for worker machines

You can use the following Deployment Manager template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

#### Example 7.107. 06\_worker.py Deployment Manager template

```

def GenerateConfig(context):

 resources = [{
 'name': context.properties['infra_id'] + '-' + context.env['name'],
 'type': 'compute.v1.instance',

```

```

 'properties': {
 'disks': [{
 'autoDelete': True,
 'boot': True,
 'initializeParams': {
 'diskSizeGb': context.properties['root_volume_size'],
 'sourceImage': context.properties['image']
 }
 }],
 'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' +
context.properties['machine_type'],
 'metadata': {
 'items': [{
 'key': 'user-data',
 'value': context.properties['ignition']
 }]
 },
 'networkInterfaces': [{
 'subnetwork': context.properties['compute_subnet']
 }],
 'serviceAccounts': [{
 'email': context.properties['service_account_email'],
 'scopes': ['https://www.googleapis.com/auth/cloud-platform']
 }],
 'tags': {
 'items': [
 context.properties['infra_id'] + '-worker',
]
 },
 'zone': context.properties['zone']
 }
]
}

return {'resources': resources}

```

### 7.12.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

### 7.12.20. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

#### Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
 -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

#### TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration** → **Cluster Settings** → **Configuration** → **OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

### 7.12.21. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

#### Prerequisites

- You added machines to your cluster.

#### Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

#### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 63m v1.27.3
```

```
master-1 Ready master 63m v1.27.3
master-2 Ready master 64m v1.27.3
```

The output lists all of the machines that you created.

## NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

## Example output

```
NAME AGE REQUESTOR CONDITION
csr-8b2br 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
csr-8vnps 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

## NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

## NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

<sup>1</sup> **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

#### NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

#### Example output

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

<sup>1</sup> **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

#### Example output

| NAME     | STATUS | ROLES  | AGE | VERSION |
|----------|--------|--------|-----|---------|
| master-0 | Ready  | master | 73m | v1.27.3 |
| master-1 | Ready  | master | 73m | v1.27.3 |
| master-2 | Ready  | master | 74m | v1.27.3 |
| worker-0 | Ready  | worker | 11m | v1.27.3 |
| worker-1 | Ready  | worker | 11m | v1.27.3 |

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

**7.12.22. Optional: Adding the ingress DNS records**

If you removed the DNS zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the ingress load balancer. You can create either a wildcard **\*.apps.{baseDomain}**, or specific records. You can use A, CNAME, and other records per your requirements.

**Prerequisites**

- Configure a GCP account.
- Remove the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.
- Create the worker machines.

**Procedure**

1. Wait for the Ingress router to create a load balancer and populate the **EXTERNAL-IP** field:

```
$ oc -n openshift-ingress get service router-default
```

**Example output**

| NAME           | TYPE         | CLUSTER-IP    | EXTERNAL-IP    | PORT(S)                    | AGE |
|----------------|--------------|---------------|----------------|----------------------------|-----|
| router-default | LoadBalancer | 172.30.18.154 | 35.233.157.184 | 80:32288/TCP,443:31215/TCP | 98  |

## 2. Add the A record to your zones:

- To use A records:
  - i. Export the variable for the router IP address:

```
$ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
```

- ii. Add the A record to the private zones:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name
*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
```

- iii. For an external cluster, also add the A record to the public zones:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name
*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction execute --zone
${BASE_DOMAIN_ZONE_NAME}
```

- To add explicit domains instead of using a wildcard, create entries for each of the cluster's current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}
{"\n"}{end}{end}' routes
```

### Example output

```
oauth-openshift.apps.your.cluster.domain.example.com
console-openshift-console.apps.your.cluster.domain.example.com
downloads-openshift-console.apps.your.cluster.domain.example.com
alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com
prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com
```

## 7.12.23. Completing a GCP installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Google Cloud Platform (GCP) user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

### Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned GCP infrastructure.
- Install the **oc** CLI and log in.

Procedure

- 1. Complete the cluster installation:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

- 2. Observe the running state of your cluster.

- a. Run the following command to view the current cluster version and status:

```
$ oc get clusterversion
```

Example output

```
NAME VERSION AVAILABLE PROGRESSING SINCE STATUS
version False True 24m Working towards 4.5.4: 99% complete
```

- b. Run the following command to view the Operators managed on the control plane by the Cluster Version Operator (CVO):

```
$ oc get clusteroperators
```

Example output

```
NAME SINCE VERSION AVAILABLE PROGRESSING DEGRADED
authentication 4.5.4 True False False 7m56s
cloud-credential 4.5.4 True False False 31m
```

|                                          |       |       |       |       |     |
|------------------------------------------|-------|-------|-------|-------|-----|
| cluster-autoscaler                       | 4.5.4 | True  | False | False | 16m |
| console                                  | 4.5.4 | True  | False | False | 10m |
| csi-snapshot-controller                  | 4.5.4 | True  | False | False | 16m |
| dns                                      | 4.5.4 | True  | False | False | 22m |
| etcd                                     | 4.5.4 | False | False | False | 25s |
| image-registry                           | 4.5.4 | True  | False | False | 16m |
| ingress                                  | 4.5.4 | True  | False | False | 16m |
| insights                                 | 4.5.4 | True  | False | False | 17m |
| kube-apiserver                           | 4.5.4 | True  | False | False | 19m |
| kube-controller-manager                  | 4.5.4 | True  | False | False | 20m |
| kube-scheduler                           | 4.5.4 | True  | False | False | 20m |
| kube-storage-version-migrator            | 4.5.4 | True  | False | False | 16m |
| machine-api                              | 4.5.4 | True  | False | False | 22m |
| machine-config                           | 4.5.4 | True  | False | False | 22m |
| marketplace                              | 4.5.4 | True  | False | False | 16m |
| monitoring                               | 4.5.4 | True  | False | False | 10m |
| network                                  | 4.5.4 | True  | False | False | 23m |
| node-tuning                              | 4.5.4 | True  | False | False | 23m |
| openshift-apiserver                      | 4.5.4 | True  | False | False | 17m |
| openshift-controller-manager             | 4.5.4 | True  | False | False | 15m |
| openshift-samples                        | 4.5.4 | True  | False | False | 16m |
| operator-lifecycle-manager               | 4.5.4 | True  | False | False | 22m |
| operator-lifecycle-manager-catalog       | 4.5.4 | True  | False | False | 22m |
| operator-lifecycle-manager-packageserver | 4.5.4 | True  | False | False | 18m |
| service-ca                               | 4.5.4 | True  | False | False | 23m |
| service-catalog-apiserver                | 4.5.4 | True  | False | False | 23m |
| service-catalog-controller-manager       | 4.5.4 | True  | False | False | 23m |
| storage                                  | 4.5.4 | True  | False | False | 17m |

- c. Run the following command to view your cluster pods:

```
$ oc get pods --all-namespaces
```

### Example output

```

NAMESPACE NAME
READY STATUS RESTARTS AGE
kube-system etcd-member-ip-10-0-3-111.us-east-
2.compute.internal 1/1 Running 0 35m
kube-system etcd-member-ip-10-0-3-239.us-east-
2.compute.internal 1/1 Running 0 37m

```

When the current cluster version is **AVAILABLE**, the installation is complete.

### 7.12.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 7.12.25. Next steps

- [Customize your cluster](#).
- [Configure image streams](#) for the Cluster Samples Operator and the **must-gather** tool.
- Learn how to [use Operator Lifecycle Manager \(OLM\) on restricted networks](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).
- If necessary, you can [opt out of remote health reporting](#).
- If necessary, see [Registering your disconnected cluster](#)

## 7.13. INSTALLING A THREE-NODE CLUSTER ON GCP

In OpenShift Container Platform version 4.14, you can install a three-node cluster on Google Cloud Platform (GCP). A three-node cluster consists of three control plane machines, which also act as compute machines. This type of cluster provides a smaller, more resource efficient cluster, for cluster administrators and developers to use for testing, development, and production.

You can install a three-node cluster using either installer-provisioned or user-provisioned infrastructure.

### 7.13.1. Configuring a three-node cluster

You configure a three-node cluster by setting the number of worker nodes to **0** in the **install-config.yaml** file before deploying the cluster. Setting the number of worker nodes to **0** ensures that the control plane machines are schedulable. This allows application workloads to be scheduled to run from

the control plane nodes.

## NOTE

Because application workloads run from control plane nodes, additional subscriptions are required, as the control plane nodes are considered to be compute nodes.

## Prerequisites

- You have an existing **install-config.yaml** file.

## Procedure

1. Set the number of compute replicas to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

### Example **install-config.yaml** file for a three-node cluster

```
apiVersion: v1
baseDomain: example.com
compute:
- name: worker
 platform: {}
 replicas: 0
...
```

2. If you are deploying a cluster with user-provisioned infrastructure:
  - After you create the Kubernetes manifest files, make sure that the **spec.mastersSchedulable** parameter is set to **true** in **cluster-scheduler-02-config.yml** file. You can locate this file in **<installation\_directory>/manifests**. For more information, see "Creating the Kubernetes manifest and Ignition config files" in "Installing a cluster on user-provisioned infrastructure in GCP by using Deployment Manager templates".
  - Do not create additional worker nodes.

### Example **cluster-scheduler-02-config.yml** file for a three-node cluster

```
apiVersion: config.openshift.io/v1
kind: Scheduler
metadata:
 creationTimestamp: null
 name: cluster
spec:
 mastersSchedulable: true
 policy:
 name: ""
status: {}
```

## 7.13.2. Next steps

- [Installing a cluster on GCP with customizations](#)

- [Installing a cluster on user-provisioned infrastructure in GCP by using Deployment Manager templates](#)

## 7.14. INSTALLATION CONFIGURATION PARAMETERS FOR GCP

Before you deploy an OpenShift Container Platform cluster on Google Cloud Platform (GCP), you provide parameters to customize your cluster and the platform that hosts it. When you create the **install-config.yaml** file, you provide values for the required parameters through the command line. You can then modify the **install-config.yaml** file to customize your cluster further.

### 7.14.1. Available installation configuration parameters for GCP

The following tables specify the required, optional, and GCP-specific installation configuration parameters that you can set as part of the installation process.

#### NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

#### 7.14.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 7.44. Required parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                            | Values                                                                   |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| <b>apiVersion:</b> | The API version for the <b>install-config.yaml</b> content. The current version is <b>v1</b> . The installation program may also support older API versions.                                                                                                                                                                           | String                                                                   |
| <b>baseDomain:</b> | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <b>baseDomain</b> and <b>metadata.name</b> parameter values that uses the <b>&lt;metadata.name&gt;.&lt;baseDomain&gt;</b> format. | A fully-qualified domain or subdomain name, such as <b>example.com</b> . |
| <b>metadata:</b>   | Kubernetes resource <b>ObjectMeta</b> , from which only the <b>name</b> parameter is consumed.                                                                                                                                                                                                                                         | Object                                                                   |

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                | Values                                                                                                                                                                                                                                            |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>metadata:<br/>name:</code> | The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code> .                                                                                                                                                                                                                                                                                                               | String of lowercase letters, hyphens (-), and periods (.), such as <b>dev</b> .                                                                                                                                                                   |
| <code>platform:</code>           | The configuration for the specific platform upon which to perform the installation: <b>alibabacloud</b> , <b>aws</b> , <b>baremetal</b> , <b>azure</b> , <b>gcp</b> , <b>ibmcloud</b> , <b>nutanix</b> , <b>openstack</b> , <b>powervs</b> , <b>vsphere</b> , or <code>{}</code> . For additional information about <b>platform</b> . <code>&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows. | Object                                                                                                                                                                                                                                            |
| <code>pullSecret:</code>         | Get a <a href="#">pull secret from Red Hat OpenShift Cluster Manager</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.                                                                                                                                                                                                                                           | <pre>{<br/>  "auths":{<br/>    "cloud.openshift.com":{<br/>      "auth":"b3Blb=",<br/>      "email":"you@example.com"<br/>    },<br/>    "quay.io":{<br/>      "auth":"b3Blb=",<br/>      "email":"you@example.com"<br/>    }<br/>  }<br/>}</pre> |

7.14.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

Table 7.45. Network parameters

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                   | Values                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:</code>                                     | The configuration for the cluster network.                                                                                                                                                                                                                                                    | Object<br><br><b>NOTE</b><br>You cannot modify parameters specified by the <b>networking</b> object after installation.                                                                             |
| <code>networking:<br/>networkType:</code>                    | The Red Hat OpenShift Networking network plugin to install.                                                                                                                                                                                                                                   | Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b> . <b>OpenShiftSDN</b> is a CNI plugin for all-Linux networks. <b>OVNKubernetes</b> is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is <b>OVNKubernetes</b> . |
| <code>networking:<br/>clusterNetwork:</code>                 | The IP address blocks for pods.<br><br>The default value is <b>10.128.0.0/14</b> with a host prefix of <b>/23</b> .<br><br>If you specify multiple IP address blocks, the blocks must not overlap.                                                                                            | An array of objects. For example:<br><br><code>networking:<br/>clusterNetwork:<br/>- cidr: 10.128.0.0/14<br/>hostPrefix: 23</code>                                                                                                                                                    |
| <code>networking:<br/>clusterNetwork:<br/>cidr:</code>       | Required if you use <b>networking.clusterNetwork</b> . An IP address block.<br><br>An IPv4 network.                                                                                                                                                                                           | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between <b>0</b> and <b>32</b> .                                                                                                                                        |
| <code>networking:<br/>clusterNetwork:<br/>hostPrefix:</code> | The subnet prefix length to assign to each individual node. For example, if <b>hostPrefix</b> is set to <b>23</b> then each node is assigned a <b>/23</b> subnet out of the given <b>cidr</b> . A <b>hostPrefix</b> value of <b>23</b> provides 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. | A subnet prefix.<br><br>The default value is <b>23</b> .                                                                                                                                                                                                                              |
| <code>networking:<br/>serviceNetwork:</code>                 | The IP address block for services. The default value is <b>172.30.0.0/16</b> .<br><br>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.                                                                                    | An array with an IP address block in CIDR format. For example:<br><br><code>networking:<br/>serviceNetwork:<br/>- 172.30.0.0/16</code>                                                                                                                                                |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                     | Values                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:<br/>machineNetwork:</code>           | The IP address blocks for machines.<br><br>If you specify multiple IP address blocks, the blocks must not overlap.                                                                                                                                                                                                              | An array of objects. For example:<br><br><code>networking:<br/>machineNetwork:<br/>- cidr: 10.0.0.0/16</code>                                                                                                                                                                             |
| <code>networking:<br/>machineNetwork:<br/>cidr:</code> | Required if you use <b>networking.machineNetwork</b> . An IP address block. The default value is <b>10.0.0.0/16</b> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <b>192.168.126.0/24</b> . For IBM Power® Virtual Server, the default value is <b>192.168.0.0/24</b> . | An IP network block in CIDR notation.<br><br>For example, <b>10.0.0.0/16</b> .<br><br> <b>NOTE</b><br><br>Set the <b>networking.machineNetwork</b> to match the CIDR that the preferred NIC resides in. |

### 7.14.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 7.46. Optional parameters**

| Parameter                                             | Description                                                                                                                                                                                                                                                 | Values       |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <code>additionalTrustBundle:</code>                   | A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.                                                                                          | String       |
| <code>capabilities:</code>                            | Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the "Cluster capabilities" page in <i>Installing</i> . | String array |
| <code>capabilities:<br/>baselineCapabilitySet:</code> | Selects an initial set of optional capabilities to enable. Valid values are <b>None</b> , <b>v4.11</b> , <b>v4.12</b> and <b>vCurrent</b> . The default value is <b>vCurrent</b> .                                                                          | String       |

| Parameter                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                             |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| capabilities:<br>additionalEnabledCapabilities: | Extends the set of optional capabilities beyond what you specify in <b>baselineCapabilitySet</b> . You may specify multiple capabilities in this parameter.                                                                                                                                                                                                                                                                                                                                                    | String array                                                       |
| cpuPartitioningMode:                            | Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <i>Workload partitioning</i> page in the <i>Scalability and Performance</i> section. | <b>None</b> or <b>AllNodes</b> . <b>None</b> is the default value. |
| compute:                                        | The configuration for the machines that comprise the compute nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                            | Array of <b>MachinePool</b> objects.                               |
| compute:<br>architecture:                       | Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <b>amd64</b> and <b>arm64</b> .                                                                                                                                                                                                                                                                       | String                                                             |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Values                                                                                      |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>compute:</b><br><b>hyperthreading:</b> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div> | <b>Enabled</b> or <b>Disabled</b>                                                           |
| <b>compute:</b><br><b>name:</b>           | Required if you use <b>compute</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                | <b>worker</b>                                                                               |
| <b>compute:</b><br><b>platform:</b>       | Required if you use <b>compute</b> . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <b>controlPlane.platform</b> parameter value.                                                                                                                                                                                                                                                                                              | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |
| <b>compute:</b><br><b>replicas:</b>       | The number of compute machines, which are also known as worker machines, to provision.                                                                                                                                                                                                                                                                                                                                                                                                            | A positive integer greater than or equal to <b>2</b> . The default value is <b>3</b> .      |
| <b>featureSet:</b>                        | Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see "Enabling features using feature gates".                                                                                                                                                                                                                                | String. The name of the feature set to enable, such as <b>TechPreviewNoUpgrade</b> .        |
| <b>controlPlane:</b>                      | The configuration for the machines that comprise the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                               | Array of <b>MachinePool</b> objects.                                                        |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Values                                                                                              |

| <code>imageContentSources:</code>                          | Sources and repositories for the release-image content.                                                                                                                                                                                                                                                                                                                                    | Array of objects. Includes a <b>source</b> and, optionally, <b>mirrors</b> , as described in the following rows of this table.                                                               |
| <code>imageContentSources:</code><br><code>source:</code>  | Required if you use <b>imageContentSources</b> . Specify the repository that users refer to, for example, in image pull specifications.                                                                                                                                                                                                                                                    | String                                                                                                                                                                                       |
| <code>imageContentSources:</code><br><code>mirrors:</code> | Specify one or more repositories that may also contain the same images.                                                                                                                                                                                                                                                                                                                    | Array of strings                                                                                                                                                                             |
| <code>publish:</code>                                      | How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.                                                                                                                                                                                                                                                                          | <b>Internal</b> or <b>External</b> . To deploy a private cluster, which cannot be accessed from the internet, set <b>publish</b> to <b>Internal</b> . The default value is <b>External</b> . |
| <code>sshKey:</code>                                       | <div><div>The SSH key to authenticate access to your cluster machines.</div><div><b>NOTE</b><br/>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <b>ssh-agent</b> process uses.</div></div> | For example, <b>sshKey: ssh-ed25519 AAAA...</b>                                                                                                                                              |

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.

**NOTE**

If you are installing on GCP into a shared virtual private cloud (VPC), **credentialsMode** must be set to **Passthrough** or **Manual**.

**IMPORTANT**

Setting this parameter to **Manual** enables alternatives to storing administrator-level secrets in the **kube-system** project, which require additional configuration steps. For more information, see "Alternatives to storing administrator-level secrets in the kube-system project".

7.14.1.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

Table 7.47. Additional GCP parameters

| Parameter                                                  | Description                                                                                                                                                                                                                                                                                                                            | Values                                                      |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| controlPlane:<br>platform:<br>gcp:<br>osImage:<br>project: | Optional. By default, the installation program downloads and installs the Red Hat Enterprise Linux CoreOS (RHCOS) image that is used to boot control plane machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for control plane machines only. | String. The name of GCP project where the image is located. |

| Parameter                                           | Description                                                                                                                                                                                                                                                                              | Values                                                      |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| <code>controlPlane.platform.gcp.osImage.name</code> | The name of the custom RHCOS image that the installation program is to use to boot control plane machines. If you use <b>controlPlane.platform.gcp.osImage.project</b> , this field is required.                                                                                         | String. The name of the RHCOS image.                        |
| <code>compute.platform.gcp.osImage.project</code>   | Optional. By default, the installation program downloads and installs the RHCOS image that is used to boot compute machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for compute machines only. | String. The name of GCP project where the image is located. |

| Parameter                                       | Description                                                                                                                                                                                                                                                        | Values                               |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| <code>compute:platform:gcp:osimage:name:</code> | The name of the custom RHCOS image that the installation program is to use to boot compute machines. If you use <b>compute.platform.gcp.osImage.project</b> , this field is required.                                                                              | String. The name of the RHCOS image. |
| <code>platform:gcp:network:</code>              | The name of the existing Virtual Private Cloud (VPC) where you want to deploy your cluster. If you want to deploy your cluster into a shared VPC, you must set <b>platform.gcp.networkProjectID</b> with the name of the GCP project that contains the shared VPC. | String.                              |
| <code>platform:gcp:networkProjectID:</code>     | Optional. The name of the GCP project that contains the shared VPC where you want to deploy your cluster.                                                                                                                                                          | String.                              |

| Parameter                                       | Description                                                                           | Values                                              |
|-------------------------------------------------|---------------------------------------------------------------------------------------|-----------------------------------------------------|
| <code>platform: gcp: projectID:</code>          | The name of the GCP project where the installation program installs the cluster.      | String.                                             |
| <code>platform: gcp: region:</code>             | The name of the GCP region that hosts your cluster.                                   | Any valid region name, such as <b>us-central1</b> . |
| <code>platform: gcp: controlPlaneSubnet:</code> | The name of the existing subnet where you want to deploy your control plane machines. | The subnet name.                                    |

| Parameter                                                                                                  | Description                                                                     | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform:</code><br><code>gcp:</code><br><code>computeSubnet:</code>                                 | The name of the existing subnet where you want to deploy your compute machines. | The subnet name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>platform:</code><br><code>gcp:</code><br><code>defaultMachinePlatform:</code><br><code>zones:</code> | The availability zones where the installation program creates machines.         | <p>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</p> <div><div><b>IMPORTANT</b><br/><br/>When running your cluster on GCP 64-bit ARM infrastructure, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</div></div> |

| Parameter                                                               | Description                             | Values                                                                                                                                                                                             |
|-------------------------------------------------------------------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform: gcp: defaultMachinePlatform: osDisk: diskSizeGB:</code> | The size of the disk in gigabytes (GB). | Any size between 16 GB and 65536 GB.                                                                                                                                                               |
| <code>platform: gcp: defaultMachinePlatform: osDisk: diskType:</code>   | The <a href="#">GCP disk type</a> .     | The default disk type for all machines. Control plane nodes must use the <b>pd-ssd</b> disk type. Compute nodes can use the <b>pd-ssd</b> , <b>pd-balanced</b> , or <b>pd-standard</b> disk types. |

| Parameter                                                                                                                             | Description                                                                                                                                                                                                                                                                                                 | Values                                                      |
|---------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| <code>platform:</code><br><code>gcp:</code><br><code>defaultMachinePlatform:</code><br><code>osImage:</code><br><code>project:</code> | Optional. By default, the installation program downloads and installs the RHCOS image that is used to boot control plane and compute machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for both types of machines. | String. The name of GCP project where the image is located. |
| <code>platform:</code><br><code>gcp:</code><br><code>defaultMachinePlatform:</code><br><code>osImage:</code><br><code>name:</code>    | The name of the custom RHCOS image that the installation program is to use to boot control plane and compute machines. If you use <b>platform.gcp.defaultMachinePlatform.osImage.project</b> , this field is required.                                                                                      | String. The name of the RHCOS image.                        |

| Parameter                                    | Description                                                                         | Values                                                   |
|----------------------------------------------|-------------------------------------------------------------------------------------|----------------------------------------------------------|
| platform: gcp: defaultMachinePlatform: tags: | Optional. Additional network tags to add to the control plane and compute machines. | One or more strings, for example <b>network-tag1</b> .   |
| platform: gcp: defaultMachinePlatform: type: | The <a href="#">GCP machine type</a> for control plane and compute machines.        | The GCP machine type, for example <b>n1-standard-4</b> . |

| Parameter                                                                      | Description                                                                             | Values                   |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|--------------------------|
| platform: gcp default Machine Platform: os Disk: encryption Key: kmsKey: name: | The name of the customer managed encryption key to be used for machine disk encryption. | The encryption key name. |

| Parameter                                                                          | Description                                                                         | Values                 |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|------------------------|
| platform: gcp default Machine Platform: os Disk: encryption Key: kmsKey: key Ring: | The name of the Key Management Service (KMS) key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                                                          | Description                                                        | Values            |
|------------------------------------------------------------------------------------|--------------------------------------------------------------------|-------------------|
| platform: gcp default Machine Platform: os Disk: encryption Key: kmsKey: location: | The <a href="#">GCP location</a> in which the KMS key ring exists. | The GCP location. |

| Parameter              | Description                                                                                                                                               | Values              |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| platform.gcp.projectID | The ID of the project in which the KMS key ring exists. This value defaults to the value of the <b>platform.gcp.projectID</b> parameter if it is not set. | The GCP project ID. |

| Parameter                                                                                                                                                       | Description                                                                                                                                                                                                                                                                            | Values                                                                                                                                    |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|

If absent, the Compute Engine default service account is used. For more information about GCP service accounts, see Google’s documentation on <a href="#">service accounts</a>.</p> | <p>The GCP service account email, for example<br/><b>&lt;service_account_name&gt;<br/>&lt;project_id&gt;.iam.gserviceaccount.com</b>.</p> |

| Parameter                                                                | Description                                                                                                                                                                                                                                                                                                   | Values                                                                     |
|--------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <code>platform: gcp: defaultMachinePlatform: secureBoot:</code>          | Whether to enable Shielded VM secure boot for all machines in the cluster. Shielded VMs have additional security protocols such as secure boot, firmware and integrity monitoring, and rootkit protection. For more information on Shielded VMs, see Google's documentation on <a href="#">Shielded VMs</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |
| <code>platform: gcp: defaultMachinePlatform: confidentialCompute:</code> | Whether to use Confidential VMs for all machines in the cluster. Confidential VMs provide encryption for data during processing. For more information on Confidential computing, see Google's documentation on <a href="#">Confidential computing</a> .                                                       | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |

| Param<br>eter                                                                                                                                                                   | Description                                                                                                                                                                                                                         | Values                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <div>plat<br/>for<br/>m:<br/><br/>gcp<br/>:<br/><br/>def<br/>ault<br/>Ma<br/>chi<br/>ne<br/>Plat<br/>for<br/>m:<br/><br/>on<br/>Ho<br/>stM<br/>aint<br/>ena<br/>nce<br/>:</div> | Specifies the behavior of all VMs during a host maintenance event, such as a software or hardware update. For Confidential VMs, this parameter must be set to <b>Terminate</b> . Confidential VMs do not support live VM migration. | <b>Terminate</b> or <b>Migrate</b> . The default value is <b>Migrate</b> . |

| Parameter                                                       | Description                                                                                           | Values                   |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|--------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKeyName: | The name of the customer managed encryption key to be used for control plane machine disk encryption. | The encryption key name. |

| Parameter                                                            | Description                                                                            | Values                 |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------|------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKey: keyRing: | For control plane machines, the name of the KMS key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                                             | Description                                                                                                                                                                              | Values                             |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKey: location: | For control plane machines, the GCP location in which the key ring exists. For more information about KMS locations, see Google's documentation on <a href="#">Cloud KMS locations</a> . | The GCP location for the key ring. |

| Param<br>eter                                                                                                                        | Description                                                                                                                              | Values              |
|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| control<br>Plane:<br><br>platform:<br><br>gcp<br>:<br><br>os<br>Disk:<br><br>encryption<br>Key<br>:<br><br>kmsKey:<br><br>projectId: | For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set. | The GCP project ID. |

| Parameter                                                             | Description                                                                                                                                                                                                                                                          | Values                                                                                                                      |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmserviceAccount: | The GCP service account used for the encryption request for control plane machines. If absent, the Compute Engine default service account is used. For more information about GCP service accounts, see Google’s documentation on <a href="#">service accounts</a> . | The GCP service account email, for example <b>&lt;service_account_name&gt;@&lt;project_id&gt;.iam.gserviceaccount.com</b> . |

| Parameter                                    | Description                                                                           | Values                                                                             |
|----------------------------------------------|---------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| controlPlane:platform:gcp:osDisk:diskSizeGB: | The size of the disk in gigabytes (GB). This value applies to control plane machines. | Any integer between 16 and 65536.                                                  |
| controlPlane:platform:gcp:osDisk:diskType:   | The <a href="#">GCP disk type</a> for control plane machines.                         | Control plane machines must use the <b>pd-ssd</b> disk type, which is the default. |

| Parameter                                       | Description                                                                                                                                                                                                     | Values                                                                    |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| <code>controlPlane: platform: gcp: tags:</code> | Optional. Additional network tags to add to the control plane machines. If set, this parameter overrides the <b><code>platform.gcp.defaultMachinePlatform.tags</code></b> parameter for control plane machines. | One or more strings, for example <b><code>control-plane-tag1</code></b> . |
| <code>controlPlane: platform: gcp: type:</code> | The <a href="#">GCP machine type</a> for control plane machines. If set, this parameter overrides the <b><code>platform.gcp.defaultMachinePlatform.type</code></b> parameter.                                   | The GCP machine type, for example <b><code>n1-standard-4</code></b> .     |

| Parameter                                                                                             | Description                                                                                                                                                                                                                                                                                              | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>controlPlane:</code><br><code>platform:</code><br><code>gcp:</code><br><code>zones:</code>      | The availability zones where the installation program creates control plane machines.                                                                                                                                                                                                                    | <p>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</p> <div><div><b>IMPORTANT</b><br/><br/>When running your cluster on GCP 64-bit ARM infrastructure, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</div></div> |
| <code>controlPlane:</code><br><code>platform:</code><br><code>gcp:</code><br><code>secureBoot:</code> | Whether to enable Shielded VM secure boot for control plane machines. Shielded VMs have additional security protocols such as secure boot, firmware and integrity monitoring, and rootkit protection. For more information on Shielded VMs, see Google's documentation on <a href="#">Shielded VMs</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Parameter                                                  | Description                                                                                                                                                                                                                                               | Values                                                                     |
|------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| controlPlane:<br>platform:<br>gcp:<br>confidentialCompute: | Whether to enable Confidential VMs for control plane machines. Confidential VMs provide encryption for data while it is being processed. For more information on Confidential VMs, see Google's documentation on <a href="#">Confidential Computing</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |
| controlPlane:<br>platform:<br>gcp:<br>onHostMaintenance:   | Specifies the behavior of control plane VMs during a host maintenance event, such as a software or hardware update. For Confidential VMs, this parameter must be set to <b>Terminate</b> . Confidential VMs do not support live VM migration.             | <b>Terminate</b> or <b>Migrate</b> . The default value is <b>Migrate</b> . |

| Parameter                                          | Description                                                                                     | Values                   |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------|--------------------------|
| compute:platform:gcp:osDisk:encryptionKey:keyname: | The name of the customer managed encryption key to be used for compute machine disk encryption. | The encryption key name. |

| Parameter                                          | Description                                                                      | Values                 |
|----------------------------------------------------|----------------------------------------------------------------------------------|------------------------|
| compute:platform:gcp:osDisk:encryptionKey:keyRing: | For compute machines, the name of the KMS key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                                 | Description                                                                                                                                                                        | Values                             |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| compute:platform:gcp:osDisk:encryptionKey:ksKey:location: | For compute machines, the GCP location in which the key ring exists. For more information about KMS locations, see Google's documentation on <a href="#">Cloud KMS locations</a> . | The GCP location for the key ring. |

| Parameter                                                   | Description                                                                                                                        | Values              |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| compute:platform:gcp:osDisk:encryptionKey:kmsKey:projectId: | For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set. | The GCP project ID. |

| Parameter                                                              | Description                                                                                                                                                                                                                                                                   | Values                                                                                                                      |
|------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| compute: platform: gcp: os Disk: encryption Key: kmsKeyServiceAccount: | The GCP service account used for the encryption request for compute machines. If this value is not set, the Compute Engine default service account is used. For more information about GCP service accounts, see Google’s documentation on <a href="#">service accounts</a> . | The GCP service account email, for example <b>&lt;service_account_name&gt;@&lt;project_id&gt;.iam.gserviceaccount.com</b> . |
| compute: platform: gcp: os Disk: diskSizeGB:                           | The size of the disk in gigabytes (GB). This value applies to compute machines.                                                                                                                                                                                               | Any integer between 16 and 65536.                                                                                           |

| Parameter                                         | Description                                                                                                                                                                            | Values                                                                                      |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <code>compute:platform:gcp:osDisk:diskType</code> | The <a href="#">GCP disk type</a> for compute machines.                                                                                                                                | <b>pd-ssd</b> , <b>pd-standard</b> , or <b>pd-balanced</b> . The default is <b>pd-ssd</b> . |
| <code>compute:platform:gcp:tags</code>            | Optional. Additional network tags to add to the compute machines. If set, this parameter overrides the <b>platform.gcp.defaultMachinePlatform.tags</b> parameter for compute machines. | One or more strings, for example <b>compute-network-tag1</b> .                              |
| <code>compute:platform:gcp:type</code>            | The <a href="#">GCP machine type</a> for compute machines. If set, this parameter overrides the <b>platform.gcp.defaultMachinePlatform.type</b> parameter.                             | The GCP machine type, for example <b>n1-standard-4</b> .                                    |

| Parameter                                   | Description                                                                     | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------|---------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>compute: platform: gcp: zones:</code> | The availability zones where the installation program creates compute machines. | <p>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</p> <div><div><b>IMPORTANT</b><br/><br/>When running your cluster on GCP 64-bit ARM infrastructure s, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</div></div> |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                        | Values                                                                     |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| compute:platform:gcp:secureBoot:          | Whether to enable Shielded VM secure boot for compute machines. Shielded VMs have additional security protocols such as secure boot, firmware and integrity monitoring, and rootkit protection. For more information on Shielded VMs, see Google's documentation on <a href="#">Shielded VMs</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |
| compute:platform:gcp:confidentialCompute: | Whether to enable Confidential VMs for compute machines. Confidential VMs provide encryption for data while it is being processed. For more information on Confidential VMs, see Google's documentation on <a href="#">Confidential Computing</a> .                                                | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |

| Parameter                                | Description                                                                                                                                                                                                                             | Values                                                                     |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| computePlatform: gcp on HostMaintenance: | Specifies the behavior of compute VMs during a host maintenance event, such as a software or hardware update. For Confidential VMs, this parameter must be set to <b>Terminate</b> . Confidential VMs do not support live VM migration. | <b>Terminate</b> or <b>Migrate</b> . The default value is <b>Migrate</b> . |

## 7.15. UNINSTALLING A CLUSTER ON GCP

You can remove a cluster that you deployed to Google Cloud Platform (GCP).

### 7.15.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

#### NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access. For example, some Google Cloud resources require [IAM permissions](#) in shared VPC host projects, or there might be unused [health checks that must be deleted](#).

#### Prerequisites

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

#### Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$./openshift-install destroy cluster \
--dir <installation_directory> --log-level info 1 2
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different details, specify **warn**, **debug**, or **error** instead of **info**.

#### NOTE

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the **metadata.json** file in this directory to delete the cluster.

2. Optional: Delete the **<installation\_directory>** directory and the OpenShift Container Platform installation program.

## 7.15.2. Deleting Google Cloud Platform resources with the Cloud Credential Operator utility

After uninstalling an OpenShift Container Platform cluster that uses short-term credentials managed outside the cluster, you can use the CCO utility (**ccctl**) to remove the Google Cloud Platform (GCP) resources that **ccctl** created during installation.

### Prerequisites

- Extract and prepare the **ccctl** binary.
- Uninstall an OpenShift Container Platform cluster on GCP that uses short-term credentials.

### Procedure

1. Set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

2. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
--from=$RELEASE_IMAGE \
--credentials-requests \
--included 1 \
--to=<path_to_directory_for_credentials_requests> 2
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

3. Delete the GCP resources that **ccoctl** created by running the following command:

```
$ ccoctl gcp delete \
 --name=<name> \ 1
 --project=<gcp_project_id> \ 2
 --credentials-requests-dir=<path_to_credentials_requests_directory>
```

**1** **<name>** matches the name that was originally used to create and tag the cloud resources.

**2** **<gcp\_project\_id>** is the GCP project ID in which to delete cloud resources.

### Verification

- To verify that the resources are deleted, query GCP. For more information, refer to GCP documentation.

## CHAPTER 8. INSTALLING ON IBM CLOUD

### 8.1. PREPARING TO INSTALL ON IBM CLOUD

The installation workflows documented in this section are for IBM Cloud® infrastructure environments. IBM Cloud® classic is not supported at this time. For more information about the difference between classic and VPC infrastructures, see the IBM® [documentation](#).

#### 8.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

#### 8.1.2. Requirements for installing OpenShift Container Platform on IBM Cloud

Before installing OpenShift Container Platform on IBM Cloud®, you must create a service account and configure an IBM Cloud® account. See [Configuring an IBM Cloud® account](#) for details about creating an account, enabling API services, configuring DNS, IBM Cloud® account limits, and supported IBM Cloud® regions.

You must manually manage your cloud credentials when installing a cluster to IBM Cloud®. Do this by configuring the Cloud Credential Operator (CCO) for manual mode before you install the cluster. For more information, see [Configuring IAM for IBM Cloud®](#).

#### 8.1.3. Choosing a method to install OpenShift Container Platform on IBM Cloud

You can install OpenShift Container Platform on IBM Cloud® using installer-provisioned infrastructure. This process involves using an installation program to provision the underlying infrastructure for your cluster. Installing OpenShift Container Platform on IBM Cloud® using user-provisioned infrastructure is not supported at this time.

See [Installation process](#) for more information about installer-provisioned installation processes.

##### 8.1.3.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on IBM Cloud® infrastructure that is provisioned by the OpenShift Container Platform installation program by using one of the following methods:

- [Installing a customized cluster on IBM Cloud®](#) You can install a customized cluster on IBM Cloud® infrastructure that the installation program provisions. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available [post-installation](#).
- [Installing a cluster on IBM Cloud® with network customizations](#) You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.
- [Installing a cluster on IBM Cloud® into an existing VPC](#) You can install OpenShift Container Platform on an existing IBM Cloud®. You can use this installation method if you have constraints set by the guidelines of your company, such as limits when creating new accounts or infrastructure.

- [Installing a private cluster on an existing VPC](#) You can install a private cluster on an existing Virtual Private Cloud (VPC). You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

#### 8.1.4. Next steps

- [Configuring an IBM Cloud® account](#)

## 8.2. CONFIGURING AN IBM CLOUD ACCOUNT

Before you can install OpenShift Container Platform, you must configure an IBM Cloud® account.

### 8.2.1. Prerequisites

- You have an IBM Cloud® account with a subscription. You cannot install OpenShift Container Platform on a free or trial IBM Cloud® account.

### 8.2.2. Quotas and limits on IBM Cloud

The OpenShift Container Platform cluster uses a number of IBM Cloud® components, and the default quotas and limits affect your ability to install OpenShift Container Platform clusters. If you use certain cluster configurations, deploy your cluster in certain regions, or run multiple clusters from your account, you might need to request additional resources for your IBM Cloud® account.

For a comprehensive list of the default IBM Cloud® quotas and service limits, see IBM Cloud®'s documentation for [Quotas and service limits](#).

#### Virtual Private Cloud (VPC)

Each OpenShift Container Platform cluster creates its own VPC. The default quota of VPCs per region is 10 and will allow 10 clusters. To have more than 10 clusters in a single region, you must increase this quota.

#### Application load balancer

By default, each cluster creates three application load balancers (ALBs):

- Internal load balancer for the master API server
- External load balancer for the master API server
- Load balancer for the router

You can create additional **LoadBalancer** service objects to create additional ALBs. The default quota of VPC ALBs are 50 per region. To have more than 50 ALBs, you must increase this quota.

VPC ALBs are supported. Classic ALBs are not supported for IBM Cloud®.

#### Floating IP address

By default, the installation program distributes control plane and compute machines across all availability zones within a region to provision the cluster in a highly available configuration. In each availability zone, a public gateway is created and requires a separate floating IP address.

The default quota for a floating IP address is 20 addresses per availability zone. The default cluster configuration yields three floating IP addresses:

- Two floating IP addresses in the **us-east-1** primary zone. The IP address associated with the bootstrap node is removed after installation.
- One floating IP address in the **us-east-2** secondary zone.
- One floating IP address in the **us-east-3** secondary zone.

IBM Cloud® can support up to 19 clusters per region in an account. If you plan to have more than 19 default clusters, you must increase this quota.

### Virtual Server Instances (VSI)

By default, a cluster creates VSIs using **bx2-4x16** profiles, which includes the following resources by default:

- 4 vCPUs
- 16 GB RAM

The following nodes are created:

- One **bx2-4x16** bootstrap machine, which is removed after the installation is complete
- Three **bx2-4x16** control plane nodes
- Three **bx2-4x16** compute nodes

For more information, see IBM Cloud®'s documentation on [supported profiles](#).

**Table 8.1. VSI component quotas and limits**

| VSI component | Default IBM Cloud® quota | Default cluster configuration                 | Maximum number of clusters |
|---------------|--------------------------|-----------------------------------------------|----------------------------|
| vCPU          | 200 vCPUs per region     | 28 vCPUs, or 24 vCPUs after bootstrap removal | 8 per region               |
| RAM           | 1600 GB per region       | 112 GB, or 96 GB after bootstrap removal      | 16 per region              |
| Storage       | 18 TB per region         | 1050 GB, or 900 GB after bootstrap removal    | 19 per region              |

If you plan to exceed the resources stated in the table, you must increase your IBM Cloud® account quota.

### Block Storage Volumes

For each VPC machine, a block storage device is attached for its boot volume. The default cluster configuration creates seven VPC machines, resulting in seven block storage volumes. Additional Kubernetes persistent volume claims (PVCs) of the IBM Cloud® storage class create additional block storage volumes. The default quota of VPC block storage volumes are 300 per region. To have more than 300 volumes, you must increase this quota.

## 8.2.3. Configuring DNS resolution

How you configure DNS resolution depends on the type of OpenShift Container Platform cluster you are installing:

- If you are installing a public cluster, you use IBM Cloud Internet Services (CIS).
- If you are installing a private cluster, you use IBM Cloud® DNS Services (DNS Services)

### 8.2.3.1. Using IBM Cloud Internet Services for DNS resolution

The installation program uses IBM Cloud® Internet Services (CIS) to configure cluster DNS resolution and provide name lookup for a public cluster.

#### NOTE

This offering does not support IPv6, so dual stack or IPv6 environments are not possible.

You must create a domain zone in CIS in the same account as your cluster. You must also ensure the zone is authoritative for the domain. You can do this using a root domain or subdomain.

#### Prerequisites

- You have installed the [IBM Cloud® CLI](#).
- You have an existing domain and registrar. For more information, see the IBM® [documentation](#).

#### Procedure

1. Create a CIS instance to use with your cluster:

- a. Install the CIS plugin:

```
$ ibmcloud plugin install cis
```

- b. Create the CIS instance:

```
$ ibmcloud cis instance-create <instance_name> standard 1
```

- 1** At a minimum, a **Standard** plan is required for CIS to manage the cluster subdomain and its DNS records.

2. Connect an existing domain to your CIS instance:

- a. Set the context instance for CIS:

```
$ ibmcloud cis instance-set <instance_name> 1
```

- 1** The instance cloud resource name.

- b. Add the domain for CIS:

```
$ ibmcloud cis domain-add <domain_name> 1
```

- 1 The fully qualified domain name. You can use either the root domain or subdomain value as the domain name, depending on which you plan to configure.

#### NOTE

A root domain uses the form **openshiftcorp.com**. A subdomain uses the form **clusters.openshiftcorp.com**.

3. Open the [CIS web console](#), navigate to the **Overview** page, and note your CIS name servers. These name servers will be used in the next step.
4. Configure the name servers for your domains or subdomains at the domain's registrar or DNS provider. For more information, see the IBM Cloud® [documentation](#).

### 8.2.3.2. Using IBM Cloud DNS Services for DNS resolution

The installation program uses IBM Cloud® DNS Services to configure cluster DNS resolution and provide name lookup for a private cluster.

You configure DNS resolution by creating a DNS services instance for the cluster, and then adding a DNS zone to the DNS Services instance. Ensure that the zone is authoritative for the domain. You can do this using a root domain or subdomain.

#### NOTE

IBM Cloud® does not support IPv6, so dual stack or IPv6 environments are not possible.

#### Prerequisites

- You have installed the [IBM Cloud® CLI](#).
- You have an existing domain and registrar. For more information, see the IBM® [documentation](#).

#### Procedure

1. Create a DNS Services instance to use with your cluster:
  - a. Install the DNS Services plugin by running the following command:

```
$ ibmcloud plugin install cloud-dns-services
```

- b. Create the DNS Services instance by running the following command:

```
$ ibmcloud dns instance-create <instance-name> standard-dns 1
```

- 1 At a minimum, a **Standard** plan is required for DNS Services to manage the cluster subdomain and its DNS records.

2. Create a DNS zone for the DNS Services instance:
  - a. Set the target operating DNS Services instance by running the following command:

```
$ ibmcloud dns instance-target <instance-name>
```

- b. Add the DNS zone to the DNS Services instance by running the following command:

```
$ ibmcloud dns zone-create <zone-name> 1
```

- 1 The fully qualified zone name. You can use either the root domain or subdomain value as the zone name, depending on which you plan to configure. A root domain uses the form **openshiftcorp.com**. A subdomain uses the form **clusters.openshiftcorp.com**.

3. Record the name of the DNS zone you have created. As part of the installation process, you must update the **install-config.yaml** file before deploying the cluster. Use the name of the DNS zone as the value for the **baseDomain** parameter.

#### NOTE

You do not have to manage permitted networks or configure an "A" DNS resource record. As required, the installation program configures these resources automatically.

### 8.2.4. IBM Cloud IAM Policies and API Key

To install OpenShift Container Platform into your IBM Cloud® account, the installation program requires an IAM API key, which provides authentication and authorization to access IBM Cloud® service APIs. You can use an existing IAM API key that contains the required policies or create a new one.

For an IBM Cloud® IAM overview, see the IBM Cloud® [documentation](#).

#### 8.2.4.1. Required access policies

You must assign the required access policies to your IBM Cloud® account.

**Table 8.2. Required access policies**

| Service type                      | Service                        | Access policy scope                                   | Platform access                         | Service access     |
|-----------------------------------|--------------------------------|-------------------------------------------------------|-----------------------------------------|--------------------|
| Account management                | IAM Identity Service           | All resources or a subset of resources <sup>[1]</sup> | Editor, Operator, Viewer, Administrator | Service ID creator |
| Account management <sup>[2]</sup> | Identity and Access Management | All resources                                         | Editor, Operator, Viewer, Administrator |                    |
| Account management                | Resource group only            | All resource groups in the account                    | Administrator                           |                    |

| Service type | Service                     | Access policy scope                                   | Platform access                         | Service access                                                        |
|--------------|-----------------------------|-------------------------------------------------------|-----------------------------------------|-----------------------------------------------------------------------|
| IAM services | Cloud Object Storage        | All resources or a subset of resources <sup>[1]</sup> | Editor, Operator, Viewer, Administrator | Reader, Writer, Manager, Content Reader, Object Reader, Object Writer |
| IAM services | Internet Services           | All resources or a subset of resources <sup>[1]</sup> | Editor, Operator, Viewer, Administrator | Reader, Writer, Manager                                               |
| IAM services | DNS Services                | All resources or a subset of resources <sup>[1]</sup> | Editor, Operator, Viewer, Administrator | Reader, Writer, Manager                                               |
| IAM services | VPC Infrastructure Services | All resources or a subset of resources <sup>[1]</sup> | Editor, Operator, Viewer, Administrator | Reader, Writer, Manager                                               |

1. The policy access scope should be set based on how granular you want to assign access. The scope can be set to **All resources** or **Resources based on selected attributes**
2. Optional: This access policy is only required if you want the installation program to create a resource group. For more information about resource groups, see the IBM® [documentation](#).

#### 8.2.4.2. Access policy assignment

In IBM Cloud® IAM, access policies can be attached to different subjects:

- Access group (Recommended)
- Service ID
- User

The recommended method is to define IAM access policies in an [access group](#). This helps organize all the access required for OpenShift Container Platform and enables you to onboard users and service IDs to this group. You can also assign access to [users and service IDs](#) directly, if desired.

#### 8.2.4.3. Creating an API key

You must create a user API key or a service ID API key for your IBM Cloud® account.

##### Prerequisites

- You have assigned the required access policies to your IBM Cloud® account.
- You have attached your IAM access policies to an access group, or other appropriate resource.

##### Procedure

- Create an API key, depending on how you defined your IAM access policies.  
For example, if you assigned your access policies to a user, you must create a [user API key](#). If you assigned your access policies to a service ID, you must create a [service ID API key](#). If your access policies are assigned to an access group, you can use either API key type. For more information on IBM Cloud® API keys, see [Understanding API keys](#).

### 8.2.5. Supported IBM Cloud regions

You can deploy an OpenShift Container Platform cluster to the following regions:

- **au-syd** (Sydney, Australia)
- **br-sao** (Sao Paulo, Brazil)
- **ca-tor** (Toronto, Canada)
- **eu-de** (Frankfurt, Germany)
- **eu-gb** (London, United Kingdom)
- **eu-es** (Madrid, Spain)
- **jp-osa** (Osaka, Japan)
- **jp-tok** (Tokyo, Japan)
- **us-east** (Washington DC, United States)
- **us-south** (Dallas, United States)

#### NOTE

Deploying your cluster in the **eu-es** (Madrid, Spain) region is not supported for OpenShift Container Platform 4.14.6 and earlier versions.

### 8.2.6. Next steps

- [Configuring IAM for IBM Cloud®](#)

## 8.3. CONFIGURING IAM FOR IBM CLOUD

In environments where the cloud identity and access management (IAM) APIs are not reachable, you must put the Cloud Credential Operator (CCO) into manual mode before you install the cluster.

### 8.3.1. Alternatives to storing administrator-level secrets in the kube-system project

The Cloud Credential Operator (CCO) manages cloud provider credentials as Kubernetes custom resource definitions (CRDs). You can configure the CCO to suit the security requirements of your organization by setting different values for the **credentialsMode** parameter in the **install-config.yaml** file.

Storing an administrator-level credential secret in the cluster **kube-system** project is not supported for IBM Cloud®; therefore, you must set the **credentialsMode** parameter for the CCO to **Manual** when installing OpenShift Container Platform and manage your cloud credentials manually.

Using manual mode allows each cluster component to have only the permissions it requires, without storing an administrator-level credential in the cluster. You can also use this mode if your environment does not have connectivity to the cloud provider public IAM endpoint. However, you must manually reconcile permissions with new release images for every upgrade. You must also manually supply credentials for every component that requests them.

### Additional resources

- [About the Cloud Credential Operator](#)

## 8.3.2. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

### Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

### NOTE

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

## Verification

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccoctl.rhel9
```

## Example output

```
OpenShift credentials provisioning tool
```

```
Usage:
```

```
ccoctl [command]
```

```
Available Commands:
```

```
alibabacloud Manage credentials objects for alibaba cloud
```

```
aws Manage credentials objects for AWS cloud
```

```
azure Manage credentials objects for Azure
```

```
gcp Manage credentials objects for Google cloud
```

```
help Help about any command
```

```
ibmcloud Manage credentials objects for IBM Cloud
```

```
nutanix Manage credentials objects for Nutanix
```

```
Flags:
```

```
-h, --help help for ccoctl
```

```
Use "ccoctl [command] --help" for more information about a command.
```

## Additional resources

- [Rotating API keys for IBM Cloud®](#)

## 8.3.3. Next steps

- [Installing a cluster on IBM Cloud® with customizations](#)

## 8.3.4. Additional resources

- [Preparing to update a cluster with manually maintained credentials](#)

# 8.4. INSTALLING A CLUSTER ON IBM CLOUD WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a customized cluster on infrastructure that the installation program provisions on IBM Cloud®. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

## 8.4.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

- You [configured an IBM Cloud® account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You configured the **ccctl** utility before you installed the cluster. For more information, see [Configuring IAM for IBM Cloud®](#).

### 8.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 8.4.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

### Example output

```
Agent pid 31874
```

### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

## 8.4.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 8.4.5. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

#### Prerequisites

- You have created either a user API key or service ID API key for your IBM Cloud® account.

#### Procedure

- Export your API key for your account as a global variable:

```
$ export IC_API_KEY=<api_key>
```

#### IMPORTANT

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

### 8.4.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on IBM Cloud®.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If

you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **ibmcloud** as the platform to target.
  - iii. Select the region to deploy the cluster to.
  - iv. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - v. Enter a descriptive name for your cluster.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

#### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

#### Additional resources

- [Installation configuration parameters for IBM Cloud®](#)

#### 8.4.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 8.3. Minimum resource requirements

| Machine       | Operating System | vCPU | Virtual RAM | Storage | Input/Output Per Second (IOPS) |
|---------------|------------------|------|-------------|---------|--------------------------------|
| Bootstrap     | RHCOS            | 4    | 16 GB       | 100 GB  | 300                            |
| Control plane | RHCOS            | 4    | 16 GB       | 100 GB  | 300                            |
| Compute       | RHCOS            | 2    | 8 GB        | 100 GB  | 300                            |

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 8.4.6.2. Sample customized install-config.yaml file for IBM Cloud

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

## IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and then modify it.

```
apiVersion: v1
baseDomain: example.com 1
controlPlane: 2 3
hyperthreading: Enabled 4
name: master
platform:
 ibmcloud: {}
replicas: 3
```

```

compute: 5 6
- hyperthreading: Enabled 7
 name: worker
 platform:
 ibmcloud: {}
 replicas: 3
metadata:
 name: test-cluster 8
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes 9
 serviceNetwork:
 - 172.30.0.0/16
platform:
 ibmcloud:
 region: us-south 10
credentialsMode: Manual
publish: External
pullSecret: '{"auths": ...}' 11
fips: false 12
sshKey: ssh-ed25519 AAAA... 13

```

1 8 10 11 Required. The installation program prompts you for this value.

2 5 If you do not provide these parameters and values, the installation program provides the default value.

3 6 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

4 7 Enables or disables simultaneous multithreading, also known as Hyper-Threading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

## IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

9 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

12 Enables or disables FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are

provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

13

Optional: provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

#### 8.4.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
```

```

baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> ❶
 httpsProxy: https://<username>:<pswd>@<ip>:<port> ❷
 noProxy: example.com ❸
 additionalTrustBundle: | ❹
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ❺

```

- ❶ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- ❷ A proxy URL to use for creating HTTPS connections outside the cluster.
- ❸ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- ❹ If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- ❺ Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

## NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 8.4.7. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (**ccctl**) to create the required IBM Cloud® resources.

#### Prerequisites

- You have configured the **ccctl** binary.
- You have an existing **install-config.yaml** file.

#### Procedure

1. Edit the **install-config.yaml** configuration file so that it contains the **credentialsMode** parameter set to **Manual**.

#### Example install-config.yaml configuration file

```
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual 1
compute:
- architecture: amd64
 hyperthreading: Enabled
```

- 1** This line is added to set the **credentialsMode** parameter to **Manual**.

2. To generate the manifests, run the following command from the directory that contains the installation program:

```
$./openshift-install create manifests --dir <installation_directory>
```

3. From the directory that contains the installation program, set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
```

```
--included \1
--install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
--to=<path_to_directory_for_credentials_requests> \3
```

- 1 The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 labels:
 controller-tools.k8s.io: "1.0"
 name: openshift-image-registry-ibmcos
 namespace: openshift-cloud-credential-operator
spec:
 secretRef:
 name: installer-cloud-credentials
 namespace: openshift-image-registry
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: IBMCloudProviderSpec
 policies:
 - attributes:
 - name: serviceName
 value: cloud-object-storage
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
 - crn:v1:bluemix:public:iam::::role:Operator
 - crn:v1:bluemix:public:iam::::role:Editor
 - crn:v1:bluemix:public:iam::::serviceRole:Reader
 - crn:v1:bluemix:public:iam::::serviceRole:Writer
 - attributes:
 - name: resourceType
 value: resource-group
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
```

5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id \
--credentials-requests-dir=<path_to_credential_requests_directory> \1
--name=<cluster_name> \2
--output-dir=<installation_directory> \3
--resource-group-name=<resource_group_name> \4
```

-

- 1 Specify the directory containing the files for the component **CredentialsRequest** objects.
- 2 Specify the name of the OpenShift Container Platform cluster.
- 3 Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 4 Optional: Specify the name of the resource group used for scoping the access policies.

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroupName <installation_directory>/manifests/cluster-
infrastructure-02-config.yml
```

#### Verification

- Ensure that the appropriate secrets were generated in your cluster's **manifests** directory.

### 8.4.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

#### Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 8.4.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

## IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

#### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

## Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

## Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

## 8.4.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- [Accessing the web console](#)

### 8.4.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- [About remote health monitoring](#)

### 8.4.12. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#) .

## 8.5. INSTALLING A CLUSTER ON IBM CLOUD WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a cluster with a customized network configuration on infrastructure that the installation program provisions on IBM Cloud®. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

You must set most of the network configuration parameters during installation, and you can modify only **kubeProxy** configuration parameters in a running cluster.

### 8.5.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.

- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an IBM Cloud® account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You configured the **ccctl** utility before you installed the cluster. For more information, see [Configuring IAM for IBM Cloud®](#).

### 8.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 8.5.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**8.5.4. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 8.5.5. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

### Prerequisites

- You have created either a user API key or service ID API key for your IBM Cloud® account.

### Procedure

- Export your API key for your account as a global variable:

```
$ export IC_API_KEY=<api_key>
```

### IMPORTANT

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

## 8.5.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on IBM Cloud®.

### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the **~/.powervs** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
- Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- Select **ibmcloud** as the platform to target.
  - Select the region to deploy the cluster to.
  - Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - Enter a descriptive name for your cluster.
- Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
  - Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

#### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

## Additional resources

- [Installation configuration parameters for IBM Cloud®](#)

### 8.5.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 8.4. Minimum resource requirements**

| Machine       | Operating System | vCPU | Virtual RAM | Storage | Input/Output Per Second (IOPS) |
|---------------|------------------|------|-------------|---------|--------------------------------|
| Bootstrap     | RHCOS            | 4    | 16 GB       | 100 GB  | 300                            |
| Control plane | RHCOS            | 4    | 16 GB       | 100 GB  | 300                            |
| Compute       | RHCOS            | 2    | 8 GB        | 100 GB  | 300                            |

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 8.5.6.2. Sample customized install-config.yaml file for IBM Cloud

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

## IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and then modify it.

```

apiVersion: v1
baseDomain: example.com 1
controlPlane: 2 3
 hyperthreading: Enabled 4
 name: master
 platform:
 ibmcloud: {}
 replicas: 3
compute: 5 6
- hyperthreading: Enabled 7
 name: worker
 platform:
 ibmcloud: {}
 replicas: 3
metadata:
 name: test-cluster 8
networking: 9
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes 10
 serviceNetwork:
 - 172.30.0.0/16
platform:
 ibmcloud:
 region: us-south 11
credentialsMode: Manual
publish: External
pullSecret: '{"auths": ...}' 12
fips: false 13
sshKey: ssh-ed25519 AAAA... 14

```

1 8 11 12 Required. The installation program prompts you for this value.

2 5 9 If you do not provide these parameters and values, the installation program provides the default value.

3 6 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

4 7 Enables or disables simultaneous multithreading, also known as Hyper-Threading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

- 10 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 13 Enables or disables FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 14 Optional: provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

#### 8.5.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

## NOTE

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 8.5.7. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (**ccctl**) to create the required IBM Cloud® resources.

#### Prerequisites

- You have configured the **ccctl** binary.
- You have an existing **install-config.yaml** file.

#### Procedure

1. Edit the **install-config.yaml** configuration file so that it contains the **credentialsMode** parameter set to **Manual**.

#### Example install-config.yaml configuration file

```
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual 1
compute:
 - architecture: amd64
 hyperthreading: Enabled
```

- 1** This line is added to set the **credentialsMode** parameter to **Manual**.

2. To generate the manifests, run the following command from the directory that contains the installation program:

```
$./openshift-install create manifests --dir <installation_directory>
```

- From the directory that contains the installation program, set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

- Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- Specify the location of the **install-config.yaml** file.
- Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample CredentialsRequest object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 labels:
 controller-tools.k8s.io: "1.0"
 name: openshift-image-registry-ibmcos
 namespace: openshift-cloud-credential-operator
spec:
 secretRef:
 name: installer-cloud-credentials
 namespace: openshift-image-registry
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: IBMCloudProviderSpec
 policies:
 - attributes:
 - name: serviceName
 value: cloud-object-storage
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
 - crn:v1:bluemix:public:iam::::role:Operator
 - crn:v1:bluemix:public:iam::::role:Editor
 - crn:v1:bluemix:public:iam::::serviceRole:Reader
 - crn:v1:bluemix:public:iam::::serviceRole:Writer
```

- attributes:
  - name: resourceType
  - value: resource-group
- roles:
  - crn:v1:bluemix:public:iam::::role:Viewer

5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id \
 --credentials-requests-dir=<path_to_credential_requests_directory> \ 1
 --name=<cluster_name> \ 2
 --output-dir=<installation_directory> \ 3
 --resource-group-name=<resource_group_name> \ 4
```

- 1** Specify the directory containing the files for the component **CredentialsRequest** objects.
- 2** Specify the name of the OpenShift Container Platform cluster.
- 3** Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 4** Optional: Specify the name of the resource group used for scoping the access policies.

## NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroupName <installation_directory>/manifests/cluster-
infrastructure-02-config.yml
```

## Verification

- Ensure that the appropriate secrets were generated in your cluster's **manifests** directory.

## 8.5.8. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

### Phase 1

You can customize the following network-related fields in the **install-config.yaml** file before you create the manifest files:

- **networking.networkType**
- **networking.clusterNetwork**

- **networking.serviceNetwork**
- **networking.machineNetwork**

For more information on these fields, refer to *Installation configuration parameters*.

#### NOTE

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

#### IMPORTANT

The CIDR range **172.17.0.0/16** is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

## Phase 2

After creating the manifest files by running **openshift-install create manifests**, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the **install-config.yaml** file during phase 2. However, you can further customize the network plugin during phase 2.

### 8.5.9. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

#### IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

## Prerequisites

- You have created the **install-config.yaml** file and completed any modifications to it.

## Procedure

1. Change to the directory that contains the installation program and create the manifests:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1** **<installation\_directory>** specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yml** in the **<installation\_directory>/manifests/** directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
```

3. Specify the advanced network configuration for your cluster in the **cluster-network-03-config.yml** file, such as in the following examples:

#### Specify a different VXLAN port for the OpenShift SDN network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 openshiftSDNConfig:
 vxlanPort: 4800
```

#### Enable IPsec for the OVN-Kubernetes network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 ovnKubernetesConfig:
 ipsecConfig: {}
```

4. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program consumes the **manifests/** directory when you create the Ignition config files.

### 8.5.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group:

#### **clusterNetwork**

IP address pools from which pod IP addresses are allocated.

#### **serviceNetwork**

IP address pool for services.

#### **defaultNetwork.type**

Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

### 8.5.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 8.5. Cluster Network Operator configuration object**

| Field                       | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metadata.name</b>        | <b>string</b> | The name of the CNO object. This name is always <b>cluster</b> .                                                                                                                                                                                                                                                                                                                                    |
| <b>spec.clusterNetwork</b>  | <b>array</b>  | <p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec:   clusterNetwork:     - cidr: 10.128.0.0/19       hostPrefix: 23     - cidr: 10.128.32.0/19       hostPrefix: 23</pre>                                                                          |
| <b>spec.serviceNetwork</b>  | <b>array</b>  | <p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</p> <pre>spec:   serviceNetwork:     - 172.30.0.0/14</pre> <p>You can customize this field only in the <b>install-config.yaml</b> file before you create the manifests. The value is read-only in the manifest file.</p> |
| <b>spec.defaultNetwork</b>  | <b>object</b> | Configures the network plugin for the cluster network.                                                                                                                                                                                                                                                                                                                                              |
| <b>spec.kubeProxyConfig</b> | <b>object</b> | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.                                                                                                                                                                                                                            |

#### defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

**Table 8.6. defaultNetwork object**

| Field | Type | Description |
|-------|------|-------------|
|-------|------|-------------|

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>type</b>                | <b>string</b> | <p>Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b>. The Red Hat OpenShift Networking network plugin is selected during installation. You can change this value by migrating from OpenShift SDN to OVN-Kubernetes.</p> <div>  <div> <p><b>NOTE</b></p> <p>OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.</p> </div> </div> |
| <b>openshiftSDNConfig</b>  | <b>object</b> | This object is only valid for the OpenShift SDN network plugin.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ovnKubernetesConfig</b> | <b>object</b> | This object is only valid for the OVN-Kubernetes network plugin.                                                                                                                                                                                                                                                                                                                                                                               |

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

**Table 8.7. openshiftSDNConfig object**

| Field       | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b> | <b>string</b>  | <p>Configures the network isolation mode for OpenShift SDN. The default value is <b>NetworkPolicy</b>.</p> <p>The values <b>Multitenant</b> and <b>Subnet</b> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>mtu</b>  | <b>integer</b> | <p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>50</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1450</b>.</p> <p>This value cannot be changed after cluster installation.</p> |

| Field            | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vxlanPort</b> | <b>integer</b> | <p>The port to use for all VXLAN packets. The default value is <b>4789</b>. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port <b>9000</b> and port <b>9999</b>.</p> |

### Example OpenShift SDN configuration

```
defaultNetwork:
 type: OpenShiftSDN
 openshiftSDNConfig:
 mode: NetworkPolicy
 mtu: 1450
 vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

**Table 8.8. ovnKubernetesConfig object**

| Field              | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>         | <b>integer</b> | <p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>100</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1400</b>.</p> |
| <b>genevePort</b>  | <b>integer</b> | The port to use for all Geneve packets. The default value is <b>6081</b> . This value cannot be changed after cluster installation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipsecConfig</b> | <b>object</b>  | Specify an empty object to enable IPsec encryption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Field                    | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>policyAuditConfig</b> | <b>object</b> | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.                                                                                                                                                                                                                                                                           |
| <b>gatewayConfig</b>     | <b>object</b> | <p>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</p> <div><b>NOTE</b><p>While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.</p></div> |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <b>v4InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>100.64.0.0/16</b> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <b>clusterNetwork.cidr</b> value is <b>10.128.0.0/14</b> and the <b>clusterNetwork.hostPrefix</b> value is <b>/23</b>, then the maximum number of nodes is <b><math>2^{(23-14)}=512</math></b>.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>100.64.0.0/16</b> . |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| <b>v6InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>fd98::/48</b> IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>fd98::/48</b> . |

Table 8.9. **policyAuditConfig** object

| Field              | Type    | Description                                                                                                           |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------|
| <b>rateLimit</b>   | integer | The maximum number of messages to generate every second per node. The default value is <b>20</b> messages per second. |
| <b>maxFileSize</b> | integer | The maximum size for the audit log in bytes. The default value is <b>50000000</b> or 50 MB.                           |
| <b>maxLogFiles</b> | integer | The maximum number of log files that are retained.                                                                    |

| Field                 | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination</b>    | string | <p>One of the following additional audit log targets:</p> <p><b>libc</b><br/>The libc <b>syslog()</b> function of the journald process on the host.</p> <p><b>udp:&lt;host&gt;:&lt;port&gt;</b><br/>A syslog server. Replace <b>&lt;host&gt;:&lt;port&gt;</b> with the host and port of the syslog server.</p> <p><b>unix:&lt;file&gt;</b><br/>A Unix Domain Socket file specified by <b>&lt;file&gt;</b>.</p> <p><b>null</b><br/>Do not send the audit logs to any additional target.</p> |
| <b>syslogFacility</b> | string | The syslog facility, such as <b>kern</b> , as defined by RFC5424. The default value is <b>local0</b> .                                                                                                                                                                                                                                                                                                                                                                                     |

Table 8.10. gatewayConfig object

| Field                 | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>routingViaHost</b> | <b>boolean</b> | <p>Set this field to <b>true</b> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <b>false</b>.</p> <p>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <b>true</b>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</p> |
| <b>ipForwarding</b>   | <b>object</b>  | You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <b>ipForwarding</b> specification in the <b>Network</b> resource. Specify <b>Restricted</b> to only allow IP forwarding for Kubernetes related traffic. Specify <b>Global</b> to allow forwarding of all IP traffic. For new installations, the default is <b>Restricted</b> . For updates to OpenShift Container Platform 4.14, the default is <b>Global</b> .                                                                                                                                                                                                                                                                                |

### Example OVN-Kubernetes configuration with IPsec enabled

```
defaultNetwork:
 type: OVNKubernetes
 ovnKubernetesConfig:
 mtu: 1400
 genevePort: 6081
 ipsecConfig: {}
```

### kubeProxyConfig object configuration (OpenShiftSDN container network interface only)

The values for the **kubeProxyConfig** object are defined in the following table:

Table 8.11. **kubeProxyConfig** object

| Field                                          | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>iptablesSyncPeriod</b>                      | <b>string</b> | <p>The refresh period for <b>iptables</b> rules. The default value is <b>30s</b>. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a> documentation.</p> <div>  <div> <p><b>NOTE</b></p> <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the <b>iptablesSyncPeriod</b> parameter is no longer necessary.</p> </div> </div> |
| <b>proxyArguments.iptables-min-sync-period</b> | <b>array</b>  | <p>The minimum duration before refreshing <b>iptables</b> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a>. The default value is:</p> <div>  <pre>kubeProxyConfig:   proxyArguments:     iptables-min-sync-period:       - 0s</pre> </div>                                                              |

### 8.5.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ ❶
--log-level=info ❷
```

- ❶ For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- ❷ To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 8.5.12. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

##### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.

To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 8.5.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

### Example output

```
system:admin
```

## Additional resources

- [Accessing the web console](#)

### 8.5.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

## Additional resources

- [About remote health monitoring](#)

### 8.5.15. Next steps

- [Customize your cluster.](#)
- If necessary, you can [opt out of remote health reporting](#) .

## 8.6. INSTALLING A CLUSTER ON IBM CLOUD INTO AN EXISTING VPC

In OpenShift Container Platform version 4.14, you can install a cluster into an existing Virtual Private Cloud (VPC) on IBM Cloud®. The installation program provisions the rest of the required infrastructure, which you can then further customize. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### 8.6.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.

- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an IBM Cloud® account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You configured the **ccctl** utility before you installed the cluster. For more information, see [Configuring IAM for IBM Cloud®](#).

### 8.6.2. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into the subnets of an existing IBM® Virtual Private Cloud (VPC). Deploying OpenShift Container Platform into an existing VPC can help you avoid limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are in your existing subnets, it cannot choose subnet CIDRs and so forth. You must configure networking for the subnets to which you will install the cluster.

#### 8.6.2.1. Requirements for using your VPC

You must correctly configure the existing VPC and its subnets before you install the cluster. The installation program does not create the following components:

- NAT gateways
- Subnets
- Route tables
- VPC network

The installation program cannot:

- Subdivide network ranges for the cluster to use
- Set route tables for the subnets
- Set VPC options like DHCP

#### NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

#### 8.6.2.2. VPC validation

The VPC and all of the subnets must be in an existing resource group. The cluster is deployed to this resource group.

As part of the installation, specify the following in the **install-config.yaml** file:

- The name of the resource group

- The name of VPC
- The subnets for control plane machines and compute machines

To ensure that the subnets that you provide are suitable, the installation program confirms the following:

- All of the subnets that you specify exist.
- For each availability zone in the region, you specify:
  - One subnet for control plane machines.
  - One subnet for compute machines.
- The machine CIDR that you specified contains the subnets for the compute machines and control plane machines.

#### NOTE

Subnet IDs are not supported.

### 8.6.2.3. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed to the entire network.
- TCP port 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

### 8.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

**8.6.4. Generating a key pair for cluster node SSH access**

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 8.6.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

## Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

## Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 8.6.6. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

## Prerequisites

- You have created either a user API key or service ID API key for your IBM Cloud® account.

## Procedure

- Export your API key for your account as a global variable:

```
$ export IC_API_KEY=<api_key>
```

## IMPORTANT

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

### 8.6.7. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on IBM Cloud®.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

## NOTE

Always delete the **~/powers** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powers
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **ibmcloud** as the platform to target.
  - iii. Select the region to deploy the cluster to.
  - iv. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - v. Enter a descriptive name for your cluster.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
  3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- [Installation configuration parameters for IBM Cloud®](#)

**8.6.7.1. Minimum resource requirements for cluster installation**

Each cluster machine must meet the following minimum requirements:

**Table 8.12. Minimum resource requirements**

| Machine       | Operating System | vCPU | Virtual RAM | Storage | Input/Output Per Second (IOPS) |
|---------------|------------------|------|-------------|---------|--------------------------------|
| Bootstrap     | RHCOS            | 4    | 16 GB       | 100 GB  | 300                            |
| Control plane | RHCOS            | 4    | 16 GB       | 100 GB  | 300                            |
| Compute       | RHCOS            | 2    | 8 GB        | 100 GB  | 300                            |

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 8.6.7.2. Sample customized install-config.yaml file for IBM Cloud

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

## IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and then modify it.

```
apiVersion: v1
baseDomain: example.com 1
controlPlane: 2 3
 hyperthreading: Enabled 4
 name: master
 platform:
 ibmcloud: {}
 replicas: 3
compute: 5 6
- hyperthreading: Enabled 7
 name: worker
 platform:
 ibmcloud: {}
 replicas: 3
metadata:
 name: test-cluster 8
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14 9
 hostPrefix: 23
 machineNetwork:
```

```

- cidr: 10.0.0.0/16
networkType: OVNKubernetes 10
serviceNetwork:
- 172.30.0.0/16
platform:
ibmcloud:
 region: eu-gb 11
 resourceGroupName: eu-gb-example-network-rg 12
 networkResourceGroupName: eu-gb-example-existing-network-rg 13
 vpcName: eu-gb-example-network-1 14
 controlPlaneSubnets: 15
 - eu-gb-example-network-1-cp-eu-gb-1
 - eu-gb-example-network-1-cp-eu-gb-2
 - eu-gb-example-network-1-cp-eu-gb-3
 computeSubnets: 16
 - eu-gb-example-network-1-compute-eu-gb-1
 - eu-gb-example-network-1-compute-eu-gb-2
 - eu-gb-example-network-1-compute-eu-gb-3
credentialsMode: Manual
publish: External
pullSecret: '{"auths": ...}' 17
fips: false 18
sshKey: ssh-ed25519 AAAA... 19

```

1 8 11 17 Required. The installation program prompts you for this value.

2 5 If you do not provide these parameters and values, the installation program provides the default value.

3 6 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

4 7 Enables or disables simultaneous multithreading, also known as Hyper-Threading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

9 The machine CIDR must contain the subnets for the compute machines and control plane machines.

10 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

12 The name of an existing resource group. All installer-provisioned cluster resources are deployed to this resource group. If undefined, a new resource group is created for the cluster.

- 13 Specify the name of the resource group that contains the existing virtual private cloud (VPC). The existing VPC and subnets should be in this resource group. The cluster will be installed to this VPC.
- 14 Specify the name of an existing VPC.
- 15 Specify the name of the existing subnets to which to deploy the control plane machines. The subnets must belong to the VPC that you specified. Specify a subnet for each availability zone in the region.
- 16 Specify the name of the existing subnets to which to deploy the compute machines. The subnets must belong to the VPC that you specified. Specify a subnet for each availability zone in the region.
- 18 Enables or disables FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 19 Optional: provide the **sshKey** value that you use to access the machines in your cluster.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

#### 8.6.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

## NOTE

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 8.6.8. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (**ccctl**) to create the required IBM Cloud® resources.

#### Prerequisites

- You have configured the **ccctl** binary.
- You have an existing **install-config.yaml** file.

#### Procedure

1. Edit the **install-config.yaml** configuration file so that it contains the **credentialsMode** parameter set to **Manual**.

#### Example install-config.yaml configuration file

```
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual 1
compute:
 - architecture: amd64
 hyperthreading: Enabled
```

- 1** This line is added to set the **credentialsMode** parameter to **Manual**.

2. To generate the manifests, run the following command from the directory that contains the installation program:

```
$./openshift-install create manifests --dir <installation_directory>
```

- From the directory that contains the installation program, set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

- Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \ ❶
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ ❷
 --to=<path_to_directory_for_credentials_requests> ❸
```

- The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- Specify the location of the **install-config.yaml** file.
- Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample CredentialsRequest object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 labels:
 controller-tools.k8s.io: "1.0"
 name: openshift-image-registry-ibmcos
 namespace: openshift-cloud-credential-operator
spec:
 secretRef:
 name: installer-cloud-credentials
 namespace: openshift-image-registry
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: IBMCloudProviderSpec
 policies:
 - attributes:
 - name: serviceName
 value: cloud-object-storage
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
 - crn:v1:bluemix:public:iam::::role:Operator
 - crn:v1:bluemix:public:iam::::role:Editor
 - crn:v1:bluemix:public:iam::::serviceRole:Reader
 - crn:v1:bluemix:public:iam::::serviceRole:Writer
```

```
- attributes:
 - name: resourceType
 value: resource-group
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
```

5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id \
 --credentials-requests-dir=<path_to_credential_requests_directory> \
 --name=<cluster_name> \
 --output-dir=<installation_directory> \
 --resource-group-name=<resource_group_name>
```

- 1 Specify the directory containing the files for the component **CredentialsRequest** objects.
- 2 Specify the name of the OpenShift Container Platform cluster.
- 3 Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 4 Optional: Specify the name of the resource group used for scoping the access policies.

## NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroupName <installation_directory>/manifests/cluster-
infrastructure-02-config.yml
```

## Verification

- Ensure that the appropriate secrets were generated in your cluster's **manifests** directory.

## 8.6.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

## IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

## Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/./openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 8.6.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

## IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

#### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

-

## Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 8.6.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- [Accessing the web console](#)

### 8.6.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- [About remote health monitoring](#)

### 8.6.13. Next steps

- [Customize your cluster.](#)
- Optional: [Opt out of remote health reporting](#) .

## 8.7. INSTALLING A PRIVATE CLUSTER ON IBM CLOUD

In OpenShift Container Platform version 4.14, you can install a private cluster into an existing VPC. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### 8.7.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an IBM Cloud® account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You configured the **ccctl** utility before you installed the cluster. For more information, see [Configuring IAM for IBM Cloud®](#).

### 8.7.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

#### IMPORTANT

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.
- Create a DNS zone using IBM Cloud® DNS Services and specify it as the base domain of the cluster. For more information, see "Using IBM Cloud® DNS Services to configure DNS resolution".
- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.

- The hosts on the network that you provision.
- The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company's guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

### 8.7.3. Private clusters in IBM Cloud

To create a private cluster on IBM Cloud®, you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

The cluster still requires access to internet to access the IBM Cloud® APIs.

The following items are not required or created when you install a private cluster:

- Public subnets
- Public network load balancers, which support public ingress
- A public DNS zone that matches the **baseDomain** for the cluster

The installation program does use the **baseDomain** that you specify to create a private DNS zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

#### 8.7.3.1. Limitations

Private clusters on IBM Cloud® are subject only to the limitations associated with the existing VPC that was used for cluster deployment.

### 8.7.4. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into the subnets of an existing IBM® Virtual Private Cloud (VPC). Deploying OpenShift Container Platform into an existing VPC can help you avoid limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are in your existing subnets, it cannot choose subnet CIDRs and so forth. You must configure networking for the subnets to which you will install the cluster.

#### 8.7.4.1. Requirements for using your VPC

You must correctly configure the existing VPC and its subnets before you install the cluster. The installation program does not create the following components:

- NAT gateways
- Subnets
- Route tables

- VPC network

The installation program cannot:

- Subdivide network ranges for the cluster to use
- Set route tables for the subnets
- Set VPC options like DHCP

#### NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

### 8.7.4.2. VPC validation

The VPC and all of the subnets must be in an existing resource group. The cluster is deployed to this resource group.

As part of the installation, specify the following in the **install-config.yaml** file:

- The name of the resource group
- The name of VPC
- The subnets for control plane machines and compute machines

To ensure that the subnets that you provide are suitable, the installation program confirms the following:

- All of the subnets that you specify exist.
- For each availability zone in the region, you specify:
  - One subnet for control plane machines.
  - One subnet for compute machines.
- The machine CIDR that you specified contains the subnets for the compute machines and control plane machines.

#### NOTE

Subnet IDs are not supported.

### 8.7.4.3. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed to the entire network.
- TCP port 22 ingress (SSH) is allowed to the entire network.

- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

### 8.7.5. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 8.7.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

## 8.7.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a bastion host on your cloud network or a machine that has access to the to the network through a VPN.

For more information about private cluster installation requirements, see "Private clusters".

### Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space.

### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 8.7.8. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

#### Prerequisites

- You have created either a user API key or service ID API key for your IBM Cloud® account.

#### Procedure

- Export your API key for your account as a global variable:

```
$ export IC_API_KEY=<api_key>
```

#### IMPORTANT

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

### 8.7.9. Manually creating the installation configuration file

When installing a private OpenShift Container Platform cluster, you must manually generate the installation configuration file.

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

### NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

#### Additional resources

- [Installation configuration parameters for IBM Cloud®](#)

#### 8.7.9.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 8.13. Minimum resource requirements

| Machine       | Operating System | vCPU | Virtual RAM | Storage | Input/Output Per Second (IOPS) |
|---------------|------------------|------|-------------|---------|--------------------------------|
| Bootstrap     | RHCOS            | 4    | 16 GB       | 100 GB  | 300                            |
| Control plane | RHCOS            | 4    | 16 GB       | 100 GB  | 300                            |
| Compute       | RHCOS            | 2    | 8 GB        | 100 GB  | 300                            |

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 8.7.9.2. Sample customized install-config.yaml file for IBM Cloud

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

## IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and then modify it.

```
apiVersion: v1
baseDomain: example.com 1
controlPlane: 2 3
 hyperthreading: Enabled 4

sshKey: ssh-ed25519 AAAA... 21

```

<sup>1</sup> <sup>8</sup> <sup>12</sup> <sup>19</sup> Required.

<sup>2</sup> <sup>5</sup> If you do not provide these parameters and values, the installation program provides the default value.

<sup>3</sup> <sup>6</sup> The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

<sup>4</sup> <sup>7</sup> Enables or disables simultaneous multithreading, also known as Hyper-Threading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

<sup>9</sup> The machine CIDR must contain the subnets for the compute machines and control plane machines.

<sup>10</sup> The CIDR must contain the subnets defined in **platform.ibmcloud.controlPlaneSubnets** and **platform.ibmcloud.computeSubnets**.

<sup>11</sup> The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

- 13 The name of an existing resource group. All installer-provisioned cluster resources are deployed to this resource group. If undefined, a new resource group is created for the cluster.
- 14 Specify the name of the resource group that contains the existing virtual private cloud (VPC). The existing VPC and subnets should be in this resource group. The cluster will be installed to this VPC.
- 15 Specify the name of an existing VPC.
- 16 Specify the name of the existing subnets to which to deploy the control plane machines. The subnets must belong to the VPC that you specified. Specify a subnet for each availability zone in the region.
- 17 Specify the name of the existing subnets to which to deploy the compute machines. The subnets must belong to the VPC that you specified. Specify a subnet for each availability zone in the region.
- 18 How to publish the user-facing endpoints of your cluster. Set **publish** to **Internal** to deploy a private cluster. The default value is **External**.
- 20 Enables or disables FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

#### IMPORTANT

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 21 Optional: provide the **sshKey** value that you use to access the machines in your cluster.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 8.7.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

## NOTE
