| <code>networking:<br/>clusterNetwork:<br/>hostPrefix:</code> | The subnet prefix length to assign to each individual node. For example, if <b>hostPrefix</b> is set to <b>23</b> then each node is assigned a <b>/23</b> subnet out of the given <b>cidr</b> . A <b>hostPrefix</b> value of <b>23</b> provides 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. | A subnet prefix.<br><br>The default value is <b>23</b> .                                                                                                                                                                                                                              |
| <code>networking:<br/>serviceNetwork:</code>                 | The IP address block for services. The default value is <b>172.30.0.0/16</b> .<br><br>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.                                                                                    | An array with an IP address block in CIDR format. For example:<br><br><code>networking:<br/>serviceNetwork:<br/>- 172.30.0.0/16</code>                                                                                                                                                |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                         | Values                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:<br/>machineNetwork:</code>           | <p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p> <p>If you specify multiple IP kernel arguments, the <b>machineNetwork.cidr</b> value must be the CIDR of the primary network.</p>                                                                         | <p>An array of objects. For example:</p> <pre>networking:   machineNetwork:     - cidr: 10.0.0.0/16</pre>                                                                                                                                                                                                    |
| <code>networking:<br/>machineNetwork:<br/>cidr:</code> | <p>Required if you use <b>networking.machineNetwork</b>. An IP address block. The default value is <b>10.0.0.0/16</b> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <b>192.168.126.0/24</b>. For IBM Power® Virtual Server, the default value is <b>192.168.0.0/24</b>.</p> | <p>An IP network block in CIDR notation.</p> <p>For example, <b>10.0.0.0/16</b>.</p> <div>  <p><b>NOTE</b></p> <p>Set the <b>networking.machineNetwork</b> to match the CIDR that the preferred NIC resides in.</p> </div> |

### 16.6.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 16.61. Optional parameters

| Parameter                                             | Description                                                                                                                                                                                                                                                 | Values       |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <code>additionalTrustBundle:</code>                   | A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.                                                                                          | String       |
| <code>capabilities:</code>                            | Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the "Cluster capabilities" page in <i>Installing</i> . | String array |
| <code>capabilities:<br/>baselineCapabilitySet:</code> | <p>Selects an initial set of optional capabilities to enable. Valid values are <b>None</b>, <b>v4.11</b>, <b>v4.12</b> and <b>vCurrent</b>.</p> <p>The default value is <b>vCurrent</b>.</p>                                                                | String       |

| Parameter                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                             |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| capabilities:<br>additionalEnabledCapabilities: | Extends the set of optional capabilities beyond what you specify in <b>baselineCapabilitySet</b> . You may specify multiple capabilities in this parameter.                                                                                                                                                                                                                                                                                                                                                    | String array                                                       |
| cpuPartitioningMode:                            | Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <i>Workload partitioning</i> page in the <i>Scalability and Performance</i> section. | <b>None</b> or <b>AllNodes</b> . <b>None</b> is the default value. |
| compute:                                        | The configuration for the machines that comprise the compute nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                            | Array of <b>MachinePool</b> objects.                               |
| compute:<br>architecture:                       | Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <b>s390x</b> (the default).                                                                                                                                                                                                                                                                                    | String                                                             |
| compute:<br>hyperthreading:                     | Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b> , on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.<br><br> <b>IMPORTANT</b><br><br>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.                               | <b>Enabled</b> or <b>Disabled</b>                                  |

| Parameter                             | Description                                                                                                                                                                                                                                                        | Values                                                                                      |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>compute:</b><br>name:              | Required if you use <b>compute</b> . The name of the machine pool.                                                                                                                                                                                                 | <b>worker</b>                                                                               |
| <b>compute:</b><br>platform:          | Required if you use <b>compute</b> . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <b>controlPlane.platform</b> parameter value.                                                               | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |
| <b>compute:</b><br>replicas:          | The number of compute machines, which are also known as worker machines, to provision.                                                                                                                                                                             | A positive integer greater than or equal to <b>2</b> . The default value is <b>3</b> .      |
| <b>featureSet:</b>                    | Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see "Enabling features using feature gates". | String. The name of the feature set to enable, such as <b>TechPreviewNoUpgrade</b> .        |
| <b>controlPlane:</b>                  | The configuration for the machines that comprise the control plane.                                                                                                                                                                                                | Array of <b>MachinePool</b> objects.                                                        |
| <b>controlPlane:</b><br>architecture: | Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <b>s390x</b> (the default).                                        | String                                                                                      |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Values                                                                                      |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>controlPlane:</b><br><b>hyperthreading:</b> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div> | <b>Enabled</b> or <b>Disabled</b>                                                           |
| <b>controlPlane:</b><br><b>name:</b>           | Required if you use <b>controlPlane</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                 | <b>master</b>                                                                               |
| <b>controlPlane:</b><br><b>platform:</b>       | Required if you use <b>controlPlane</b> . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <b>compute.platform</b> parameter value.                                                                                                                                                                                                                                                                                          | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |
| <b>controlPlane:</b><br><b>replicas:</b>       | The number of control plane machines to provision.                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Supported values are <b>3</b> , or <b>1</b> when deploying single-node OpenShift.           |
| <b>credentialsMode:</b>                        | The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.                                                                                                                                                                                                                                                            | <b>Mint, Passthrough, Manual</b> or an empty string (""). <sup>[1]</sup>                    |
| <b>fips:</b>                                   | Enable or disable FIPS mode. The default is <b>false</b> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default                                                                                                                                                                                                                                                                                         | <b>false</b> or <b>true</b>                                                                 |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Values |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
|           | <p>Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p> <div data-bbox="488 262 592 1281">  </div> <p><b>IMPORTANT</b></p> <p>To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see <a href="#">Installing the system in FIPS mode</a>. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.</p> <div data-bbox="488 1330 592 1525">  </div> <p><b>NOTE</b></p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p> |        |

| Parameter                                    | Description                                                                                                                             | Values                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| sshKey:   | <p>The SSH key to authenticate access to your cluster machines.</p> <div>  <p><b>NOTE</b></p> <p>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <b>ssh-agent</b> process uses.</p> </div> | For example, <b>sshKey: ssh-ed25519 AAAA...</b> |

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.

## CHAPTER 17. INSTALLING ON IBM POWER

### 17.1. PREPARING TO INSTALL ON IBM POWER

#### 17.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

#### 17.1.2. Choosing a method to install OpenShift Container Platform on IBM Power

You can install a cluster on IBM Power® infrastructure that you provision, by using one of the following methods:

- **Installing a cluster on IBM Power®** You can install OpenShift Container Platform on IBM Power® infrastructure that you provision.
- **Installing a cluster on IBM Power® in a restricted network** You can install OpenShift Container Platform on IBM Power® infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

### 17.2. INSTALLING A CLUSTER ON IBM POWER

In OpenShift Container Platform version 4.14, you can install a cluster on IBM Power® infrastructure that you provision.

#### IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

#### 17.2.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned [persistent storage using OpenShift Data Foundation](#) or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with **ReadWriteMany** access.

- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 17.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 17.2.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

#### 17.2.3.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 17.1. Minimum required hosts**

| Hosts                           | Description                                                                                                                                                                                            |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines    | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |

| Hosts                                                                   | Description                                                                                |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines. |

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#) .

17.2.3.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 17.2. Minimum resource requirements

| Machine       | Operating System | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS            | 2        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS            | 2        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS            | 2        | 8 GB        | 100 GB  | 300                               |

- 1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
- 2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 17.2.3.3. Minimum IBM Power requirements

You can install OpenShift Container Platform version 4.14 on the following IBM® hardware:

- IBM Power®9 or IBM Power®10 processor-based systems

## NOTE

Support for RHCOS functionality for all IBM Power®8 models, IBM Power® AC922, IBM Power® IC922, and IBM Power® LC922 is deprecated in OpenShift Container Platform 4.14. Red Hat recommends that you use later hardware models.

## Hardware requirements

- Six logical partitions (LPARs) across multiple PowerVM servers

## Operating system requirements

- One instance of an IBM Power®9 or Power10 processor-based system

On your IBM Power® instance, set up:

- Three LPARs for OpenShift Container Platform control plane machines
- Two LPARs for OpenShift Container Platform compute machines
- One LPAR for the temporary OpenShift Container Platform bootstrap machine

## Disk storage for the IBM Power guest virtual machines

- Local storage, or storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**

- Dedicated physical adapter, or SR-IOV virtual function
- Available by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM® vNIC

**Storage / main memory**

- 100 GB / 16 GB for OpenShift Container Platform control plane machines
- 100 GB / 8 GB for OpenShift Container Platform compute machines
- 100 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

**17.2.3.4. Recommended IBM Power system requirements****Hardware requirements**

- Six LPARs across multiple PowerVM servers

**Operating system requirements**

- One instance of an IBM Power®9 or IBM Power®10 processor-based system

On your IBM Power® instance, set up:

- Three LPARs for OpenShift Container Platform control plane machines
- Two LPARs for OpenShift Container Platform compute machines
- One LPAR for the temporary OpenShift Container Platform bootstrap machine

**Disk storage for the IBM Power guest virtual machines**

- Local storage, or storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**

- Dedicated physical adapter, or SR-IOV virtual function
- Available by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM® vNIC

**Storage / main memory**

- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

**17.2.3.5. Certificate signing requests management**

Because your cluster has limited access to automatic machine management when you use infrastructure

that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 17.2.3.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

#### NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

#### 17.2.3.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

#### 17.2.3.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

## IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

**Table 17.3. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
|          | <b>10256</b>       | openshift-sdn                                                                                                                               |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

**Table 17.4. Ports used for all-machine to control plane communications**

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

Table 17.5. Ports used for control plane machine to control plane machine communications

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

### NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

### Additional resources

- [Configuring chrony time service](#)

### 17.2.3.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

### NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster\_name>** is the cluster name and **<base\_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster\_name>.<base\_domain>..**

Table 17.6. Required DNS records

| Component              | Record                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Kubernetes API         | <b>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                            | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                              |
|                        | <b>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                        | <p>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</p> <div>  <p><b>IMPORTANT</b></p> <p>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</p> </div>                      |
| Routes                 | <b>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                         | <p>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</p> <p>For example, <b>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</b> is used as a wildcard route to the OpenShift Container Platform console.</p> |
| Bootstrap machine      | <b>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                      | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                                |
| Control plane machines | <b>&lt;control_plane&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b> | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                 |
| Compute machines       | <b>&lt;compute&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>       | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                        |

## NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

**17.2.3.7.1. Example DNS configuration for user-provisioned clusters**

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

**Example 17.1. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root (
 2019070700 ; serial
 3H ; refresh (3 hours)
 30M ; retry (30 minutes)
 2W ; expiry (2 weeks)
 1W) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.

```

- 1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

- 2 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- 3 Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

#### NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- 4 Provides name resolution for the bootstrap machine.
- 5 6 7 Provides name resolution for the control plane machines.
- 8 9 Provides name resolution for the compute machines.

### Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

#### Example 17.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (
 2019070700 ; serial
 3H ; refresh (3 hours)
 30M ; retry (30 minutes)
 2W ; expiry (2 weeks)
 1W) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR control-plane0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR control-plane1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR control-plane2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR compute0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR compute1.ocp4.example.com. 8
;
;EOF
```

- 1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- 2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- 3 Provides reverse DNS resolution for the bootstrap machine.
- 4 5 6 Provides reverse DNS resolution for the control plane machines.
- 7 8 Provides reverse DNS resolution for the compute machines.

#### NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

### 17.2.3.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

#### NOTE

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
  - Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
  - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

#### IMPORTANT

Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 17.7. API load balancer**

| Port | Back-end machines (pool members) | Internal | External | Description |
|------|----------------------------------|----------|----------|-------------|
|------|----------------------------------|----------|----------|-------------|

| Port         | Back-end machines (pool members)                                                                                                                                                                                                              | Internal | External | Description           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|-----------------------|
| <b>6443</b>  | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <b>/readyz</b> endpoint for the API server health check probe. | X        | X        | Kubernetes API server |
| <b>22623</b> | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.                                                                                       | X        |          | Machine config server |

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.  
Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 17.8. Application Ingress load balancer**

| Port       | Back-end machines (pool members)                                                   | Internal | External | Description   |
|------------|------------------------------------------------------------------------------------|----------|----------|---------------|
| <b>443</b> | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTPS traffic |

| Port | Back-end machines (pool members)                                                   | Internal | External | Description  |
|------|------------------------------------------------------------------------------------|----------|----------|--------------|
| 80   | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTP traffic |

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

### 17.2.3.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy\_connect\_any=1**.

#### Example 17.3. Sample API and application Ingress load balancer configuration

```
global
 log 127.0.0.1 local2
 pidfile /var/run/haproxy.pid
 maxconn 4000
 daemon
defaults
 mode http
 log global
 option dontlognull
 option http-server-close
 option redispatch
 retries 3
 timeout http-request 10s
 timeout queue 1m
 timeout connect 10s
 timeout client 1m
 timeout server 1m
 timeout http-keep-alive 10s
 timeout check 10s
 maxconn 3000
listen api-server-6443 1
```

```

bind *:6443
mode tcp
option httpchk GET /readyz HTTP/1.0
option log-health-checks
balance roundrobin
server bootstrap bootstrap.ocp4.example.com:6443 verify none check check-ssl inter 10s fall 2
rise 3 backup 2
server master0 master0.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
server master1 master1.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
server master2 master2.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
listen machine-config-server-22623 3
bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 4
server master0 master0.ocp4.example.com:22623 check inter 1s
server master1 master1.ocp4.example.com:22623 check inter 1s
server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 5
bind *:443
mode tcp
balance source
server worker0 worker0.ocp4.example.com:443 check inter 1s
server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 6
bind *:80
mode tcp
balance source
server worker0 worker0.ocp4.example.com:80 check inter 1s
server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1 Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 2 4 The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 3 Port **22623** handles the machine config server traffic and points to the control plane machines.
- 5 Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 6 Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

#### NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltp** on the HAProxy node.

**17.2.4. Preparing the user-provisioned infrastructure**

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

**Prerequisites**

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

**Procedure**

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
  - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
  - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

**NOTE**

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

**NOTE**

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.
3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.

### IMPORTANT

By default, port **1936** is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
  - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
  - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.  
See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
  - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
  - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.  
See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

### NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

## 17.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
  - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- 1** Replace **<nameserver\_ip>** with the IP address of the nameserver, **<cluster\_name>** with your cluster name, and **<base\_domain>** with your base domain name.

**Example output**

```
api.ocp4.example.com. 604800 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

**Example output**

```
api-int.ocp4.example.com. 604800 IN A 192.168.1.5
```

- c. Test an example **\*.apps.<cluster\_name>.<base\_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

**Example output**

```
random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.
<cluster_name>.<base_domain>
```

### Example output

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

### Example output

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
    - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

### Example output

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
```

- 1** Provides the record name for the Kubernetes internal API.

- 2** Provides the record name for the Kubernetes API.

### NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

## Example output

```
96.1.168.192.in-addr.arpa. 604800 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

### 17.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 17.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

## Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

## Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 17.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

## Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

#### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 17.2.9. Manually creating the installation configuration file

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

#### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

**NOTE**

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

**Additional resources**

- [Installation configuration parameters for IBM Power®](#)

**17.2.9.1. Sample install-config.yaml file for IBM Power**

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```

apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
 name: worker
 replicas: 0 4
 architecture: ppc64le
controlPlane: 5
 hyperthreading: Enabled 6
 name: master
 replicas: 3 7
 architecture: ppc64le
metadata:
 name: test 8
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14 9
 hostPrefix: 23 10
 networkType: OVNKubernetes 11
 serviceNetwork: 12
 - 172.30.0.0/16
platform:
 none: {} 13
fips: false 14
pullSecret: '{"auths": ...}' 15
sshKey: 'ssh-ed25519 AAAA...' 16

```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2 5

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

- 3 6** Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

#### NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

#### IMPORTANT

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 4** You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

#### NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7** The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8** The cluster name that you specified in your DNS records.
- 9** A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

#### NOTE

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

- 10** The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a **/23** subnet out of the given **cidr**, which allows for 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

**11**

The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

- 12 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 13 You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Power® infrastructure.

### IMPORTANT

Clusters that are installed with the platform type **none** are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

- 14 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 15 The [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
- 16 The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

## 17.2.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

## Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.

5

Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 17.2.9.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

#### Prerequisites

- You have an existing **install-config.yaml** file.

#### Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
- name: worker
 platform: {}
 replicas: 0
```

## NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

### 17.2.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group:

#### **clusterNetwork**

IP address pools from which pod IP addresses are allocated.

#### **serviceNetwork**

IP address pool for services.

#### **defaultNetwork.type**

Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

#### 17.2.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 17.9. Cluster Network Operator configuration object**

| Field                       | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metadata.name</b>        | <b>string</b> | The name of the CNO object. This name is always <b>cluster</b> .                                                                                                                                                                                                                                                                                                                                    |
| <b>spec.clusterNetwork</b>  | <b>array</b>  | <p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec:   clusterNetwork:     - cidr: 10.128.0.0/19       hostPrefix: 23     - cidr: 10.128.32.0/19       hostPrefix: 23</pre>                                                                          |
| <b>spec.serviceNetwork</b>  | <b>array</b>  | <p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</p> <pre>spec:   serviceNetwork:     - 172.30.0.0/14</pre> <p>You can customize this field only in the <b>install-config.yaml</b> file before you create the manifests. The value is read-only in the manifest file.</p> |
| <b>spec.defaultNetwork</b>  | <b>object</b> | Configures the network plugin for the cluster network.                                                                                                                                                                                                                                                                                                                                              |
| <b>spec.kubeProxyConfig</b> | <b>object</b> | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.                                                                                                                                                                                                                            |

### defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 17.10. **defaultNetwork** object

| Field | Type | Description |
|-------|------|-------------|
|-------|------|-------------|

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>type</b>                | <b>string</b> | <p>Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b>. The Red Hat OpenShift Networking network plugin is selected during installation. You can change this value by migrating from OpenShift SDN to OVN-Kubernetes.</p> <div>  <div> <b>NOTE</b><br/> OpenShift Container Platform uses the OVN-Kubernetes network plugin by default. </div> </div> |
| <b>openshiftSDNConfig</b>  | <b>object</b> | This object is only valid for the OpenShift SDN network plugin.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ovnKubernetesConfig</b> | <b>object</b> | This object is only valid for the OVN-Kubernetes network plugin.                                                                                                                                                                                                                                                                                                                                                                      |

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

Table 17.11. **openshiftSDNConfig** object

| Field       | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b> | <b>string</b>  | <p>Configures the network isolation mode for OpenShift SDN. The default value is <b>NetworkPolicy</b>.</p> <p>The values <b>Multitenant</b> and <b>Subnet</b> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>mtu</b>  | <b>integer</b> | <p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>50</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1450</b>.</p> <p>This value cannot be changed after cluster installation.</p> |

| Field            | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vxlanPort</b> | <b>integer</b> | <p>The port to use for all VXLAN packets. The default value is <b>4789</b>. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port <b>9000</b> and port <b>9999</b>.</p> |

### Example OpenShift SDN configuration

```
defaultNetwork:
 type: OpenShiftSDN
 openshiftSDNConfig:
 mode: NetworkPolicy
 mtu: 1450
 vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

**Table 17.12. `ovnKubernetesConfig` object**

| Field              | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>         | <b>integer</b> | <p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>100</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1400</b>.</p> |
| <b>genevePort</b>  | <b>integer</b> | The port to use for all Geneve packets. The default value is <b>6081</b> . This value cannot be changed after cluster installation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipsecConfig</b> | <b>object</b>  | Specify an empty object to enable IPsec encryption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Field                    | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>policyAuditConfig</b> | <b>object</b> | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.                                                                                                                                                                                                                                                                           |
| <b>gatewayConfig</b>     | <b>object</b> | <p>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</p> <div><b>NOTE</b><p>While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.</p></div> |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <b>v4InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>100.64.0.0/16</b> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <b>clusterNetwork.cidr</b> value is <b>10.128.0.0/14</b> and the <b>clusterNetwork.hostPrefix</b> value is <b>/23</b>, then the maximum number of nodes is <b><math>2^{(23-14)}=512</math></b>.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>100.64.0.0/16</b> . |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| <b>v6InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>fd98::/48</b> IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>fd98::/48</b> . |

Table 17.13. **policyAuditConfig** object

| Field              | Type    | Description                                                                                                           |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------|
| <b>rateLimit</b>   | integer | The maximum number of messages to generate every second per node. The default value is <b>20</b> messages per second. |
| <b>maxFileSize</b> | integer | The maximum size for the audit log in bytes. The default value is <b>50000000</b> or 50 MB.                           |
| <b>maxLogFiles</b> | integer | The maximum number of log files that are retained.                                                                    |

| Field                 | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination</b>    | string | <p>One of the following additional audit log targets:</p> <p><b>libc</b><br/>The libc <b>syslog()</b> function of the journald process on the host.</p> <p><b>udp:&lt;host&gt;:&lt;port&gt;</b><br/>A syslog server. Replace <b>&lt;host&gt;:&lt;port&gt;</b> with the host and port of the syslog server.</p> <p><b>unix:&lt;file&gt;</b><br/>A Unix Domain Socket file specified by <b>&lt;file&gt;</b>.</p> <p><b>null</b><br/>Do not send the audit logs to any additional target.</p> |
| <b>syslogFacility</b> | string | The syslog facility, such as <b>kern</b> , as defined by RFC5424. The default value is <b>local0</b> .                                                                                                                                                                                                                                                                                                                                                                                     |

Table 17.14. gatewayConfig object

| Field                 | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>routingViaHost</b> | <b>boolean</b> | <p>Set this field to <b>true</b> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <b>false</b>.</p> <p>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <b>true</b>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</p> |
| <b>ipForwarding</b>   | <b>object</b>  | You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <b>ipForwarding</b> specification in the <b>Network</b> resource. Specify <b>Restricted</b> to only allow IP forwarding for Kubernetes related traffic. Specify <b>Global</b> to allow forwarding of all IP traffic. For new installations, the default is <b>Restricted</b> . For updates to OpenShift Container Platform 4.14, the default is <b>Global</b> .                                                                                                                                                                                                                                                                                |

### Example OVN-Kubernetes configuration with IPsec enabled

```
defaultNetwork:
 type: OVNKubernetes
 ovnKubernetesConfig:
```

```
mtu: 1400
genevePort: 6081
ipsecConfig: {}
```

### kubeProxyConfig object configuration (OpenShiftSDN container network interface only)

The values for the **kubeProxyConfig** object are defined in the following table:

Table 17.15. kubeProxyConfig object

| Field                                          | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>iptablesSyncPeriod</b>                      | <b>string</b> | <p>The refresh period for <b>iptables</b> rules. The default value is <b>30s</b>. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a> documentation.</p> <div>  <p><b>NOTE</b></p> <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the <b>iptablesSyncPeriod</b> parameter is no longer necessary.</p> </div> |
| <b>proxyArguments.iptables-min-sync-period</b> | <b>array</b>  | <p>The minimum duration before refreshing <b>iptables</b> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a>. The default value is:</p> <pre>kubeProxyConfig:   proxyArguments:     iptables-min-sync-period:       - 0s</pre>                                                                                                                                                  |

### 17.2.11. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

## IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program (without an architecture postfix) runs on ppc64le only. This installer program is also available as a Mac OS version.

## Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

## Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

## WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

## IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

2. Check that the **mastersSchedulable** parameter in the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
  - a. Open the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** file.
  - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

```
.
├── auth
│ ├── kubeadmin-password
│ └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

## 17.2.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Power® infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Follow either the steps to use an ISO image or network PXE booting to install RHCOS on the machines.

### 17.2.12.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.

- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

## Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your **bootstrap.ign** Ignition config file:

```
$ sha512sum <installation_directory>/bootstrap.ign
```

The digests are provided to the **coreos-installer** in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

### IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign 1
```

### Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
 0 0 0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"},"passwd":{"users":[{"name":"core","sshAuthorizedKeys":["ssh-rsa...
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Although it is possible to obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page, the recommended way to obtain the correct version of your RHCOS images are from the output of **openshift-install** command:

```
$ openshift-install coreos print-stream-json | grep "\.iso[^\.]"
```

### Example output

```
"location": "<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-
<release>-live.aarch64.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-
```

```
<release>-live.ppc64le.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live.s390x.iso",
"location": "<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live.x86_64.iso",
```

## IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

**rhcos-<version>-live.<architecture>.iso**

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:
  - Burn the ISO image to a disk and boot it directly.
  - Use ISO redirection by using a lights-out management (LOM) interface.
6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

## NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the **coreos-installer** command as outlined in the following steps, instead of adding kernel arguments.

7. Run the **coreos-installer** command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=sha512-<digest> 1 2
```

- 1 1 You must run the **coreos-installer** command by using **sudo**, because the **core** user does not have the required root privileges to perform the installation.
- 2 The **--ignition-hash** option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. **<digest>** is the Ignition config file SHA512 digest obtained in a preceding step.

## NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running **coreos-installer**.

The following example initializes a bootstrap node installation to the **/dev/sda** device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=sha512-
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

### IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, you must reboot the system. During the system reboot, it applies the Ignition config file that you specified.
10. Check the console output to verify that Ignition ran.

### Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

11. Continue to create the other machines for your cluster.

### IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

### NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster\_name>.<base\_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install\_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 17.2.12.1.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

#### 17.2.12.1.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

#### IMPORTANT

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

#### NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the [dracut.cmdline manual page](#).

The following examples are the networking options for ISO installation.

#### Configuring DHCP or static IP addresses

To configure an IP address, either use DHCP (**ip=dhcp**) or set an individual static IP address (**ip=<host\_ip>**). If setting a static IP, you must then identify the DNS server IP address (**nameserver=<dns\_ip>**) on each node. The following example sets:

- The node's IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The hostname to **core0.example.com**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```

**NOTE**

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

## Configuring an IP address without a static hostname

You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node's IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0::enp1s0:none
nameserver=4.4.4.41
```

## Specifying multiple network interfaces

You can specify multiple network interfaces by setting multiple **ip=** entries.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

## Configuring default gateway and route

Optional: You can configure routes to additional networks by setting an **rd.route=** value.

**NOTE**

When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

- Run the following command to configure the default gateway:

```
ip=::10.10.10.254:::
```

- Enter the following command to configure the route for the additional network:

```
rd.route=20.20.20.0/24:20.20.20.254:enp2s0
```

## Disabling DHCP on a single interface

You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the **enp1s0** interface has a static networking configuration and DHCP is disabled for **enp2s0**, which is not used:

■

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=:::core0.example.com:enp2s0:none
```

### Combining DHCP and static IP configurations

You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
ip=enp1s0:dhcp
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

### Configuring VLANs on individual interfaces

Optional: You can configure VLANs on individual interfaces by using the **vlan=** parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0
```

- To configure a VLAN on a network interface and to use DHCP, run the following command:

```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

### Providing multiple DNS servers

You can provide multiple DNS servers by adding a **nameserver=** entry for each server, for example:

```
nameserver=1.1.1.1
nameserver=8.8.8.8
```

### Bonding multiple network interfaces to a single interface

Optional: You can bond multiple network interfaces to a single interface by using the **bond=** option.

Refer to the following examples:

- The syntax for configuring a bonded interface is: **bond=<name>[:<network\_interfaces>][:options]**  
**<name>** is the bonding device name (**bond0**), **<network\_interfaces>** represents a comma-separated list of physical (ethernet) interfaces (**em1,em2**), and *options* is a comma-separated list of bonding options. Enter **modinfo bonding** to see available options.
- When you create a bonded interface using **bond=**, you must specify how the IP address is assigned and other information for the bonded interface.

- To configure the bonded interface to use DHCP, set the bond's IP address to **dhcp**. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp
```

- To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

## Bonding multiple SR-IOV network interfaces to a dual port NIC interface

**IMPORTANT**

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Optional: You can bond multiple SR-IOV network interfaces to a dual port NIC interface by using the **bond=** option.

On each node, you must perform the following tasks:

1. Create the SR-IOV virtual functions (VFs) following the guidance in [Managing SR-IOV devices](#). Follow the procedure in the "Attaching SR-IOV networking devices to virtual machines" section.
2. Create the bond, attach the desired VFs to the bond and set the bond link state up following the guidance in [Configuring network bonding](#). Follow any of the described procedures to create the bond.

The following examples illustrate the syntax you must use:

- The syntax for configuring a bonded interface is **bond=<name>[:<network\_interfaces>][:options]**. **<name>** is the bonding device name (**bond0**), **<network\_interfaces>** represents the virtual functions (VFs) by their known name in the kernel and shown in the output of the **ip link** command (**eno1f0**, **eno2f0**), and **options** is a comma-separated list of bonding options. Enter **modinfo bonding** to see available options.
- When you create a bonded interface using **bond=**, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond's IP address to **dhcp**. For example:

```
bond=bond0:eno1f0,eno2f0:mode=active-backup
ip=bond0:dhcp
```

- To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:eno1f0,eno2f0:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

### 17.2.12.2. Installing RHCOS by using PXE booting

You can use PXE booting to install RHCOS on the machines.

## Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

## Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

### IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign 1
```

### Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
 0 0 0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"},"passwd":{"users":[{"name":"core","sshAuthorizedKeys":["ssh-rsa...
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Although it is possible to obtain the RHCOS **kernel**, **initramfs** and **rootfs** files that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page, the recommended way to obtain the correct version of your RHCOS files are from the output of **openshift-install** command:

```
$ openshift-install coreos print-stream-json | grep -Eo 'https.*(kernel-|initramfs-|rootfs-)\w+(\.img)?'
```

### Example output

```
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
kernel-aarch64"
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
initramfs.aarch64.img"
```

```
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
rootfs.aarch64.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/49.84.202110081256-0/ppc64le/rhcos-
<release>-live-kernel-ppc64le"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-
initramfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-
rootfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-kernel-
s390x"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-
initramfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-
rootfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-kernel-
x86_64"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-
initramfs.x86_64.img"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-
rootfs.x86_64.img"
```

## IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel:** rhcos-<version>-live-kernel-<architecture>
- **initramfs:** rhcos-<version>-live-initramfs.<architecture>.img
- **rootfs:** rhcos-<version>-live-rootfs.<architecture>.img

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

## IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.
6. Configure PXE installation for the RHCOS images and begin the installation. Modify the following example menu entry for your environment and verify that the image and Ignition files are properly accessible:

DEFAULT pxeboot

TIMEOUT 20

PROMPT 0

LABEL pxeboot

KERNEL http://<HTTP\_server>/rhcos-<version>-live-kernel-<architecture> **1**

APPEND initrd=http://<HTTP\_server>/rhcos-<version>-live-initramfs.<architecture>.img

coreos.live.rootfs\_url=http://<HTTP\_server>/rhcos-<version>-live-rootfs.<architecture>.img

coreos.inst.install\_dev=/dev/sda coreos.inst.ignition\_url=http://<HTTP\_server>/bootstrap.ign

**2 3**

- 1 1** Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.
- 2** If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
- 3** Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.rootfs\_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition\_url** parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.

## NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **APPEND** line. For example, add **console=tty0 console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#) and "Enabling the serial console for PXE and ISO installation" in the "Advanced RHCOS installation configuration" section.

7. Monitor the progress of the RHCOS installation on the console of the machine.

## IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.
9. Check the console output to verify that Ignition ran.

## Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Continue to create the machines for your cluster.

## IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

## NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster\_name>.<base\_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install\_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 17.2.12.3. Enabling multipathing with kernel arguments on RHCOS

In OpenShift Container Platform version 4.14, during installation, you can enable multipathing for provisioned nodes. RHCOS supports multipathing on the primary disk. Multipathing provides added benefits of stronger resilience to hardware failure to achieve higher host availability.

During the initial cluster creation, you might want to add kernel arguments to all master or worker nodes. To add kernel arguments to master or worker nodes, you can create a **MachineConfig** object and inject that object into the set of manifest files used by Ignition during cluster setup.

#### Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory>
```

2. Decide if you want to add kernel arguments to worker or control plane nodes.
  - Create a machine config file. For example, create a **99-master-kargs-mpath.yaml** that instructs the cluster to add the **master** label and identify the multipath kernel argument:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
 labels:
 machineconfiguration.openshift.io/role: "master"
 name: 99-master-kargs-mpath
spec:
 kernelArguments:
 - 'rd.multipath=default'
 - 'root=/dev/disk/by-label/dm-mpath-root'
```

### 3. To enable multipathing on worker nodes:

- Create a machine config file. For example, create a **99-worker-kargs-mpath.yaml** that instructs the cluster to add the **worker** label and identify the multipath kernel argument:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
 labels:
 machineconfiguration.openshift.io/role: "worker"
 name: 99-worker-kargs-mpath
spec:
 kernelArguments:
 - 'rd.multipath=default'
 - 'root=/dev/disk/by-label/dm-mpath-root'
```

You can now continue on to create the cluster.

### IMPORTANT

Additional postinstallation steps are required to fully enable multipathing. For more information, see “Enabling multipathing with kernel arguments on RHCOS” in *Postinstallation machine configuration tasks*.

In case of MPIO failure, use the bootlist command to update the boot device list with alternate logical device names. The command displays a boot list and it designates the possible boot devices for when the system is booted in normal mode.

- To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```
$ bootlist -m normal -o
sda
```

- To update the boot list for normal mode and add alternate device names, enter the following command:

```
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
sdc
sdd
sde
```

If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

### 17.2.13. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

## Procedure

1. Monitor the bootstrap process:

```
$./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

## IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

## 17.2.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

### Example output

```
system:admin
```

## 17.2.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

### Prerequisites

- You added machines to your cluster.

## Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 63m v1.27.3
master-1 Ready master 63m v1.27.3
master-2 Ready master 64m v1.27.3
```

The output lists all of the machines that you created.

### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

## Example output

```
NAME AGE REQUESTOR CONDITION
csr-8b2br 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
csr-8vnps 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

### NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

### NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

**1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

## Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

### 17.2.16. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

#### Prerequisites

- Your control plane has initialized.

#### Procedure

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

#### Example output

| NAME                                     | VERSION | AVAILABLE | PROGRESSING | DEGRADED  |
|------------------------------------------|---------|-----------|-------------|-----------|
| SINCE                                    |         |           |             |           |

| openshift-samples                        | 4.14.0  | True      | False       | False 32m |
| operator-lifecycle-manager               | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-catalog       | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-packageserver | 4.14.0  | True      | False       | False 32m |
| service-ca                               | 4.14.0  | True      | False       | False 38m |
| storage                                  | 4.14.0  | True      | False       | False 37m |

2. Configure the Operators that are not available.

### 17.2.16.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

#### 17.2.16.1.1. Configuring registry storage for IBM Power

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Power®.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

#### IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

#### Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

#### NOTE

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

#### Example output

No resources found in openshift-image-registry namespace

#### NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

#### Example output

```
storage:
 pvc:
 claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

#### Example output

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED | SINCE |
|----------------|---------|-----------|-------------|----------|-------|
| image-registry | 4.14    | True      | False       | False    | 6h50m |

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

#### 17.2.16.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

#### Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

### WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

## 17.2.17. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

### Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

### Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

### Example output

| NAME                    | VERSION | AVAILABLE | PROGRESSING | DEGRADED | SINCE |
|-------------------------|---------|-----------|-------------|----------|-------|
| authentication          | 4.14.0  | True      | False       | False    | 19m   |
| baremetal               | 4.14.0  | True      | False       | False    | 37m   |
| cloud-credential        | 4.14.0  | True      | False       | False    | 40m   |
| cluster-autoscaler      | 4.14.0  | True      | False       | False    | 37m   |
| config-operator         | 4.14.0  | True      | False       | False    | 38m   |
| console                 | 4.14.0  | True      | False       | False    | 26m   |
| csi-snapshot-controller | 4.14.0  | True      | False       | False    | 37m   |
| dns                     | 4.14.0  | True      | False       | False    | 37m   |
| etcd                    | 4.14.0  | True      | False       | False    | 36m   |
| image-registry          | 4.14.0  | True      | False       | False    | 31m   |
| ingress                 | 4.14.0  | True      | False       | False    | 30m   |
| insights                | 4.14.0  | True      | False       | False    | 31m   |
| kube-apiserver          | 4.14.0  | True      | False       | False    | 26m   |

|                                          |        |      |       |       |     |
|------------------------------------------|--------|------|-------|-------|-----|
| kube-controller-manager                  | 4.14.0 | True | False | False | 36m |
| kube-scheduler                           | 4.14.0 | True | False | False | 36m |
| kube-storage-version-migrator            | 4.14.0 | True | False | False | 37m |
| machine-api                              | 4.14.0 | True | False | False | 29m |
| machine-approver                         | 4.14.0 | True | False | False | 37m |
| machine-config                           | 4.14.0 | True | False | False | 36m |
| marketplace                              | 4.14.0 | True | False | False | 37m |
| monitoring                               | 4.14.0 | True | False | False | 29m |
| network                                  | 4.14.0 | True | False | False | 38m |
| node-tuning                              | 4.14.0 | True | False | False | 37m |
| openshift-apiserver                      | 4.14.0 | True | False | False | 32m |
| openshift-controller-manager             | 4.14.0 | True | False | False | 30m |
| openshift-samples                        | 4.14.0 | True | False | False | 32m |
| operator-lifecycle-manager               | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-catalog       | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-packageserver | 4.14.0 | True | False | False | 32m |
| service-ca                               | 4.14.0 | True | False | False | 38m |
| storage                                  | 4.14.0 | True | False | False | 37m |

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

## Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

#### Example output

```

NAMESPACE NAME READY STATUS
RESTARTS AGE
openshift-apiserver-operator openshift-apiserver-operator-85cb746d55-zqhs8 1/1
Running 1 9m
openshift-apiserver apiserver-67b9g 1/1 Running 0
3m
openshift-apiserver apiserver-ljcmx 1/1 Running 0
1m
openshift-apiserver apiserver-z25h4 1/1 Running 0
2m
openshift-authentication-operator authentication-operator-69d5d8bf84-vh2n8 1/1
Running 0 5m
...
```

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> 1
```

- 1** Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. Additional steps are required to enable multipathing. Do not enable multipathing during installation.

See "Enabling multipathing with kernel arguments on RHCOS" in the *Postinstallation machine configuration tasks* documentation for more information.

### 17.2.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 17.2.19. Next steps

- [Enabling multipathing with kernel arguments on RHCOS](#).

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).

## 17.3. INSTALLING A CLUSTER ON IBM POWER IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.14, you can install a cluster on IBM Power® infrastructure that you provision in a restricted network.

### IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you install an OpenShift Container Platform cluster.

### 17.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [created a mirror registry for installation in a restricted network](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.
- Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

### IMPORTANT

Ensure that installation steps are performed on a machine with access to the installation media.

- You provisioned [persistent storage using OpenShift Data Foundation](#) or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with **ReadWriteMany** access.
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

### NOTE

Be sure to also review this site list if you are configuring a proxy.

### 17.3.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

### IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

#### 17.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

#### 17.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### 17.3.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

##### 17.3.4.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 17.16. Minimum required hosts**

| Hosts | Description |
|-------|-------------|
|-------|-------------|

| Hosts                                                                   | Description                                                                                                                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine                                         | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines                                            | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.                                                                                                             |

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#) .

17.3.4.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 17.17. Minimum resource requirements

| Machine       | Operating System | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS            | 2        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS            | 2        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS            | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 17.3.4.3. Minimum IBM Power requirements

You can install OpenShift Container Platform version 4.14 on the following IBM® hardware:

- IBM Power®9 or IBM Power®10 processor-based systems

## NOTE

Support for RHCOS functionality for all IBM Power®8 models, IBM Power® AC922, IBM Power® IC922, and IBM Power® LC922 is deprecated in OpenShift Container Platform 4.14. Red Hat recommends that you use later hardware models.

## Hardware requirements

- Six logical partitions (LPARs) across multiple PowerVM servers

## Operating system requirements

- One instance of an IBM Power®9 or Power10 processor-based system

On your IBM Power® instance, set up:

- Three LPARs for OpenShift Container Platform control plane machines
- Two LPARs for OpenShift Container Platform compute machines
- One LPAR for the temporary OpenShift Container Platform bootstrap machine

## Disk storage for the IBM Power guest virtual machines

- Local storage, or storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**

- Dedicated physical adapter, or SR-IOV virtual function
- Available by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM® vNIC

**Storage / main memory**

- 100 GB / 16 GB for OpenShift Container Platform control plane machines
- 100 GB / 8 GB for OpenShift Container Platform compute machines
- 100 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

**17.3.4.4. Recommended IBM Power system requirements****Hardware requirements**

- Six LPARs across multiple PowerVM servers

**Operating system requirements**

- One instance of an IBM Power®9 or IBM Power®10 processor-based system

On your IBM Power® instance, set up:

- Three LPARs for OpenShift Container Platform control plane machines
- Two LPARs for OpenShift Container Platform compute machines
- One LPAR for the temporary OpenShift Container Platform bootstrap machine

**Disk storage for the IBM Power guest virtual machines**

- Local storage, or storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**

- Dedicated physical adapter, or SR-IOV virtual function
- Available by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM® vNIC

**Storage / main memory**

- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

**17.3.4.5. Certificate signing requests management**

Because your cluster has limited access to automatic machine management when you use infrastructure

that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

#### 17.3.4.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

#### NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

##### 17.3.4.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

##### 17.3.4.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**Table 17.18. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                                  |
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                                  |
|          | <b>10256</b>       | openshift-sdn                                                                                                                               |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                                       |
|          | <b>6081</b>        | Geneve                                                                                                                                      |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                                |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000-32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

**Table 17.19. Ports used for all-machine to control plane communications**

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

**Table 17.20. Ports used for control plane machine to control plane machine communications**

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379-2380</b> | etcd server and peer ports |

### NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

### Additional resources

- [Configuring chrony time service](#)

### 17.3.4.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

### NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster\_name>** is the cluster name and **<base\_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster\_name>.<base\_domain>..**

**Table 17.21. Required DNS records**

| Component      | Record                                               | Description                                                                                                                                                                                                |
|----------------|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Kubernetes API | <b>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b> | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. |

| Component              | Record                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | <b>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                        | <p>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</p> <div>  <p><b>IMPORTANT</b></p> <p>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</p> </div>                      |
| Routes                 | <b>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                         | <p>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</p> <p>For example, <b>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</b> is used as a wildcard route to the OpenShift Container Platform console.</p> |
| Bootstrap machine      | <b>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                      | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                                |
| Control plane machines | <b>&lt;control_plane&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b> | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                 |
| Compute machines       | <b>&lt;compute&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>       | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                        |

## NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

## TIP

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

### 17.3.4.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

#### Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

##### Example 17.4. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (
 2019070700 ; serial
 3H ; refresh (3 hours)
 30M ; retry (30 minutes)
 2W ; expiry (2 weeks)
 1W) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
;
ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5

control-plane2.ocp4.example.com. IN A 192.168.1.99 7
;
compute0.ocp4.example.com. IN A 192.168.1.11 8
compute1.ocp4.example.com. IN A 192.168.1.7 9
;
;EOF
```

- 1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
- 2 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- 3 Provides name resolution for the wildcard routes. The record refers to the IP address of the

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- 4 Provides name resolution for the bootstrap machine.
- 5 6 7 Provides name resolution for the control plane machines.
- 8 9 Provides name resolution for the compute machines.

**Example DNS PTR record configuration for a user-provisioned cluster**

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

**Example 17.5. Sample DNS zone database for reverse records**

```
$TTL 1W
@ IN SOA ns1.example.com. root (
 2019070700 ; serial
 3H ; refresh (3 hours)
 30M ; retry (30 minutes)
 2W ; expiry (2 weeks)
 1W) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR control-plane0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR control-plane1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR control-plane2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR compute0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR compute1.ocp4.example.com. 8
;
;EOF
```

- 1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- 2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- 3 Provides reverse DNS resolution for the bootstrap machine.
- 4 5 6 Provides reverse DNS resolution for the control plane machines.

**7 8** Provides reverse DNS resolution for the compute machines.

#### NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

### 17.3.4.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

#### NOTE

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
  - Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
  - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

#### IMPORTANT

Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 17.22. API load balancer**

| Port        | Back-end machines (pool members)                                                                                                                                                                                                              | Internal | External | Description           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|-----------------------|
| <b>6443</b> | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <b>/readyz</b> endpoint for the API server health check probe. | X        | X        | Kubernetes API server |

| Port         | Back-end machines (pool members)                                                                                                                        | Internal | External | Description           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|-----------------------|
| <b>22623</b> | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. | X        |          | Machine config server |

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 17.23. Application Ingress load balancer**

| Port       | Back-end machines (pool members)                                                   | Internal | External | Description   |
|------------|------------------------------------------------------------------------------------|----------|----------|---------------|
| <b>443</b> | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTPS traffic |
| <b>80</b>  | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTP traffic  |

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

#### 17.3.4.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy\_connect\_any=1**.

#### Example 17.6. Sample API and application Ingress load balancer configuration

```
global
 log 127.0.0.1 local2
 pidfile /var/run/haproxy.pid
 maxconn 4000
 daemon
defaults
 mode http
 log global
 option dontlognull
 option http-server-close
 option redispatch
 retries 3
 timeout http-request 10s
 timeout queue 1m
 timeout connect 10s
 timeout client 1m
 timeout server 1m
 timeout http-keep-alive 10s
 timeout check 10s
 maxconn 3000
listen api-server-6443 1
 bind *:6443
 mode tcp
 option httpchk GET /readyz HTTP/1.0
 option log-health-checks
 balance roundrobin
 server bootstrap bootstrap.ocp4.example.com:6443 verify none check check-ssl inter 10s fall 2
 rise 3 backup 2
 server master0 master0.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
```

```

fall 2 rise 3
server master1 master1.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
server master2 master2.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
listen machine-config-server-22623 ③
bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup ④
server master0 master0.ocp4.example.com:22623 check inter 1s
server master1 master1.ocp4.example.com:22623 check inter 1s
server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 ⑤
bind *:443
mode tcp
balance source
server worker0 worker0.ocp4.example.com:443 check inter 1s
server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 ⑥
bind *:80
mode tcp
balance source
server worker0 worker0.ocp4.example.com:80 check inter 1s
server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- ① Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- ② ④ The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- ③ Port **22623** handles the machine config server traffic and points to the control plane machines.
- ⑤ Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- ⑥ Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

#### NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

#### TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

### 17.3.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

## Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

## Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
  - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
  - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

### NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

### NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.

### IMPORTANT

By default, port **1936** is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
  - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
  - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.  
See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
  - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
  - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.  
See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.
6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

### NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

## 17.3.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

### IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

### Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

## Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
  - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- 1 Replace **<nameserver\_ip>** with the IP address of the nameserver, **<cluster\_name>** with your cluster name, and **<base\_domain>** with your base domain name.

## Example output

```
api.ocp4.example.com. 604800 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

## Example output

```
api-int.ocp4.example.com. 604800 IN A 192.168.1.5
```

- c. Test an example **\*.apps.<cluster\_name>.<base\_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

## Example output

```
random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

## NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
    - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
```

- 1** Provides the record name for the Kubernetes internal API.
- 2** Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
96.1.168.192.in-addr.arpa. 604800 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

### 17.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 17.3.8. Manually creating the installation configuration file

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

## Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

### NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

## Additional resources

- [Installation configuration parameters for IBM Power®](#)

### 17.3.8.1. Sample install-config.yaml file for IBM Power

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
 name: worker
 replicas: 0 4
 architecture : ppc64le
controlPlane: 5
 hyperthreading: Enabled 6
 name: master
 replicas: 3 7
```

[illegible]

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
- 2 5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 3 6 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

## NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

## IMPORTANT

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 4** You must set this value to **0** when you install OpenShift Container Platform on user-provisioned

**NOTE**

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8 The cluster name that you specified in your DNS records.
- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

**NOTE**

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a **/23** subnet out of the given **cidr**, which allows for 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 12 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 13 You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Power® infrastructure.

**IMPORTANT**

Clusters that are installed with the platform type **none** are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

- 14 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 15 For **<local\_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, **registry.example.com** or **registry.example.com:5000**. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.
- 16 The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

## NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- 17 Provide the contents of the certificate file that you used for your mirror registry.
- 18 Provide the **imageContentSources** section according to the output of the command that you used to mirror the repository.

## IMPORTANT

- When using the **oc adm release mirror** command, use the output from the **imageContentSources** section.
- When using **oc mirror** command, use the **repositoryDigestMirrors** section of the **ImageContentSourcePolicy** file that results from running the command.
- **ImageContentSourcePolicy** is deprecated. For more information see *Configuring image registry repository mirroring*.

### 17.3.8.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to

hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 17.3.8.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

#### Prerequisites

- You have an existing **install-config.yaml** file.

#### Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
- name: worker
 platform: {}
 replicas: 0
```

## NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

### 17.3.9. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group:

#### **clusterNetwork**

IP address pools from which pod IP addresses are allocated.

#### **serviceNetwork**

IP address pool for services.

#### **defaultNetwork.type**

Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

#### 17.3.9.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 17.24. Cluster Network Operator configuration object**

| Field                       | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metadata.name</b>        | <b>string</b> | The name of the CNO object. This name is always <b>cluster</b> .                                                                                                                                                                                                                                                                                                                                    |
| <b>spec.clusterNetwork</b>  | <b>array</b>  | <p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec:   clusterNetwork:     - cidr: 10.128.0.0/19       hostPrefix: 23     - cidr: 10.128.32.0/19       hostPrefix: 23</pre>                                                                          |
| <b>spec.serviceNetwork</b>  | <b>array</b>  | <p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</p> <pre>spec:   serviceNetwork:     - 172.30.0.0/14</pre> <p>You can customize this field only in the <b>install-config.yaml</b> file before you create the manifests. The value is read-only in the manifest file.</p> |
| <b>spec.defaultNetwork</b>  | <b>object</b> | Configures the network plugin for the cluster network.                                                                                                                                                                                                                                                                                                                                              |
| <b>spec.kubeProxyConfig</b> | <b>object</b> | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.                                                                                                                                                                                                                            |

### defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 17.25. **defaultNetwork** object

| Field | Type | Description |
|-------|------|-------------|
|-------|------|-------------|

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>type</b>                | <b>string</b> | <p>Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b>. The Red Hat OpenShift Networking network plugin is selected during installation. You can change this value by migrating from OpenShift SDN to OVN-Kubernetes.</p> <div>  <div> <p><b>NOTE</b></p> <p>OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.</p> </div> </div> |
| <b>openshiftSDNConfig</b>  | <b>object</b> | This object is only valid for the OpenShift SDN network plugin.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ovnKubernetesConfig</b> | <b>object</b> | This object is only valid for the OVN-Kubernetes network plugin.                                                                                                                                                                                                                                                                                                                                                                               |

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

**Table 17.26. openshiftSDNConfig object**

| Field       | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b> | <b>string</b>  | <p>Configures the network isolation mode for OpenShift SDN. The default value is <b>NetworkPolicy</b>.</p> <p>The values <b>Multitenant</b> and <b>Subnet</b> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>mtu</b>  | <b>integer</b> | <p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>50</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1450</b>.</p> <p>This value cannot be changed after cluster installation.</p> |

| Field            | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vxlanPort</b> | <b>integer</b> | <p>The port to use for all VXLAN packets. The default value is <b>4789</b>. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port <b>9000</b> and port <b>9999</b>.</p> |

### Example OpenShift SDN configuration

```
defaultNetwork:
 type: OpenShiftSDN
 openshiftSDNConfig:
 mode: NetworkPolicy
 mtu: 1450
 vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

**Table 17.27. ovnKubernetesConfig object**

| Field              | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>         | <b>integer</b> | <p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>100</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1400</b>.</p> |
| <b>genevePort</b>  | <b>integer</b> | The port to use for all Geneve packets. The default value is <b>6081</b> . This value cannot be changed after cluster installation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipsecConfig</b> | <b>object</b>  | Specify an empty object to enable IPsec encryption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Field                    | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>policyAuditConfig</b> | <b>object</b> | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.                                                                                                                                                                                                                                                                           |
| <b>gatewayConfig</b>     | <b>object</b> | <p>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</p> <div><b>NOTE</b><p>While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.</p></div> |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <b>v4InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>100.64.0.0/16</b> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <b>clusterNetwork.cidr</b> value is <b>10.128.0.0/14</b> and the <b>clusterNetwork.hostPrefix</b> value is <b>/23</b>, then the maximum number of nodes is <b><math>2^{(23-14)}=512</math></b>.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>100.64.0.0/16</b> . |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| <b>v6InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>fd98::/48</b> IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>fd98::/48</b> . |

Table 17.28. **policyAuditConfig** object

| Field              | Type    | Description                                                                                                           |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------|
| <b>rateLimit</b>   | integer | The maximum number of messages to generate every second per node. The default value is <b>20</b> messages per second. |
| <b>maxFileSize</b> | integer | The maximum size for the audit log in bytes. The default value is <b>50000000</b> or 50 MB.                           |
| <b>maxLogFiles</b> | integer | The maximum number of log files that are retained.                                                                    |

| Field                 | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination</b>    | string | <p>One of the following additional audit log targets:</p> <p><b>libc</b><br/>The libc <b>syslog()</b> function of the journald process on the host.</p> <p><b>udp:&lt;host&gt;:&lt;port&gt;</b><br/>A syslog server. Replace <b>&lt;host&gt;:&lt;port&gt;</b> with the host and port of the syslog server.</p> <p><b>unix:&lt;file&gt;</b><br/>A Unix Domain Socket file specified by <b>&lt;file&gt;</b>.</p> <p><b>null</b><br/>Do not send the audit logs to any additional target.</p> |
| <b>syslogFacility</b> | string | The syslog facility, such as <b>kern</b> , as defined by RFC5424. The default value is <b>local0</b> .                                                                                                                                                                                                                                                                                                                                                                                     |

Table 17.29. gatewayConfig object

| Field                 | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>routingViaHost</b> | <b>boolean</b> | <p>Set this field to <b>true</b> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <b>false</b>.</p> <p>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <b>true</b>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</p> |
| <b>ipForwarding</b>   | <b>object</b>  | You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <b>ipForwarding</b> specification in the <b>Network</b> resource. Specify <b>Restricted</b> to only allow IP forwarding for Kubernetes related traffic. Specify <b>Global</b> to allow forwarding of all IP traffic. For new installations, the default is <b>Restricted</b> . For updates to OpenShift Container Platform 4.14, the default is <b>Global</b> .                                                                                                                                                                                                                                                                                |

### Example OVN-Kubernetes configuration with IPsec enabled

```
defaultNetwork:
 type: OVNKubernetes
 ovnKubernetesConfig:
```

```
mtu: 1400
genevePort: 6081
ipsecConfig: {}
```

### kubeProxyConfig object configuration (OpenShiftSDN container network interface only)

The values for the **kubeProxyConfig** object are defined in the following table:

Table 17.30. kubeProxyConfig object

| Field                                          | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>iptablesSyncPeriod</b>                      | <b>string</b> | <p>The refresh period for <b>iptables</b> rules. The default value is <b>30s</b>. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a> documentation.</p> <div>  <p><b>NOTE</b></p> <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the <b>iptablesSyncPeriod</b> parameter is no longer necessary.</p> </div> |
| <b>proxyArguments.iptables-min-sync-period</b> | <b>array</b>  | <p>The minimum duration before refreshing <b>iptables</b> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a>. The default value is:</p> <pre>kubeProxyConfig:   proxyArguments:     iptables-min-sync-period:       - 0s</pre>                                                                                                                                                  |

### 17.3.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

## IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program (without an architecture postfix) runs on ppc64le only. This installer program is also available as a Mac OS version.

## Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

## Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

## WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

## IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

2. Check that the **mastersSchedulable** parameter in the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
  - a. Open the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** file.
  - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

```
.
├── auth
│ ├── kubeadmin-password
│ └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

### 17.3.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Power® infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Follow either the steps to use an ISO image or network PXE booting to install RHCOS on the machines.

#### 17.3.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

## Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

## Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your **bootstrap.ign** Ignition config file:

```
$ sha512sum <installation_directory>/bootstrap.ign
```

The digests are provided to the **coreos-installer** in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

### IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign 1
```

### Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
 0 0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"},"passwd":{"users":[{"name":"core","sshAuthorizedKeys":["ssh-rsa...
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Although it is possible to obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page, the recommended way to obtain the correct version of your RHCOS images are from the output of **openshift-install** command:

```
$ openshift-install coreos print-stream-json | grep '\.iso[^\.]'
```

## Example output

```
"location": "<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-
<release>-live.aarch64.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-
<release>-live.ppc64le.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-
live.s390x.iso",
"location": "<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-
live.x86_64.iso",
```

## IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

**rhcos-<version>-live.<architecture>.iso**

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:
  - Burn the ISO image to a disk and boot it directly.
  - Use ISO redirection by using a lights-out management (LOM) interface.
6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

## NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the **coreos-installer** command as outlined in the following steps, instead of adding kernel arguments.

7. Run the **coreos-installer** command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=sha512-<digest> 1 2
```

- 1 1 You must run the **coreos-installer** command by using **sudo**, because the **core** user does not have the required root privileges to perform the installation.
- 2 The **--ignition-hash** option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. **<digest>** is the Ignition config file SHA512 digest obtained in a preceding step.

**NOTE**

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running **coreos-installer**.

The following example initializes a bootstrap node installation to the **/dev/sda** device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=sha512-
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, you must reboot the system. During the system reboot, it applies the Ignition config file that you specified.
10. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

11. Continue to create the other machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

## NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster\_name>.<base\_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install\_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 17.3.11.1.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

#### 17.3.11.1.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

## IMPORTANT

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

## NOTE

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the [dracut.cmdline manual page](#).

The following examples are the networking options for ISO installation.

Configuring DHCP or static IP addresses

To configure an IP address, either use DHCP (**ip=dhcp**) or set an individual static IP address (**ip=<host\_ip>**). If setting a static IP, you must then identify the DNS server IP address (**nameserver=<dns\_ip>**) on each node. The following example sets:

- The node's IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**

- The hostname to **core0.example.com**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```

## NOTE

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

### Configuring an IP address without a static hostname

You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node's IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0::enp1s0:none
nameserver=4.4.4.41
```

### Specifying multiple network interfaces

You can specify multiple network interfaces by setting multiple **ip=** entries.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

### Configuring default gateway and route

Optional: You can configure routes to additional networks by setting an **rd.route=** value.

## NOTE

When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

- Run the following command to configure the default gateway:

```
ip=::10.10.10.254:::
```

- Enter the following command to configure the route for the additional network:

```
rd.route=20.20.20.0/24:20.20.20.254:enp2s0
```

#### Disabling DHCP on a single interface

You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the **enp1s0** interface has a static networking configuration and DHCP is disabled for **enp2s0**, which is not used:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=:::core0.example.com:enp2s0:none
```

#### Combining DHCP and static IP configurations

You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
ip=enp1s0:dhcp
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

#### Configuring VLANs on individual interfaces

Optional: You can configure VLANs on individual interfaces by using the **vlan=** parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0
```

- To configure a VLAN on a network interface and to use DHCP, run the following command:

```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

#### Providing multiple DNS servers

You can provide multiple DNS servers by adding a **nameserver=** entry for each server, for example:

```
nameserver=1.1.1.1
nameserver=8.8.8.8
```

#### Bonding multiple network interfaces to a single interface

Optional: You can bond multiple network interfaces to a single interface by using the **bond=** option. Refer to the following examples:

- The syntax for configuring a bonded interface is: **bond=<name>[:<network\_interfaces>][:options]**  
**<name>** is the bonding device name (**bond0**), **<network\_interfaces>** represents a comma-separated list of physical (ethernet) interfaces (**em1,em2**), and *options* is a comma-separated list of bonding options. Enter **modinfo bonding** to see available options.
- When you create a bonded interface using **bond=**, you must specify how the IP address is assigned and other information for the bonded interface.

- To configure the bonded interface to use DHCP, set the bond's IP address to **dhcp**. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp
```

- To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

Bonding multiple SR-IOV network interfaces to a dual port NIC interface

## IMPORTANT

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Optional: You can bond multiple SR-IOV network interfaces to a dual port NIC interface by using the **bond=** option.

On each node, you must perform the following tasks:

1. Create the SR-IOV virtual functions (VFs) following the guidance in [Managing SR-IOV devices](#). Follow the procedure in the "Attaching SR-IOV networking devices to virtual machines" section.
2. Create the bond, attach the desired VFs to the bond and set the bond link state up following the guidance in [Configuring network bonding](#). Follow any of the described procedures to create the bond.

The following examples illustrate the syntax you must use:

- The syntax for configuring a bonded interface is **bond=<name>[:<network\_interfaces>][:<options>]**. **<name>** is the bonding device name (**bond0**), **<network\_interfaces>** represents the virtual functions (VFs) by their known name in the kernel and shown in the output of the **ip link** command (**eno1f0**, **eno2f0**), and **options** is a comma-separated list of bonding options. Enter **modinfo bonding** to see available options.
- When you create a bonded interface using **bond=**, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond's IP address to **dhcp**. For example:

```
bond=bond0:eno1f0,eno2f0:mode=active-backup
ip=bond0:dhcp
```

- To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:eno1f0,eno2f0:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

### 17.3.11.2. Installing RHCOS by using PXE booting

You can use PXE booting to install RHCOS on the machines.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

#### Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

#### IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign 1
```

#### Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
 0 0 0 0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"},"passwd":{"users":[{"name":"core","sshAuthorizedKeys":["ssh-rsa...
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Although it is possible to obtain the RHCOS **kernel**, **initramfs** and **rootfs** files that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page, the recommended way to obtain the correct version of your RHCOS files are from

the output of **openshift-install** command:

```
$ openshift-install coreos print-stream-json | grep -Eo '"https.*(kernel|initramfs|rootfs.)w+(\.img)?"'
```

### Example output

```
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
kernel-aarch64"
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
initramfs.aarch64.img"
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
rootfs.aarch64.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/49.84.202110081256-0/ppc64le/rhcos-
<release>-live-kernel-ppc64le"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-
initramfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-
rootfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-kernel-
s390x"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-
initramfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-
rootfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-kernel-
x86_64"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-
initramfs.x86_64.img"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-
rootfs.x86_64.img"
```

### IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel:** rhcos-<version>-live-kernel-<architecture>
- **initramfs:** rhcos-<version>-live-initramfs.<architecture>.img
- **rootfs:** rhcos-<version>-live-rootfs.<architecture>.img

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

## IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.
6. Configure PXE installation for the RHCOS images and begin the installation.  
Modify the following example menu entry for your environment and verify that the image and Ignition files are properly accessible:

```

DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
 KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> 1
 APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
 coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-rootfs.<architecture>.img
 coreos.inst.install_dev=/dev/sda coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
2 3

```

- 1 1** Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.
- 2** If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
- 3** Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.rootfs\_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition\_url** parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.

## NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **APPEND** line. For example, add **console=tty0 console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#) and "Enabling the serial console for PXE and ISO installation" in the "Advanced RHCOS installation configuration" section.

7. Monitor the progress of the RHCOS installation on the console of the machine.

## IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.
9. Check the console output to verify that Ignition ran.

### Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Continue to create the machines for your cluster.

### IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

### NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster\_name>.<base\_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install\_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

#### 17.3.11.3. Enabling multipathing with kernel arguments on RHCOS

In OpenShift Container Platform version 4.14, during installation, you can enable multipathing for provisioned nodes. RHCOS supports multipathing on the primary disk. Multipathing provides added benefits of stronger resilience to hardware failure to achieve higher host availability.

During the initial cluster creation, you might want to add kernel arguments to all master or worker nodes. To add kernel arguments to master or worker nodes, you can create a **MachineConfig** object and inject that object into the set of manifest files used by Ignition during cluster setup.

### Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory>
```

2. Decide if you want to add kernel arguments to worker or control plane nodes.

- Create a machine config file. For example, create a **99-master-kargs-mpath.yaml** that instructs the cluster to add the **master** label and identify the multipath kernel argument:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
 labels:
 machineconfiguration.openshift.io/role: "master"
 name: 99-master-kargs-mpath
spec:
 kernelArguments:
 - 'rd.multipath=default'
 - 'root=/dev/disk/by-label/dm-mpath-root'
```

3. To enable multipathing on worker nodes:

- Create a machine config file. For example, create a **99-worker-kargs-mpath.yaml** that instructs the cluster to add the **worker** label and identify the multipath kernel argument:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
 labels:
 machineconfiguration.openshift.io/role: "worker"
 name: 99-worker-kargs-mpath
spec:
 kernelArguments:
 - 'rd.multipath=default'
 - 'root=/dev/disk/by-label/dm-mpath-root'
```

You can now continue on to create the cluster.

## IMPORTANT

Additional postinstallation steps are required to fully enable multipathing. For more information, see “Enabling multipathing with kernel arguments on RHCOS” in *Postinstallation machine configuration tasks*.

In case of MPIO failure, use the `bootlist` command to update the boot device list with alternate logical device names. The command displays a boot list and it designates the possible boot devices for when the system is booted in normal mode.

- a. To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```
$ bootlist -m normal -o
sda
```

- b. To update the boot list for normal mode and add alternate device names, enter the following command:

```
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
sdc
sdd
```

sde

If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

### 17.3.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

#### Procedure

1. Monitor the bootstrap process:

```
$./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

#### Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

#### IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 17.3.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

### 17.3.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

#### Prerequisites

- You added machines to your cluster.

#### Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

#### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 63m v1.27.3
master-1 Ready master 63m v1.27.3
master-2 Ready master 64m v1.27.3
```

The output lists all of the machines that you created.

## NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

## Example output

```
NAME AGE REQUESTOR CONDITION
csr-8b2br 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
csr-8vnps 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

## NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

## NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

**1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

#### NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

#### Example output

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

**1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

#### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
```

```

master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3

```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

**17.3.15. Initial Operator configuration**

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

| NAME                          | VERSION | AVAILABLE | PROGRESSING | DEGRADED | SINCE |
|-------------------------------|---------|-----------|-------------|----------|-------|
| authentication                | 4.14.0  | True      | False       | False    | 19m   |
| baremetal                     | 4.14.0  | True      | False       | False    | 37m   |
| cloud-credential              | 4.14.0  | True      | False       | False    | 40m   |

|                                          |        |      |       |       |     |
|------------------------------------------|--------|------|-------|-------|-----|
| network                                  | 4.14.0 | True | False | False | 38m |
| node-tuning                              | 4.14.0 | True | False | False | 37m |
| openshift-apiserver                      | 4.14.0 | True | False | False | 32m |
| openshift-controller-manager             | 4.14.0 | True | False | False | 30m |
| openshift-samples                        | 4.14.0 | True | False | False | 32m |
| operator-lifecycle-manager               | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-catalog       | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-packageserver | 4.14.0 | True | False | False | 32m |
| service-ca                               | 4.14.0 | True | False | False | 38m |
| storage                                  | 4.14.0 | True | False | False | 37m |

2. Configure the Operators that are not available.

### 17.3.15.1. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

#### Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
 -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

#### TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration** → **Cluster Settings** → **Configuration** → **OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

### 17.3.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

#### 17.3.15.2.1. Changing the image registry's management state

To start the image registry, you must change the Image Registry Operator configuration's **managementState** from **Removed** to **Managed**.

#### Procedure

- Change **managementState** Image Registry Operator configuration from **Removed** to **Managed**. For example:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"managementState": "Managed"}}'
```

### 17.3.15.2.2. Configuring registry storage for IBM Power

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Power®.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

#### IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

#### Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

#### NOTE

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

#### Example output

```
No resources found in openshift-image-registry namespace
```

#### NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

#### Example output

```
storage:
 pvc:
 claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

#### Example output

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED | SINCE |
|----------------|---------|-----------|-------------|----------|-------|
| image-registry | 4.14    | True      | False       | False    | 6h50m |

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

#### 17.3.15.2.3. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

#### Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

17.3.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

| NAME                          | VERSION | AVAILABLE | PROGRESSING | DEGRADED  |
|-------------------------------|---------|-----------|-------------|-----------|
| SINCE                         |         |           |             |           |
| authentication                | 4.14.0  | True      | False       | False 19m |
| baremetal                     | 4.14.0  | True      | False       | False 37m |
| cloud-credential              | 4.14.0  | True      | False       | False 40m |
| cluster-autoscaler            | 4.14.0  | True      | False       | False 37m |
| config-operator               | 4.14.0  | True      | False       | False 38m |
| console                       | 4.14.0  | True      | False       | False 26m |
| csi-snapshot-controller       | 4.14.0  | True      | False       | False 37m |
| dns                           | 4.14.0  | True      | False       | False 37m |
| etcd                          | 4.14.0  | True      | False       | False 36m |
| image-registry                | 4.14.0  | True      | False       | False 31m |
| ingress                       | 4.14.0  | True      | False       | False 30m |
| insights                      | 4.14.0  | True      | False       | False 31m |
| kube-apiserver                | 4.14.0  | True      | False       | False 26m |
| kube-controller-manager       | 4.14.0  | True      | False       | False 36m |
| kube-scheduler                | 4.14.0  | True      | False       | False 36m |
| kube-storage-version-migrator | 4.14.0  | True      | False       | False 37m |
| machine-api                   | 4.14.0  | True      | False       | False 29m |

|                                          |        |      |       |       |     |
|------------------------------------------|--------|------|-------|-------|-----|
| machine-approver                         | 4.14.0 | True | False | False | 37m |
| machine-config                           | 4.14.0 | True | False | False | 36m |
| marketplace                              | 4.14.0 | True | False | False | 37m |
| monitoring                               | 4.14.0 | True | False | False | 29m |
| network                                  | 4.14.0 | True | False | False | 38m |
| node-tuning                              | 4.14.0 | True | False | False | 37m |
| openshift-apiserver                      | 4.14.0 | True | False | False | 32m |
| openshift-controller-manager             | 4.14.0 | True | False | False | 30m |
| openshift-samples                        | 4.14.0 | True | False | False | 32m |
| operator-lifecycle-manager               | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-catalog       | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-packageserver | 4.14.0 | True | False | False | 32m |
| service-ca                               | 4.14.0 | True | False | False | 38m |
| storage                                  | 4.14.0 | True | False | False | 37m |

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

## Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

### Example output

| NAMESPACE                         | NAME                                          | READY | STATUS    |
|-----------------------------------|-----------------------------------------------|-------|-----------|
| RESTARTS                          | AGE                                           |       |           |
| openshift-apiserver-operator      | openshift-apiserver-operator-85cb746d55-zqhs8 | 1/1   |           |
| Running 1 9m                      |                                               |       |           |
| openshift-apiserver               | apiserver-67b9g                               | 1/1   | Running 0 |
| 3m                                |                                               |       |           |
| openshift-apiserver               | apiserver-ljcmx                               | 1/1   | Running 0 |
| 1m                                |                                               |       |           |
| openshift-apiserver               | apiserver-z25h4                               | 1/1   | Running 0 |
| 2m                                |                                               |       |           |
| openshift-authentication-operator | authentication-operator-69d5d8bf84-vh2n8      | 1/1   |           |
| Running 0 5m                      |                                               |       |           |
| ...                               |                                               |       |           |

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> 1
```

- 1** Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

- Additional steps are required to enable multipathing. Do not enable multipathing during installation.  
See "Enabling multipathing with kernel arguments on RHCOS" in the *Postinstallation machine configuration tasks* documentation for more information.
- Register your cluster on the [Cluster registration](#) page.

### 17.3.17. Next steps

- [Enabling multipathing with kernel arguments on RHCOS](#) .
- [Customize your cluster](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).
- If necessary, you can [opt out of remote health reporting](#) .
- If necessary, see [Registering your disconnected cluster](#)

## 17.4. INSTALLATION CONFIGURATION PARAMETERS FOR IBM POWER

Before you deploy an OpenShift Container Platform cluster, you provide a customized **install-config.yaml** installation configuration file that describes the details for your environment.

### 17.4.1. Available installation configuration parameters for IBM Power

The following tables specify the required, optional, and IBM Power-specific installation configuration parameters that you can set as part of the installation process.

## NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

### 17.4.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 17.31. Required parameters

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                            | Values                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>apiVersion:</b>         | The API version for the <b>install-config.yaml</b> content. The current version is <b>v1</b> . The installation program may also support older API versions.                                                                                                                                                                           | String                                                                          |
| <b>baseDomain:</b>         | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <b>baseDomain</b> and <b>metadata.name</b> parameter values that uses the <b>&lt;metadata.name&gt;.&lt;baseDomain&gt;</b> format. | A fully-qualified domain or subdomain name, such as <b>example.com</b> .        |
| <b>metadata:</b>           | Kubernetes resource <b>ObjectMeta</b> , from which only the <b>name</b> parameter is consumed.                                                                                                                                                                                                                                         | Object                                                                          |
| <b>metadata:<br/>name:</b> | The name of the cluster. DNS records for the cluster are all subdomains of <b>{{.metadata.name}}.{{.baseDomain}}</b> .                                                                                                                                                                                                                 | String of lowercase letters, hyphens (-), and periods (.), such as <b>dev</b> . |

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                          | Values                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform:</code>   | The configuration for the specific platform upon which to perform the installation: <b>alibabacloud</b> , <b>aws</b> , <b>baremetal</b> , <b>azure</b> , <b>gcp</b> , <b>ibmcloud</b> , <b>nutanix</b> , <b>openstack</b> , <b>powervs</b> , <b>vsphere</b> , or <code>{}</code> . For additional information about <b>platform</b> . <b>&lt;platform&gt;</b> parameters, consult the table for your specific platform that follows. | Object                                                                                                                                                                                                |
| <code>pullSecret:</code> | Get a <a href="#">pull secret from Red Hat OpenShift Cluster Manager</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.                                                                                                                                                                                                                                     | <pre>{   "auths":{     "cloud.openshift.com":{       "auth":"b3Blb=",       "email":"you@example.com"     },     "quay.io":{       "auth":"b3Blb=",       "email":"you@example.com"     }   } }</pre> |

17.4.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

- If you use the Red Hat OpenShift Networking OVN-Kubernetes network plugin, both IPv4 and IPv6 address families are supported.
- If you use the Red Hat OpenShift Networking OpenShift SDN network plugin, only the IPv4 address family is supported.

If you configure your cluster to use both IP address families, review the following requirements:

- Both IP families must use the same network interface for the default gateway.
- Both IP families must have the default gateway.
- You must specify IPv4 and IPv6 addresses in the same order for all network configuration parameters. For example, in the following configuration IPv4 addresses are listed before IPv6 addresses.

`networking:`  
`clusterNetwork:`

```

- cidr: 10.128.0.0/14
 hostPrefix: 23
- cidr: fd00:10:128::/56
 hostPrefix: 64
serviceNetwork:
- 172.30.0.0/16
- fd00:172:16::/112

```

## NOTE

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

Table 17.32. Network parameters

| Parameter                                              | Description                                                                                                                                                                                        | Values                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:</code>                               | The configuration for the cluster network.                                                                                                                                                         | Object<br><br> <b>NOTE</b><br>You cannot modify parameters specified by the <b>networking</b> object after installation.                                                                           |
| <code>networking:<br/>networkType:</code>              | The Red Hat OpenShift Networking network plugin to install.                                                                                                                                        | Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b> . <b>OpenShiftSDN</b> is a CNI plugin for all-Linux networks. <b>OVNKubernetes</b> is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is <b>OVNKubernetes</b> . |
| <code>networking:<br/>clusterNetwork:</code>           | The IP address blocks for pods.<br><br>The default value is <b>10.128.0.0/14</b> with a host prefix of <b>/23</b> .<br><br>If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example:<br><br><code>networking:<br/>clusterNetwork:<br/>- cidr: 10.128.0.0/14<br/>  hostPrefix: 23</code>                                                                                                                                                  |
| <code>networking:<br/>clusterNetwork:<br/>cidr:</code> | Required if you use <b>networking.clusterNetwork</b> . An IP address block.<br><br>An IPv4 network.                                                                                                | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between <b>0</b> and <b>32</b> .                                                                                                                                        |

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                                                     | Values                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:<br/>clusterNetwork:<br/>hostPrefix:</code> | The subnet prefix length to assign to each individual node. For example, if <b>hostPrefix</b> is set to <b>23</b> then each node is assigned a <b>/23</b> subnet out of the given <b>cidr</b> . A <b>hostPrefix</b> value of <b>23</b> provides 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses.                                   | A subnet prefix.<br><br>The default value is <b>23</b> .                                                                                                                                                                                                                                    |
| <code>networking:<br/>serviceNetwork:</code>                 | The IP address block for services. The default value is <b>172.30.0.0/16</b> .<br><br>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.                                                                                                                      | An array with an IP address block in CIDR format. For example:<br><br><code>networking:<br/>serviceNetwork:<br/>- 172.30.0.0/16</code>                                                                                                                                                      |
| <code>networking:<br/>machineNetwork:</code>                 | The IP address blocks for machines.<br><br>If you specify multiple IP address blocks, the blocks must not overlap.<br><br>If you specify multiple IP kernel arguments, the <b>machineNetwork.cidr</b> value must be the CIDR of the primary network.                                                                            | An array of objects. For example:<br><br><code>networking:<br/>machineNetwork:<br/>- cidr: 10.0.0.0/16</code>                                                                                                                                                                               |
| <code>networking:<br/>machineNetwork:<br/>cidr:</code>       | Required if you use <b>networking.machineNetwork</b> . An IP address block. The default value is <b>10.0.0.0/16</b> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <b>192.168.126.0/24</b> . For IBM Power® Virtual Server, the default value is <b>192.168.0.0/24</b> . | An IP network block in CIDR notation.<br><br>For example, <b>10.0.0.0/16</b> .<br><br> <b>NOTE</b><br><br>Set the <b>networking.machineNetwork</b> to match the CIDR that the preferred NIC resides in. |

### 17.4.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 17.33. Optional parameters

| Parameter                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                             |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| <b>additionalTrustBundle:</b>                           | A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.                                                                                                                                                                                                                                                                                                                                             | String                                                             |
| <b>capabilities:</b>                                    | Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the "Cluster capabilities" page in <i>Installing</i> .                                                                                                                                                                                                                                                    | String array                                                       |
| <b>capabilities:<br/>baselineCapabilitySet:</b>         | Selects an initial set of optional capabilities to enable. Valid values are <b>None</b> , <b>v4.11</b> , <b>v4.12</b> and <b>vCurrent</b> . The default value is <b>vCurrent</b> .                                                                                                                                                                                                                                                                                                                             | String                                                             |
| <b>capabilities:<br/>additionalEnabledCapabilities:</b> | Extends the set of optional capabilities beyond what you specify in <b>baselineCapabilitySet</b> . You may specify multiple capabilities in this parameter.                                                                                                                                                                                                                                                                                                                                                    | String array                                                       |
| <b>cpuPartitioningMode:</b>                             | Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <i>Workload partitioning</i> page in the <i>Scalability and Performance</i> section. | <b>None</b> or <b>AllNodes</b> . <b>None</b> is the default value. |
| <b>compute:</b>                                         | The configuration for the machines that comprise the compute nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                            | Array of <b>MachinePool</b> objects.                               |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Values                                                                                      |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <code>compute:<br/>architecture:</code>   | Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <b>ppc64le</b> (the default).                                                                                                                                                                                                                                                                      | String                                                                                      |
| <code>compute:<br/>hyperthreading:</code> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div> | <b>Enabled</b> or <b>Disabled</b>                                                           |
| <code>compute:<br/>name:</code>           | Required if you use <b>compute</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                 | <b>worker</b>                                                                               |
| <code>compute:<br/>platform:</code>       | Required if you use <b>compute</b> . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <b>controlPlane.platform</b> parameter value.                                                                                                                                                                                                                                                                                               | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |
| <code>compute:<br/>replicas:</code>       | The number of compute machines, which are also known as worker machines, to provision.                                                                                                                                                                                                                                                                                                                                                                                                             | A positive integer greater than or equal to <b>2</b> . The default value is <b>3</b> .      |
| <code>featureSet:</code>                  | Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see "Enabling features using feature gates".                                                                                                                                                                                                                                 | String. The name of the feature set to enable, such as <b>TechPreviewNoUpgrade</b> .        |

| Parameter                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Values                                                                                      |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>controlPlane:</b>                     | The configuration for the machines that comprise the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                                      | Array of <b>MachinePool</b> objects.                                                        |
| <b>controlPlane:<br/>architecture:</b>   | Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <b>ppc64le</b> (the default).                                                                                                                                                                                                                                                                            | String                                                                                      |
| <b>controlPlane:<br/>hyperthreading:</b> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div> | <b>Enabled</b> or <b>Disabled</b>                                                           |
| <b>controlPlane:<br/>name:</b>           | Required if you use <b>controlPlane</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                  | <b>master</b>                                                                               |
| <b>controlPlane:<br/>platform:</b>       | Required if you use <b>controlPlane</b> . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <b>compute.platform</b> parameter value.                                                                                                                                                                                                                                                                                           | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |
| <b>controlPlane:<br/>replicas:</b>       | The number of control plane machines to provision.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Supported values are <b>3</b> , or <b>1</b> when deploying single-node OpenShift.           |

| Parameter                     | Description                                                                                                                                                                                                                                  | Values                                                                                  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <code>credentialsMode:</code> | The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported. | <b>Mint, Passthrough, Manual</b> or an empty string ( <code>""</code> ). <sup>[1]</sup> |

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Values                      |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|
| <b>fips:</b> | <p>Enable or disable FIPS mode. The default is <b>false</b> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p> <div>  <p><b>IMPORTANT</b></p> <p>To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see <a href="#">Installing the system in FIPS mode</a>. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.</p> </div> <div>  <p><b>NOTE</b></p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p> </div> | <b>false</b> or <b>true</b> |

| Parameter                                        | Description                                                                                                                                                                                                                                                                                                                                                                               | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <code>imageContentSources:</code>                | Sources and repositories for the release-image content.                                                                                                                                                                                                                                                                                                                                   | Array of objects. Includes a <b>source</b> and, optionally, <b>mirrors</b> , as described in the following rows of this table.                                                                                                                                                                                                                                                                                                                                 |
| <code>imageContentSources:<br/>  source:</code>  | Required if you use <b>imageContentSources</b> . Specify the repository that users refer to, for example, in image pull specifications.                                                                                                                                                                                                                                                   | String                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>imageContentSources:<br/>  mirrors:</code> | Specify one or more repositories that may also contain the same images.                                                                                                                                                                                                                                                                                                                   | Array of strings                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>publish:</code>                            | How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.                                                                                                                                                                                                                                                                         | <p><b>Internal</b> or <b>External</b>. The default value is <b>External</b>.</p> <p>Setting this field to <b>Internal</b> is not supported on non-cloud platforms.</p> <div>  <p><b>IMPORTANT</b></p> <p>If the value of the field is set to <b>Internal</b>, the cluster will become non-functional. For more information, refer to <a href="#">BZ#1953035</a>.</p> </div> |
| <code>sshKey:</code>                             | <p>The SSH key to authenticate access to your cluster machines.</p> <div>  <p><b>NOTE</b></p> <p>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <b>ssh-agent</b> process uses.</p> </div> | For example, <b>sshKey: ssh-ed25519 AAAA...</b>                                                                                                                                                                                                                                                                                                                                                                                                                |

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.

## CHAPTER 18. INSTALLING ON IBM POWER VIRTUAL SERVER

### 18.1. PREPARING TO INSTALL ON IBM POWER VIRTUAL SERVER

The installation workflows documented in this section are for IBM Power® Virtual Server infrastructure environments.

#### 18.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

#### IMPORTANT

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

#### 18.1.2. Requirements for installing OpenShift Container Platform on IBM Power Virtual Server

Before installing OpenShift Container Platform on IBM Power® Virtual Server you must create a service account and configure an IBM Cloud® account. See [Configuring an IBM Cloud® account](#) for details about creating an account, configuring DNS and supported IBM Power® Virtual Server regions.

You must manually manage your cloud credentials when installing a cluster to IBM Power® Virtual Server. Do this by configuring the Cloud Credential Operator (CCO) for manual mode before you install the cluster.

#### 18.1.3. Choosing a method to install OpenShift Container Platform on IBM Power Virtual Server

You can install OpenShift Container Platform on IBM Power® Virtual Server using installer-provisioned infrastructure. This process involves using an installation program to provision the underlying infrastructure for your cluster. Installing OpenShift Container Platform on IBM Power® Virtual Server using user-provisioned infrastructure is not supported at this time.

See [Installation process](#) for more information about installer-provisioned installation processes.

##### 18.1.3.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on IBM Power® Virtual Server infrastructure that is provisioned by the OpenShift Container Platform installation program by using one of the following methods:

- **Installing a customized cluster on IBM Power® Virtual Server** You can install a customized cluster on IBM Power® Virtual Server infrastructure that the installation program provisions. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available [post-installation](#).
- **Installing a cluster on IBM Power® Virtual Server into an existing VPC** You can install OpenShift Container Platform on IBM Power® Virtual Server into an existing Virtual Private Cloud (VPC). You can use this installation method if you have constraints set by the guidelines of your company, such as limits when creating new accounts or infrastructure.
- **Installing a private cluster on IBM Power® Virtual Server** You can install a private cluster on IBM Power® Virtual Server. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.
- **Installing a cluster on IBM Power® Virtual Server in a restricted network** You can install OpenShift Container Platform on IBM Power® Virtual Server on installer-provisioned infrastructure by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components.

#### 18.1.4. Configuring the Cloud Credential Operator utility

The Cloud Credential Operator (CCO) manages cloud provider credentials as Kubernetes custom resource definitions (CRDs). To install a cluster on IBM Power® Virtual Server, you must set the CCO to **manual** mode as part of the installation process.

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

#### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

#### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).

#### Procedure

1. Set a variable for the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)
```

**NOTE**

Ensure that the architecture of the **\$RELEASE\_IMAGE** matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make **ccoctl** executable by running the following command:

```
$ chmod 775 ccoctl
```

**Verification**

- To verify that **ccoctl** is ready to use, display the help file. Use a relative file name when you run the command, for example:

```
$./ccoctl.rhel9
```

**Example output**

```
OpenShift credentials provisioning tool
```

```
Usage:
```

```
ccoctl [command]
```

```
Available Commands:
```

```
alibabacloud Manage credentials objects for alibaba cloud
```

```
aws Manage credentials objects for AWS cloud
```

```
azure Manage credentials objects for Azure
```

```
gcp Manage credentials objects for Google cloud
```

```
help Help about any command
```

```
ibmcloud Manage credentials objects for IBM Cloud
```

```
nutanix Manage credentials objects for Nutanix
```

```
Flags:
```

```
-h, --help help for ccoctl
```

```
Use "ccoctl [command] --help" for more information about a command.
```

**Additional resources**

- [Rotating API keys](#)

**18.1.5. Next steps**

- [Configuring an IBM Cloud® account](#)

**18.2. CONFIGURING AN IBM CLOUD ACCOUNT**

Before you can install OpenShift Container Platform, you must configure an IBM Cloud® account.

## IMPORTANT

IBM Power Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

### 18.2.1. Prerequisites

- You have an IBM Cloud® account with a subscription. You cannot install OpenShift Container Platform on a free or on a trial IBM Cloud® account.

### 18.2.2. Quotas and limits on IBM Power Virtual Server

The OpenShift Container Platform cluster uses several IBM Cloud® and IBM Power® Virtual Server components, and the default quotas and limits affect your ability to install OpenShift Container Platform clusters. If you use certain cluster configurations, deploy your cluster in certain regions, or run multiple clusters from your account, you might need to request additional resources for your IBM Cloud® account.

For a comprehensive list of the default IBM Cloud® quotas and service limits, see the IBM Cloud® documentation for [Quotas and service limits](#).

#### Virtual Private Cloud

Each OpenShift Container Platform cluster creates its own Virtual Private Cloud (VPC). The default quota of VPCs per region is 10. If you have 10 VPCs created, you will need to increase your quota before attempting an installation.

#### Application load balancer

By default, each cluster creates two application load balancers (ALBs):

- Internal load balancer for the control plane API server
- External load balancer for the control plane API server

You can create additional **LoadBalancer** service objects to create additional ALBs. The default quota of VPC ALBs are 50 per region. To have more than 50 ALBs, you must increase this quota.

VPC ALBs are supported. Classic ALBs are not supported for IBM Power® Virtual Server.

#### Cloud connections

There is a limit of two cloud connections per IBM Power® Virtual Server instance. It is recommended that you have only one cloud connection in your IBM Power® Virtual Server instance to serve your cluster.

## NOTE

Cloud Connections are no longer supported in **dal10**. A transit gateway is used instead.

### Dynamic Host Configuration Protocol Service

There is a limit of one Dynamic Host Configuration Protocol (DHCP) service per IBM Power® Virtual Server instance.

### Networking

Due to networking limitations, there is a restriction of one OpenShift cluster installed through IPI per zone per account. This is not configurable.

### Virtual Server Instances

By default, a cluster creates server instances with the following resources :

- 0.5 CPUs
- 32 GB RAM
- System Type: **s922**
- Processor Type: **uncapped, shared**
- Storage Tier: **Tier-3**

The following nodes are created:

- One bootstrap machine, which is removed after the installation is complete
- Three control plane nodes
- Three compute nodes

For more information, see [Creating a Power Systems Virtual Server](#) in the IBM Cloud® documentation.

## 18.2.3. Configuring DNS resolution

How you configure DNS resolution depends on the type of OpenShift Container Platform cluster you are installing:

- If you are installing a public cluster, you use IBM Cloud® Internet Services (CIS).
- If you are installing a private cluster, you use IBM Cloud® DNS Services (DNS Services).

## 18.2.4. Using IBM Cloud Internet Services for DNS resolution

The installation program uses IBM Cloud® Internet Services (CIS) to configure cluster DNS resolution and provide name lookup for a public cluster.

### NOTE

This offering does not support IPv6, so dual stack or IPv6 environments are not possible.

You must create a domain zone in CIS in the same account as your cluster. You must also ensure the zone is authoritative for the domain. You can do this using a root domain or subdomain.

### Prerequisites

- You have installed the [IBM Cloud® CLI](#).

- You have an existing domain and registrar. For more information, see the IBM® [documentation](#).

## Procedure

1. Create a CIS instance to use with your cluster:

- a. Install the CIS plugin:

```
$ ibmcloud plugin install cis
```

- b. Log in to IBM Cloud® by using the CLI:

```
$ ibmcloud login
```

- c. Create the CIS instance:

```
$ ibmcloud cis instance-create <instance_name> standard 1
```

- 1** At a minimum, a **Standard** plan is required for CIS to manage the cluster subdomain and its DNS records.

2. Connect an existing domain to your CIS instance:

- a. Set the context instance for CIS:

```
$ ibmcloud cis instance-set <instance_CRN> 1
```

- 1** The instance CRN (Cloud Resource Name). For example: **ibmcloud cis instance-set crn:v1:bluemix:public:power-iaas:osa21:a/65b64c1f1c29460d8c2e4bbfbd893c2c:c09233ac-48a5-4ccb-a051-d1cfb3fc7eb5::**

- b. Add the domain for CIS:

```
$ ibmcloud cis domain-add <domain_name> 1
```

- 1** The fully qualified domain name. You can use either the root domain or subdomain value as the domain name, depending on which you plan to configure.

### NOTE

A root domain uses the form **openshiftcorp.com**. A subdomain uses the form **clusters.openshiftcorp.com**.

3. Open the [CIS web console](#), navigate to the **Overview** page, and note your CIS name servers. These name servers will be used in the next step.
4. Configure the name servers for your domains or subdomains at the domain's registrar or DNS provider. For more information, see the IBM Cloud® [documentation](#).

## 18.2.5. IBM Cloud IAM Policies and API Key

To install OpenShift Container Platform into your IBM Cloud® account, the installation program requires an IAM API key, which provides authentication and authorization to access IBM Cloud® service APIs. You can use an existing IAM API key that contains the required policies or create a new one.

For an IBM Cloud® IAM overview, see the IBM Cloud® [documentation](#).

### 18.2.5.1. Pre-requisite permissions

**Table 18.1. Pre-requisite permissions**

| Role                                                                                    | Access                                                                                                                                                       |
|-----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Viewer, Operator, Editor, Administrator, Reader, Writer, Manager                        | Internet Services service in <resource_group> resource group                                                                                                 |
| Viewer, Operator, Editor, Administrator, User API key creator, Service ID creator       | IAM Identity Service service                                                                                                                                 |
| Viewer, Operator, Administrator, Editor, Reader, Writer, Manager, Console Administrator | VPC Infrastructure Services service in <resource_group> resource group                                                                                       |
| Viewer                                                                                  | Resource Group: Access to view the resource group itself. The resource type should equal <b>Resource group</b> , with a value of <your_resource_group_name>. |

### 18.2.5.2. Cluster-creation permissions

**Table 18.2. Cluster-creation permissions**

| Role                                                                                            | Access                                                  |
|-------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| Viewer                                                                                          | <resource_group> (Resource Group Created for Your Team) |
| Viewer, Operator, Editor, Reader, Writer, Manager                                               | All service in Default resource group                   |
| Viewer, Reader                                                                                  | Internet Services service                               |
| Viewer, Operator, Reader, Writer, Manager, Content Reader, Object Reader, Object Writer, Editor | Cloud Object Storage service                            |

| Role                                                                                    | Access                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Viewer                                                                                  | Default resource group: The resource type should equal <b>Resource group</b> , with a value of <b>Default</b> . If your account administrator changed your account's default resource group to something other than Default, use that value instead. |
| Viewer, Operator, Editor, Reader, Manager                                               | IBM Power® Virtual Server service in <resource_group> resource group                                                                                                                                                                                 |
| Viewer, Operator, Editor, Reader, Writer, Manager, Administrator                        | Internet Services service in <resource_group> resource group: CIS functional scope string equals reliability                                                                                                                                         |
| Viewer, Operator, Editor                                                                | Direct Link service                                                                                                                                                                                                                                  |

### 18.2.5.3. Access policy assignment

In IBM Cloud® IAM, access policies can be attached to different subjects:

- Access group (Recommended)
- Service ID
- User

The recommended method is to define IAM access policies in an [access group](#). This helps organize all the access required for OpenShift Container Platform and enables you to onboard users and service IDs to this group. You can also assign access to [users and service IDs](#) directly, if desired.

### 18.2.5.4. Creating an API key

You must create a user API key or a service ID API key for your IBM Cloud® account.

#### Prerequisites

- You have assigned the required access policies to your IBM Cloud® account.
- You have attached your IAM access policies to an access group, or other appropriate resource.

#### Procedure

- Create an API key, depending on how you defined your IAM access policies.  
For example, if you assigned your access policies to a user, you must create a [user API key](#). If you assigned your access policies to a service ID, you must create a [service ID API key](#). If your access policies are assigned to an access group, you can use either API key type. For more information on IBM Cloud® API keys, see [Understanding API keys](#).

### 18.2.6. Supported IBM Power Virtual Server regions and zones

You can deploy an OpenShift Container Platform cluster to the following regions:

- **dal** (Dallas, USA)
  - **dal10**
  - **dal12**
- **us-east** (Washington DC, USA)
  - **us-east**
- **eu-de** (Frankfurt, Germany)
  - **eu-de-1**
  - **eu-de-2**
- **lon** (London, UK)
  - **lon04**
  - **lon06**
- **osa** (Osaka, Japan)
  - **osa21**
- **sao** (Sao Paulo, Brazil)
  - **sao01**
- **syd** (Sydney, Australia)
  - **syd04**
- **tok** (Tokyo, Japan)
  - **tok04**
- **tor** (Toronto, Canada)
  - **tor01**

You might optionally specify the IBM Cloud® region in which the installer will create any VPC components. Supported regions in IBM Cloud® are:

- **us-south**
- **eu-de**
- **eu-gb**
- **jp-osa**
- **au-syd**

- **br-sao**
- **ca-tor**
- **jp-tok**

### 18.2.7. Next steps

- [Creating an IBM Power® Virtual Server workspace](#)

## 18.3. CREATING AN IBM POWER VIRTUAL SERVER WORKSPACE

### IMPORTANT

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

### 18.3.1. Creating an IBM Power Virtual Server workspace

Use the following procedure to create an IBM Power® Virtual Server workspace.

#### Procedure

1. To create an IBM Power® Virtual Server workspace, complete step 1 to step 5 from the IBM Cloud® documentation for [Creating an IBM Power® Virtual Server](#).
2. After it has finished provisioning, retrieve the 32-character alphanumeric Globally Unique Identifier (GUID) of your new workspace by entering the following command:

```
$ ibmcloud resource service-instance <workspace name>
```

### 18.3.2. Next steps

- [Installing a cluster on IBM Power® Virtual Server with customizations](#)

## 18.4. INSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a customized cluster on infrastructure that the installation program provisions on IBM Power Virtual Server. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

## IMPORTANT

IBM Power Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

### 18.4.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an IBM Cloud® account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You configured the **ccoctl** utility before you installed the cluster. For more information, see [Configuring the Cloud Credential Operator utility](#).

### 18.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

## IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 18.4.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added

to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 18.4.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

**18.4.5. Exporting the API key**

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

**Prerequisites**

- You have created either a user API key or service ID API key for your IBM Cloud® account.

**Procedure**

- Export your API key for your account as a global variable:

```
$ export IBMCLLOUD_API_KEY=<api_key>
```

**IMPORTANT**

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

**18.4.6. Creating the installation configuration file**

You can customize the OpenShift Container Platform cluster you install on

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the **~/.powervs** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
- Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- Select **powervs** as the platform to target.
  - Select the region to deploy the cluster to.
  - Select the zone to deploy the cluster to.
  - Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - Enter a descriptive name for your cluster.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
  3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- [Installation configuration parameters for IBM Power® Virtual Server](#)

**18.4.6.1. Sample customized install-config.yaml file for IBM Power Virtual Server**

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com
compute: ❶ ❷
- architecture: ppc64le
 hyperthreading: Enabled ❸
 name: worker
 platform: {}
 replicas: 3
controlPlane: ❹ ❺
 architecture: ppc64le
 hyperthreading: Enabled ❻
 name: master
 platform: {}
 replicas: 3
metadata:
 creationTimestamp: null
 name: example-cluster-name
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 192.168.0.0/24
 networkType: OVNKubernetes ❼
 serviceNetwork:
 - 172.30.0.0/16
platform:
 powervs:
 userID: ibm-user-id
 region: powervs-region
 zone: powervs-zone
 powervsResourceGroup: "ibmcloud-resource-group" ❽
 serviceInstanceID: "powervs-region-service-instance-id"
vpcRegion : vpc-region
```

```
publish: External
pullSecret: '{"auths": ...}' 9
sshKey: ssh-ed25519 AAAA... 10
```

- 1 4** If you do not provide these parameters and values, the installation program provides the default value.
- 2 5** The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
- 3 6** Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 7** The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 8** The name of an existing resource group.
- 9** Required. The installation program prompts you for this value.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

## 18.4.6.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

## NOTE

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 18.4.7. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (**ccctl**) to create the required IBM Cloud® resources.

#### Prerequisites

- You have configured the **ccctl** binary.
- You have an existing **install-config.yaml** file.

#### Procedure

1. Edit the **install-config.yaml** configuration file so that it contains the **credentialsMode** parameter set to **Manual**.

#### Example install-config.yaml configuration file

```
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual 1
compute:
 - architecture: ppc64le
 hyperthreading: Enabled
```

- 1** This line is added to set the **credentialsMode** parameter to **Manual**.

2. To generate the manifests, run the following command from the directory that contains the installation program:

```
$./openshift-install create manifests --dir <installation_directory>
```

- From the directory that contains the installation program, set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/' {print $3})
```

- Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \ 1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 2
 --to=<path_to_directory_for_credentials_requests> 3
```

- The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- Specify the location of the **install-config.yaml** file.
- Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample CredentialsRequest object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 labels:
 controller-tools.k8s.io: "1.0"
 name: openshift-image-registry-ibmcos
 namespace: openshift-cloud-credential-operator
spec:
 secretRef:
 name: installer-cloud-credentials
 namespace: openshift-image-registry
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: IBMCloudProviderSpec
 policies:
 - attributes:
 - name: serviceName
 value: cloud-object-storage
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
 - crn:v1:bluemix:public:iam::::role:Operator
 - crn:v1:bluemix:public:iam::::role:Editor
 - crn:v1:bluemix:public:iam::::serviceRole:Reader
 - crn:v1:bluemix:public:iam::::serviceRole:Writer
```

- attributes:
  - name: resourceType
  - value: resource-group
- roles:
  - crn:v1:bluemix:public:iam::::role:Viewer

5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id \
 --credentials-requests-dir=<path_to_credential_requests_directory> \ 1
 --name=<cluster_name> \ 2
 --output-dir=<installation_directory> \ 3
 --resource-group-name=<resource_group_name> \ 4
```

- 1** Specify the directory containing the files for the component **CredentialsRequest** objects.
- 2** Specify the name of the OpenShift Container Platform cluster.
- 3** Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 4** Optional: Specify the name of the resource group used for scoping the access policies.

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroup <installation_directory>/manifests/cluster-infrastructure-02-config.yml
```

#### Verification

- Ensure that the appropriate secrets were generated in your cluster's **manifests** directory.

### 18.4.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/./openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 18.4.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

## IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

#### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

## Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 18.4.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- [Accessing the web console](#)

### 18.4.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- [About remote health monitoring](#)

### 18.4.12. Next steps

- [Customize your cluster](#)
- If necessary, you can [opt out of remote health reporting](#)

## 18.5. INSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER INTO AN EXISTING VPC

In OpenShift Container Platform version 4.14, you can install a cluster into an existing Virtual Private Cloud (VPC) on IBM Cloud®. The installation program provisions the rest of the required infrastructure, which you can then further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

### IMPORTANT

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

### 18.5.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an IBM Cloud® account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You configured the **ccctl** utility before you installed the cluster. For more information, see [Configuring the Cloud Credential Operator utility](#).

### 18.5.2. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster using an existing IBM® Virtual Private Cloud (VPC).

Because the installation program cannot know what other components are in your existing subnets, it cannot choose subnet CIDRs and so forth. You must configure networking for the subnets to which you will install the cluster.

#### 18.5.2.1. Requirements for using your VPC

You must correctly configure the existing VPC and its subnets before you install the cluster. The installation program does not create a VPC or VPC subnet in this scenario.

The installation program cannot:

- Subdivide network ranges for the cluster to use
- Set route tables for the subnets
- Set VPC options like DHCP

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

### 18.5.2.2. VPC validation

The VPC and all of the subnets must be in an existing resource group. The cluster is deployed to this resource group.

As part of the installation, specify the following in the **install-config.yaml** file:

- The name of the resource group
- The name of VPC
- The name of the VPC subnet

To ensure that the subnets that you provide are suitable, the installation program confirms that all of the subnets you specify exists.

**NOTE**

Subnet IDs are not supported.

### 18.5.2.3. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- ICMP Ingress is allowed to the entire network.
- TCP port 22 Ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 Ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 Ingress (MCS) is allowed to the entire network.

### 18.5.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

## 18.5.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 18.5.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 18.5.6. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

#### Prerequisites

- You have created either a user API key or service ID API key for your IBM Cloud® account.

### Procedure

- Export your API key for your account as a global variable:

```
$ export IBMCLLOUD_API_KEY=<api_key>
```

### IMPORTANT

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

## 18.5.7. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on

### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

### NOTE

Always delete the **~/powers** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/powers
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Enter a descriptive name for your cluster.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- [Installation configuration parameters for IBM Power® Virtual Server](#)

**18.5.7.1. Minimum resource requirements for cluster installation**

Each cluster machine must meet the following minimum requirements:

**Table 18.3. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

- As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 18.5.7.2. Sample customized install-config.yaml file for IBM Power Virtual Server

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

## IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com
compute: ① ②
- architecture: ppc64le
 hyperthreading: Enabled ③
 name: worker
 platform: {}
 replicas: 3
controlPlane: ④ ⑤
 architecture: ppc64le
 hyperthreading: Enabled ⑥
 name: master
 platform: {}
 replicas: 3
```

```

metadata:
 creationTimestamp: null
 name: example-cluster-existing-vpc
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14 7
 hostPrefix: 23
 machineNetwork:
 - cidr: 192.168.0.0/24
 networkType: OVNKubernetes 8
 serviceNetwork:
 - 172.30.0.0/16
platform:
 powervs:
 userID: ibm-user-id
 powervsResourceGroup: "ibmcloud-resource-group"
 region: powervs-region
 vpcRegion : vpc-region
 vpcName: name-of-existing-vpc 9
 vpcSubnets: 10
 - powervs-region-example-subnet-1
 zone: powervs-zone
 serviceInstanceID: "powervs-region-service-instance-id"
 credentialsMode: Manual
 publish: External 11
 pullSecret: '{"auths": ...}' 12
 fips: false
 sshKey: ssh-ed25519 AAAA... 13

```

- 1 4 If you do not provide these parameters and values, the installation program provides the default value.
- 2 5 The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Both sections currently define a single machine pool. Only one control plane pool is used.
- 3 6 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.
- 7 The machine CIDR must contain the subnets for the compute machines and control plane machines.
- 8 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 9 Specify the name of an existing VPC.
- 10 Specify the name of the existing VPC subnet. The subnets must belong to the VPC that you specified. Specify a subnet for each availability zone in the region.
- 11 How to publish the user-facing endpoints of your cluster.

- 12 Required. The installation program prompts you for this value.
- 13 Provide the **sshKey** value that you use to access the machines in your cluster.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 18.5.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

- Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
additionalTrustBundle: | 4
```

```
-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
```

```
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

## 18.5.8. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (**ccctl**) to create the required IBM Cloud® resources.

## Prerequisites

- You have configured the **ccctl** binary.
- You have an existing **install-config.yaml** file.

## Procedure

1. Edit the **install-config.yaml** configuration file so that it contains the **credentialsMode** parameter set to **Manual**.

### Example install-config.yaml configuration file

```
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual 1
compute:
- architecture: ppc64le
 hyperthreading: Enabled
```

- 1** This line is added to set the **credentialsMode** parameter to **Manual**.

2. To generate the manifests, run the following command from the directory that contains the installation program:

```
$./openshift-install create manifests --dir <installation_directory>
```

3. From the directory that contains the installation program, set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included 1 \
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2 \
 --to=<path_to_directory_for_credentials_requests> 3
```

- 1** The **--included** parameter includes only the manifests that your specific cluster configuration requires.

- 2 Specify the location of the **install-config.yaml** file.
- 3 Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 labels:
 controller-tools.k8s.io: "1.0"
 name: openshift-image-registry-ibmcos
 namespace: openshift-cloud-credential-operator
spec:
 secretRef:
 name: installer-cloud-credentials
 namespace: openshift-image-registry
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: IBMCloudProviderSpec
 policies:
 - attributes:
 - name: serviceName
 value: cloud-object-storage
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
 - crn:v1:bluemix:public:iam::::role:Operator
 - crn:v1:bluemix:public:iam::::role:Editor
 - crn:v1:bluemix:public:iam::::serviceRole:Reader
 - crn:v1:bluemix:public:iam::::serviceRole:Writer
 - attributes:
 - name: resourceType
 value: resource-group
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
```

5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id \
 --credentials-requests-dir=<path_to_credential_requests_directory> \1
 --name=<cluster_name> \2
 --output-dir=<installation_directory> \3
 --resource-group-name=<resource_group_name> \4
```

- 1 Specify the directory containing the files for the component **CredentialsRequest** objects.
- 2 Specify the name of the OpenShift Container Platform cluster.
- 3 Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.

- 4 Optional: Specify the name of the resource group used for scoping the access policies.

## NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroup <installation_directory>/manifests/cluster-infrastructure-02-config.yml
```

## Verification

- Ensure that the appropriate secrets were generated in your cluster's **manifests** directory.

## 18.5.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

## IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

## Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 18.5.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

## Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

## Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

## Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

## Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

## Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

## Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

## Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 18.5.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

## Example output

```
system:admin
```

### Additional resources

- [Accessing the web console](#)

## 18.5.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- [About remote health monitoring](#)

## 18.5.13. Next steps

- [Customize your cluster](#)
- Optional: [Opt out of remote health reporting](#)

## 18.6. INSTALLING A PRIVATE CLUSTER ON IBM POWER VIRTUAL SERVER

In OpenShift Container Platform version 4.14, you can install a private cluster into an existing VPC and IBM Power® Virtual Server Workspace. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### IMPORTANT

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

### 18.6.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.

- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [configured an IBM Cloud® account](#) to host the cluster.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You configured the **ccoctl** utility before you installed the cluster. For more information, see [Configuring the Cloud Credential Operator utility](#).

### 18.6.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

#### IMPORTANT

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements.
- Create a DNS zone using IBM Cloud® DNS Services and specify it as the base domain of the cluster. For more information, see "Using IBM Cloud® DNS Services to configure DNS resolution".
- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company's guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

### 18.6.3. Private clusters in IBM Power Virtual Server

To create a private cluster on IBM Power® Virtual Server, you must provide an existing private Virtual Private Cloud (VPC) and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

The cluster still requires access to internet to access the IBM Cloud® APIs.

The following items are not required or created when you install a private cluster:

- Public subnets
- Public network load balancers, which support public Ingress
- A public DNS zone that matches the **baseDomain** for the cluster

You will also need to create an IBM® DNS service containing a DNS zone that matches your **baseDomain**. Unlike standard deployments on Power VS which use IBM® CIS for DNS, you must use IBM® DNS for your DNS service.

#### 18.6.3.1. Limitations

Private clusters on IBM Power® Virtual Server are subject only to the limitations associated with the existing VPC that was used for cluster deployment.

#### 18.6.4. Requirements for using your VPC

You must correctly configure the existing VPC and its subnets before you install the cluster. The installation program does not create a VPC or VPC subnet in this scenario.

The installation program cannot:

- Subdivide network ranges for the cluster to use
- Set route tables for the subnets
- Set VPC options like DHCP

#### NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

#### 18.6.4.1. VPC validation

The VPC and all of the subnets must be in an existing resource group. The cluster is deployed to this resource group.

As part of the installation, specify the following in the **install-config.yaml** file:

- The name of the resource group
- The name of VPC
- The name of the VPC subnet

To ensure that the subnets that you provide are suitable, the installation program confirms that all of the subnets you specify exists.

#### NOTE

Subnet IDs are not supported.

### 18.6.4.2. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- ICMP Ingress is allowed to the entire network.
- TCP port 22 Ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 Ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 Ingress (MCS) is allowed to the entire network.

### 18.6.5. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 18.6.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ❶
```

- ❶ Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> ❶
```

- ❶ Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

Identity added: /home/<you>/<path>/<file\_name> (<computer\_name>)

## Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

## 18.6.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

## Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

## Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 18.6.8. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

### Prerequisites

- You have created either a user API key or service ID API key for your IBM Cloud® account.

### Procedure

- Export your API key for your account as a global variable:

```
$ export IBMCLLOUD_API_KEY=<api_key>
```

#### IMPORTANT

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

## 18.6.9. Manually creating the installation configuration file

When installing a private OpenShift Container Platform cluster, you must manually generate the installation configuration file.

### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

#### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

**NOTE**

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

**Additional resources**

- [Installation configuration parameters for IBM Power® Virtual Server](#)

**18.6.9.1. Minimum resource requirements for cluster installation**

Each cluster machine must meet the following minimum requirements:

**Table 18.4. Minimum resource requirements**

| Machine       | Operating System | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS            | 2        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS            | 2        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS            | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

**NOTE**

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- [Optimizing storage](#)

**18.6.9.2. Sample customized install-config.yaml file for IBM Power Virtual Server**

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com
compute: ① ②
- architecture: ppc64le
 hyperthreading: Enabled ③
 name: worker
 platform: {}
 replicas: 3
controlPlane: ④ ⑤
 architecture: ppc64le
 hyperthreading: Enabled ⑥
 name: master
 platform: {}
 replicas: 3
metadata:
 creationTimestamp: null
 name: example-private-cluster-name
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14 ⑦
 hostPrefix: 23
```

```

machineNetwork:
- cidr: 192.168.0.0/24
networkType: OVNKubernetes 8
serviceNetwork:
- 172.30.0.0/16
platform:
 powervs:
 userID: ibm-user-id
 powervsResourceGroup: "ibmcloud-resource-group"
 region: powervs-region
 vpcName: name-of-existing-vpc 9
 cloudConnectionName: powervs-region-example-cloud-con-priv
 vpcSubnets:
 - powervs-region-example-subnet-1
 vpcRegion : vpc-region
 zone: powervs-zone
 serviceInstanceID: "powervs-region-service-instance-id"
publish: Internal 10
pullSecret: '{"auths": ...}' 11
sshKey: ssh-ed25519 AAAA... 12

```

- 1 4 If you do not provide these parameters and values, the installation program provides the default value.
- 2 5 The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Both sections currently define a single machine pool. Only one control plane pool is used.
- 3 6 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.
- 7 The machine CIDR must contain the subnets for the compute machines and control plane machines.
- 8 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 9 Specify the name of an existing VPC.
- 10 How to publish the user-facing endpoints of your cluster. Set publish to **Internal** to deploy a private cluster.
- 11 Required. The installation program prompts you for this value.
- 12 Provide the **sshKey** value that you use to access the machines in your cluster.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

**18.6.9.3. Configuring the cluster-wide proxy during installation**

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

**Prerequisites**

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

**Procedure**

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.

- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 18.6.10. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (**ccctl**) to create the required IBM Cloud® resources.

#### Prerequisites

- You have configured the **ccctl** binary.
- You have an existing **install-config.yaml** file.

## Procedure

1. Edit the **install-config.yaml** configuration file so that it contains the **credentialsMode** parameter set to **Manual**.

### Example install-config.yaml configuration file

```
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual 1
compute:
- architecture: ppc64le
 hyperthreading: Enabled
```

- 1** This line is added to set the **credentialsMode** parameter to **Manual**.

2. To generate the manifests, run the following command from the directory that contains the installation program:

```
$./openshift-install create manifests --dir <installation_directory>
```

3. From the directory that contains the installation program, set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included 1 \
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2 \
 --to=<path_to_directory_for_credentials_requests> 3
```

- 1** The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- 2** Specify the location of the **install-config.yaml** file.
- 3** Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample CredentialsRequest object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 labels:
```

```

controller-tools.k8s.io: "1.0"
name: openshift-image-registry-ibmcos
namespace: openshift-cloud-credential-operator
spec:
 secretRef:
 name: installer-cloud-credentials
 namespace: openshift-image-registry
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: IBMCloudProviderSpec
 policies:
 - attributes:
 - name: serviceName
 value: cloud-object-storage
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer
 - crn:v1:bluemix:public:iam::::role:Operator
 - crn:v1:bluemix:public:iam::::role:Editor
 - crn:v1:bluemix:public:iam::::serviceRole:Reader
 - crn:v1:bluemix:public:iam::::serviceRole:Writer
 - attributes:
 - name: resourceType
 value: resource-group
 roles:
 - crn:v1:bluemix:public:iam::::role:Viewer

```

5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```

$ ccoctl ibmcloud create-service-id \
 --credentials-requests-dir=<path_to_credential_requests_directory> \
 --name=<cluster_name> \
 --output-dir=<installation_directory> \
 --resource-group-name=<resource_group_name>

```

- 1 Specify the directory containing the files for the component **CredentialsRequest** objects.
- 2 Specify the name of the OpenShift Container Platform cluster.
- 3 Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 4 Optional: Specify the name of the resource group used for scoping the access policies.

## NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroup <installation_directory>/manifests/cluster-infrastructure-02-config.yml
```

## Verification

- Ensure that the appropriate secrets were generated in your cluster's **manifests** directory.

## 18.6.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

## IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

## Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 18.6.12. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

**NOTE**

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

**Verification**

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

**18.6.13. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

**Example output**

```
■
```

 system:admin

#### Additional resources

- [Accessing the web console](#)

### 18.6.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- [About remote health monitoring](#)

### 18.6.15. Next steps

- [Customize your cluster](#)
- Optional: [Opt out of remote health reporting](#)

## 18.7. INSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.14, you can install a cluster on IBM Cloud® in a restricted network by creating an internal mirror of the installation release content on an existing Virtual Private Cloud (VPC) on IBM Cloud®.

#### IMPORTANT

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

### 18.7.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

- You [configured an IBM Cloud® account](#) to host the cluster.
- You [mirrored the images for a disconnected installation](#) to your registry and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

### IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have an existing VPC in IBM Cloud®. When installing a cluster in a restricted network, you cannot use the installer-provisioned VPC. You must use a user-provisioned VPC that satisfies one of the following requirements:
  - Contains the mirror registry
  - Has firewall rules or a peering connection to access the mirror registry hosted elsewhere
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.
- You configured the **ccoctl** utility before you installed the cluster. For more information, see [Configuring the Cloud Credential Operator utility](#).

## 18.7.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

### 18.7.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

## 18.7.3. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into the subnets of an existing IBM® Virtual Private Cloud (VPC).

### 18.7.3.1. Requirements for using your VPC

You must correctly configure the existing VPC and its subnets before you install the cluster. The installation program does not create a VPC or VPC subnet in this scenario.

The installation program cannot:

- Subdivide network ranges for the cluster to use
- Set route tables for the subnets
- Set VPC options like DHCP

#### NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

### 18.7.3.2. VPC validation

The VPC and all of the subnets must be in an existing resource group. The cluster is deployed to this resource group.

As part of the installation, specify the following in the **install-config.yaml** file:

- The name of the resource group
- The name of VPC
- The name of the VPC subnet

To ensure that the subnets that you provide are suitable, the installation program confirms that all of the subnets you specify exists.

#### NOTE

Subnet IDs are not supported.

### 18.7.3.3. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- ICMP Ingress is allowed to the entire network.
- TCP port 22 Ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 Ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 Ingress (MCS) is allowed to the entire network.

### 18.7.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

### 18.7.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **.openshift-install gather** command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**18.7.6. Exporting the API key**

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

**Prerequisites**

- You have created either a user API key or service ID API key for your IBM Cloud® account.

**Procedure**

- Export your API key for your account as a global variable:

```
$ export IBMCLLOUD_API_KEY=<api_key>
```

## IMPORTANT

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

### 18.7.7. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the **imageContentSources** values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.
- You have retrieved a Red Hat Enterprise Linux CoreOS (RHCOS) image and uploaded it to an accessible location.

#### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

## NOTE

Always delete the **~/powers** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/powers
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **powervs** as the platform to target.
  - iii. Select the region to deploy the cluster to.
  - iv. Select the zone to deploy the cluster to.
  - v. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
  - vi. Enter a descriptive name for your cluster.
2. Edit the **install-config.yaml** file to give the additional information that is required for an installation in a restricted network.

- a. Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths":{"<mirror_host_name>:5000":{"auth":"<credentials>","email":
"you@example.com"}}}'
```

For **<mirror\_host\_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

```
additionalTrustBundle: |
 -----BEGIN CERTIFICATE-----
 /-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority, or the self-signed certificate that you generated for the mirror registry.

- c. Define the network and subnets for the VPC to install the cluster in under the parent **platform.powervs** field:

```
vpcName: <existing_vpc>
vpcSubnets: <vpcSubnet>
```

For **platform.powervs.vpcName**, specify the name for the existing IBM Cloud®. For **platform.powervs.vpcSubnets**, specify the existing subnets.

- d. Add the image content resources, which resemble the following YAML excerpt:

```
■
```

```
imageContentSources:
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
 source: quay.io/openshift-release-dev/ocp-release
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
 source: registry.redhat.io/ocp/release
```

For these values, use the **imageContentSources** that you recorded during mirror registry creation.

- e. Optional: Set the publishing strategy to **Internal**:

```
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

3. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
4. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### Additional resources

- [Installation configuration parameters for IBM Power® Virtual Server](#)

#### 18.7.7.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 18.5. Minimum resource requirements**

| Machine       | Operating System | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS            | 2        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS            | 2        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS            | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster

storage is recommended, particularly for etcd on the control plane nodes. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 18.7.7.2. Sample customized install-config.yaml file for IBM Power Virtual Server

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

## IMPORTANT

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```
apiVersion: v1
baseDomain: example.com 1
controlPlane: 2 3
 hyperthreading: Enabled 4
 name: master
 platform:
 replicas: 3
compute: 5 6
- hyperthreading: Enabled 7
 name: worker
 platform:
 ibmcloud: {}
 replicas: 3
metadata:
 name: example-restricted-cluster-name 8
networking:
```

```

clusterNetwork:
- cidr: 10.128.0.0/14 9
 hostPrefix: 23
machineNetwork:
- cidr: 10.0.0.0/16 10
networkType: OVNKubernetes 11
serviceNetwork:
- 192.168.0.0/24
platform:
 powervs:
 userid: ibm-user-id
 powervsResourceGroup: "ibmcloud-resource-group" 12
 region: "powervs-region"
 vpcRegion: "vpc-region"
 vpcName: name-of-existing-vpc 13
 vpcSubnets: 14
 - name-of-existing-vpc-subnet
 zone: "powervs-zone"
 serviceInstanceID: "service-instance-id"
 publish: Internal
 credentialsMode: Manual
 pullSecret: '{"auths":{"<local_registry>":{"auth": "<credentials>","email": "you@example.com"}}}' 15
 sshKey: ssh-ed25519 AAAA... 16
 additionalTrustBundle: | 17
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 imageContentSources: 18
 - mirrors:
 - <local_registry>/<local_repository_name>/release
 source: quay.io/openshift-release-dev/ocp-release
 - mirrors:
 - <local_registry>/<local_repository_name>/release
 source: quay.io/openshift-release-dev/ocp-v4.0-art-dev

```

1 8 Required.

2 5 If you do not provide these parameters and values, the installation program provides the default value.

3 6 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

4 7 Enables or disables simultaneous multithreading, also known as Hyper-Threading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

- 9 The machine CIDR must contain the subnets for the compute machines and control plane machines.
- 10 The CIDR must contain the subnets defined in **platform.ibmcloud.controlPlaneSubnets** and **platform.ibmcloud.computeSubnets**.
- 11 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 12 The name of an existing resource group. The existing VPC and subnets should be in this resource group. The cluster is deployed to this resource group.
- 13 Specify the name of an existing VPC.
- 14 Specify the name of the existing VPC subnet. The subnets must belong to the VPC that you specified. Specify a subnet for each availability zone in the region.
- 15 For **<local\_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.
- 16 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.
- 17 Provide the contents of the certificate file that you used for your mirror registry.
- 18 Provide the **imageContentSources** section from the output of the command to mirror the repository.

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

#### 18.7.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to

bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 18.7.8. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (**ccctl**) to create the required IBM Cloud® resources.

#### Prerequisites

- You have configured the **ccctl** binary.
- You have an existing **install-config.yaml** file.

#### Procedure

1. Edit the **install-config.yaml** configuration file so that it contains the **credentialsMode** parameter set to **Manual**.

#### Example **install-config.yaml** configuration file

```
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual 1
compute:
 - architecture: ppc64le
 hyperthreading: Enabled
```

- 1** This line is added to set the **credentialsMode** parameter to **Manual**.

- To generate the manifests, run the following command from the directory that contains the installation program:

```
$./openshift-install create manifests --dir <installation_directory>
```

- From the directory that contains the installation program, set a **\$RELEASE\_IMAGE** variable with the release image from your installation file by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk 'release image/ {print $3}')
```

- Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
 --from=$RELEASE_IMAGE \
 --credentials-requests \
 --included \1
 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
 --to=<path_to_directory_for_credentials_requests> \3
```

- The **--included** parameter includes only the manifests that your specific cluster configuration requires.
- Specify the location of the **install-config.yaml** file.
- Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

### Sample **CredentialsRequest** object

```
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
 labels:
 controller-tools.k8s.io: "1.0"
 name: openshift-image-registry-ibmcos
 namespace: openshift-cloud-credential-operator
spec:
 secretRef:
 name: installer-cloud-credentials
 namespace: openshift-image-registry
 providerSpec:
 apiVersion: cloudcredential.openshift.io/v1
 kind: IBMCloudProviderSpec
 policies:
 - attributes:
 - name: serviceName
 value: cloud-object-storage
 roles:
 - crn:v1:bluemix:public:iam:::role:Viewer
 - crn:v1:bluemix:public:iam:::role:Operator
 - crn:v1:bluemix:public:iam:::role:Editor
```

```
- crn:v1:bluemix:public:iam::::serviceRole:Reader
- crn:v1:bluemix:public:iam::::serviceRole:Writer
- attributes:
 - name: resourceType
 value: resource-group
roles:
- crn:v1:bluemix:public:iam::::role:Viewer
```

5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id \
 --credentials-requests-dir=<path_to_credential_requests_directory> \ 1
 --name=<cluster_name> \ 2
 --output-dir=<installation_directory> \ 3
 --resource-group-name=<resource_group_name> \ 4
```

- 1** Specify the directory containing the files for the component **CredentialsRequest** objects.
- 2** Specify the name of the OpenShift Container Platform cluster.
- 3** Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
- 4** Optional: Specify the name of the resource group used for scoping the access policies.

## NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroup <installation_directory>/manifests/cluster-infrastructure-02-config.yml
```

## Verification

- Ensure that the appropriate secrets were generated in your cluster's **manifests** directory.

## 18.7.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

## IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

## Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/./openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 18.7.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

## IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

#### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

## Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

## Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 18.7.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- [Accessing the web console](#)

### 18.7.12. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

#### Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
 -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Configuration → OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

**18.7.13. Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- [About remote health monitoring](#)

**18.7.14. Next steps**

- [Customize your cluster](#)
- Optional: [Opt out of remote health reporting](#)
- Optional: [Registering your disconnected cluster](#)

**18.8. UNINSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER**

You can remove a cluster that you deployed to IBM Power® Virtual Server.

**18.8.1. Removing a cluster that uses installer-provisioned infrastructure**

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

**Prerequisites**

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.
- You have configured the **ccocctl** binary.
- You have installed the IBM Cloud® CLI and installed or updated the VPC infrastructure service plugin. For more information see "Prerequisites" in the [IBM Cloud® CLI documentation](#).

**Procedure**

1. If the following conditions are met, this step is required:

- The installer created a resource group as part of the installation process.
- You or one of your applications created persistent volume claims (PVCs) after the cluster was deployed.

In which case, the PVCs are not removed when uninstalling the cluster, which might prevent the resource group from being successfully removed. To prevent a failure:

- a. Log in to the IBM Cloud® using the CLI.
- b. To list the PVCs, run the following command:

```
$ ibmcloud is volumes --resource-group-name <infrastructure_id>
```

For more information about listing volumes, see the [IBM Cloud® CLI documentation](#).

- c. To delete the PVCs, run the following command:

```
$ ibmcloud is volume-delete --force <volume_id>
```

For more information about deleting volumes, see the [IBM Cloud® CLI documentation](#).

2. Export the API key that was created as part of the installation process.

```
$ export IBM_CLOUD_API_KEY=<api_key>
```

#### NOTE

You must set the variable name exactly as specified. The installation program expects the variable name to be present to remove the service IDs that were created when the cluster was installed.

3. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$./openshift-install destroy cluster \
--dir <installation_directory> --log-level info 1 2
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

- 2** To view different details, specify **warn**, **debug**, or **error** instead of **info**.

#### NOTE

- You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the **metadata.json** file in this directory to delete the cluster.
- You might have to run the **openshift-install destroy** command up to three times to ensure a proper cleanup.

4. Remove the manual CCO credentials that were created for the cluster:

```
$ ccoctl ibmcloud delete-service-id \
 --credentials-requests-dir <path_to_credential_requests_directory> \
 --name <cluster_name>
```

#### NOTE

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

5. Optional: Delete the **<installation\_directory>** directory and the OpenShift Container Platform installation program.

## 18.9. INSTALLATION CONFIGURATION PARAMETERS FOR IBM POWER VIRTUAL SERVER

Before you deploy an OpenShift Container Platform on IBM Power® Virtual Server, you provide parameters to customize your cluster and the platform that hosts it. When you create the **install-config.yaml** file, you provide values for the required parameters through the command line. You can then modify the **install-config.yaml** file to customize your cluster further.

### 18.9.1. Available installation configuration parameters for IBM Power Virtual Server

The following tables specify the required, optional, and IBM Power Virtual Server-specific installation configuration parameters that you can set as part of the installation process.

#### NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

#### 18.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 18.6. Required parameters

| Parameter          | Description                                                                                                                                                  | Values |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <b>apiVersion:</b> | The API version for the <b>install-config.yaml</b> content. The current version is <b>v1</b> . The installation program may also support older API versions. | String |

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>baseDomain:</b>         | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <b>baseDomain</b> and <b>metadata.name</b> parameter values that uses the <b>&lt;metadata.name&gt;.&lt;baseDomain&gt;</b> format.                                                                                         | A fully-qualified domain or subdomain name, such as <b>example.com</b> .        |
| <b>metadata:</b>           | Kubernetes resource <b>ObjectMeta</b> , from which only the <b>name</b> parameter is consumed.                                                                                                                                                                                                                                                                                                                                 | Object                                                                          |
| <b>metadata:<br/>name:</b> | The name of the cluster. DNS records for the cluster are all subdomains of <b>{{.metadata.name}}</b> . <b>{{.baseDomain}}</b> .                                                                                                                                                                                                                                                                                                | String of lowercase letters, hyphens (-), and periods (.), such as <b>dev</b> . |
| <b>platform:</b>           | The configuration for the specific platform upon which to perform the installation: <b>alibabacloud</b> , <b>aws</b> , <b>baremetal</b> , <b>azure</b> , <b>gcp</b> , <b>ibmcloud</b> , <b>nutanix</b> , <b>openstack</b> , <b>powervs</b> , <b>vsphere</b> , or <b>{}</b> . For additional information about <b>platform</b> . <b>&lt;platform&gt;</b> parameters, consult the table for your specific platform that follows. | Object                                                                          |

| Parameter                                                     | Description                                                                                                                                                                                       | Values                                                                                                                                                                                                |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pullSecret:</code>                                      | Get a <a href="#">pull secret from Red Hat OpenShift Cluster Manager</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.  | <pre>{   "auths":{     "cloud.openshift.com":{       "auth":"b3Blb=",       "email":"you@example.com"     },     "quay.io":{       "auth":"b3Blb=",       "email":"you@example.com"     }   } }</pre> |
| <code>platform:<br/>powervs:<br/>userID:</code>               | The UserID is the login for the user's IBM Cloud® account.                                                                                                                                        | String. For example, <b>existing_user_id</b> .                                                                                                                                                        |
| <code>platform:<br/>powervs:<br/>powervsResourceGroup:</code> | The PowerVSResourceGroup is the resource group in which IBM Power® Virtual Server resources are created. If using an existing VPC, the existing VPC and subnets should be in this resource group. | String. For example, <b>existing_resource_group</b> .                                                                                                                                                 |
| <code>platform:<br/>powervs:<br/>region:</code>               | Specifies the IBM Cloud® colo region where the cluster will be created.                                                                                                                           | String. For example, <b>existing_region</b> .                                                                                                                                                         |
| <code>platform:<br/>powervs:<br/>zone:</code>                 | Specifies the IBM Cloud® colo region where the cluster will be created.                                                                                                                           | String. For example, <b>existing_zone</b> .                                                                                                                                                           |
| <code>platform:<br/>powervs:<br/>serviceInstanceID:</code>    | The ServiceInstanceID is the ID of the Power IAAS instance created from the IBM Cloud® Catalog.                                                                                                   | String. For example, <b>existing_service_instance_ID</b> .                                                                                                                                            |

### 18.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

## NOTE

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

**Table 18.7. Network parameters**

| Parameter                                                          | Description                                                                                                                                                                                                                                                                                   | Values                                                                                                                                                                                                      |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>networking:</b>                                                 | The configuration for the cluster network.                                                                                                                                                                                                                                                    | Object<br><br> <b>NOTE</b><br>You cannot modify parameters specified by the <b>networking</b> object after installation. |
| <b>networking:</b><br><b>networkType:</b>                          | The Red Hat OpenShift Networking network plugin to install.                                                                                                                                                                                                                                   | The default value is <b>OVNKubernetes</b> .                                                                                                                                                                 |
| <b>networking:</b><br><b>clusterNetwork:</b>                       | The IP address blocks for pods.<br>The default value is <b>10.128.0.0/14</b> with a host prefix of <b>/23</b> .<br>If you specify multiple IP address blocks, the blocks must not overlap.                                                                                                    | An array of objects. For example:<br><br><b>networking:</b><br><b>clusterNetwork:</b><br>- cidr: <b>10.128.0.0/14</b><br><b>hostPrefix: 23</b>                                                              |
| <b>networking:</b><br><b>clusterNetwork:</b><br><b>cidr:</b>       | Required if you use <b>networking.clusterNetwork</b> . An IP address block.<br><br>An IPv4 network.                                                                                                                                                                                           | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between <b>0</b> and <b>32</b> .                                                              |
| <b>networking:</b><br><b>clusterNetwork:</b><br><b>hostPrefix:</b> | The subnet prefix length to assign to each individual node. For example, if <b>hostPrefix</b> is set to <b>23</b> then each node is assigned a <b>/23</b> subnet out of the given <b>cidr</b> . A <b>hostPrefix</b> value of <b>23</b> provides 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. | A subnet prefix.<br><br>The default value is <b>23</b> .                                                                                                                                                    |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                         | Values                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:<br/>serviceNetwork:</code>           | <p>The IP address block for services. The default value is <b>172.30.0.0/16</b>.</p> <p>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.</p>                                                                                                                    | <p>An array with an IP address block in CIDR format. For example:</p> <pre>networking:   serviceNetwork:     - 172.30.0.0/16</pre>                                                                                                                                                                               |
| <code>networking:<br/>machineNetwork:</code>           | <p>The IP address blocks for machines.</p>                                                                                                                                                                                                                                                                                          | <p>An array of objects. For example:</p> <pre>networking:   machineNetwork:     - cidr: 10.0.0.0/16</pre>                                                                                                                                                                                                        |
| <code>networking:<br/>machineNetwork:<br/>cidr:</code> | <p>Required if you use <b>networking.machineNetwork</b>. An IP address block. The default value is <b>10.0.0.0/16</b> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <b>192.168.126.0/24</b>. For IBM Power® Virtual Server, the default value is <b>192.168.0.0/24</b>.</p> | <p>An IP network block in CIDR notation.</p> <p>For example, <b>192.168.0.0/24</b>.</p> <div>  <p><b>NOTE</b></p> <p>Set the <b>networking.machineNetwork</b> to match the CIDR that the preferred NIC resides in.</p> </div> |

### 18.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 18.8. Optional parameters**

| Parameter                           | Description                                                                                                                                                                                                                                                       | Values       |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <code>additionalTrustBundle:</code> | <p>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</p>                                                                                         | String       |
| <code>capabilities:</code>          | <p>Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the "Cluster capabilities" page in <i>Installing</i>.</p> | String array |

| Parameter                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                             |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| capabilities:<br>baselineCapabilitySet:         | Selects an initial set of optional capabilities to enable. Valid values are <b>None</b> , <b>v4.11</b> , <b>v4.12</b> and <b>vCurrent</b> . The default value is <b>vCurrent</b> .                                                                                                                                                                                                                                                                                                                             | String                                                             |
| capabilities:<br>additionalEnabledCapabilities: | Extends the set of optional capabilities beyond what you specify in <b>baselineCapabilitySet</b> . You may specify multiple capabilities in this parameter.                                                                                                                                                                                                                                                                                                                                                    | String array                                                       |
| cpuPartitioningMode:                            | Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <i>Workload partitioning</i> page in the <i>Scalability and Performance</i> section. | <b>None</b> or <b>AllNodes</b> . <b>None</b> is the default value. |
| compute:                                        | The configuration for the machines that comprise the compute nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                            | Array of <b>MachinePool</b> objects.                               |
| compute:<br>architecture:                       | Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <b>ppc64le</b> (the default).                                                                                                                                                                                                                                                                                  | String                                                             |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Values                                                                                                |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <b>compute:</b><br><b>hyperthreading:</b> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div> | <b>Enabled</b> or <b>Disabled</b>                                                                     |
| <b>compute:</b><br><b>name:</b>           | Required if you use <b>compute</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                | <b>worker</b>                                                                                         |
| <b>compute:</b><br><b>platform:</b>       | Required if you use <b>compute</b> . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <b>controlPlane.platform</b> parameter value. Example usage, <b>compute.platform.powervs.sysT</b><br><b>ype</b> .                                                                                                                                                                                                                          | <b>alibabacldoud, aws, azure, gcp, ibmcldoud, nutanix, openstack, powervs, vsphere</b> , or <b>{}</b> |
| <b>compute:</b><br><b>replicas:</b>       | The number of compute machines, which are also known as worker machines, to provision.                                                                                                                                                                                                                                                                                                                                                                                                            | A positive integer greater than or equal to <b>2</b> . The default value is <b>3</b> .                |
| <b>featureSet:</b>                        | Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see "Enabling features using feature gates".                                                                                                                                                                                                                                | String. The name of the feature set to enable, such as <b>TechPreviewNoUpgrade</b> .                  |
| <b>controlPlane:</b>                      | The configuration for the machines that comprise the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                               | Array of <b>MachinePool</b> objects.                                                                  |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Values                                                                                      |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>controlPlane:</b><br><b>architecture:</b>   | Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <b>ppc64le</b> (the default).                                                                                                                                                                                                                                                                            | String                                                                                      |
| <b>controlPlane:</b><br><b>hyperthreading:</b> | <p>Whether to enable or disable simultaneous multithreading, or <b>hyperthreading</b>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</p> <div>  <p><b>IMPORTANT</b></p> <p>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</p> </div> | <b>Enabled</b> or <b>Disabled</b>                                                           |
| <b>controlPlane:</b><br><b>name:</b>           | Required if you use <b>controlPlane</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                  | <b>master</b>                                                                               |
| <b>controlPlane:</b><br><b>platform:</b>       | Required if you use <b>controlPlane</b> . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <b>compute.platform</b> parameter value. Example usage, <b>controlPlane.platform.powervs.processors</b> .                                                                                                                                                                                                                          | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |
| <b>controlPlane:</b><br><b>replicas:</b>       | The number of control plane machines to provision.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Supported values are <b>3</b> , or <b>1</b> when deploying single-node OpenShift.           |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                                       | Values                                                                                                                                                            |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>credentialsMode:</b>                      | The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.                                                                                                                      | <b>Mint, Passthrough, Manual</b> or an empty string (""). <sup>[1]</sup>                                                                                          |
| <b>imageContentSources:</b>                  | Sources and repositories for the release-image content.                                                                                                                                                                                                                                                                                                           | Array of objects. Includes a <b>source</b> and, optionally, <b>mirrors</b> , as described in the following rows of this table.                                    |
| <b>imageContentSources:<br/>source:</b>      | Required if you use <b>imageContentSources</b> . Specify the repository that users refer to, for example, in image pull specifications.                                                                                                                                                                                                                           | String                                                                                                                                                            |
| <b>imageContentSources:<br/>mirrors:</b>     | Specify one or more repositories that may also contain the same images.                                                                                                                                                                                                                                                                                           | Array of strings                                                                                                                                                  |
| <b>publish:</b>                              | How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.                                                                                                                                                                                                                                                 | <b>Internal</b> or <b>External</b> . The default value is <b>External</b> .<br><br>Setting this field to <b>Internal</b> is not supported on non-cloud platforms. |
| <b>sshKey:</b>                               | The SSH key to authenticate access to your cluster machines.<br><br> <b>NOTE</b><br>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <b>ssh-agent</b> process uses. | For example, <b>sshKey: ssh-ed25519 AAAA...</b>                                                                                                                   |
| <b>platform:<br/>powervs:<br/>vpcRegion:</b> | Specifies the IBM Cloud® region in which to create VPC resources.                                                                                                                                                                                                                                                                                                 | String. For example, <b>existing_vpc_region</b> .                                                                                                                 |

| Parameter                                                                 | Description                                                                                                                                                                      | Values                                                                                                                   |
|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>platform:</b><br><b>powervs:</b><br><b>vpcSubnets:</b>                 | Specifies existing subnets (by name) where cluster resources will be created.                                                                                                    | String. For example, <b>powervs_region_example_subnet</b> .                                                              |
| <b>platform:</b><br><b>powervs:</b><br><b>vpcName:</b>                    | Specifies the IBM Cloud® name.                                                                                                                                                   | String. For example, <b>existing_vpcName</b> .                                                                           |
| <b>platform:</b><br><b>powervs:</b><br><br><b>cloudConnectionName:</b>    | The CloudConnectionName is the name of an existing PowerVS Cloud connection.                                                                                                     | String. For example, <b>existing_cloudConnectionName</b> .                                                               |
| <b>platform:</b><br><b>powervs:</b><br><br><b>clusterOSImage:</b>         | The ClusterOSImage is a pre-created IBM Power® Virtual Server boot image that overrides the default image for cluster nodes.                                                     | String. For example, <b>existing_cluster_os_image</b> .                                                                  |
| <b>platform:</b><br><b>powervs:</b><br><br><b>defaultMachinePlatform:</b> | The DefaultMachinePlatform is the default configuration used when installing on IBM Power® Virtual Server for machine pools that do not define their own platform configuration. | String. For example, <b>existing_machine_platform</b> .                                                                  |
| <b>platform:</b><br><b>powervs:</b><br><b>memoryGiB:</b>                  | The size of a virtual machine's memory, in GB.                                                                                                                                   | The valid integer must be an integer number of GB that is at least 2 and no more than 64, depending on the machine type. |
| <b>platform:</b><br><b>powervs:</b><br><b>procType:</b>                   | The ProcType defines the processor sharing model for the instance.                                                                                                               | The valid values are Capped, Dedicated, and Shared.                                                                      |

| Parameter                                 | Description                                                   | Values                                                                                             |
|-------------------------------------------|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <pre>platform: powervs: processors:</pre> | The Processors defines the processing units for the instance. | The number of processors must be from .5 to 32 cores. The processors must be in increments of .25. |
| <pre>platform: powervs: sysType:</pre>    | The SysType defines the system type for the instance.         | The system type must be either <b>e980</b> or <b>s922</b> .                                        |

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.

#### NOTE

Cloud connections are no longer supported in the **install-config.yaml** while deploying in the **dal10** region, as they have been replaced by the Power Edge Router (PER).

## CHAPTER 19. INSTALLING ON OPENSTACK

### 19.1. PREPARING TO INSTALL ON OPENSTACK

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP).

#### 19.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).

#### 19.1.2. Choosing a method to install OpenShift Container Platform on OpenStack

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See [Installation process](#) for more information about installer-provisioned and user-provisioned installation processes.

##### 19.1.2.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on Red Hat OpenStack Platform (RHOSP) infrastructure that is provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- **Installing a cluster on OpenStack with customizations** You can install a customized cluster on RHOSP. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available [post-installation](#).
- **Installing a cluster on OpenStack with Kuryr** You can install a customized OpenShift Container Platform cluster on RHOSP that uses Kuryr SDN. Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.
- **Installing a cluster on OpenStack in a restricted network** You can install OpenShift Container Platform on RHOSP in a restricted or disconnected network by creating an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

##### 19.1.2.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on RHOSP infrastructure that you provision, by using one of the following methods:

- **Installing a cluster on OpenStack on your own infrastructure** You can install OpenShift

Container Platform on user-provisioned RHOSP infrastructure. By using this installation method, you can integrate your cluster with existing infrastructure and modifications. For installations on user-provisioned infrastructure, you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. You can use the provided Ansible playbooks to assist with the deployment process.

- [Installing a cluster on OpenStack with Kuryr on your own infrastructure](#) You can install OpenShift Container Platform on user-provisioned RHOSP infrastructure that uses Kuryr SDN.

### 19.1.3. Scanning RHOSP endpoints for legacy HTTPS certificates

Beginning with OpenShift Container Platform 4.10, HTTPS certificates must contain subject alternative name (SAN) fields. Run the following script to scan each HTTPS endpoint in a Red Hat OpenStack Platform (RHOSP) catalog for legacy certificates that only contain the **CommonName** field.

#### IMPORTANT

OpenShift Container Platform does not check the underlying RHOSP infrastructure for legacy certificates prior to installation or updates. Use the provided script to check for these certificates yourself. Failing to update legacy certificates prior to installing or updating a cluster will result in cluster dysfunction.

#### Prerequisites

- On the machine where you run the script, have the following software:
  - Bash version 4.0 or greater
  - **grep**
  - [OpenStack client](#)
  - **jq**
  - [OpenSSL version 1.1.1l or greater](#)
- Populate the machine with RHOSP credentials for the target cloud.

#### Procedure

1. Save the following script to your machine:

```
#!/usr/bin/env bash

set -Eeuo pipefail

declare catalog san
catalog="$(mktemp)"
san="$(mktemp)"
readonly catalog san

declare invalid=0

openstack catalog list --format json --column Name --column Endpoints \
| jq -r '.[] | .Name as $name | .Endpoints[] | select(.interface=="public") | [$name, .interface,
```

```

.url] | join(" ")' \
| sort \
> "$catalog"

while read -r name interface url; do
Ignore HTTP
if [[${url#"http://"} != "$url"]]; then
continue
fi

Remove the schema from the URL
noschema=${url#"https://"}

If the schema was not HTTPS, error
if [["$noschema" == "$url"]]; then
echo "ERROR (unknown schema): $name $interface $url"
exit 2
fi

Remove the path and only keep host and port
noschema=${noschema%%/*}
host=${noschema%%.*}
port=${noschema##*.}

Add the port if was implicit
if [["$port" == "$host"]]; then
port=443
fi

Get the SAN fields
openssl s_client -showcerts -servername "$host" -connect "$host:$port" </dev/null
2>/dev/null \
| openssl x509 -noout -ext subjectAltName \
> "$san"

openssl returns the empty string if no SAN is found.
If a SAN is found, openssl is expected to return something like:
#
X509v3 Subject Alternative Name:
DNS:standalone, DNS:osp1, IP Address:192.168.2.1, IP Address:10.254.1.2
if [["$(grep -c "Subject Alternative Name" "$san" || true)" -gt 0]]; then
echo "PASS: $name $interface $url"
else
invalid=$((invalid+1))
echo "INVALID: $name $interface $url"
fi
done < "$catalog"

clean up temporary files
rm "$catalog" "$san"

if [[$invalid -gt 0]]; then
echo "${invalid} legacy certificates were detected. Update your certificates to include a SAN
field."
exit 1

```

```

else
echo "All HTTPS certificates for this cloud are valid."
fi

```

2. Run the script.
3. Replace any certificates that the script reports as **INVALID** with certificates that contain SAN fields.

### IMPORTANT

You must replace all legacy HTTPS certificates before you install OpenShift Container Platform 4.10 or update a cluster to that version. Legacy certificates will be rejected with the following message:

```
x509: certificate relies on legacy Common Name field, use SANs instead
```

#### 19.1.3.1. Scanning RHOSP endpoints for legacy HTTPS certificates manually

Beginning with OpenShift Container Platform 4.10, HTTPS certificates must contain subject alternative name (SAN) fields. If you do not have access to the prerequisite tools that are listed in "Scanning RHOSP endpoints for legacy HTTPS certificates", perform the following steps to scan each HTTPS endpoint in a Red Hat OpenStack Platform (RHOSP) catalog for legacy certificates that only contain the **CommonName** field.

### IMPORTANT

OpenShift Container Platform does not check the underlying RHOSP infrastructure for legacy certificates prior to installation or updates. Use the following steps to check for these certificates yourself. Failing to update legacy certificates prior to installing or updating a cluster will result in cluster dysfunction.

#### Procedure

1. On a command line, run the following command to view the URL of RHOSP public endpoints:

```
$ openstack catalog list
```

Record the URL for each HTTPS endpoint that the command returns.

2. For each public endpoint, note the host and the port.

### TIP

Determine the host of an endpoint by removing the scheme, the port, and the path.

3. For each endpoint, run the following commands to extract the SAN field of the certificate:

- a. Set a **host** variable:

```
$ host=<host_name>
```

- b. Set a **port** variable:

```
$ port=<port_number>
```

If the URL of the endpoint does not have a port, use the value **443**.

- c. Retrieve the SAN field of the certificate:

```
$ openssl s_client -showcerts -servername "$host" -connect "$host:$port" </dev/null
2>/dev/null \
| openssl x509 -noout -ext subjectAltName
```

### Example output

```
X509v3 Subject Alternative Name:
DNS:your.host.example.net
```

For each endpoint, look for output that resembles the previous example. If there is no output for an endpoint, the certificate of that endpoint is invalid and must be re-issued.

### IMPORTANT

You must replace all legacy HTTPS certificates before you install OpenShift Container Platform 4.10 or update a cluster to that version. Legacy certificates are rejected with the following message:

```
x509: certificate relies on legacy Common Name field, use SANs instead
```

## 19.2. PREPARING TO INSTALL A CLUSTER THAT USES SR-IOV OR OVS-DPDK ON OPENSTACK

Before you install a OpenShift Container Platform cluster that uses single-root I/O virtualization (SR-IOV) or Open vSwitch with the Data Plane Development Kit (OVS-DPDK) on Red Hat OpenStack Platform (RHOSP), you must understand the requirements for each technology and then perform preparatory tasks.

### 19.2.1. Requirements for clusters on RHOSP that use either SR-IOV or OVS-DPDK

If you use SR-IOV or OVS-DPDK with your deployment, you must meet the following requirements:

- RHOSP compute nodes must use a flavor that supports huge pages.

#### 19.2.1.1. Requirements for clusters on RHOSP that use SR-IOV

To use single-root I/O virtualization (SR-IOV) with your deployment, you must meet the following requirements:

- [Plan your Red Hat OpenStack Platform \(RHOSP\) SR-IOV deployment](#) .
- OpenShift Container Platform must support the NICs that you use. For a list of supported NICs, see "About Single Root I/O Virtualization (SR-IOV) hardware networks" in the "Hardware networks" subsection of the "Networking" documentation.
- For each node that will have an attached SR-IOV NIC, your RHOSP cluster must have:

- One instance from the RHOSP quota
- One port attached to the machines subnet
- One port for each SR-IOV Virtual Function
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space
- SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.
  - For more information about configuring performant RHOSP compute nodes, see [Configuring Compute nodes for performance](#).

### 19.2.1.2. Requirements for clusters on RHOSP that use OVS-DPDK

To use Open vSwitch with the Data Plane Development Kit (OVS-DPDK) with your deployment, you must meet the following requirements:

- Plan your Red Hat OpenStack Platform (RHOSP) OVS-DPDK deployment by referring to [Planning your OVS-DPDK deployment](#) in the Network Functions Virtualization Planning and Configuration Guide.
- Configure your RHOSP OVS-DPDK deployment according to [Configuring an OVS-DPDK deployment](#) in the Network Functions Virtualization Planning and Configuration Guide.

### 19.2.2. Preparing to install a cluster that uses SR-IOV

You must configure RHOSP before you install a cluster that uses SR-IOV on it.

When installing a cluster using SR-IOV, you must deploy clusters using cgroup v1. For more information, [Enabling Linux control group version 1 \(cgroup v1\)](#).

#### 19.2.2.1. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports [single root I/O virtualization \(SR-IOV\)](#), you can provision SR-IOV networks that compute machines run on.

#### NOTE

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.

#### Prerequisites

- Your cluster supports SR-IOV.

#### NOTE

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.

- You created radio and uplink provider networks as part of your RHOSP deployment. The names **radio** and **uplink** are used in all example commands to represent these networks.

## Procedure

1. On a command line, create a radio RHOSP network:

```
$ openstack network create radio --provider-physical-network radio --provider-network-type flat --external
```

2. Create an uplink RHOSP network:

```
$ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
```

3. Create a subnet for the radio network:

```
$ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio
```

4. Create a subnet for the uplink network:

```
$ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink
```

### 19.2.3. Preparing to install a cluster that uses OVS-DPDK

You must configure RHOSP before you install a cluster that uses SR-IOV on it.

- Complete [Creating a flavor and deploying an instance for OVS-DPDK](#) before you install a cluster on RHOSP.

After you perform preinstallation tasks, install your cluster by following the most relevant OpenShift Container Platform on RHOSP installation instructions. Then, perform the tasks under "Next steps" on this page.

### 19.2.4. Next steps

- For either type of deployment:
  - [Configure the Node Tuning Operator with huge pages support](#) .
- To complete SR-IOV configuration after you deploy your cluster:
  - [Install the SR-IOV Operator](#) .
  - [Configure your SR-IOV network device](#) .
  - [Create SR-IOV compute machines](#) .
- Consult the following references after you deploy your cluster to improve its performance:
  - [A test pod template for clusters that use OVS-DPDK on OpenStack](#) .
  - [A test pod template for clusters that use SR-IOV on OpenStack](#) .

- [A performance profile template for clusters that use OVS-DPDK on OpenStack](#) .

## 19.3. INSTALLING A CLUSTER ON OPENSTACK WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP). To customize the installation, modify parameters in the **install-config.yaml** before you install the cluster.

### 19.3.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see [Optimizing storage](#).
- You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see [Recommended practices for scaling the cluster](#) .
- You have the metadata service enabled in RHOSP.

### 19.3.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

**Table 19.1. Recommended resources for a default OpenShift Container Platform cluster on RHOSP**

| Resource              | Value |
|-----------------------|-------|
| Floating IP addresses | 3     |
| Ports                 | 15    |
| Routers               | 1     |
| Subnets               | 1     |
| RAM                   | 88 GB |
| vCPUs                 | 22    |

| Resource             | Value                                                                 |
|----------------------|-----------------------------------------------------------------------|
| Volume storage       | 275 GB                                                                |
| Instances            | 7                                                                     |
| Security groups      | 3                                                                     |
| Security group rules | 60                                                                    |
| Server groups        | 2 – plus 1 for each additional availability zone in each machine pool |

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

### IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

### NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run **openstack quota set --secgroups 3 --secgroup-rules 60 <project>** as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

#### 19.3.2.1. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

#### 19.3.2.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory and 2 vCPUs
- At least 100 GB storage space from the RHOSP quota

## TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 19.3.2.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

### 19.3.2.4. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you can provision your own API and application ingress load balancing infrastructure to use in place of the default, internal load balancing solution. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

## NOTE

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
  - Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
  - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

## IMPORTANT

Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 19.2. API load balancer**

| Port         | Back-end machines (pool members)                                                                                                                                                                                                              | Internal | External | Description           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|-----------------------|
| <b>6443</b>  | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <b>/readyz</b> endpoint for the API server health check probe. | X        | X        | Kubernetes API server |
| <b>22623</b> | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.                                                                                       | X        |          | Machine config server |

## NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer:** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

## TIP

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 19.3. Application Ingress load balancer

| Port       | Back-end machines (pool members)                                                   | Internal | External | Description   |
|------------|------------------------------------------------------------------------------------|----------|----------|---------------|
| <b>443</b> | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTPS traffic |
| <b>80</b>  | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTP traffic  |

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

#### 19.3.2.4.1. Example load balancer configuration for clusters that are deployed with user-managed load balancers

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for clusters that are deployed with user-managed load balancers. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy\_connect\_any=1**.

#### Example 19.1. Sample API and application Ingress load balancer configuration

```
global
 log 127.0.0.1 local2
 pidfile /var/run/haproxy.pid
 maxconn 4000
 daemon
defaults
 mode http
 log global
 option dontlognull
 option http-server-close
 option redispatch
 retries 3
```

```

timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
timeout server 1m
timeout http-keep-alive 10s
timeout check 10s
maxconn 3000
listen api-server-6443 1
 bind *:6443
 mode tcp
 option httpchk GET /readyz HTTP/1.0
 option log-health-checks
 balance roundrobin
 server bootstrap bootstrap.ocp4.example.com:6443 verify none check check-ssl inter 10s fall 2
 rise 3 backup 2
 server master0 master0.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
 fall 2 rise 3
 server master1 master1.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
 fall 2 rise 3
 server master2 master2.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
 fall 2 rise 3
listen machine-config-server-22623 3
 bind *:22623
 mode tcp
 server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 4
 server master0 master0.ocp4.example.com:22623 check inter 1s
 server master1 master1.ocp4.example.com:22623 check inter 1s
 server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 5
 bind *:443
 mode tcp
 balance source
 server worker0 worker0.ocp4.example.com:443 check inter 1s
 server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 6
 bind *:80
 mode tcp
 balance source
 server worker0 worker0.ocp4.example.com:80 check inter 1s
 server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1 Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 2 4 The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 3 Port **22623** handles the machine config server traffic and points to the control plane machines.
- 5 Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 6 Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

### 19.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 19.3.4. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.

**IMPORTANT**

If [the Red Hat OpenStack Platform \(RHOSP\) object storage service](#), commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

## IMPORTANT

RHOSP 17 sets the **rgw\_max\_attr\_size** parameter of Ceph RGW to 256 characters. This setting causes issues with uploading container images to the OpenShift Container Platform registry. You must set the value of **rgw\_max\_attr\_size** to at least 1024 characters.

Before installation, check if your RHOSP deployment is affected by this problem. If it is, reconfigure Ceph RGW.

## Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On [Ceph RGW](#), the **account in url** option is enabled.

## Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

```
$ openstack role add --user <user> --project <project> swiftoperator
```

Your RHOSP deployment can now use Swift for the image registry.

## 19.3.5. Configuring an image registry with custom storage on clusters that run on RHOSP

After you install a cluster on Red Hat OpenStack Platform (RHOSP), you can use a Cinder volume that is in a specific availability zone for registry storage.

## Procedure

1. Create a YAML file that specifies the storage class and availability zone to use. For example:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
 name: custom-csi-storageclass
provisioner: cinder.csi.openstack.org
volumeBindingMode: WaitForFirstConsumer
allowVolumeExpansion: true
parameters:
 availability: <availability_zone_name>
```

## NOTE

OpenShift Container Platform does not verify the existence of the availability zone you choose. Verify the name of the availability zone before you apply the configuration.

- From a command line, apply the configuration:

```
$ oc apply -f <storage_class_file_name>
```

### Example output

```
storageclass.storage.k8s.io/custom-csi-storageclass created
```

- Create a YAML file that specifies a persistent volume claim (PVC) that uses your storage class and the **openshift-image-registry** namespace. For example:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
 name: csi-pvc-imageregistry
 namespace: openshift-image-registry ❶
 annotations:
 imageregistry.openshift.io: "true"
spec:
 accessModes:
 - ReadWriteOnce
 volumeMode: Filesystem
 resources:
 requests:
 storage: 100Gi ❷
 storageClassName: <your_custom_storage_class> ❸
```

- ❶ Enter the namespace **openshift-image-registry**. This namespace allows the Cluster Image Registry Operator to consume the PVC.
- ❷ Optional: Adjust the volume size.
- ❸ Enter the name of the storage class that you created.

- From a command line, apply the configuration:

```
$ oc apply -f <pvc_file_name>
```

### Example output

```
persistentvolumeclaim/csi-pvc-imageregistry created
```

- Replace the original persistent volume claim in the image registry configuration with the new claim:

```
$ oc patch configs.imageregistry.operator.openshift.io/cluster --type 'json' -p='[{"op":
"replace", "path": "/spec/storage/pvc/claim", "value": "csi-pvc-imageregistry"}]'
```

### Example output

```
config.imageregistry.operator.openshift.io/cluster patched
```

Over the next several minutes, the configuration is updated.

Verification

To confirm that the registry is using the resources that you defined:

- 1. Verify that the PVC claim value is identical to the name that you provided in your PVC definition:

```
$ oc get configs.imageregistry.operator.openshift.io/cluster -o yaml
```

Example output

```
...
status:
 ...
 managementState: Managed
 pvc:
 claim: csi-pvc-imageregistry
 ...
```

- 2. Verify that the status of the PVC is **Bound**:

```
$ oc get pvc -n openshift-image-registry csi-pvc-imageregistry
```

Example output

| NAME                  | STATUS                  | VOLUME                                   | CAPACITY | ACCESS MODES |
|-----------------------|-------------------------|------------------------------------------|----------|--------------|
| STORAGECLASS          | AGE                     |                                          |          |              |
| csi-pvc-imageregistry | Bound                   | pvc-72a8f9c9-f462-11e8-b6b6-fa163e18b7b5 | 100Gi    |              |
| RWO                   | custom-csi-storageclass | 11m                                      |          |              |

19.3.6. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- [Configure OpenStack’s networking service to have DHCP agents forward instances' DNS queries](#)

Procedure

- 1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

|                     |      |             |
|---------------------|------|-------------|
| +-----+-----+-----+ |      |             |
| ID                  | Name | Router Type |
| +-----+-----+-----+ |      |             |

```
| 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External |
+-----+-----+-----+
```

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

## IMPORTANT

If the external network's CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the **install-config.yaml** file before you start the installation process.

The default network ranges are:

| Network               | Range         |
|-----------------------|---------------|
| <b>machineNetwork</b> | 10.0.0.0/16   |
| <b>serviceNetwork</b> | 172.30.0.0/16 |
| <b>clusterNetwork</b> | 10.128.0.0/14 |

## WARNING

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

## NOTE

If the Neutron trunk service plugin is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

### 19.3.7. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

#### Procedure

1. Create the **clouds.yaml** file:
  - If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

## IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in [a separate file](#) from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
 shiftstack:
 auth:
 auth_url: http://10.10.14.42:5000/v3
 project_name: shiftstack
 username: <username>
 password: <password>
 user_domain_name: Default
 project_domain_name: Default
 dev-env:
 region_name: RegionOne
 auth:
 username: <username>
 password: <password>
 project_name: 'devonly'
 auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
  - a. Copy the certificate authority file to your machine.
  - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
 shiftstack:
 ...
 cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

## TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
  - a. The value of the **OS\_CLIENT\_CONFIG\_FILE** environment variable
  - b. The current directory
  - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**

- d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`  
The installation program searches for **clouds.yaml** in that order.

### 19.3.8. Setting OpenStack Cloud Controller Manager options

Optionally, you can edit the OpenStack Cloud Controller Manager (CCM) configuration for your cluster. This configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of configuration parameters, see the "OpenStack Cloud Controller Manager reference guide" page in the "Installing on OpenStack" documentation.

#### Procedure

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

```
$ openshift-install --dir <destination_directory> create manifests
```

2. In a text editor, open the cloud-provider configuration manifest file. For example:

```
$ vi openshift/manifests/cloud-provider-config.yaml
```

3. Modify the options according to the CCM reference guide.  
Configuring Octavia for load balancing is a common case for clusters that do not use Kuryr. For example:

```
#...
[LoadBalancer]
lb-provider = "amphora" 1
floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a" 2
create-monitor = True 3
monitor-delay = 10s 4
monitor-timeout = 10s 5
monitor-max-retries = 1 6
#...
```

- 1 This property sets the Octavia provider that your load balancer uses. It accepts **"ovn"** or **"amphora"** as values. If you choose to use OVN, you must also set **lb-method** to **SOURCE\_IP\_PORT**.
- 2 This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.
- 3 This property controls whether the cloud provider creates health monitors for Octavia load balancers. Set the value to **True** to create health monitors. As of RHOSP 16.2, this feature is only available for the Amphora provider.
- 4 This property sets the frequency with which endpoints are monitored. The value must be in the **time.ParseDuration()** format. This property is required if the value of the **create-monitor** property is **True**.
- 5 This property sets the time that monitoring requests are open before timing out. The value must be in the **time.ParseDuration()** format. This property is required if the value of the

**create-monitor** property is **True**.

- 6 This property defines how many successful monitoring requests are required before a load balancer is marked as online. The value must be an integer. This property is required if the value of the **create-monitor** property is **True**.

#### IMPORTANT

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

#### IMPORTANT

You must set the value of the **create-monitor** property to **True** if you use services that have the value of the **.spec.externalTrafficPolicy** property set to **Local**. The OVN Octavia provider in RHOSP 16.2 does not support health monitors. Therefore, services that have **ETP** parameter values set to **Local** might not respond when the **lb-provider** value is set to **"ovn"**.

#### IMPORTANT

For installations that use Kuryr, Kuryr handles relevant services. There is no need to configure Octavia load balancing in the cloud provider.

4. Save the changes to the file and proceed with installation.

#### TIP

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a **SchedulingDisabled** status.

### 19.3.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 19.3.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.
  - iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
  - iv. Specify the floating IP address to use for external access to the OpenShift API.
  - v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.
  - vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
  - vii. Enter a name for your cluster. The name must be 14 or fewer characters long.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- [Installation configuration parameters for OpenStack](#)

### 19.3.10.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

#### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.

- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 19.3.10.2. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

#### NOTE

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIPs** and **platform.openstack.ingressVIPs** that are outside of the DHCP allocation pool.

#### IMPORTANT

The CIDR ranges for networks are not adjustable after cluster installation. Red Hat does not provide direct guidance on determining the range during cluster installation because it requires careful consideration of the number of created pods per namespace.

### 19.3.10.3. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the **install-config.yaml** file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

#### NOTE

Be sure that your **install-config.yaml** file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

#### Prerequisites

- The RHOSP [Bare Metal service \(Ironic\)](#) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as [a RHOSP flavor](#).
- If your cluster runs on an RHOSP version that is more than 16.1.6 and less than 16.2.4, bare metal workers do not function due to a [known issue](#) that causes the metadata service to be unavailable for services on OpenShift Container Platform nodes.
- The RHOSP network supports both VM and bare metal server attachment.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an **install-config.yaml** file as part of the OpenShift Container Platform installation process.

## Procedure

1. In the **install-config.yaml** file, edit the flavors for machines:
  - a. If you want to use bare-metal control plane machines, change the value of **controlPlane.platform.openstack.type** to a bare metal flavor.
  - b. Change the value of **compute.platform.openstack.type** to a bare metal flavor.
  - c. If you want to deploy your machines on a pre-existing network, change the value of **platform.openstack.machinesSubnet** to the RHOSP subnet UUID of the network. Control plane and compute machines must use the same subnet.

### An example bare metal **install-config.yaml** file

```
controlPlane:
 platform:
 openstack:
 type: <bare_metal_control_plane_flavor> ❶
 ...

compute:
 - architecture: amd64
 hyperthreading: Enabled
 name: worker
 platform:
 openstack:
 type: <bare_metal_compute_flavor> ❷
 replicas: 3
 ...

platform:
 openstack:
 machinesSubnet: <subnet_UUID> ❸
 ...
```

- ❶ If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
- ❷ Change this value to a bare metal flavor to use for compute machines.
- ❸ If you want to use a pre-existing network, change this value to the UUID of the RHOSP subnet.

Use the updated **install-config.yaml** file to complete the installation process. The compute machines that are created during deployment use the flavor that you added to the file.

## NOTE

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

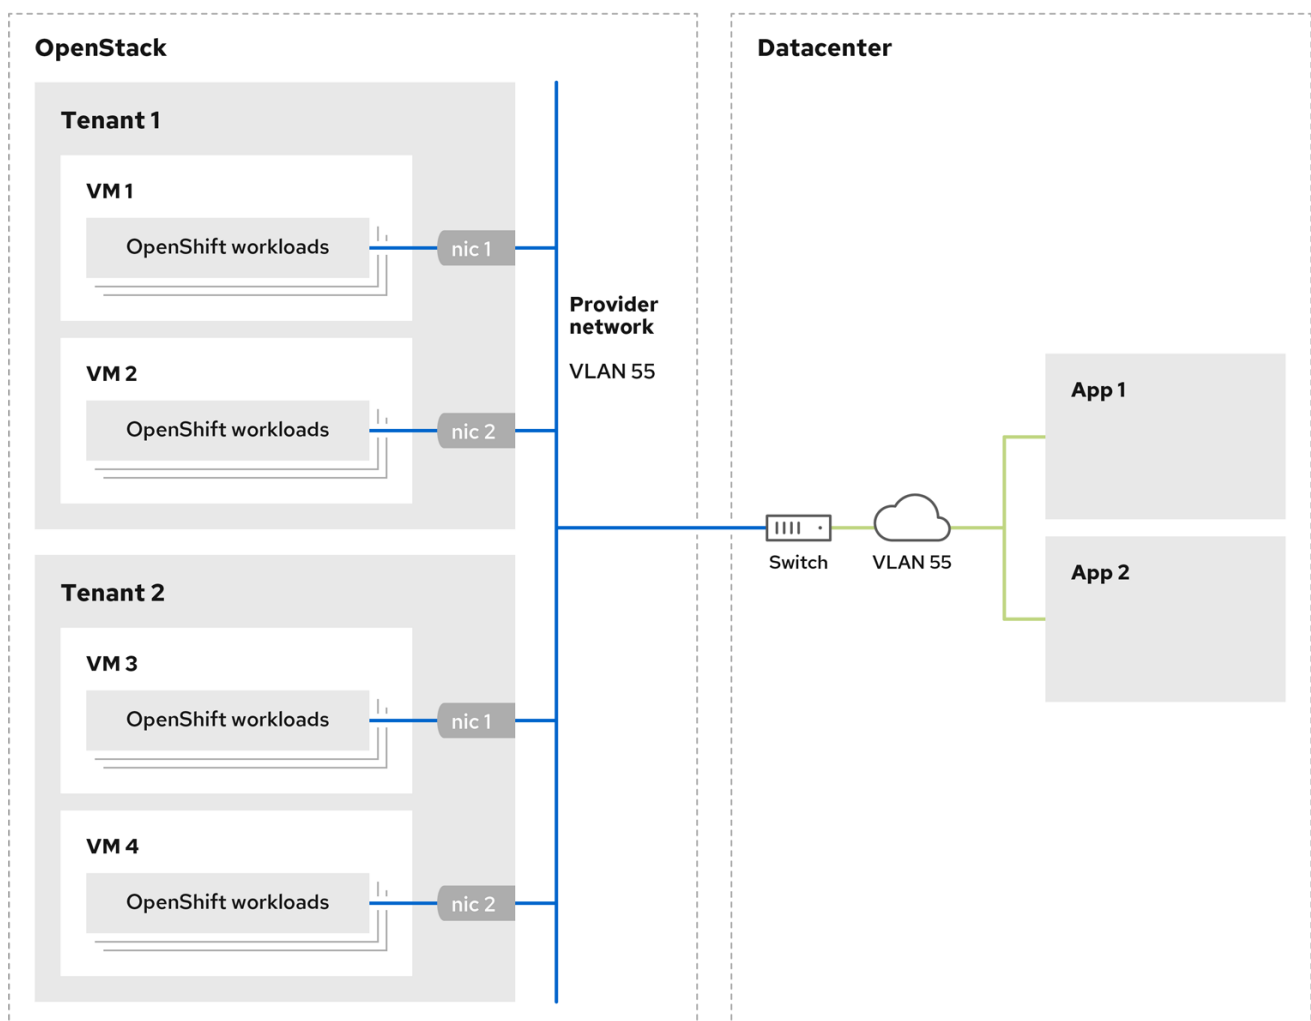

```
$./openshift-install wait-for install-complete --log-level debug
```

### 19.3.10.4. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

I70\_OpenShift\_0621

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

#### NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in [the RHOSP documentation](#).

#### 19.3.10.4.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service \(Neutron\) is enabled](#) and accessible through the RHOSP networking API.
- The RHOSP networking service has the [port security and allowed address pairs extensions enabled](#).
- The provider network can be shared with other tenants.

#### TIP

Use the **openstack network create** command with the **--share** flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

#### TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read [the provider networks documentation](#).

If the cluster is owned by the **admin** user, you must run the installer as that user to create ports on the network.

## IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is **169.254.169.254** by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create [role-based access control \(RBAC\)](#) rules that limit network access to a single project.

### 19.3.10.4.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

#### Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

#### Procedure

1. In a text editor, open the **install-config.yaml** file.
2. Set the value of the **platform.openstack.apiVIPs** property to the IP address for the API VIP.
3. Set the value of the **platform.openstack.ingressVIPs** property to the IP address for the Ingress VIP.
4. Set the value of the **platform.openstack.machinesSubnet** property to the UUID of the provider network subnet.
5. Set the value of the **networking.machineNetwork.cidr** property to the CIDR block of the provider network subnet.

## IMPORTANT

The **platform.openstack.apiVIPs** and **platform.openstack.ingressVIPs** properties must both be unassigned IP addresses from the **networking.machineNetwork.cidr** block.

### Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
 openstack:
 apiVIPs: 1
```

```

- 192.0.2.13
ingressVIPs: 2
- 192.0.2.23
machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
...
networking:
 machineNetwork:
 - cidr: 192.0.2.0/24

```

- 1 2** In OpenShift Container Platform 4.12 and later, the **apiVIP** and **ingressVIP** configuration settings are deprecated. Instead, use a list format to enter values in the **apiVIPs** and **ingressVIPs** configuration settings.

### WARNING

You cannot set the **platform.openstack.externalNetwork** or **platform.openstack.externalDNS** parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the **install-config.yaml** file to deploy the cluster on the provider network.

### TIP

You can add additional networks, including provider networks, to the **platform.openstack.additionalNetworkIDs** list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

#### 19.3.10.5. Sample customized **install-config.yaml** file for RHOSP

This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

### IMPORTANT

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```

apiVersion: v1
baseDomain: example.com
controlPlane:
 name: master
 platform: {}
 replicas: 3
compute:
 - name: worker

```

```

platform:
 openstack:
 type: ml.large
 replicas: 3
metadata:
 name: example
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 serviceNetwork:
 - 172.30.0.0/16
 networkType: OVNKubernetes
platform:
 openstack:
 cloud: mycloud
 externalNetwork: external
 computeFlavor: m1.xlarge
 apiFloatingIP: 128.0.0.1
 fips: false
 pullSecret: '{"auths": ...}'
 sshKey: ssh-ed25519 AAAA...

```

### 19.3.10.6. Optional: Configuring a cluster with dual-stack networking

#### IMPORTANT

Dual-stack configuration for OpenStack is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

You can create a dual-stack cluster on RHOSP. However, the dual-stack configuration is enabled only if you are using an RHOSP network with IPv4 and IPv6 subnets.

#### NOTE

RHOSP does not support the following configurations:

- Conversion of an IPv4 single-stack cluster to a dual-stack cluster network.
- IPv6 as the primary address family for dual-stack cluster network.

#### 19.3.10.6.1. Deploying the dual-stack cluster

##### Procedure

1. Create a network with IPv4 and IPv6 subnets. The available address modes for **ipv6-ra-mode** and **ipv6-address-mode** fields are: **stateful**, **stateless** and **slaac**.

**NOTE**

The dualstack network MTU must accommodate both the minimum MTU for IPv6, which is 1280, and the OVN-Kubernetes encapsulation overhead, which is 100.

**NOTE**

DHCP must be enabled on the subnets.

2. Create the API and Ingress VIPs ports.
3. Add the IPv6 subnet to the router to enable router advertisements. If you are using a provider network, you can enable router advertisements by adding the network as an external gateway, which also enables external connectivity.
4. To configure IPv4 and IPv6 address endpoints for cluster nodes, edit the **install-config.yaml** file. The following is an example of an **install-config.yaml** file.

**Example install-config.yaml**

```
apiVersion: v1
baseDomain: mydomain.test
featureSet: TechPreviewNoUpgrade 1
compute:
- name: worker
 platform:
 openstack:
 type: m1.xlarge
 replicas: 3
controlPlane:
 name: master
 platform:
 openstack:
 type: m1.xlarge
 replicas: 3
metadata:
 name: mycluster
networking:
 machineNetwork: 2
 - cidr: "192.168.25.0/24"
 - cidr: "fd2e:6f44:5dd8:c956::/64"
 clusterNetwork: 3
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 - cidr: fd01::/48
 hostPrefix: 64
 serviceNetwork: 4
 - 172.30.0.0/16
 - fd02::/112
platform:
```

```

openstack:
 ingressVIPs: ['192.168.25.79', 'fd2e:6f44:5dd8:c956:f816:3eff:fef1:1bad'] 5
 apiVIPs: ['192.168.25.199', 'fd2e:6f44:5dd8:c956:f816:3eff:fe78:cf36'] 6
 controlPlanePort: 7
 fixedIPs: 8
 - subnet: 9
 name: subnet-v4
 id: subnet-v4-id
 - subnet: 10
 name: subnet-v6
 id: subnet-v6-id
 network: 11
 name: dualstack
 id: network-id

```

- 1 Dual-stack clusters are supported only with the **TechPreviewNoUpgrade** value.
- 2 3 4 You must specify an IP address range in the **cidr** field for both IPv4 and IPv6 address families.
- 5 Specify the virtual IP (VIP) address endpoints for the Ingress VIP services to provide an interface to the cluster.
- 6 Specify the virtual IP (VIP) address endpoints for the API VIP services to provide an interface to the cluster.
- 7 Specify the dual-stack network details that are used by all the nodes across the cluster.
- 8 The CIDR of any subnet specified in this field must match the CIDRs listed on **networks.machineNetwork**.
- 9 10 11 You can specify a value for either **name** or **id**, or both.

### 19.3.10.7. Installation configuration for a cluster on OpenStack with a user-managed load balancer

The following example **install-config.yaml** file demonstrates how to configure a cluster that uses an external, user-managed load balancer rather than the default internal load balancer.

```

apiVersion: v1
baseDomain: mydomain.test
compute:
- name: worker
 platform:
 openstack:
 type: m1.xlarge
 replicas: 3
controlPlane:
 name: master
 platform:
 openstack:
 type: m1.xlarge
 replicas: 3
metadata:
 name: mycluster

```

```

networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 192.168.10.0/24
platform:
 openstack:
 cloud: mycloud
 machinesSubnet: 8586bf1a-cc3c-4d40-bdf6-c243decc603a 1
 apiVIPs:
 - 192.168.10.5
 ingressVIPs:
 - 192.168.10.7
 loadBalancer:
 type: UserManaged 2

```

**1** Regardless of which load balancer you use, the load balancer is deployed to this subnet.

**2** The **UserManaged** value indicates that you are using an user-managed load balancer.

### 19.3.11. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1** Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 19.3.12. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

#### 19.3.12.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

##### Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"
 <external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"
 <external_network>
```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

## NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your **/etc/hosts** file:

- **<api\_floating\_ip> api.<cluster\_name>.<base\_domain>**
- **<application\_floating\_ip> grafana-openshift-monitoring.apps.<cluster\_name>.<base\_domain>**
- **<application\_floating\_ip> prometheus-k8s-openshift-monitoring.apps.<cluster\_name>.<base\_domain>**
- **<application\_floating\_ip> oauth-openshift.apps.<cluster\_name>.<base\_domain>**
- **<application\_floating\_ip> console-openshift-console.apps.<cluster\_name>.<base\_domain>**
- **application\_floating\_ip integrated-oauth-server-openshift-authentication.apps.<cluster\_name>.<base\_domain>**

The cluster domain names in the **/etc/hosts** file grant access to the web console and the monitoring interface of your cluster locally. You can also use the **kubectl** or **oc**. You can access the user applications by using the additional entries pointing to the **<application\_floating\_ip>**. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

4. Add the FIPs to the **install-config.yaml** file as the values of the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you use these values, you must also enter an external network as the value of the **platform.openstack.externalNetwork** parameter in the **install-config.yaml** file.

## TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 19.3.12.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **install-config.yaml** file, do not define the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you cannot provide an external network, you can also leave **platform.openstack.externalNetwork** blank. If you do not provide a value for **platform.openstack.externalNetwork**, a router is not created for

you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

## NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

## 19.3.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

## IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

## Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 19.3.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster's status during or after installation.

### Procedure

1. In the cluster environment, export the administrator's kubeconfig file:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

```
$ oc get nodes
```

3. View your cluster's version:

```
$ oc get clusterversion
```

4. View your Operators' status:

```
$ oc get clusteroperator
```

5. View all running pods in the cluster:

```
$ oc get pods -A
```

### 19.3.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 19.3.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 19.3.17. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

## 19.4. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR

### IMPORTANT

Kuryr is a deprecated feature. Deprecated functionality is still included in OpenShift Container Platform and continues to be supported; however, it will be removed in a future release of this product and is not recommended for new deployments.

For the most recent list of major functionality that has been deprecated or removed within OpenShift Container Platform, refer to the *Deprecated and removed features* section of the OpenShift Container Platform release notes.

In OpenShift Container Platform version 4.14, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP) that uses Kuryr SDN. To customize the installation, modify parameters in the **install-config.yaml** before you install the cluster.

### 19.4.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).

- You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see [Optimizing storage](#).
- You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see [Recommended practices for scaling the cluster](#).

### 19.4.2. About Kuryr SDN

#### IMPORTANT

Kuryr is a deprecated feature. Deprecated functionality is still included in OpenShift Container Platform and continues to be supported; however, it will be removed in a future release of this product and is not recommended for new deployments.

For the most recent list of major functionality that has been deprecated or removed within OpenShift Container Platform, refer to the *Deprecated and removed features* section of the OpenShift Container Platform release notes.

[Kuryr](#) is a container network interface (CNI) plugin solution that uses the [Neutron](#) and [Octavia](#) Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the **openshift-kuryr** namespace:

- **kuryr-controller** – a single service instance installed on a **master** node. This is modeled in OpenShift Container Platform as a **Deployment** object.
- **kuryr-cni** – a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a **DaemonSet** object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.

- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The **ovn-octavia** Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

### 19.4.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster's minimum requirements:

**Table 19.4. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr**

| Resource              | Value                                                                 |
|-----------------------|-----------------------------------------------------------------------|
| Floating IP addresses | 3 - plus the expected number of Services of LoadBalancer type         |
| Ports                 | 1500 - 1 needed per Pod                                               |
| Routers               | 1                                                                     |
| Subnets               | 250 - 1 needed per Namespace/Project                                  |
| Networks              | 250 - 1 needed per Namespace/Project                                  |
| RAM                   | 112 GB                                                                |
| vCPUs                 | 28                                                                    |
| Volume storage        | 275 GB                                                                |
| Instances             | 7                                                                     |
| Security groups       | 250 - 1 needed per Service and per NetworkPolicy                      |
| Security group rules  | 1000                                                                  |
| Server groups         | 2 - plus 1 for each additional availability zone in each machine pool |
| Load balancers        | 100 - 1 needed per Service                                            |

| Resource                | Value                                   |
|-------------------------|-----------------------------------------|
| Load balancer listeners | 500 - 1 needed per Service-exposed port |
| Load balancer pools     | 500 - 1 needed per Service-exposed port |

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

### IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

### IMPORTANT

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods' booting time.
- Each network policy is mapped into an RHOSP security group, and depending on the **NetworkPolicy** spec, one or more rules are added to the security group.
- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota.  
If you are using RHOSP version 15 or earlier, or the **ovn-octavia driver**, each load balancer has a security group with the user project.
- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment's size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them.  
If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.

- Use **openvswitch** firewall driver if ML2/OVS Neutron driver is used instead of **ovs-hybrid**.

### 19.4.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

#### Procedure

- Increase the quotas for a project by running the following command:

```
$ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets
250 --networks 250 <project>
```

### 19.4.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the **trunks** extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to **openvswitch** instead of **ovs\_hybrid** so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

### 19.4.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)'s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

#### NOTE

The following steps only capture the key pieces required during the [deployment of RHOSP](#) when dealing with Octavia. It is also important to note that [registry methods](#) vary.

This example uses the local registry method.

#### Procedure

1. If you are using the local registry, create a template to upload the images to the registry. For example:

```
(undercloud) $ openstack overcloud container image prepare \
-e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
--namespace=registry.access.redhat.com/rhosp13 \
--push-destination=<local-ip-from-undercloud.conf>:8787 \
--prefix=openstack- \
--tag-from-label {version}-{product-version} \
--output-env-file=/home/stack/templates/overcloud_images.yaml \
--output-images-file /home/stack/local_registry_images.yaml
```

2. Verify that the **local\_registry\_images.yaml** file contains the Octavia images. For example:

```
...
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
 push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
 push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
 push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
 push_destination: <local-ip-from-undercloud.conf>:8787
```

#### NOTE

The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from **registry.redhat.io** to the Undercloud node:

```
(undercloud) $ sudo openstack overcloud container image upload \
--config-file /home/stack/local_registry_images.yaml \
--verbose
```

This may take some time depending on the speed of your network and Undercloud disk.

4. Install or update your Overcloud environment with Octavia:

```
$ openstack overcloud deploy --templates \
-e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
-e octavia_timeouts.yaml
```

#### NOTE

This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see [installation of Octavia using Director](#).

#### NOTE

When leveraging Kuryr SDN, the Overcloud installation requires the Neutron **trunk** extension. This is available by default on director deployments. Use the **openvswitch** firewall instead of the default **ovs-hybrid** when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

### 19.4.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```
$ openstack loadbalancer provider list
```

### Example output

```
+-----+-----+
| name | description |
+-----+-----+
amphora	The Octavia Amphora driver.
octavia	Deprecated alias of the Octavia Amphora driver.
ovn	Octavia OVN driver.
+-----+-----+
```

Beginning with RHOSP version 16, the Octavia OVN provider driver (**ovn**) is supported on OpenShift Container Platform on RHOSP deployments.

**ovn** is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If **ovn** is enabled, however, Kuryr uses it.

If Kuryr uses **ovn** instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

You can [configure your cluster to use the Octavia OVN driver](#) after your RHOSP cloud is upgraded from version 13 to version 16.

#### 19.4.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

##### RHOSP general limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.
- Clusters that use the OVN Octavia provider driver support **Service** objects for which the **.spec.selector** property is unspecified only if the **.subsets.addresses** property of the **Endpoints** object includes the subnet of the nodes or pods.
- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.
- Configuring the **sessionAffinity=ClientIP** property on **Service** objects does not have an effect. Kuryr does not support this setting.

##### RHOSP version limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources. Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.
- Kuryr SDN does not support automatic unidling by a service.

#### **RHOSP upgrade limitations**

As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a [load balancer failover](#).
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

#### **19.4.3.5. Control plane machines**

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

#### **19.4.3.6. Compute machines**

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory and 2 vCPUs
- At least 100 GB storage space from the RHOSP quota

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

**19.4.3.7. Bootstrap machine**

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

**19.4.3.8. Load balancing requirements for user-provisioned infrastructure**

Before you install OpenShift Container Platform, you can provision your own API and application ingress load balancing infrastructure to use in place of the default, internal load balancing solution. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
  - Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
  - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 19.5. API load balancer**

| Port         | Back-end machines (pool members)                                                                                                                                                                                                              | Internal | External | Description           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|-----------------------|
| <b>6443</b>  | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <b>/readyz</b> endpoint for the API server health check probe. | X        | X        | Kubernetes API server |
| <b>22623</b> | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.                                                                                       | X        |          | Machine config server |

## NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer:** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

## TIP

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 19.6. Application Ingress load balancer**

| Port       | Back-end machines (pool members)                                                   | Internal | External | Description   |
|------------|------------------------------------------------------------------------------------|----------|----------|---------------|
| <b>443</b> | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTPS traffic |

| Port | Back-end machines (pool members)                                                   | Internal | External | Description  |
|------|------------------------------------------------------------------------------------|----------|----------|--------------|
| 80   | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTP traffic |

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

#### 19.4.3.8.1. Example load balancer configuration for clusters that are deployed with user-managed load balancers

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for clusters that are deployed with user-managed load balancers. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy\_connect\_any=1**.

#### Example 19.2. Sample API and application Ingress load balancer configuration

```
global
 log 127.0.0.1 local2
 pidfile /var/run/haproxy.pid
 maxconn 4000
 daemon
defaults
 mode http
 log global
 option dontlognull
 option http-server-close
 option redispatch
 retries 3
 timeout http-request 10s
 timeout queue 1m
 timeout connect 10s
 timeout client 1m
 timeout server 1m
 timeout http-keep-alive 10s
 timeout check 10s
```

```

maxconn 3000
listen api-server-6443 1
bind *:6443
mode tcp
option httpchk GET /readyz HTTP/1.0
option log-health-checks
balance roundrobin
server bootstrap bootstrap.ocp4.example.com:6443 verify none check check-ssl inter 10s fall 2
rise 3 backup 2
server master0 master0.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
server master1 master1.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
server master2 master2.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
listen machine-config-server-22623 3
bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 4
server master0 master0.ocp4.example.com:22623 check inter 1s
server master1 master1.ocp4.example.com:22623 check inter 1s
server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 5
bind *:443
mode tcp
balance source
server worker0 worker0.ocp4.example.com:443 check inter 1s
server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 6
bind *:80
mode tcp
balance source
server worker0 worker0.ocp4.example.com:80 check inter 1s
server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1** Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 2** **4** The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 3** Port **22623** handles the machine config server traffic and points to the control plane machines.
- 5** Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 6** Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

#### NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltpu** on the HAProxy node.

#### 19.4.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

#### 19.4.5. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftoperator** role. Add the role to an account before you run the installation program.

**IMPORTANT**

If [the Red Hat OpenStack Platform \(RHOSP\) object storage service](#), commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

**IMPORTANT**

RHOSP 17 sets the **rgw\_max\_attr\_size** parameter of Ceph RGW to 256 characters. This setting causes issues with uploading container images to the OpenShift Container Platform registry. You must set the value of **rgw\_max\_attr\_size** to at least 1024 characters.

Before installation, check if your RHOSP deployment is affected by this problem. If it is, reconfigure Ceph RGW.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On [Ceph RGW](#), the **account in url** option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

```
$ openstack role add --user <user> --project <project> swiftoperator
```

Your RHOSP deployment can now use Swift for the image registry.

19.4.6. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- [Configure OpenStack’s networking service to have DHCP agents forward instances' DNS queries](#)

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

```
+-----+-----+-----+
| ID | Name | Router Type |
+-----+-----+-----+
| 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External |
+-----+-----+-----+
```

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

**IMPORTANT**

If the external network's CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the **install-config.yaml** file before you start the installation process.

The default network ranges are:

| Network               | Range         |
|-----------------------|---------------|
| <b>machineNetwork</b> | 10.0.0.0/16   |
| <b>serviceNetwork</b> | 172.30.0.0/16 |
| <b>clusterNetwork</b> | 10.128.0.0/14 |

**WARNING**

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

**NOTE**

If the Neutron trunk service plugin is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

### 19.4.7. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

#### Procedure

1. Create the **clouds.yaml** file:
  - If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

**IMPORTANT**

Remember to add a password to the **auth** field. You can also keep secrets in [a separate file](#) from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

■

```

clouds:
 shiftstack:
 auth:
 auth_url: http://10.10.14.42:5000/v3
 project_name: shiftstack
 username: <username>
 password: <password>
 user_domain_name: Default
 project_domain_name: Default
 dev-env:
 region_name: RegionOne
 auth:
 username: <username>
 password: <password>
 project_name: 'devonly'
 auth_url: 'https://10.10.14.22:5001/v2.0'

```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

- a. Copy the certificate authority file to your machine.
- b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```

clouds:
 shiftstack:
 ...
 cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"

```

### TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
  - a. The value of the **OS\_CLIENT\_CONFIG\_FILE** environment variable
  - b. The current directory
  - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
  - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**

The installation program searches for **clouds.yaml** in that order.

## 19.4.8. Setting OpenStack Cloud Controller Manager options

Optionally, you can edit the OpenStack Cloud Controller Manager (CCM) configuration for your cluster. This configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of configuration parameters, see the "OpenStack Cloud Controller Manager reference guide" page in the "Installing on OpenStack" documentation.

## Procedure

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

```
$ openshift-install --dir <destination_directory> create manifests
```

2. In a text editor, open the cloud-provider configuration manifest file. For example:

```
$ vi openshift/manifests/cloud-provider-config.yaml
```

3. Modify the options according to the CCM reference guide.  
Configuring Octavia for load balancing is a common case for clusters that do not use Kuryr. For example:

```
#...
[LoadBalancer]
lb-provider = "amphora" 1
floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a" 2
create-monitor = True 3
monitor-delay = 10s 4
monitor-timeout = 10s 5
monitor-max-retries = 1 6
#...
```

- 1 This property sets the Octavia provider that your load balancer uses. It accepts **"ovn"** or **"amphora"** as values. If you choose to use OVN, you must also set **lb-method** to **SOURCE\_IP\_PORT**.
- 2 This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.
- 3 This property controls whether the cloud provider creates health monitors for Octavia load balancers. Set the value to **True** to create health monitors. As of RHOSP 16.2, this feature is only available for the Amphora provider.
- 4 This property sets the frequency with which endpoints are monitored. The value must be in the **time.ParseDuration()** format. This property is required if the value of the **create-monitor** property is **True**.
- 5 This property sets the time that monitoring requests are open before timing out. The value must be in the **time.ParseDuration()** format. This property is required if the value of the **create-monitor** property is **True**.
- 6 This property defines how many successful monitoring requests are required before a load balancer is marked as online. The value must be an integer. This property is required if the value of the **create-monitor** property is **True**.

**IMPORTANT**

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

**IMPORTANT**

You must set the value of the **create-monitor** property to **True** if you use services that have the value of the **.spec.externalTrafficPolicy** property set to **Local**. The OVN Octavia provider in RHOSP 16.2 does not support health monitors. Therefore, services that have **ETP** parameter values set to **Local** might not respond when the **lb-provider** value is set to **"ovn"**.

**IMPORTANT**

For installations that use Kuryr, Kuryr handles relevant services. There is no need to configure Octavia load balancing in the cloud provider.

4. Save the changes to the file and proceed with installation.

**TIP**

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a **SchedulingDisabled** status.

### 19.4.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

## 19.4.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If

you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.
  - iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
  - iv. Specify the floating IP address to use for external access to the OpenShift API.
  - v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.
  - vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
  - vii. Enter a name for your cluster. The name must be 14 or fewer characters long.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

#### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

#### Additional resources

- [Installation configuration parameters for OpenStack](#)

#### 19.4.10.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

## NOTE

Kuryr installations default to HTTP proxies.

## Prerequisites

- For Kuryr installations on restricted networks that use the **Proxy** object, the proxy must be able to reply to the router that the cluster uses. To add a static route for the proxy configuration, from a command line as the root user, enter:
- ```
$ ip route add <cluster_network_cidr> via <installer_subnet_gateway>
```
- The restricted subnet must have a gateway that is defined and available to be linked to the **Router** resource that Kuryr creates.
 - You have an existing **install-config.yaml** file.
 - You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

Procedure

- Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
  additionalTrustBundle: | 4
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
  additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use ***** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

NOTE

The installation program does not support the proxy **readinessEndpoints** field.

NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

19.4.10.2. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

NOTE

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIPs** and **platform.openstack.ingressVIPs** that are outside of the DHCP allocation pool.

IMPORTANT

The CIDR ranges for networks are not adjustable after cluster installation. Red Hat does not provide direct guidance on determining the range during cluster installation because it requires careful consideration of the number of created pods per namespace.

19.4.10.3. Sample customized **install-config.yaml** file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OVN-Kubernetes network plugin, you must modify the **install-config.yaml** file to include **Kuryr** as the desired **networking.networkType**. This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
```

```

name: master
platform: {}
replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
      replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16 ❶
  networkType: Kuryr ❷
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
    trunkSupport: true ❸
    octaviaSupport: true ❹
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA...

```

- ❶ The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the **serviceNetwork** property. The larger range is required to prevent IP address conflicts.
- ❷ The cluster network plugin to install. The supported values are **Kuryr**, **OVNKubernetes**, and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- ❸ ❹ Both **trunkSupport** and **octaviaSupport** are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

19.4.10.4. Installation configuration for a cluster on OpenStack with a user-managed load balancer

The following example **install-config.yaml** file demonstrates how to configure a cluster that uses an external, user-managed load balancer rather than the default internal load balancer.

```

apiVersion: v1
baseDomain: mydomain.test
compute:
- name: worker
  platform:

```

```

  openstack:
    type: m1.xlarge
  replicas: 3
controlPlane:
  name: master
  platform:
    openstack:
      type: m1.xlarge
    replicas: 3
metadata:
  name: mycluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 192.168.10.0/24
platform:
  openstack:
    cloud: mycloud
    machinesSubnet: 8586bf1a-cc3c-4d40-bdf6-c243decc603a ❶
    apiVIPs:
      - 192.168.10.5
    ingressVIPs:
      - 192.168.10.7
  loadBalancer:
    type: UserManaged ❷

```

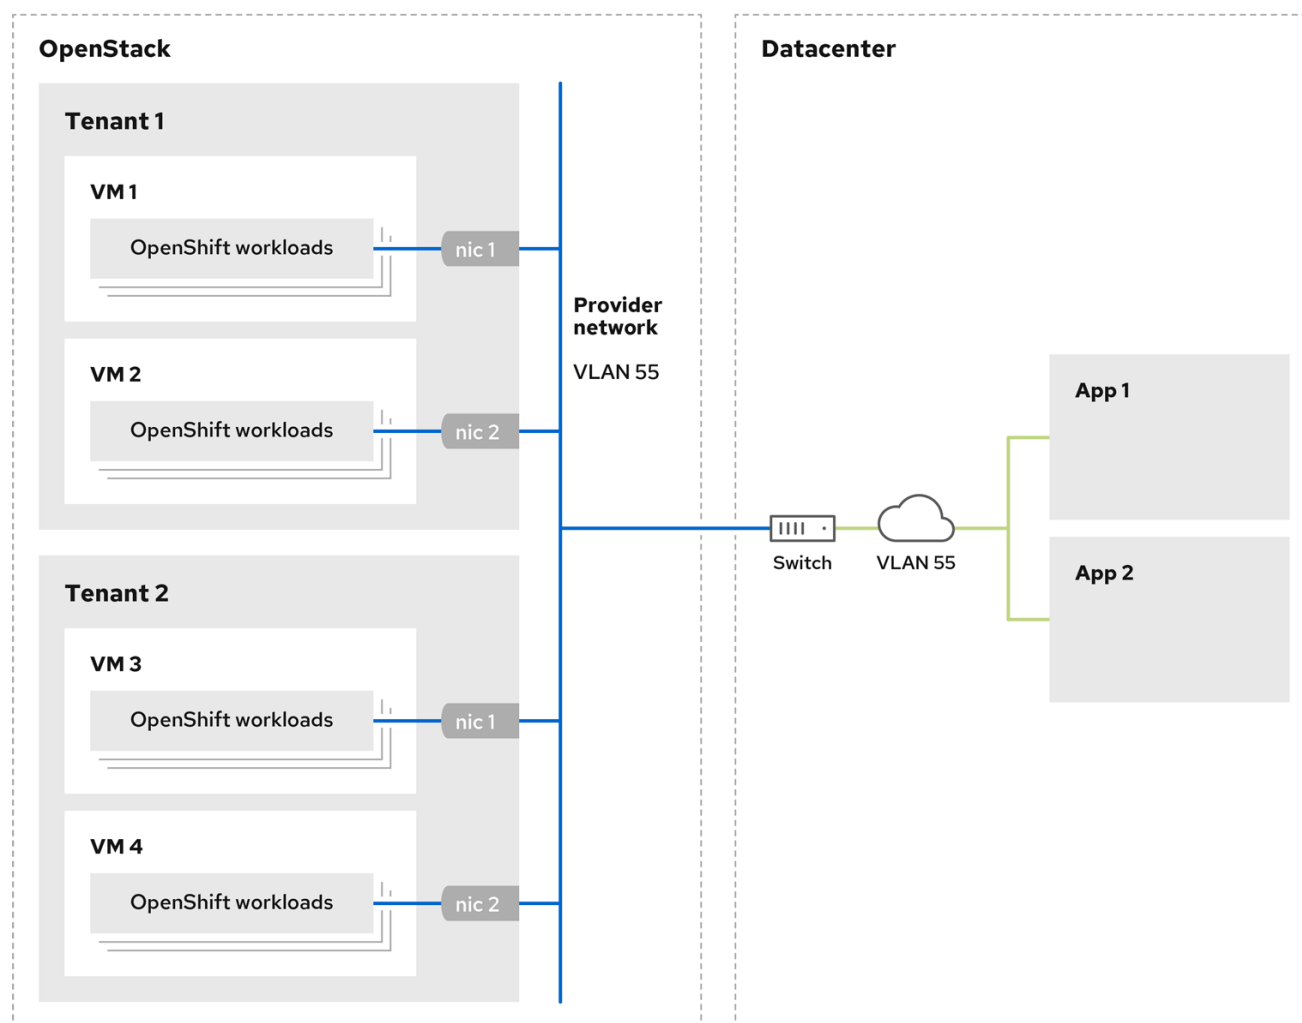

- ❶ Regardless of which load balancer you use, the load balancer is deployed to this subnet.
- ❷ The **UserManaged** value indicates that you are using an user-managed load balancer.

19.4.10.5. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

170_OpenShift_0621

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in [the RHOSP documentation](#).

19.4.10.5.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service \(Neutron\) is enabled](#) and accessible through the RHOSP networking API.
- The RHOSP networking service has the [port security and allowed address pairs extensions enabled](#).

- The provider network can be shared with other tenants.

TIP

Use the **openstack network create** command with the **--share** flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read [the provider networks documentation](#).

If the cluster is owned by the **admin** user, you must run the installer as that user to create ports on the network.

IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is **169.254.169.254** by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route  
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create [role-based access control \(RBAC\)](#) rules that limit network access to a single project.

19.4.10.5.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

1. In a text editor, open the **install-config.yaml** file.
2. Set the value of the **platform.openstack.apiVIPs** property to the IP address for the API VIP.
3. Set the value of the **platform.openstack.ingressVIPs** property to the IP address for the Ingress VIP.
4. Set the value of the **platform.openstack.machinesSubnet** property to the UUID of the provider network subnet.
5. Set the value of the **networking.machineNetwork.cidr** property to the CIDR block of the provider network subnet.

IMPORTANT

The **platform.openstack.apiVIPs** and **platform.openstack.ingressVIPs** properties must both be unassigned IP addresses from the **networking.machineNetwork.cidr** block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIPs: 1
    - 192.0.2.13
    ingressVIPs: 2
    - 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
    # ...
  networking:
    machineNetwork:
      - cidr: 192.0.2.0/24
```

- 1 2 In OpenShift Container Platform 4.12 and later, the **apiVIP** and **ingressVIP** configuration settings are deprecated. Instead, use a list format to enter values in the **apiVIPs** and **ingressVIPs** configuration settings.

WARNING

You cannot set the **platform.openstack.externalNetwork** or **platform.openstack.externalDNS** parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the **install-config.yaml** file to deploy the cluster on the provider network.

TIP

You can add additional networks, including provider networks, to the **platform.openstack.additionalNetworkIDs** list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

19.4.10.6. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation.

Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the **cluster-network-03-config.yml** manifest file to configure ports pool behavior:

- The **enablePortPoolsPrepopulation** parameter controls pool prepopulation, which forces Kuryr to add Neutron ports to the pools when the first pod that is configured to use the dedicated network for pods is created in a namespace. The default value is **false**.
- The **poolMinPorts** parameter is the minimum number of free ports that are kept in the pool. The default value is **1**.
- The **poolMaxPorts** parameter is the maximum number of free ports that are kept in the pool. A value of **0** disables that upper bound. This is the default setting.
If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.
- The **poolBatchPorts** parameter defines the maximum number of Neutron ports that can be created at once. The default value is **3**.

19.4.10.7. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the **install-config.yaml** file.

Procedure

1. From a command line, create the manifest files:

```
$ ./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation_directory>**, specify the name of the directory that contains the **install-config.yaml** file for your cluster.
2. Create a file that is named **cluster-network-03-config.yml** in the **<installation_directory>/manifests/** directory:

```
$ touch <installation_directory>/manifests/cluster-network-03-config.yml 1
```

- 1 For **<installation_directory>**, specify the directory name that contains the **manifests/** directory for your cluster.

After creating the file, several network configuration files are in the **manifests/** directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-network-*
```

Example output

```
cluster-network-01-crd.yml
cluster-network-02-config.yml
cluster-network-03-config.yml
```

3. Open the **cluster-network-03-config.yml** file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

```
$ oc edit networks.operator.openshift.io cluster
```

4. Edit the settings to meet your requirements. The following file is provided as an example:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  serviceNetwork:
    - 172.30.0.0/16
  defaultNetwork:
    type: Kuryr
    kuryrConfig:
      enablePortPoolsPrepopulation: false 1
      poolMinPorts: 1 2
      poolBatchPorts: 3 3
      poolMaxPorts: 5 4
      openstackServiceNetwork: 172.30.0.0/15 5
```

- 1 Set **enablePortPoolsPrepopulation** to **true** to make Kuryr create new Neutron ports when the first pod on the network for pods is created in a namespace. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is **false**.

- 2 Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of **poolMinPorts**. The default value is **1**.
- 3 **poolBatchPorts** controls the number of new ports that are created if the number of free ports is lower than the value of **poolMinPorts**. The default value is **3**.
- 4 If the number of free ports in a pool is higher than the value of **poolMaxPorts**, Kuryr deletes them until the number matches that value. Setting this value to **0** disables this upper bound, preventing pools from shrinking. The default value is **0**.
- 5 The **openStackServiceNetwork** parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia's LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of **openStackServiceNetwork** must be at least twice the size of the value of **serviceNetwork**, and the value of **serviceNetwork** must overlap entirely with the range that is defined by **openStackServiceNetwork**.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the **serviceNetwork** parameter.

If this parameter is not set, the CNO uses an expanded value of **serviceNetwork** that is determined by decrementing the prefix size by 1.

5. Save the **cluster-network-03-config.yml** file, and exit the text editor.
6. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program deletes the **manifests/** directory while creating the cluster.

19.4.11. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the **~/.ssh/authorized_keys** list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

19.4.12. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

19.4.12.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"
<external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"
<external_network>
```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your **/etc/hosts** file:

- **<api_floating_ip> api.<cluster_name>.<base_domain>**
- **<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>**
- **application_floating_ip integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>**

The cluster domain names in the **/etc/hosts** file grant access to the web console and the monitoring interface of your cluster locally. You can also use the **kubectl** or **oc**. You can access the user applications by using the additional entries pointing to the **<application_floating_ip>**. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

4. Add the FIPs to the **install-config.yaml** file as the values of the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you use these values, you must also enter an external network as the value of the **platform.openstack.externalNetwork** parameter in the **install-config.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

19.4.12.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **install-config.yaml** file, do not define the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you cannot provide an external network, you can also leave **platform.openstack.externalNetwork** blank. If you do not provide a value for **platform.openstack.externalNetwork**, a router is not created for

you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

19.4.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \ ❶
--log-level=info ❷
```

- ❶ For **<installation_directory>**, specify the location of your customized **./install-config.yaml** file.
- ❷ To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation_directory>/openshift_install.log**.

IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

19.4.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster's status during or after installation.

Procedure

1. In the cluster environment, export the administrator's kubeconfig file:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

```
$ oc get nodes
```

3. View your cluster's version:

```
$ oc get clusterversion
```

4. View your Operators' status:

```
$ oc get clusteroperator
```

5. View all running pods in the cluster:

```
$ oc get pods -A
```

19.4.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

19.4.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

19.4.17. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

19.5. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.14, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

19.5.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- You have an RHOSP account where you want to install OpenShift Container Platform.
- You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see [Recommended practices for scaling the cluster](#).

- On the machine from which you run the installation program, you have:
 - A single directory in which you can keep the files you create during the installation process
 - Python 3

19.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

19.5.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 19.7. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

Resource	Value
Floating IP addresses	3
Ports	15
Routers	1
Subnets	1
RAM	88 GB
vCPUs	22
Volume storage	275 GB

Resource	Value
Instances	7
Security groups	3
Security group rules	60
Server groups	2 – plus 1 for each additional availability zone in each machine pool

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run **openstack quota set --secgroups 3 --secgroup-rules 60 <project>** as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

19.5.3.1. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

19.5.3.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota

- A port from the RHOSP quota
- A flavor with at least 8 GB memory and 2 vCPUs
- At least 100 GB storage space from the RHOSP quota

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

19.5.3.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

19.5.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

- a. Register with Red Hat Subscription Manager:

```
$ sudo subscription-manager register # If not done already
```

- b. Pull the latest subscription data:

```
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
```

- c. Disable the current repositories:

```
$ sudo subscription-manager repos --disable=* # If not done already
```

d. Add the required repositories:

```
$ sudo subscription-manager repos \
  --enable=rhel-8-for-x86_64-baseos-rpms \
  --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
  --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
  --enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
ansible-collections-openstack
```

3. Ensure that the **python** command points to **python3**:

```
$ sudo alternatives --set python /usr/bin/python3
```

19.5.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

```
$ xargs -n 1 curl -O <<< '
  https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/bootstrap.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/common.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/compute-nodes.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/control-
plane.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/inventory.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/network.yaml
  https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/security-groups.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
bootstrap.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
compute-nodes.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
```

```
control-plane.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
load-balancers.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
network.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
security-groups.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
containers.yaml'
```

The playbooks are downloaded to your machine.

IMPORTANT

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

IMPORTANT

You must match any edits you make in the **bootstrap.yaml**, **compute-nodes.yaml**, **control-plane.yaml**, **network.yaml**, and **security-groups.yaml** files to the corresponding playbooks that are prefixed with **down-**. For example, edits to the **bootstrap.yaml** file must be reflected in the **down-bootstrap.yaml** file, too. If you do not edit both files, the supported cluster removal process will fail.

19.5.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

19.5.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

19.5.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

1. Log in to the Red Hat Customer Portal's [Product Downloads page](#).
2. Under **Version**, select the most recent release of OpenShift Container Platform 4.14 for Red Hat Enterprise Linux (RHEL) 8.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the *Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)*.
4. Decompress the image.

NOTE

You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like **.gz** or **.tgz**. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. From the image that you downloaded, create an image that is named **rhcos** in your cluster by using the RHOSP CLI:

```
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-
${RHCOS_VERSION}-openstack.qcow2 rhcos
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either **.raw** or **.qcow2** formats. If you use Ceph, you must use the **.raw** format.

**WARNING**

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

19.5.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- [Configure OpenStack's networking service to have DHCP agents forward instances' DNS queries](#)

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

```
+-----+-----+-----+
| ID                | Name          | Router Type |
+-----+-----+-----+
| 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
+-----+-----+-----+
```

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

**NOTE**

If the Neutron trunk service plugin is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

19.5.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

19.5.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"  
<external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"  
<external_network>
```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

```
$ openstack floating ip create --description "bootstrap machine" <external_network>
```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>  
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your **/etc/hosts** file:

- **<api_floating_ip> api.<cluster_name>.<base_domain>**
- **<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>**
- **application_floating_ip integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>**

The cluster domain names in the **/etc/hosts** file grant access to the web console and the monitoring interface of your cluster locally. You can also use the **kubectl** or **oc**. You can access the user applications by using the additional entries pointing to the **<application_floating_ip>**. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

5. Add the FIPs to the **inventory.yaml** file as the values of the following variables:

- **os_api_fip**
- **os_bootstrap_fip**
- **os_ingress_fip**

If you use these values, you must also enter an external network as the value of the **os_external_network** variable in the **inventory.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

19.5.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **inventory.yaml** file, do not define the following variables:

- **os_api_fip**
- **os_bootstrap_fip**

- **os_ingress_fip**

If you cannot provide an external network, you can also leave **os_external_network** blank. If you do not provide a value for **os_external_network**, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the **wait-for** command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

19.5.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:

- If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in [a separate file](#) from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      auth_url: http://10.10.14.42:5000/v3
      project_name: shiftstack
      username: <username>
      password: <password>
      user_domain_name: Default
      project_domain_name: Default
```

```
dev-env:
  region_name: RegionOne
  auth:
    username: <username>
    password: <password>
    project_name: 'devonly'
    auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
 - a. Copy the certificate authority file to your machine.
 - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
  shiftstack:
    ...
  cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**

The installation program searches for **clouds.yaml** in that order.

19.5.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following

- a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

NOTE

Always delete the **~/powers** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/powers
```

- b. At the prompts, provide the configuration details for your cloud:
- Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- Select **openstack** as the platform to target.
 - Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
 - Specify the floating IP address to use for external access to the OpenShift API.
 - Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.
 - Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
 - Enter a name for your cluster. The name must be 14 or fewer characters long.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file **install-config.yaml** in the directory that you specified.

Additional resources

- [Installation configuration parameters for OpenStack](#)

19.5.12.1. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

NOTE

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIPs** and **platform.openstack.ingressVIPs** that are outside of the DHCP allocation pool.

**IMPORTANT**

The CIDR ranges for networks are not adjustable after cluster installation. Red Hat does not provide direct guidance on determining the range during cluster installation because it requires careful consideration of the number of created pods per namespace.

19.5.12.2. Sample customized `install-config.yaml` file for RHOSP

This sample **`install-config.yaml`** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your **`install-config.yaml`** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:

  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
  fips: false
  pullSecret: '{"auths": ...}'
  sshKey: ssh-ed25519 AAAA...
```

19.5.12.3. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["networking"]["machineNetwork"] = [{"cidr": "192.168.0.0/18"}]; 1
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

- 1** Insert a value that matches your intended Neutron subnet, e.g. **192.0.2.0/24**.

- To set the value manually, open the file and set the value of **networking.machineCIDR** to something that matches your intended Neutron subnet.

19.5.12.4. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["compute"][0]["replicas"] = 0;
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

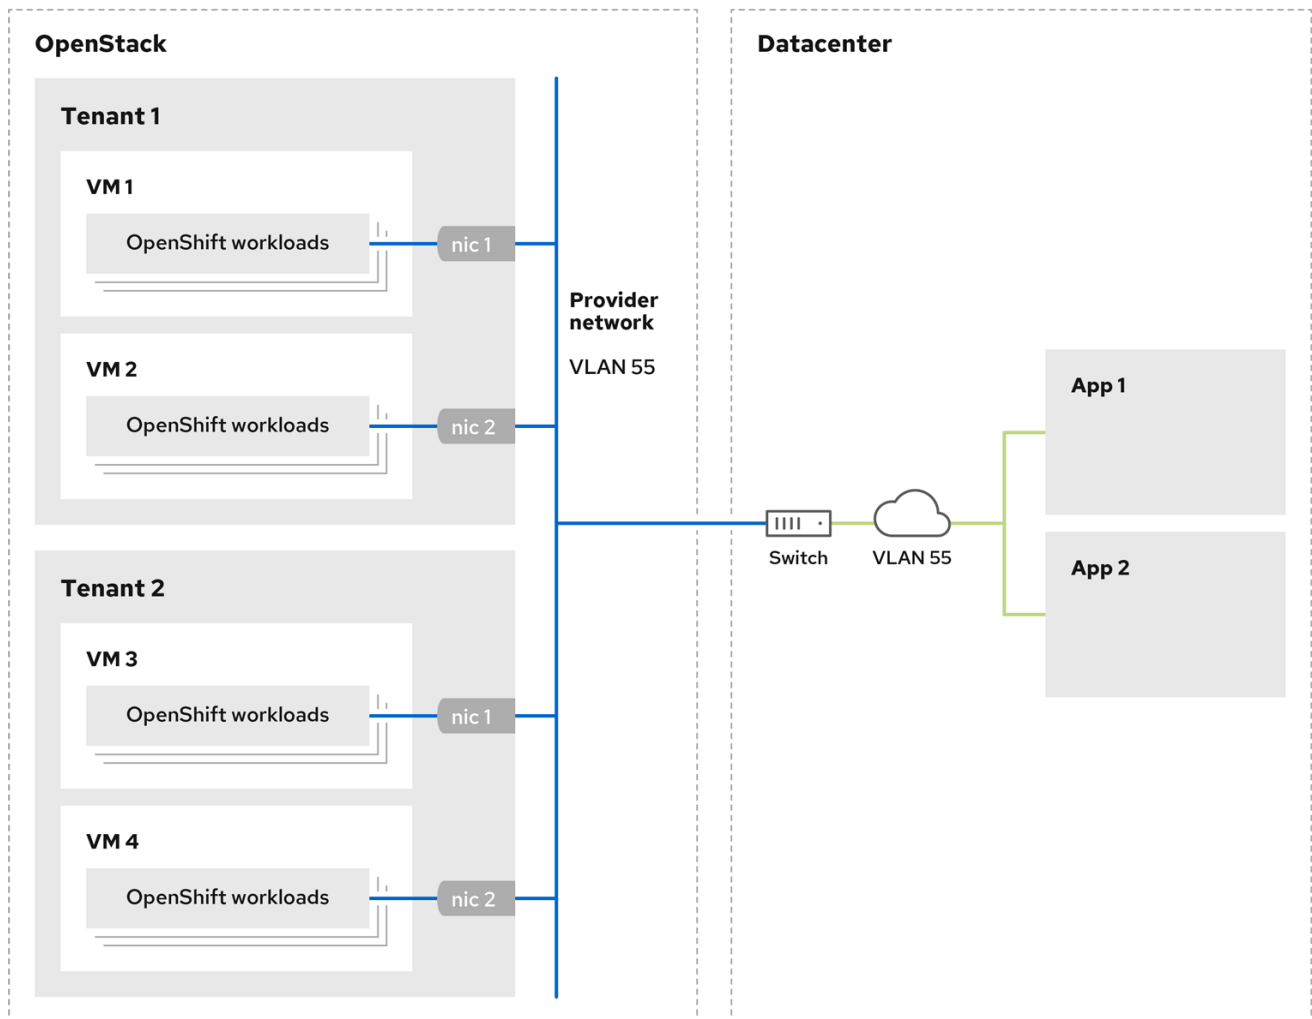

- To set the value manually, open the file and set the value of **compute.<first entry>.replicas** to **0**.

19.5.12.5. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

I70_OpenShift_0621

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in [the RHOSP documentation](#).

19.5.12.5.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service \(Neutron\) is enabled](#) and accessible through the RHOSP networking API.
- The RHOSP networking service has the [port security and allowed address pairs extensions enabled](#).
- The provider network can be shared with other tenants.

TIP

Use the **openstack network create** command with the **--share** flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read [the provider networks documentation](#).

If the cluster is owned by the **admin** user, you must run the installer as that user to create ports on the network.

IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is **169.254.169.254** by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route  
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create [role-based access control \(RBAC\)](#) rules that limit network access to a single project.

19.5.12.5.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

1. In a text editor, open the **install-config.yaml** file.
2. Set the value of the **platform.openstack.apiVIPs** property to the IP address for the API VIP.
3. Set the value of the **platform.openstack.ingressVIPs** property to the IP address for the Ingress VIP.
4. Set the value of the **platform.openstack.machinesSubnet** property to the UUID of the provider network subnet.
5. Set the value of the **networking.machineNetwork.cidr** property to the CIDR block of the provider network subnet.

IMPORTANT

The **platform.openstack.apiVIPs** and **platform.openstack.ingressVIPs** properties must both be unassigned IP addresses from the **networking.machineNetwork.cidr** block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIPs: ①
      - 192.0.2.13
    ingressVIPs: ②
      - 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
    # ...
  networking:
    machineNetwork:
      - cidr: 192.0.2.0/24
```

- ① ② In OpenShift Container Platform 4.12 and later, the **apiVIP** and **ingressVIP** configuration settings are deprecated. Instead, use a list format to enter values in the **apiVIPs** and **ingressVIPs** configuration settings.

**WARNING**

You cannot set the **platform.openstack.externalNetwork** or **platform.openstack.externalDNS** parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the **install-config.yaml** file to deploy the cluster on the provider network.

TIP

You can add additional networks, including provider networks, to the **platform.openstack.additionalNetworkIDs** list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

19.5.13. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines, compute machine sets, and control plane machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the compute machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.
3. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.
 4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory> 1
```

- 1 For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

```
.
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

5. Export the metadata file's **infraID** key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

TIP

Extract the **infraID** key from **metadata.json** and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

19.5.14. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, **bootstrap.ign**.
- The infrastructure ID from the installer's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see **Creating the Kubernetes manifest and Ignition config files**
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
 - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap\n').decode().strip()
files.append(
{
    'path': '/etc/hostname',
    'mode': 420,
    'contents': {
        'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
    }
})
```

```

ca_cert_path = os.environ.get('OS_CACERT', "")
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

    files.append(
        {
            'path': '/opt/openshift/tls/cloud-ca-cert.pem',
            'mode': 420,
            'contents': {
                'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64
            }
        }
    )

    ignition['storage']['files'] = files;

    with open('bootstrap.ign', 'w') as f:
        json.dump(ignition, f)

```

- Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```

$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign
<image_name>

```

- Get the image's details:

```

$ openstack image show <image_name>

```

Make a note of the **file** value; it follows the pattern **v2/images/<image_ID>/file**.

NOTE

Verify that the image you created is active.

- Retrieve the image service's public address:

```

$ openstack catalog show image

```

- Combine the public address with the image **file** value and save the result as the storage location. The location follows the pattern **<image_service_public_URL>/v2/images/<image_ID>/file**.

- Generate an auth token and save the token ID:

```

$ openstack token issue -c id -f value

```

- Insert the following content into a file called **\$INFRA_ID-bootstrap-ignition.json** and edit the placeholders to match your own values:

```

{
  "ignition": {

```

```

"config": {
  "merge": [{
    "source": "<storage_url>", ❶
    "httpHeaders": [{
      "name": "X-Auth-Token", ❷
      "value": "<token_ID>" ❸
    }]
  }],
  "security": {
    "tls": {
      "certificateAuthorities": [{
        "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>" ❹
      }]
    }
  },
  "version": "3.2.0"
}

```

- ❶ Replace the value of **ignition.config.merge.source** with the bootstrap Ignition file storage URL.
- ❷ Set **name** in **httpHeaders** to **"X-Auth-Token"**.
- ❸ Set **value** in **httpHeaders** to your token's ID.
- ❹ If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

WARNING

The bootstrap Ignition file contains sensitive information, like **clouds.yaml** credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

19.5.15. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

NOTE

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

Prerequisites

- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

```
$ for index in $(seq 0 2); do
  MASTER_HOSTNAME="$INFRA_ID-master-$index\n"
  python -c "import base64, json, sys;
  ignition = json.load(sys.stdin);
  storage = ignition.get('storage', {});
  files = storage.get('files', []);
  files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
'data:text/plain;charset=utf-8;base64,' +
base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
'filesystem': 'root'});
  storage['files'] = files;
  ignition['storage'] = storage
  json.dump(ignition, sys.stdout)" <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: **<INFRA_ID>-master-0-ignition.json**, **<INFRA_ID>-master-1-ignition.json**, and **<INFRA_ID>-master-2-ignition.json**.

19.5.16. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the **inventory.yaml** playbook:

Example external network value in the **inventory.yaml** Ansible playbook

```
...
# The public network providing connectivity to the cluster. If not
# provided, the cluster external connectivity must be provided in another
# way.
```

```
# Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
os_external_network: 'external'
```

```
...
```

IMPORTANT

If you did not provide a value for **os_external_network** in the **inventory.yaml** file, you must ensure that VMs can access Glance and an external connection yourself.

- Optional: Add external network and floating IP (FIP) address values to the **inventory.yaml** playbook:

Example FIP values in the **inventory.yaml** Ansible playbook

```
...
# OpenShift API floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the Control Plane to
# serve the OpenShift API.
os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the worker nodes to serve
# the applications.
os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
os_bootstrap_fip: '203.0.113.20'
```

IMPORTANT

If you do not define values for **os_api_fip** and **os_ingress_fip**, you must perform postinstallation network configuration.

If you do not define a value for **os_bootstrap_fip**, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

- On a command line, create security groups by running the **security-groups.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

- On a command line, create a network, subnet, and router by running the **network.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml network.yaml
```

- Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2>
"$INFRA_ID-nodes"
```

Optionally, you can use the **inventory.yaml** file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

19.5.16.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the **inventory.yaml** file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

NOTE

Be sure that your **install-config.yaml** file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

Prerequisites

- The RHOSP [Bare Metal service \(Ironic\)](#) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as [a RHOSP flavor](#).
- If your cluster runs on an RHOSP version that is more than 16.1.6 and less than 16.2.4, bare metal workers do not function due to a [known issue](#) that causes the metadata service to be unavailable for services on OpenShift Container Platform nodes.
- The RHOSP network supports both VM and bare metal server attachment.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an **inventory.yaml** file as part of the OpenShift Container Platform installation process.

Procedure

1. In the **inventory.yaml** file, edit the flavors for machines:
 - a. If you want to use bare-metal control plane machines, change the value of **os_flavor_master** to a bare metal flavor.
 - b. Change the value of **os_flavor_worker** to a bare metal flavor.

An example bare metal inventory.yaml file

```
all:
  hosts:
    localhost:
      ansible_connection: local
      ansible_python_interpreter: "{{ansible_playbook_python}}"
```

```
# User-provided values
os_subnet_range: '10.0.0.0/16'
os_flavor_master: 'my-bare-metal-flavor' 1
os_flavor_worker: 'my-bare-metal-flavor' 2
os_image_rhcos: 'rhcos'
os_external_network: 'external'
...
```

- 1 If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
- 2 Change this value to a bare metal flavor to use for compute machines.

Use the updated **inventory.yaml** file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

NOTE

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

19.5.17. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **bootstrap.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the **bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml bootstrap.yaml
```

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

```
$ openstack console log show "$INFRA_ID-bootstrap"
```

19.5.18. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
- The **inventory.yaml**, **common.yaml**, and **control-plane.yaml** Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. If the control plane Ignition config files aren't already in your working directory, copy them into it.
3. On a command line, run the **control-plane.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml control-plane.yaml
```

4. Run the following command to monitor the bootstrapping process:

```
$ openshift-install wait-for bootstrap-complete
```

You will see messages that confirm that the control plane machines are running and have joined the cluster:

```
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
...
INFO It is now safe to remove the bootstrap resources
```

19.5.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

19.5.20. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **down-bootstrap.yaml** Ansible playbooks are in a common directory.
- The control plane machines are running.
 - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the **down-bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml down-bootstrap.yaml
```

The bootstrap port, server, and floating IP address are deleted.

**WARNING**

If you did not disable the bootstrap Ignition file URL earlier, do so now.

19.5.21. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **compute-nodes.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the playbook:

```
$ ansible-playbook -i inventory.yaml compute-nodes.yaml
```

Next steps

- Approve the certificate signing requests for the machines.

19.5.22. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.27.3
master-1	Ready	master	63m	v1.27.3
master-2	Ready	master	64m	v1.27.3

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrapper	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrap** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

```
NAME      AGE   REQUESTOR                                     CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

```
NAME      STATUS    ROLES    AGE   VERSION
master-0  Ready     master   73m   v1.27.3
master-1  Ready     master   73m   v1.27.3
master-2  Ready     master   74m   v1.27.3
worker-0  Ready     worker   11m   v1.27.3
worker-1  Ready     worker   11m   v1.27.3
```

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

19.5.23. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

Prerequisites

- You have the installation program (**openshift-install**)

Procedure

- On a command line, enter:

```
$ openshift-install --log-level debug wait-for install-complete
```

The program outputs the console URL, as well as the administrator's login information.

19.5.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

19.5.25. Next steps

- [Customize your cluster.](#)
- If necessary, you can [opt out of remote health reporting](#) .
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#) .

19.6. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR ON YOUR OWN INFRASTRUCTURE

IMPORTANT

Kuryr is a deprecated feature. Deprecated functionality is still included in OpenShift Container Platform and continues to be supported; however, it will be removed in a future release of this product and is not recommended for new deployments.

For the most recent list of major functionality that has been deprecated or removed within OpenShift Container Platform, refer to the *Deprecated and removed features* section of the OpenShift Container Platform release notes.

In OpenShift Container Platform version 4.14, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

19.6.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).

- You have an RHOSP account where you want to install OpenShift Container Platform.
- You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see [Recommended practices for scaling the cluster](#).
- On the machine from which you run the installation program, you have:
 - A single directory in which you can keep the files you create during the installation process
 - Python 3

19.6.2. About Kuryr SDN

IMPORTANT

Kuryr is a deprecated feature. Deprecated functionality is still included in OpenShift Container Platform and continues to be supported; however, it will be removed in a future release of this product and is not recommended for new deployments.

For the most recent list of major functionality that has been deprecated or removed within OpenShift Container Platform, refer to the *Deprecated and removed features* section of the OpenShift Container Platform release notes.

[Kuryr](#) is a container network interface (CNI) plugin solution that uses the [Neutron](#) and [Octavia](#) Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the **openshift-kuryr** namespace:

- **kuryr-controller** – a single service instance installed on a **master** node. This is modeled in OpenShift Container Platform as a **Deployment** object.
- **kuryr-cni** – a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a **DaemonSet** object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The **ovn-octavia** Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

19.6.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster's minimum requirements:

Table 19.8. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr

Resource	Value
Floating IP addresses	3 - plus the expected number of Services of LoadBalancer type
Ports	1500 - 1 needed per Pod
Routers	1
Subnets	250 - 1 needed per Namespace/Project
Networks	250 - 1 needed per Namespace/Project
RAM	112 GB
vCPUs	28
Volume storage	275 GB
Instances	7
Security groups	250 - 1 needed per Service and per NetworkPolicy
Security group rules	1000
Server groups	2 - plus 1 for each additional availability zone in each machine pool

Resource	Value
Load balancers	100 - 1 needed per Service
Load balancer listeners	500 - 1 needed per Service-exposed port
Load balancer pools	500 - 1 needed per Service-exposed port

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

IMPORTANT

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods' booting time.
- Each network policy is mapped into an RHOSP security group, and depending on the **NetworkPolicy** spec, one or more rules are added to the security group.
- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota.
If you are using RHOSP version 15 or earlier, or the **ovn-octavia driver**, each load balancer has a security group with the user project.
- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment's size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them.
If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.

- Use Neutron Trunk ports extension.
- Use **openvswitch** firewall driver if ML2/OVS Neutron driver is used instead of **ovs-hybrid**.

19.6.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

Procedure

- Increase the quotas for a project by running the following command:

```
$ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
```

19.6.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the **trunks** extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to **openvswitch** instead of **ovs_hybrid** so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

19.6.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)'s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

NOTE

The following steps only capture the key pieces required during the [deployment of RHOSP](#) when dealing with Octavia. It is also important to note that [registry methods](#) vary.

This example uses the local registry method.

Procedure

1. If you are using the local registry, create a template to upload the images to the registry. For example:

```
(undercloud) $ openstack overcloud container image prepare \
-e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
--namespace=registry.access.redhat.com/rhosp13 \
--push-destination=<local-ip-from-undercloud.conf>:8787 \
--prefix=openstack-
```

```
--tag-from-label {version}-{product-version} \
--output-env-file=/home/stack/templates/overcloud_images.yaml \
--output-images-file /home/stack/local_registry_images.yaml
```

2. Verify that the **local_registry_images.yaml** file contains the Octavia images. For example:

```
...
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
  push_destination: <local-ip-from-undercloud.conf>:8787
```

NOTE

The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from **registry.redhat.io** to the Undercloud node:

```
(undercloud) $ sudo openstack overcloud container image upload \
--config-file /home/stack/local_registry_images.yaml \
--verbose
```

This may take some time depending on the speed of your network and Undercloud disk.

4. Install or update your Overcloud environment with Octavia:

```
$ openstack overcloud deploy --templates \
-e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
-e octavia_timeouts.yaml
```

NOTE

This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see [installation of Octavia using Director](#).

NOTE

When leveraging Kuryr SDN, the Overcloud installation requires the Neutron **trunk** extension. This is available by default on director deployments. Use the **openvswitch** firewall instead of the default **ovs-hybrid** when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

19.6.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```
$ openstack loadbalancer provider list
```

Example output

```
+-----+-----+
| name | description |
+-----+-----+
| amphora | The Octavia Amphora driver. |
| octavia | Deprecated alias of the Octavia Amphora driver. |
| ovn | Octavia OVN driver. |
+-----+-----+
```

Beginning with RHOSP version 16, the Octavia OVN provider driver (**ovn**) is supported on OpenShift Container Platform on RHOSP deployments.

ovn is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If **ovn** is enabled, however, Kuryr uses it.

If Kuryr uses **ovn** instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

19.6.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

RHOSP general limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.
- Clusters that use the OVN Octavia provider driver support **Service** objects for which the **.spec.selector** property is unspecified only if the **.subsets.addresses** property of the **Endpoints** object includes the subnet of the nodes or pods.
- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.
- Configuring the **sessionAffinity=ClientIP** property on **Service** objects does not have an effect. Kuryr does not support this setting.

RHOSP version limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources. Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.
- Kuryr SDN does not support automatic unidling by a service.

RHOSP upgrade limitations

As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a [load balancer failover](#).
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

19.6.3.5. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

19.6.3.6. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory and 2 vCPUs

- At least 100 GB storage space from the RHOSP quota

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

19.6.3.7. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

19.6.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

19.6.5. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

- a. Register with Red Hat Subscription Manager:

```
$ sudo subscription-manager register # If not done already
```

- b. Pull the latest subscription data:

```
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
```

- c. Disable the current repositories:

```
$ sudo subscription-manager repos --disable=* # If not done already
```

- d. Add the required repositories:

```
$ sudo subscription-manager repos \
--enable=rhel-8-for-x86_64-baseos-rpms \
--enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
--enable=ansible-2.9-for-rhel-8-x86_64-rpms \
--enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
ansible-collections-openstack
```

3. Ensure that the **python** command points to **python3**:

```
$ sudo alternatives --set python /usr/bin/python3
```

19.6.6. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

```
$ xargs -n 1 curl -O <<< '
https://raw.githubusercontent.com/openshift/installer/release-
```

```

4.14/upi/openstack/bootstrap.yaml
    https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/common.yaml
    https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/compute-nodes.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/control-
plane.yaml
    https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/inventory.yaml
    https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/network.yaml
    https://raw.githubusercontent.com/openshift/installer/release-
4.14/upi/openstack/security-groups.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
bootstrap.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
compute-nodes.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
control-plane.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
load-balancers.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
network.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
security-groups.yaml
    https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/down-
containers.yaml'

```

The playbooks are downloaded to your machine.

IMPORTANT

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

IMPORTANT

You must match any edits you make in the **bootstrap.yaml**, **compute-nodes.yaml**, **control-plane.yaml**, **network.yaml**, and **security-groups.yaml** files to the corresponding playbooks that are prefixed with **down-**. For example, edits to the **bootstrap.yaml** file must be reflected in the **down-bootstrap.yaml** file, too. If you do not edit both files, the supported cluster removal process will fail.

19.6.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

19.6.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

19.6.9. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

1. Log in to the Red Hat Customer Portal's [Product Downloads page](#).
2. Under **Version**, select the most recent release of OpenShift Container Platform 4.14 for Red Hat Enterprise Linux (RHEL) 8.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the *Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)*.

- Decompress the image.

NOTE

You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like **.gz** or **.tgz**. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

- From the image that you downloaded, create an image that is named **rhcos** in your cluster by using the RHOSP CLI:

```
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-
${RHCOS_VERSION}-openstack.qcow2 rhcos
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either **.raw** or **.qcow2** formats. If you use Ceph, you must use the **.raw** format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

19.6.10. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- [Configure OpenStack's networking service to have DHCP agents forward instances' DNS queries](#)

Procedure

- Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

Example output

ID	Name	Router Type
148a8023-62a7-4672-b018-003462f8d7dc	public_network	External

A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

NOTE

If the Neutron trunk service plugin is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

19.6.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

19.6.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"
<external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"
<external_network>
```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

```
$ openstack floating ip create --description "bootstrap machine" <external_network>
```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your **/etc/hosts** file:

- **<api_floating_ip> api.<cluster_name>.<base_domain>**
- **<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>**
- **<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>**
- **application_floating_ip integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>**

The cluster domain names in the **/etc/hosts** file grant access to the web console and the monitoring interface of your cluster locally. You can also use the **kubectl** or **oc**. You can access the user applications by using the additional entries pointing to the **<application_floating_ip>**. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

5. Add the FIPs to the **inventory.yaml** file as the values of the following variables:

- **os_api_fip**
- **os_bootstrap_fip**
- **os_ingress_fip**

If you use these values, you must also enter an external network as the value of the **os_external_network** variable in the **inventory.yaml** file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

19.6.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **inventory.yaml** file, do not define the following variables:

- **os_api_fip**
- **os_bootstrap_fip**

- **os_ingress_fip**

If you cannot provide an external network, you can also leave **os_external_network** blank. If you do not provide a value for **os_external_network**, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the **wait-for** command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

19.6.12. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:

- If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

IMPORTANT

Remember to add a password to the **auth** field. You can also keep secrets in [a separate file](#) from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      auth_url: http://10.10.14.42:5000/v3
      project_name: shiftstack
      username: <username>
      password: <password>
      user_domain_name: Default
      project_domain_name: Default
```

```
dev-env:
  region_name: RegionOne
  auth:
    username: <username>
    password: <password>
    project_name: 'devonly'
    auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
 - a. Copy the certificate authority file to your machine.
 - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
  shiftstack:
    ...
    cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**
 The installation program searches for **clouds.yaml** in that order.

19.6.13. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following

- a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

NOTE

Always delete the **~/powers** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/powers
```

- b. At the prompts, provide the configuration details for your cloud:
- Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- Select **openstack** as the platform to target.
 - Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.
 - Specify the floating IP address to use for external access to the OpenShift API.
 - Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.
 - Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.
 - Enter a name for your cluster. The name must be 14 or fewer characters long.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file **install-config.yaml** in the directory that you specified.

Additional resources

- [Installation configuration parameters for OpenStack](#)

19.6.13.1. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet's GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster's primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the **platform.openstack.machinesSubnet** subnet must be attached to a router that is connected to the **externalNetwork** network.
- If the **platform.openstack.machinesSubnet** value is set in the **install-config.yaml** file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the **platform.openstack.externalDNS** property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

NOTE

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network's CIDR block. To override these default values, set values for **platform.openstack.apiVIPs** and **platform.openstack.ingressVIPs** that are outside of the DHCP allocation pool.

**IMPORTANT**

The CIDR ranges for networks are not adjustable after cluster installation. Red Hat does not provide direct guidance on determining the range during cluster installation because it requires careful consideration of the number of created pods per namespace.

19.6.13.2. Sample customized install-config.yaml file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OVN-Kubernetes network plugin, you must modify the **install-config.yaml** file to include **Kuryr** as the desired **networking.networkType**. This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
    replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
  - 172.30.0.0/16 ①
  networkType: Kuryr ②
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
    trunkSupport: true ③
    octaviaSupport: true ④
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA...
```

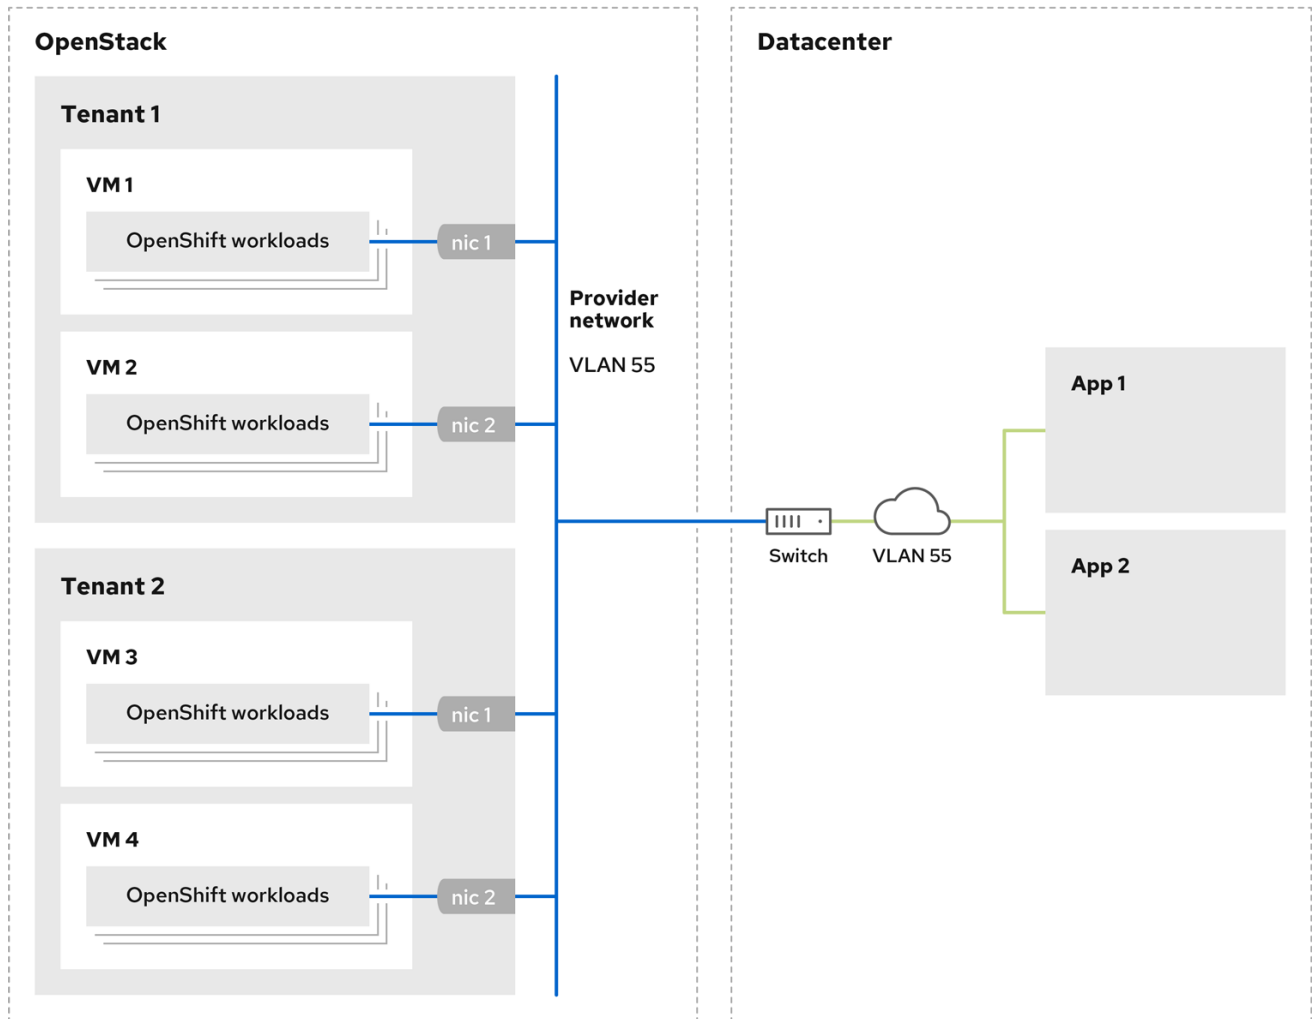

- 1 The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the **serviceNetwork** property. The larger range is required to prevent IP address conflicts.
- 2 The cluster network plugin to install. The supported values are **Kuryr**, **OVNKubernetes**, and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 3 4 Both **trunkSupport** and **octaviaSupport** are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

19.6.13.3. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

170_OpenShift_0621

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in [the RHOSP documentation](#).

19.6.13.3.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service \(Neutron\) is enabled](#) and accessible through the RHOSP networking API.
- The RHOSP networking service has the [port security and allowed address pairs extensions enabled](#).

- The provider network can be shared with other tenants.

TIP

Use the **openstack network create** command with the **--share** flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read [the provider networks documentation](#).

If the cluster is owned by the **admin** user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is **169.254.169.254** by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route  
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create [role-based access control \(RBAC\)](#) rules that limit network access to a single project.

19.6.13.3.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

1. In a text editor, open the **install-config.yaml** file.
2. Set the value of the **platform.openstack.apiVIPs** property to the IP address for the API VIP.
3. Set the value of the **platform.openstack.ingressVIPs** property to the IP address for the Ingress VIP.
4. Set the value of the **platform.openstack.machinesSubnet** property to the UUID of the provider network subnet.
5. Set the value of the **networking.machineNetwork.cidr** property to the CIDR block of the provider network subnet.

IMPORTANT

The **platform.openstack.apiVIPs** and **platform.openstack.ingressVIPs** properties must both be unassigned IP addresses from the **networking.machineNetwork.cidr** block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIPs: 1
    - 192.0.2.13
    ingressVIPs: 2
    - 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
    # ...
  networking:
    machineNetwork:
      - cidr: 192.0.2.0/24
```

- 1 2** In OpenShift Container Platform 4.12 and later, the **apiVIP** and **ingressVIP** configuration settings are deprecated. Instead, use a list format to enter values in the **apiVIPs** and **ingressVIPs** configuration settings.

WARNING

You cannot set the **platform.openstack.externalNetwork** or **platform.openstack.externalDNS** parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the **install-config.yaml** file to deploy the cluster on the provider network.

TIP

You can add additional networks, including provider networks, to the **platform.openstack.additionalNetworkIDs** list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

19.6.13.4. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation.

Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the **cluster-network-03-config.yml** manifest file to configure ports pool behavior:

- The **enablePortPoolsPrepopulation** parameter controls pool prepopulation, which forces Kuryr to add Neutron ports to the pools when the first pod that is configured to use the dedicated network for pods is created in a namespace. The default value is **false**.
- The **poolMinPorts** parameter is the minimum number of free ports that are kept in the pool. The default value is **1**.
- The **poolMaxPorts** parameter is the maximum number of free ports that are kept in the pool. A value of **0** disables that upper bound. This is the default setting.
If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.
- The **poolBatchPorts** parameter defines the maximum number of Neutron ports that can be created at once. The default value is **3**.

19.6.13.5. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the **install-config.yaml** file.

Procedure

1. From a command line, create the manifest files:

```
$ ./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation_directory>**, specify the name of the directory that contains the **install-config.yaml** file for your cluster.
2. Create a file that is named **cluster-network-03-config.yml** in the **<installation_directory>/manifests/** directory:

```
$ touch <installation_directory>/manifests/cluster-network-03-config.yml 1
```

- 1 For **<installation_directory>**, specify the directory name that contains the **manifests/** directory for your cluster.

After creating the file, several network configuration files are in the **manifests/** directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-network-*
```

Example output

```
cluster-network-01-crd.yml
cluster-network-02-config.yml
cluster-network-03-config.yml
```

3. Open the **cluster-network-03-config.yml** file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

```
$ oc edit networks.operator.openshift.io cluster
```

4. Edit the settings to meet your requirements. The following file is provided as an example:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  serviceNetwork:
    - 172.30.0.0/16
  defaultNetwork:
    type: Kuryr
    kuryrConfig:
      enablePortPoolsPrepopulation: false 1
      poolMinPorts: 1 2
      poolBatchPorts: 3 3
      poolMaxPorts: 5 4
      openstackServiceNetwork: 172.30.0.0/15 5
```

- 1 Set **enablePortPoolsPrepopulation** to **true** to make Kuryr create new Neutron ports when the first pod on the network for pods is created in a namespace. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is **false**.

- 2 Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of **poolMinPorts**. The default value is **1**.
- 3 **poolBatchPorts** controls the number of new ports that are created if the number of free ports is lower than the value of **poolMinPorts**. The default value is **3**.
- 4 If the number of free ports in a pool is higher than the value of **poolMaxPorts**, Kuryr deletes them until the number matches that value. Setting this value to **0** disables this upper bound, preventing pools from shrinking. The default value is **0**.
- 5 The **openStackServiceNetwork** parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia's LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of **openStackServiceNetwork** must be at least twice the size of the value of **serviceNetwork**, and the value of **serviceNetwork** must overlap entirely with the range that is defined by **openStackServiceNetwork**.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the **serviceNetwork** parameter.

If this parameter is not set, the CNO uses an expanded value of **serviceNetwork** that is determined by decrementing the prefix size by 1.

5. Save the **cluster-network-03-config.yml** file, and exit the text editor.
6. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program deletes the **manifests/** directory while creating the cluster.

19.6.13.6. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
```

```
data = yaml.safe_load(open(path));
data["networking"]["machineNetwork"] = [{"cidr": "192.168.0.0/18"}]; 1
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

1 Insert a value that matches your intended Neutron subnet, e.g. **192.0.2.0/24**.

- To set the value manually, open the file and set the value of **networking.machineCIDR** to something that matches your intended Neutron subnet.

19.6.13.7. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the **install-config.yaml** file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:
 - To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["compute"][0]["replicas"] = 0;
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

- To set the value manually, open the file and set the value of **compute.<first entry>.replicas** to **0**.

19.6.13.8. Modifying the network type

By default, the installation program selects the **OpenShiftSDN** network type. To use Kuryr instead, change the value in the installation configuration file that the program generated.

Prerequisites

- You have the file **install-config.yaml** that was generated by the OpenShift Container Platform installation program

Procedure

1. In a command prompt, browse to the directory that contains **install-config.yaml**.
2. From that directory, either run a script to edit the **install-config.yaml** file or update the file manually:

- To set the value by using a script, run:

```
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["networking"]["networkType"] = "Kuryr";
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

- To set the value manually, open the file and set **networking.networkType** to **"Kuryr"**.

19.6.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory> 1
```

- 1** For **<installation_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines, compute machine sets, and control plane machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the compute machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.
3. Check that the **mastersSchedulable** parameter in the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
 - a. Open the **<installation_directory>/manifests/cluster-scheduler-02-config.yml** file.
 - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
 - c. Save and exit the file.
 4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory> 1
```

- 1** For **<installation_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation_directory>/auth** directory:

```
.
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

5. Export the metadata file's **infraID** key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

TIP

Extract the **infraID** key from **metadata.json** and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

19.6.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, **bootstrap.ign**.
- The infrastructure ID from the installer's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see **Creating the Kubernetes manifest and Ignition config files**
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
 - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap\n').decode().strip()
files.append(
{
    'path': '/etc/hostname',
    'mode': 420,
    'contents': {
        'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
    }
})

ca_cert_path = os.environ.get('OS_CACERT', "")
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

    files.append(
{
```

```

        'path': '/opt/openshift/tls/cloud-ca-cert.pem',
        'mode': 420,
        'contents': {
            'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64
        }
    })

    ignition['storage']['files'] = files;

    with open('bootstrap.ign', 'w') as f:
        json.dump(ignition, f)

```

- Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```

$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign
<image_name>

```

- Get the image's details:

```

$ openstack image show <image_name>

```

Make a note of the **file** value; it follows the pattern **v2/images/<image_ID>/file**.

NOTE

Verify that the image you created is active.

- Retrieve the image service's public address:

```

$ openstack catalog show image

```

- Combine the public address with the image **file** value and save the result as the storage location. The location follows the pattern **<image_service_public_URL>/v2/images/<image_ID>/file**.

- Generate an auth token and save the token ID:

```

$ openstack token issue -c id -f value

```

- Insert the following content into a file called **\$INFRA_ID-bootstrap-ignition.json** and edit the placeholders to match your own values:

```

{
  "ignition": {
    "config": {
      "merge": [{
        "source": "<storage_url>", ❶
        "httpHeaders": [{
          "name": "X-Auth-Token", ❷
          "value": "<token_ID>" ❸
        }]
      }]
    }
  },

```

```

    "security": {
      "tls": {
        "certificateAuthorities": [{
          "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>" 4
        }]
      }
    },
    "version": "3.2.0"
  }
}

```

- 1 Replace the value of **ignition.config.merge.source** with the bootstrap Ignition file storage URL.
- 2 Set **name** in **httpHeaders** to **"X-Auth-Token"**.
- 3 Set **value** in **httpHeaders** to your token's ID.
- 4 If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

WARNING

The bootstrap Ignition file contains sensitive information, like **clouds.yaml** credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

19.6.16. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

NOTE

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

Prerequisites

- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
 - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

```
$ for index in $(seq 0 2); do
  MASTER_HOSTNAME="$INFRA_ID-master-$index\n"
  python -c "import base64, json, sys;
  ignition = json.load(sys.stdin);
  storage = ignition.get('storage', {});
  files = storage.get('files', []);
  files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
'data:text/plain;charset=utf-8;base64,' +
base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
'filesystem': 'root'});
  storage['files'] = files;
  ignition['storage'] = storage
  json.dump(ignition, sys.stdout)" <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: **<INFRA_ID>-master-0-ignition.json**, **<INFRA_ID>-master-1-ignition.json**, and **<INFRA_ID>-master-2-ignition.json**.

19.6.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the **inventory.yaml** playbook:

Example external network value in the **inventory.yaml** Ansible playbook

```
...
# The public network providing connectivity to the cluster. If not
# provided, the cluster external connectivity must be provided in another
# way.

# Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
os_external_network: 'external'
...
```

IMPORTANT

If you did not provide a value for **os_external_network** in the **inventory.yaml** file, you must ensure that VMs can access Glance and an external connection yourself.

- Optional: Add external network and floating IP (FIP) address values to the **inventory.yaml** playbook:

Example FIP values in the **inventory.yaml** Ansible playbook

```
...
# OpenShift API floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the Control Plane to
# serve the OpenShift API.
os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the worker nodes to serve
# the applications.
os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
os_bootstrap_fip: '203.0.113.20'
```

IMPORTANT

If you do not define values for **os_api_fip** and **os_ingress_fip**, you must perform postinstallation network configuration.

If you do not define a value for **os_bootstrap_fip**, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

- On a command line, create security groups by running the **security-groups.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

- On a command line, create a network, subnet, and router by running the **network.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml network.yaml
```

- Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2>
"$INFRA_ID-nodes"
```

19.6.18. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **bootstrap.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the **bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml bootstrap.yaml
```

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

```
$ openstack console log show "$INFRA_ID-bootstrap"
```

19.6.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program's metadata file is set as an environment variable (**\$INFRA_ID**).
- The **inventory.yaml**, **common.yaml**, and **control-plane.yaml** Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. If the control plane Ignition config files aren't already in your working directory, copy them into it.
3. On a command line, run the **control-plane.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml control-plane.yaml
```

4. Run the following command to monitor the bootstrapping process:

```
■
```

```
$ openshift-install wait-for bootstrap-complete
```

You will see messages that confirm that the control plane machines are running and have joined the cluster:

```
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
...
INFO It is now safe to remove the bootstrap resources
```

19.6.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

19.6.21. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **down-bootstrap.yaml** Ansible playbooks are in a common directory.

- The control plane machines are running.
 - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the **down-bootstrap.yaml** playbook:

```
$ ansible-playbook -i inventory.yaml down-bootstrap.yaml
```

The bootstrap port, server, and floating IP address are deleted.

WARNING

If you did not disable the bootstrap Ignition file URL earlier, do so now.

19.6.22. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The **inventory.yaml**, **common.yaml**, and **compute-nodes.yaml** Ansible playbooks are in a common directory.
- The **metadata.json** file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the playbook:

```
$ ansible-playbook -i inventory.yaml compute-nodes.yaml
```

Next steps

- Approve the certificate signing requests for the machines.

19.6.23. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

- Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

NAME	STATUS	ROLES	AGE	VERSION
master-0	Ready	master	63m	v1.27.3
master-1	Ready	master	63m	v1.27.3
master-2	Ready	master	64m	v1.27.3

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

- Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-8b2br	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrap	Pending
csr-8vnps	15m	system:serviceaccount:openshift-machine-config-operator:node-bootstrap	Pending
...			

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrap** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

1 **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

NAME	AGE	REQUESTOR	CONDITION
csr-bfd72	5m26s	system:node:ip-10-0-50-126.us-east-2.compute.internal	Pending
csr-c57lv	5m26s	system:node:ip-10-0-95-157.us-east-2.compute.internal	Pending
...			

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

Example output

```
NAME      STATUS  ROLES  AGE  VERSION
master-0  Ready   master 73m  v1.27.3
master-1  Ready   master 73m  v1.27.3
master-2  Ready   master 74m  v1.27.3
worker-0  Ready   worker 11m  v1.27.3
worker-1  Ready   worker 11m  v1.27.3
```

NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

19.6.24. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

Prerequisites

- You have the installation program (**openshift-install**)

Procedure

- On a command line, enter:

```
$ openshift-install --log-level debug wait-for install-complete
```

The program outputs the console URL, as well as the administrator's login information.

19.6.25. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

19.6.26. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- If you need to enable external access to node ports, [configure ingress cluster traffic by using a node port](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

19.7. INSTALLING A CLUSTER ON OPENSTACK IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.14, you can install a cluster on Red Hat OpenStack Platform (RHOSP) in a restricted network by creating an internal mirror of the installation release content.

19.7.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the [Supported platforms for OpenShift clusters](#) section. You can also compare platform support across different versions by viewing the [OpenShift Container Platform on RHOSP support matrix](#).
- You [created a registry on your mirror host](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see [Recommended practices for scaling the cluster](#).
- You have the metadata service enabled in RHOSP.

19.7.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

19.7.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

19.7.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 19.9. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

Resource	Value
Floating IP addresses	3
Ports	15
Routers	1
Subnets	1
RAM	88 GB
vCPUs	22

Resource	Value
Volume storage	275 GB
Instances	7
Security groups	3
Security group rules	60
Server groups	2 – plus 1 for each additional availability zone in each machine pool

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run **openstack quota set --secgroups 3 --secgroup-rules 60 <project>** as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

19.7.3.1. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

19.7.3.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory and 2 vCPUs
- At least 100 GB storage space from the RHOSP quota

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

19.7.3.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

19.7.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

19.7.5. Enabling Swift on RHOSP

Swift is operated by a user account with the **swiftooperator** role. Add the role to an account before you run the installation program.

**IMPORTANT**

If [the Red Hat OpenStack Platform \(RHOSP\) object storage service](#), commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

**IMPORTANT**

RHOSP 17 sets the **rgw_max_attr_size** parameter of Ceph RGW to 256 characters. This setting causes issues with uploading container images to the OpenShift Container Platform registry. You must set the value of **rgw_max_attr_size** to at least 1024 characters.

Before installation, check if your RHOSP deployment is affected by this problem. If it is, reconfigure Ceph RGW.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On [Ceph RGW](#), the **account in url** option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

```
$ openstack role add --user <user> --project <project> swiftoperator
```

Your RHOSP deployment can now use Swift for the image registry.

19.7.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called **clouds.yaml**. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the **clouds.yaml** file:
 - If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

**IMPORTANT**

Remember to add a password to the **auth** field. You can also keep secrets in [a separate file](#) from **clouds.yaml**.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see [Config files](#) in the RHOSP documentation.

```
clouds:
  shiftstack:
    auth:
      auth_url: http://10.10.14.42:5000/v3
      project_name: shiftstack
      username: <username>
      password: <password>
      user_domain_name: Default
      project_domain_name: Default
    dev-env:
      region_name: RegionOne
      auth:
        username: <username>
        password: <password>
        project_name: 'devonly'
        auth_url: 'https://10.10.14.22:5001/v2.0'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
 - a. Copy the certificate authority file to your machine.
 - b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```
clouds:
  shiftstack:
    ...
    cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

TIP

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:
 - a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
 - b. The current directory
 - c. A Unix-specific user configuration directory, for example **~/.config/openstack/clouds.yaml**
 - d. A Unix-specific site configuration directory, for example **/etc/openstack/clouds.yaml**
The installation program searches for **clouds.yaml** in that order.

19.7.7. Setting OpenStack Cloud Controller Manager options

Optionally, you can edit the OpenStack Cloud Controller Manager (CCM) configuration for your cluster. This configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of configuration parameters, see the "OpenStack Cloud Controller Manager reference guide" page in the "Installing on OpenStack" documentation.

Procedure

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

```
$ openshift-install --dir <destination_directory> create manifests
```

2. In a text editor, open the cloud-provider configuration manifest file. For example:

```
$ vi openshift/manifests/cloud-provider-config.yaml
```

3. Modify the options according to the CCM reference guide.
Configuring Octavia for load balancing is a common case for clusters that do not use Kuryr. For example:

```
#...
[LoadBalancer]
lb-provider = "amphora" ❶
floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a" ❷
create-monitor = True ❸
monitor-delay = 10s ❹
monitor-timeout = 10s ❺
monitor-max-retries = 1 ❻
#...
```

- ❶ This property sets the Octavia provider that your load balancer uses. It accepts **"ovn"** or **"amphora"** as values. If you choose to use OVN, you must also set **lb-method** to **SOURCE_IP_PORT**.
- ❷ This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.
- ❸ This property controls whether the cloud provider creates health monitors for Octavia load balancers. Set the value to **True** to create health monitors. As of RHOSP 16.2, this feature is only available for the Amphora provider.
- ❹ This property sets the frequency with which endpoints are monitored. The value must be in the **time.ParseDuration()** format. This property is required if the value of the **create-monitor** property is **True**.
- ❺ This property sets the time that monitoring requests are open before timing out. The value must be in the **time.ParseDuration()** format. This property is required if the value of the **create-monitor** property is **True**.
- ❻ This property defines how many successful monitoring requests are required before a load balancer is marked as online. The value must be an integer. This property is required if the value of the **create-monitor** property is **True**.

**IMPORTANT**

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

**IMPORTANT**

You must set the value of the **create-monitor** property to **True** if you use services that have the value of the **.spec.externalTrafficPolicy** property set to **Local**. The OVN Octavia provider in RHOSP 16.2 does not support health monitors. Therefore, services that have **ETP** parameter values set to **Local** might not respond when the **lb-provider** value is set to **"ovn"**.

**IMPORTANT**

For installations that use Kuryr, Kuryr handles relevant services. There is no need to configure Octavia load balancing in the cloud provider.

4. Save the changes to the file and proceed with installation.

TIP

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a **SchedulingDisabled** status.

19.7.8. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network Red Hat OpenStack Platform (RHOSP) environment.

Prerequisites

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

Procedure

1. Log in to the Red Hat Customer Portal's [Product Downloads page](#).
2. Under **Version**, select the most recent release of OpenShift Container Platform 4.14 for RHEL 8.

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the **Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)** image.
4. Decompress the image.

NOTE

You must decompress the image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like **.gz** or **.tgz**. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. Upload the image that you decompressed to a location that is accessible from the bastion server, like Glance. For example:

```
$ openstack image create --file rhcos-44.81.202003110027-0-openstack.x86_64.qcow2 --
disk-format qcow2 rhcos-${RHCOS_VERSION}
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either **.raw** or **.qcow2** formats. If you use Ceph, you must use the **.raw** format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

19.7.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the **imageContentSources** values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.
- You have retrieved a Red Hat Enterprise Linux CoreOS (RHCOS) image and uploaded it to an accessible location.

Procedure

1. Create the **install-config.yaml** file.
 - a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

NOTE

Always delete the **~/.powervs** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
 - i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **openstack** as the platform to target.

For these values, use the **imageContentSources** that you recorded during mirror registry creation.

- d. Optional: Set the publishing strategy to **Internal**:

```
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- [Installation configuration parameters for OpenStack](#)

19.7.9.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

NOTE

Kuryr installations default to HTTP proxies.

Prerequisites

- For Kuryr installations on restricted networks that use the **Proxy** object, the proxy must be able to reply to the router that the cluster uses. To add a static route for the proxy configuration, from a command line as the root user, enter:
- ```
$ ip route add <cluster_network_cidr> via <installer_subnet_gateway>
```
- The restricted subnet must have a gateway that is defined and available to be linked to the **Router** resource that Kuryr creates.
  - You have an existing **install-config.yaml** file.
  - You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: example.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

## NOTE

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 19.7.9.2. Sample customized **install-config.yaml** file for restricted OpenStack installations

This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
 name: master
 platform: {}
 replicas: 3
compute:
- name: worker
 platform:
 openstack:
 type: ml.large
 replicas: 3
metadata:
 name: example
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 serviceNetwork:
 - 172.30.0.0/16
 networkType: OVNKubernetes
platform:
 openstack:
```

```
region: region1
cloud: mycloud
externalNetwork: external
computeFlavor: m1.xlarge
apiFloatingIP: 128.0.0.1
fips: false
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA...
additionalTrustBundle: |
```

-----BEGIN CERTIFICATE-----

[illegible]

-----END CERTIFICATE-----

```
imageContentSources:

 source: quay.io/openshift-release-dev/ocp-release
- mirrors:
 - <mirror_registry>/<repo_name>/release
 source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
```

### 19.7.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

## IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

## NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

## Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

## Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

## 19.7.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

### 19.7.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

## Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>"
<external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"
<external_network>
```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

## NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your **/etc/hosts** file:

- **<api\_floating\_ip> api.<cluster\_name>.<base\_domain>**
- **<application\_floating\_ip> grafana-openshift-monitoring.apps.<cluster\_name>.<base\_domain>**
- **<application\_floating\_ip> prometheus-k8s-openshift-monitoring.apps.<cluster\_name>.<base\_domain>**
- **<application\_floating\_ip> oauth-openshift.apps.<cluster\_name>.<base\_domain>**
- **<application\_floating\_ip> console-openshift-console.apps.<cluster\_name>.<base\_domain>**
- **application\_floating\_ip integrated-oauth-server-openshift-authentication.apps.<cluster\_name>.<base\_domain>**

The cluster domain names in the **/etc/hosts** file grant access to the web console and the monitoring interface of your cluster locally. You can also use the **kubectl** or **oc**. You can access the user applications by using the additional entries pointing to the **<application\_floating\_ip>**. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

4. Add the FIPs to the **install-config.yaml** file as the values of the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you use these values, you must also enter an external network as the value of the **platform.openstack.externalNetwork** parameter in the **install-config.yaml** file.

## TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 19.7.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the **install-config.yaml** file, do not define the following parameters:

- **platform.openstack.ingressFloatingIP**
- **platform.openstack.apiFloatingIP**

If you cannot provide an external network, you can also leave **platform.openstack.externalNetwork** blank. If you do not provide a value for **platform.openstack.externalNetwork**, a router is not created for

you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

## NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your **/etc/hosts** file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

## 19.7.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

## IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

## Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

## Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1** For **<installation\_directory>**, specify the location of your customized **./install-config.yaml** file.
- 2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to **<installation\_directory>/openshift\_install.log**.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 19.7.13. Verifying cluster status

You can verify your OpenShift Container Platform cluster's status during or after installation.

### Procedure

1. In the cluster environment, export the administrator's kubeconfig file:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

```
$ oc get nodes
```

3. View your cluster's version:

```
$ oc get clusterversion
```

4. View your Operators' status:

```
$ oc get clusteroperator
```

5. View all running pods in the cluster:

```
$ oc get pods -A
```

### 19.7.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

#### Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 19.7.15. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

#### Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
 -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

#### TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration** → **Cluster Settings** → **Configuration** → **OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

### 19.7.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 19.7.17. Next steps

- [Customize your cluster](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).
- If necessary, you can [opt out of remote health reporting](#).
- If necessary, see [Registering your disconnected cluster](#)
- [Configure image streams](#) for the Cluster Samples Operator and the **must-gather** tool.
- Learn how to [use Operator Lifecycle Manager \(OLM\) on restricted networks](#).
- If you did not configure RHOSP to accept application traffic over floating IP addresses, [configure RHOSP access with floating IP addresses](#).

## 19.8. CONFIGURING NETWORK SETTINGS AFTER INSTALLING OPENSTACK

You can configure network settings for an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) cluster after installation.

### 19.8.1. Configuring application access with floating IP addresses

After you install OpenShift Container Platform, configure Red Hat OpenStack Platform (RHOSP) to allow application network traffic.

#### NOTE

You do not need to perform this procedure if you provided values for **platform.openstack.apiFloatingIP** and **platform.openstack.ingressFloatingIP** in the **install-config.yaml** file, or **os\_api\_fip** and **os\_ingress\_fip** in the **inventory.yaml** playbook, during installation. The floating IP addresses are already set.

#### Prerequisites

- OpenShift Container Platform cluster must be installed
- Floating IP addresses are enabled as described in the OpenShift Container Platform on RHOSP installation documentation.

#### Procedure

After you install the OpenShift Container Platform cluster, attach a floating IP address to the ingress port:

1. Show the port:

```
$ openstack port show <cluster_name>--<cluster_ID>-ingress-port
```

2. Attach the port to the IP address:

```
$ openstack floating ip set --port <ingress_port_ID> <apps_FIP>
```

3. Add a wildcard **A** record for **\*apps.** to your DNS file:

```
*.apps.<cluster_name>.<base_domain> IN A <apps_FIP>
```

#### NOTE

If you do not control the DNS server but want to enable application access for non-production purposes, you can add these hostnames to **/etc/hosts**:

```
<apps_FIP> console-openshift-console.apps.<cluster name>.<base domain>
<apps_FIP> integrated-oauth-server-openshift-authentication.apps.<cluster name>.<base domain>
<apps_FIP> oauth-openshift.apps.<cluster name>.<base domain>
<apps_FIP> prometheus-k8s-openshift-monitoring.apps.<cluster name>.<base domain>
<apps_FIP> <app name>.apps.<cluster name>.<base domain>
```

### 19.8.2. Enabling OVS hardware offloading

For clusters that run on Red Hat OpenStack Platform (RHOSP), you can enable [Open vSwitch \(OVS\)](#) hardware offloading.

OVS is a multi-layer virtual switch that enables large-scale, multi-server network virtualization.

### Prerequisites

- You installed a cluster on RHOSP that is configured for single-root input/output virtualization (SR-IOV).
- You installed the SR-IOV Network Operator on your cluster.
- You created two **hw-offload** type virtual function (VF) interfaces on your cluster.

### NOTE

Application layer gateway flows are broken in OpenShift Container Platform version 4.10, 4.11, and 4.12. Also, you cannot offload the application layer gateway flow for OpenShift Container Platform version 4.13.

### Procedure

1. Create an **SriovNetworkNodePolicy** policy for the two **hw-offload** type VF interfaces that are on your cluster:

#### The first virtual function interface

```
apiVersion: sriovnetwork.openshift.io/v1
kind: SriovNetworkNodePolicy 1
metadata:
 name: "hwoffload9"
 namespace: openshift-sriov-network-operator
spec:
 deviceType: netdevice
 isRdma: true
 nicSelector:
 pfNames: 2
 - ens6
 nodeSelector:
 feature.node.kubernetes.io/network-sriov.capable: 'true'
 numVfs: 1
 priority: 99
 resourceName: "hwoffload9"
```

- 1** Insert the **SriovNetworkNodePolicy** value here.
- 2** Both interfaces must include physical function (PF) names.

#### The second virtual function interface

```
apiVersion: sriovnetwork.openshift.io/v1
kind: SriovNetworkNodePolicy 1
metadata:
```

```

name: "hwoffload10"
namespace: openshift-sriov-network-operator
spec:
 deviceType: netdevice
 isRdma: true
 nicSelector:
 pfNames: 2
 - ens5
 nodeSelector:
 feature.node.kubernetes.io/network-sriov.capable: 'true'
 numVfs: 1
 priority: 99
 resourceName: "hwoffload10"

```

- 1 Insert the **SriovNetworkNodePolicy** value here.
- 2 Both interfaces must include physical function (PF) names.

2. Create **NetworkAttachmentDefinition** resources for the two interfaces:

#### A **NetworkAttachmentDefinition** resource for the first interface

```

apiVersion: k8s.cni.cncf.io/v1
kind: NetworkAttachmentDefinition
metadata:
 annotations:
 k8s.v1.cni.cncf.io/resourceName: openshift.io/hwoffload9
 name: hwoffload9
 namespace: default
spec:
 config: '{ "cniVersion":"0.3.1", "name":"hwoffload9","type":"host-device","device":"ens6"
}'

```

#### A **NetworkAttachmentDefinition** resource for the second interface

```

apiVersion: k8s.cni.cncf.io/v1
kind: NetworkAttachmentDefinition
metadata:
 annotations:
 k8s.v1.cni.cncf.io/resourceName: openshift.io/hwoffload10
 name: hwoffload10
 namespace: default
spec:
 config: '{ "cniVersion":"0.3.1", "name":"hwoffload10","type":"host-device","device":"ens5"
}'

```

3. Use the interfaces that you created with a pod. For example:

#### A pod that uses the two OVS offload interfaces

```

apiVersion: v1
kind: Pod
metadata:

```

```

name: dpdk-testpmd
namespace: default
annotations:
 irq-load-balancing.crio.io: disable
 cpu-quota.crio.io: disable
 k8s.v1.cni.cncf.io/resourceName: openshift.io/hwoffload9
 k8s.v1.cni.cncf.io/resourceName: openshift.io/hwoffload10
spec:
 restartPolicy: Never
 containers:
 - name: dpdk-testpmd
 image: quay.io/krister/centos8_nfv-container-dpdk-testpmd:latest

```

### 19.8.3. Attaching an OVS hardware offloading network

You can attach an Open vSwitch (OVS) hardware offloading network to your cluster.

#### Prerequisites

- Your cluster is installed and running.
- You provisioned an OVS hardware offloading network on Red Hat OpenStack Platform (RHOSP) to use with your cluster.

#### Procedure

1. Create a file named **network.yaml** from the following template:

```

spec:
 additionalNetworks:
 - name: hwoffload1
 namespace: cnf
 rawCNICfg: '{ "cniVersion": "0.3.1", "name": "hwoffload1", "type": "host-
device", "pciBusId": "0000:00:05.0", "ipam": {} }' 1
 type: Raw

```

where:

#### pciBusId

Specifies the device that is connected to the offloading network. If you do not have it, you can find this value by running the following command:

```
$ oc describe SrioNetworkNodeState -n openshift-sriov-network-operator
```

2. From a command line, enter the following command to patch your cluster with the file:

```
$ oc apply -f network.yaml
```

### 19.8.4. Enabling IPv6 connectivity to pods on RHOSP

To enable IPv6 connectivity between pods that have additional networks that are on different nodes, disable port security for the IPv6 port of the server. Disabling port security obviates the need to create

allowed address pairs for each IPv6 address that is assigned to pods and enables traffic on the security group.

### IMPORTANT

Only the following IPv6 additional network configurations are supported:

- SLAAC and host-device
- SLAAC and MACVLAN
- DHCP stateless and host-device
- DHCP stateless and MACVLAN

### Procedure

- On a command line, enter the following command:

```
$ openstack port set --no-security-group --disable-port-security <compute_ipv6_port> 1
```

1 1 Specify the IPv6 port of the compute server.

### IMPORTANT

This command removes security groups from the port and disables port security. Traffic restrictions are removed entirely from the port.

## 19.8.5. Create pods that have IPv6 connectivity on RHOSP

After you enable IPv6 connectivity for pods and add it to them, create pods that have secondary IPv6 connections.

### Procedure

1. Define pods that use your IPv6 namespace and the annotation **k8s.v1.cni.cncf.io/networks:** **<additional\_network\_name>**, where **<additional\_network\_name>** is the name of the additional network. For example, as part of a **Deployment** object:

```
apiVersion: apps/v1
kind: Deployment
metadata:
 name: hello-openshift
 namespace: ipv6
spec:
 affinity:
 podAntiAffinity:
 requiredDuringSchedulingIgnoredDuringExecution:
 - labelSelector:
 matchExpressions:
 - key: app
 operator: In
 values:
```

```

 - hello-openshift
replicas: 2
selector:
 matchLabels:
 app: hello-openshift
template:
 metadata:
 labels:
 app: hello-openshift
 annotations:
 k8s.v1.cni.cncf.io/networks: ipv6
 spec:
 securityContext:
 runAsNonRoot: true
 seccompProfile:
 type: RuntimeDefault
 containers:
 - name: hello-openshift
 securityContext:
 allowPrivilegeEscalation: false
 capabilities:
 drop:
 - ALL
 image: quay.io/openshift/origin-hello-openshift
 ports:
 - containerPort: 8080

```

2. Create the pod. For example, on a command line, enter the following command:

```
$ oc create -f <ipv6_enabled_resource> ❶
```

- ❶ Specify the file that contains your resource definition.

### 19.8.6. Adding IPv6 connectivity to pods on RHOSP

After you enable IPv6 connectivity in pods, add connectivity to them by using a Container Network Interface (CNI) configuration.

#### Procedure

1. To edit the Cluster Network Operator (CNO), enter the following command:

```
$ oc edit networks.operator.openshift.io cluster
```

2. Specify your CNI configuration under the **spec** field. For example, the following configuration uses a SLAAC address mode with MACVLAN:

```

...
spec:
 additionalNetworks:
 - name: ipv6
 namespace: ipv6 ❶

```

```
rawCNICongig: '{ "cniVersion": "0.3.1", "name": "ipv6", "type": "macvlan", "master": "ens4"}'
```

2

```
type: Raw
```

1

Be sure to create pods in the same namespace.

2

The interface in the network attachment "**master**" field can differ from "**ens4**" when more networks are configured or when a different kernel driver is used.

## NOTE

If you are using stateful address mode, include the IP Address Management (IPAM) in the CNI configuration.

DHCPv6 is not supported by Multus.

3. Save your changes and quit the text editor to commit your changes.

## Verification

- On a command line, enter the following command:

```
$ oc get network-attachment-definitions -A
```

## Example output

| NAMESPACE | NAME | AGE |
|-----------|------|-----|
| ipv6      | ipv6 | 21h |

You can now create pods that have secondary IPv6 connections.

# 19.9. OPENSTACK CLOUD CONTROLLER MANAGER REFERENCE GUIDE

## 19.9.1. The OpenStack Cloud Controller Manager

Beginning with OpenShift Container Platform 4.12, clusters that run on Red Hat OpenStack Platform (RHOSP) were switched from the legacy OpenStack cloud provider to the external OpenStack Cloud Controller Manager (CCM). This change follows the move in Kubernetes from in-tree, legacy cloud providers to external cloud providers that are implemented by using the [Cloud Controller Manager](#).

To preserve user-defined configurations for the legacy cloud provider, existing configurations are mapped to new ones as part of the migration process. It searches for a configuration called **cloud-provider-config** in the **openshift-config** namespace.

## NOTE

The config map name **cloud-provider-config** is not statically configured. It is derived from the **spec.cloudConfig.name** value in the **infrastructure/cluster** CRD.

Found configurations are synchronized to the **cloud-conf** config map in the **openshift-cloud-controller-manager** namespace.

As part of this synchronization, the OpenStack CCM Operator alters the new config map such that its properties are compatible with the external cloud provider. The file is changed in the following ways:

- The **[Global] secret-name**, **[Global] secret-namespace**, and **[Global] kubeconfig-path** options are removed. They do not apply to the external cloud provider.
- The **[Global] use-clouds**, **[Global] clouds-file**, and **[Global] cloud** options are added.
- The entire **[BlockStorage]** section is removed. External cloud providers no longer perform storage operations. Block storage configuration is managed by the Cinder CSI driver.

Additionally, the CCM Operator enforces a number of default options. Values for these options are always overridden as follows:

```
[Global]
use-clouds = true
clouds-file = /etc/openstack/secret/clouds.yaml
cloud = openstack
...

[LoadBalancer]
enabled = true 1
```

**1** If the network is configured to use Kuryr, this value is **false**.

The **clouds-value** value, `/etc/openstack/secret/clouds.yaml`, is mapped to the **openstack-cloud-credentials** config in the **openshift-cloud-controller-manager** namespace. You can modify the RHOSP cloud in this file as you do any other **clouds.yaml** file.

### 19.9.2. The OpenStack Cloud Controller Manager (CCM) config map

An OpenStack CCM config map defines how your cluster interacts with your RHOSP cloud. By default, this configuration is stored under the **cloud.conf** key in the **cloud-conf** config map in the **openshift-cloud-controller-manager** namespace.

#### IMPORTANT

The **cloud-conf** config map is generated from the **cloud-provider-config** config map in the **openshift-config** namespace.

To change the settings that are described by the **cloud-conf** config map, modify the **cloud-provider-config** config map.

As part of this synchronization, the CCM Operator overrides some options. For more information, see "The RHOSP Cloud Controller Manager".

For example:

#### An example **cloud-conf** config map

```
apiVersion: v1
```

```

data:
 cloud.conf: |
 [Global] ❶
 secret-name = openstack-credentials
 secret-namespace = kube-system
 region = regionOne
 [LoadBalancer]
 enabled = True
kind: ConfigMap
metadata:
 creationTimestamp: "2022-12-20T17:01:08Z"
 name: cloud-conf
 namespace: openshift-cloud-controller-manager
 resourceVersion: "2519"
 uid: cbbeedaf-41ed-41c2-9f37-4885732d3677

```

- ❶ Set global options by using a **clouds.yaml** file rather than modifying the config map.

The following options are present in the config map. Except when indicated otherwise, they are mandatory for clusters that run on RHOSP.

### 19.9.2.1. Load balancer options

CCM supports several load balancer options for deployments that use Octavia.

#### NOTE

Neutron-LBaaS support is deprecated.

| Option                     | Description                                                                                                                                                                                                                                                                                                |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>enabled</b>             | Whether or not to enable the <b>LoadBalancer</b> type of services integration. The default value is <b>true</b> .                                                                                                                                                                                          |
| <b>floating-network-id</b> | Optional. The external network used to create floating IP addresses for load balancer virtual IP addresses (VIPs). If there are multiple external networks in the cloud, this option must be set or the user must specify <b>loadbalancer.openstack.org/floating-network-id</b> in the service annotation. |
| <b>floating-subnet-id</b>  | Optional. The external network subnet used to create floating IP addresses for the load balancer VIP. Can be overridden by the service annotation <b>loadbalancer.openstack.org/floating-subnet-id</b> .                                                                                                   |

| Option                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>floating-subnet</b>      | <p>Optional. A name pattern (glob or regular expression if starting with ~) for the external network subnet used to create floating IP addresses for the load balancer VIP. Can be overridden by the service annotation <b>loadbalancer.openstack.org/floating-subnet</b>. If multiple subnets match the pattern, the first one with available IP addresses is used.</p>                                                                                                                                                                                                                                                                                                                                                  |
| <b>floating-subnet-tags</b> | <p>Optional. Tags for the external network subnet used to create floating IP addresses for the load balancer VIP. Can be overridden by the service annotation <b>loadbalancer.openstack.org/floating-subnet-tags</b>. If multiple subnets match these tags, the first one with available IP addresses is used.</p> <p>If the RHOSP network is configured with sharing disabled, for example, with the <b>--no-share</b> flag used during creation, this option is unsupported. Set the network to share to use this option.</p>                                                                                                                                                                                           |
| <b>lb-method</b>            | <p>The load balancing algorithm used to create the load balancer pool. For the Amphora provider the value can be <b>ROUND_ROBIN</b>, <b>LEAST_CONNECTIONS</b>, or <b>SOURCE_IP</b>. The default value is <b>ROUND_ROBIN</b>.</p> <p>For the OVN provider, only the <b>SOURCE_IP_PORT</b> algorithm is supported.</p> <p>For the Amphora provider, if using the <b>LEAST_CONNECTIONS</b> or <b>SOURCE_IP</b> methods, configure the <b>create-monitor</b> option as <b>true</b> in the <b>cloud-provider-config</b> config map on the <b>openshift-config</b> namespace and <b>ETP:Local</b> on the load-balancer type service to allow balancing algorithm enforcement in the client to service endpoint connections.</p> |
| <b>lb-provider</b>          | <p>Optional. Used to specify the provider of the load balancer, for example, <b>amphora</b> or <b>octavia</b>. Only the Amphora and Octavia providers are supported.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>lb-version</b>           | <p>Optional. The load balancer API version. Only <b>"v2"</b> is supported.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>subnet-id</b>            | <p>The ID of the Networking service subnet on which load balancer VIPs are created. For dual stack deployments, leave this option unset. The OpenStack cloud provider automatically selects which subnet to use for a load balancer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Option                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>network-id</b>                    | The ID of the Networking service network on which load balancer VIPs are created. Unnecessary if <b>subnet-id</b> is set. If this property is not set, the network is automatically selected based on the network that cluster nodes use.                                                                                                                                                                                                                                                                                                                                                         |
| <b>create-monitor</b>                | <p>Whether or not to create a health monitor for the service load balancer. A health monitor is required for services that declare <b>externalTrafficPolicy: Local</b>. The default value is <b>false</b>.</p> <p>This option is unsupported if you use RHOSP earlier than version 17 with the <b>ovn</b> provider.</p>                                                                                                                                                                                                                                                                           |
| <b>monitor-delay</b>                 | The interval in seconds by which probes are sent to members of the load balancer. The default value is <b>5</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>monitor-max-retries</b>           | The number of successful checks that are required to change the operating status of a load balancer member to <b>ONLINE</b> . The valid range is <b>1</b> to <b>10</b> , and the default value is <b>1</b> .                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>monitor-timeout</b>               | The time in seconds that a monitor waits to connect to the back end before it times out. The default value is <b>3</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>internal-lb</b>                   | Whether or not to create an internal load balancer without floating IP addresses. The default value is <b>false</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>LoadBalancerClass "ClassName"</b> | <p>This is a config section that comprises a set of options:</p> <ul style="list-style-type: none"> <li>● <b>floating-network-id</b></li> <li>● <b>floating-subnet-id</b></li> <li>● <b>floating-subnet</b></li> <li>● <b>floating-subnet-tags</b></li> <li>● <b>network-id</b></li> <li>● <b>subnet-id</b></li> </ul> <p>The behavior of these options is the same as that of the identically named options in the load balancer section of the CCM config file.</p> <p>You can set the <b>ClassName</b> value by specifying the service annotation <b>loadbalancer.openstack.org/class</b>.</p> |

| Option               | Description                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------|
| <b>max-shared-lb</b> | The maximum number of services that can share a load balancer. The default value is <b>2</b> . |

### 19.9.2.2. Options that the Operator overrides

The CCM Operator overrides the following options, which you might recognize from configuring RHOSP. Do not configure them yourself. They are included in this document for informational purposes only.

| Option                    | Description                                                                                                                                                                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>auth-url</b>           | The RHOSP Identity service URL. For example, <a href="http://128.110.154.166/identity">http://128.110.154.166/identity</a> .                                                                                                                                                                                                 |
| <b>os-endpoint-type</b>   | The type of endpoint to use from the service catalog.                                                                                                                                                                                                                                                                        |
| <b>username</b>           | The Identity service user name.                                                                                                                                                                                                                                                                                              |
| <b>password</b>           | The Identity service user password.                                                                                                                                                                                                                                                                                          |
| <b>domain-id</b>          | The Identity service user domain ID.                                                                                                                                                                                                                                                                                         |
| <b>domain-name</b>        | The Identity service user domain name.                                                                                                                                                                                                                                                                                       |
| <b>tenant-id</b>          | <p>The Identity service project ID. Leave this option unset if you are using Identity service application credentials.</p> <p>In version 3 of the Identity API, which changed the identifier <b>tenant</b> to <b>project</b>, the value of <b>tenant-id</b> is automatically mapped to the project construct in the API.</p> |
| <b>tenant-name</b>        | The Identity service project name.                                                                                                                                                                                                                                                                                           |
| <b>tenant-domain-id</b>   | The Identity service project domain ID.                                                                                                                                                                                                                                                                                      |
| <b>tenant-domain-name</b> | The Identity service project domain name.                                                                                                                                                                                                                                                                                    |
| <b>user-domain-id</b>     | The Identity service user domain ID.                                                                                                                                                                                                                                                                                         |
| <b>user-domain-name</b>   | The Identity service user domain name.                                                                                                                                                                                                                                                                                       |

| Option             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>use-clouds</b>  | <p>Whether or not to fetch authorization credentials from a <b>clouds.yaml</b> file. Options set in this section are prioritized over values read from the <b>clouds.yaml</b> file.</p> <p>CCM searches for the file in the following places:</p> <ol style="list-style-type: none"> <li>1. The value of the <b>clouds-file</b> option.</li> <li>2. A file path stored in the environment variable <b>OS_CLIENT_CONFIG_FILE</b>.</li> <li>3. The directory <b>pkg/openstack</b>.</li> <li>4. The directory <b>~/config/openstack</b>.</li> <li>5. The directory <b>/etc/openstack</b>.</li> </ol> |
| <b>clouds-file</b> | The file path of a <b>clouds.yaml</b> file. It is used if the <b>use-clouds</b> option is set to <b>true</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>cloud</b>       | The named cloud in the <b>clouds.yaml</b> file that you want to use. It is used if the <b>use-clouds</b> option is set to <b>true</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## 19.10. UNINSTALLING A CLUSTER ON OPENSTACK

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP).

### 19.10.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

#### NOTE

If you deployed your cluster to the AWS C2S Secret Region, the installation program does not support destroying the cluster; you must manually remove the cluster resources.

#### NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access. For example, some Google Cloud resources require [IAM permissions](#) in shared VPC host projects, or there might be unused [health checks that must be deleted](#).

#### Prerequisites

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

## Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$./openshift-install destroy cluster \
--dir <installation_directory> --log-level info 1 2
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2** To view different details, specify **warn**, **debug**, or **error** instead of **info**.

### NOTE

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the **metadata.json** file in this directory to delete the cluster.

2. Optional: Delete the **<installation\_directory>** directory and the OpenShift Container Platform installation program.

## 19.11. UNINSTALLING A CLUSTER ON RHOSP FROM YOUR OWN INFRASTRUCTURE

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP) on user-provisioned infrastructure.

### 19.11.1. Downloading playbook dependencies

The Ansible playbooks that simplify the removal process on user-provisioned infrastructure require several Python modules. On the machine where you will run the process, add the modules' repositories and then download them.

### NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

## Prerequisites

- Python 3 is installed on your machine.

## Procedure

1. On a command line, add the repositories:
  - a. Register with Red Hat Subscription Manager:

```
$ sudo subscription-manager register # If not done already
```

- b. Pull the latest subscription data:

```
$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
```

- c. Disable the current repositories:

```
$ sudo subscription-manager repos --disable=* # If not done already
```

- d. Add the required repositories:

```
$ sudo subscription-manager repos \
 --enable=rhel-8-for-x86_64-baseos-rpms \
 --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
 --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
 --enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk
```

3. Ensure that the **python** command points to **python3**:

```
$ sudo alternatives --set python /usr/bin/python3
```

### 19.11.2. Removing a cluster from RHOSP that uses your own infrastructure

You can remove an OpenShift Container Platform cluster on Red Hat OpenStack Platform (RHOSP) that uses your own infrastructure. To complete the removal process quickly, run several Ansible playbooks.

#### Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies."
- You have the playbooks that you used to install the cluster.
- You modified the playbooks that are prefixed with **down-** to reflect any changes that you made to their corresponding installation playbooks. For example, changes to the **bootstrap.yaml** file are reflected in the **down-bootstrap.yaml** file.
- All of the playbooks are in a common directory.

#### Procedure

1. On a command line, run the playbooks that you downloaded:

```
$ ansible-playbook -i inventory.yaml \
 down-bootstrap.yaml \
 down-control-plane.yaml \
 down-compute-nodes.yaml \
 down-load-balancers.yaml \
 down-network.yaml \
 down-security-groups.yaml
```

- 2. Remove any DNS record changes you made for the OpenShift Container Platform installation.

OpenShift Container Platform is removed from your infrastructure.

## 19.12. INSTALLATION CONFIGURATION PARAMETERS FOR OPENSTACK

Before you deploy an OpenShift Container Platform cluster on Red Hat OpenStack Platform (RHOSP), you provide parameters to customize your cluster and the platform that hosts it. When you create the **install-config.yaml** file, you provide values for the required parameters through the command line. You can then modify the **install-config.yaml** file to customize your cluster further.

### 19.12.1. Available installation configuration parameters for OpenStack

The following tables specify the required, optional, and OpenStack-specific installation configuration parameters that you can set as part of the installation process.

**NOTE**

After installation, you cannot modify these parameters in the **install-config.yaml** file.

#### 19.12.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 19.10. Required parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                            | Values                                                                   |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| <b>apiVersion:</b> | The API version for the <b>install-config.yaml</b> content. The current version is <b>v1</b> . The installation program may also support older API versions.                                                                                                                                                                           | String                                                                   |
| <b>baseDomain:</b> | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <b>baseDomain</b> and <b>metadata.name</b> parameter values that uses the <b>&lt;metadata.name&gt;.&lt;baseDomain&gt;</b> format. | A fully-qualified domain or subdomain name, such as <b>example.com</b> . |

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                                                                                                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metadata:</b>           | Kubernetes resource <b>ObjectMeta</b> , from which only the <b>name</b> parameter is consumed.                                                                                                                                                                                                                                                                                                                                 | Object                                                                                                                                                                                                |
| <b>metadata:<br/>name:</b> | The name of the cluster. DNS records for the cluster are all subdomains of <b>{{.metadata.name}}.{{.baseDomain}}</b> .                                                                                                                                                                                                                                                                                                         | String of lowercase letters, hyphens (-), and periods (.), such as <b>dev</b> . The string must be 14 characters or fewer long.                                                                       |
| <b>platform:</b>           | The configuration for the specific platform upon which to perform the installation: <b>alibabacloud</b> , <b>aws</b> , <b>baremetal</b> , <b>azure</b> , <b>gcp</b> , <b>ibmcloud</b> , <b>nutanix</b> , <b>openstack</b> , <b>powervs</b> , <b>vsphere</b> , or <b>{}</b> . For additional information about <b>platform</b> . <b>&lt;platform&gt;</b> parameters, consult the table for your specific platform that follows. | Object                                                                                                                                                                                                |
| <b>pullSecret:</b>         | Get a <a href="#">pull secret from Red Hat OpenShift Cluster Manager</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.                                                                                                                                                                                                                               | <pre>{   "auths":{     "cloud.openshift.com":{       "auth":"b3Blb=",       "email":"you@example.com"     },     "quay.io":{       "auth":"b3Blb=",       "email":"you@example.com"     }   } }</pre> |

### 19.12.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

**Table 19.11. Network parameters**

| Parameter                                                          | Description                                                                                                                                                                                                                                                                                   | Values                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>networking:</b>                                                 | The configuration for the cluster network.                                                                                                                                                                                                                                                    | Object<br><br> <b>NOTE</b><br>You cannot modify parameters specified by the <b>networking</b> object after installation.                                                                            |
| <b>networking:</b><br><b>networkType:</b>                          | The Red Hat OpenShift Networking network plugin to install.                                                                                                                                                                                                                                   | Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b> . <b>OpenShiftSDN</b> is a CNI plugin for all-Linux networks. <b>OVNKubernetes</b> is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is <b>OVNKubernetes</b> . |
| <b>networking:</b><br><b>clusterNetwork:</b>                       | The IP address blocks for pods.<br><br>The default value is <b>10.128.0.0/14</b> with a host prefix of <b>/23</b> .<br><br>If you specify multiple IP address blocks, the blocks must not overlap.                                                                                            | An array of objects. For example:<br><br> <b>networking:</b><br><b>clusterNetwork:</b><br>- cidr: <b>10.128.0.0/14</b><br><b>hostPrefix: 23</b>                                                    |
| <b>networking:</b><br><b>clusterNetwork:</b><br><b>cidr:</b>       | Required if you use <b>networking.clusterNetwork</b> . An IP address block.<br><br>An IPv4 network.                                                                                                                                                                                           | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between <b>0</b> and <b>32</b> .                                                                                                                                        |
| <b>networking:</b><br><b>clusterNetwork:</b><br><b>hostPrefix:</b> | The subnet prefix length to assign to each individual node. For example, if <b>hostPrefix</b> is set to <b>23</b> then each node is assigned a <b>/23</b> subnet out of the given <b>cidr</b> . A <b>hostPrefix</b> value of <b>23</b> provides 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. | A subnet prefix.<br><br>The default value is <b>23</b> .                                                                                                                                                                                                                              |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                         | Values                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:<br/>serviceNetwork:</code>           | <p>The IP address block for services. The default value is <b>172.30.0.0/16</b>.</p> <p>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.</p>                                                                                                                    | <p>An array with an IP address block in CIDR format. For example:</p> <pre>networking:   serviceNetwork:     - 172.30.0.0/16</pre>                                                                                                                                                                            |
| <code>networking:<br/>machineNetwork:</code>           | <p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>                                                                                                                                                                                                           | <p>An array of objects. For example:</p> <pre>networking:   machineNetwork:     - cidr: 10.0.0.0/16</pre>                                                                                                                                                                                                     |
| <code>networking:<br/>machineNetwork:<br/>cidr:</code> | <p>Required if you use <b>networking.machineNetwork</b>. An IP address block. The default value is <b>10.0.0.0/16</b> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <b>192.168.126.0/24</b>. For IBM Power® Virtual Server, the default value is <b>192.168.0.0/24</b>.</p> | <p>An IP network block in CIDR notation.</p> <p>For example, <b>10.0.0.0/16</b>.</p> <div>  <p><b>NOTE</b></p> <p>Set the <b>networking.machineNetwork</b> to match the CIDR that the preferred NIC resides in.</p> </div> |

### 19.12.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 19.12. Optional parameters**

| Parameter                           | Description                                                                                                                                                                                                                                                 | Values       |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <code>additionalTrustBundle:</code> | A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.                                                                                          | String       |
| <code>capabilities:</code>          | Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the "Cluster capabilities" page in <i>Installing</i> . | String array |

| Parameter                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Values                                                             |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| <b>capabilities:</b><br><b>baselineCapabilitySet:</b>         | Selects an initial set of optional capabilities to enable. Valid values are <b>None</b> , <b>v4.11</b> , <b>v4.12</b> and <b>vCurrent</b> . The default value is <b>vCurrent</b> .                                                                                                                                                                                                                                                                                                                                               | String                                                             |
| <b>capabilities:</b><br><b>additionalEnabledCapabilities:</b> | Extends the set of optional capabilities beyond what you specify in <b>baselineCapabilitySet</b> . You may specify multiple capabilities in this parameter.                                                                                                                                                                                                                                                                                                                                                                      | String array                                                       |
| <b>cpuPartitioningMode:</b>                                   | Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <i>Workload partitioning</i> page in the <i>Scalability and Performance</i> section.                   | <b>None</b> or <b>AllNodes</b> . <b>None</b> is the default value. |
| <b>compute:</b>                                               | The configuration for the machines that comprise the compute nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Array of <b>MachinePool</b> objects.                               |
| <b>compute:</b><br><b>architecture:</b>                       | Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <b>amd64</b> and <b>arm64</b> . Not all installation options support the 64-bit ARM architecture. To verify if your installation option is supported on your platform, see <i>Supported installation methods for different platforms</i> in <i>Selecting a cluster installation method and preparing it for users</i> . | String                                                             |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Values                                                                                              |

| fips:     | <p>Enable or disable FIPS mode. The default is <b>false</b> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p> <div><div></div><div><p><b>IMPORTANT</b></p><p>To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see <a href="#">Installing the system in FIPS mode</a>. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.</p></div></div> <div><div></div><div><p><b>NOTE</b></p><p>If you are using Azure File storage, you cannot enable FIPS mode.</p></div></div> | <b>false</b> or <b>true</b> |

| Parameter                                         | Description                                                                                                                                                                                                                                                                                                                                                                                              | Values                                                                                                                                                                                       |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>imageContentSources:</b>                       | Sources and repositories for the release-image content.                                                                                                                                                                                                                                                                                                                                                  | Array of objects. Includes a <b>source</b> and, optionally, <b>mirrors</b> , as described in the following rows of this table.                                                               |
| <b>imageContentSources:</b><br><b>source:</b>     | Required if you use <b>imageContentSources</b> . Specify the repository that users refer to, for example, in image pull specifications.                                                                                                                                                                                                                                                                  | String                                                                                                                                                                                       |
| <b>imageContentSources:</b><br><b>mirrors:</b>    | Specify one or more repositories that may also contain the same images.                                                                                                                                                                                                                                                                                                                                  | Array of strings                                                                                                                                                                             |
| <b>platform:</b><br><b>aws:</b><br><b>lbType:</b> | Required to set the NLB load balancer type in AWS. Valid values are <b>Classic</b> or <b>NLB</b> . If no value is specified, the installation program defaults to <b>Classic</b> . The installation program sets the value provided here in the ingress cluster configuration object. If you do not specify a load balancer type for other Ingress Controllers, they use the type set in this parameter. | <b>Classic</b> or <b>NLB</b> . The default value is <b>Classic</b> .                                                                                                                         |
| <b>publish:</b>                                   | How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.                                                                                                                                                                                                                                                                                        | <b>Internal</b> or <b>External</b> . To deploy a private cluster, which cannot be accessed from the internet, set <b>publish</b> to <b>Internal</b> . The default value is <b>External</b> . |
| <b>sshKey:</b>                                    | <p>The SSH key to authenticate access to your cluster machines.</p> <div>  <p><b>NOTE</b></p> <p>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <b>ssh-agent</b> process uses.</p> </div>                | For example, <b>sshKey: ssh-ed25519 AAAA...</b>                                                                                                                                              |

- 1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.

NOTE

If your AWS account has service control policies (SCP) enabled, you must configure the **credentialsMode** parameter to **Mint**, **Passthrough**, or **Manual**. If you are installing on GCP into a shared virtual private cloud (VPC), **credentialsMode** must be set to **Passthrough** or **Manual**.

IMPORTANT

Setting this parameter to **Manual** enables alternatives to storing administrator-level secrets in the **kube-system** project, which require additional configuration steps. For more information, see "Alternatives to storing administrator-level secrets in the kube-system project".

19.12.1.4. Optional AWS configuration parameters

Optional AWS configuration parameters are described in the following table:

Table 19.13. Optional AWS parameters

| Parameter                                                                 | Description                                                                                                                                                                                                                                                          | Values                                                                                                                                    |
|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <div>compute:<br/>platform:<br/>aws:<br/>amiID:</div>                     | The AWS AMI used to boot compute machines for the cluster. This is required for regions that require a custom RHCOS AMI.                                                                                                                                             | Any published or custom RHCOS AMI that belongs to the set AWS region. See <i>RHCOS AMIs for AWS infrastructure</i> for available AMI IDs. |
| <div>compute:<br/>platform:<br/>aws:<br/>iamRole:</div>                   | A pre-existing AWS IAM role applied to the compute machine pool instance profiles. You can use these fields to match naming schemes and include predefined permissions boundaries for your IAM roles. If undefined, the installation program creates a new IAM role. | The name of a valid AWS IAM role.                                                                                                         |
| <div>compute:<br/>platform:<br/>aws:<br/><br/>rootVolume:<br/>iops:</div> | The Input/Output Operations Per Second (IOPS) that is reserved for the root volume.                                                                                                                                                                                  | Integer, for example <b>4000</b> .                                                                                                        |

| Parameter                                                                                                                           | Description                                                                                                                                                                            | Values                                                                                                              |
|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>size:</code>          | The size in GiB of the root volume.                                                                                                                                                    | Integer, for example <b>500</b> .                                                                                   |
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>type:</code>          | The type of the root volume.                                                                                                                                                           | Valid <a href="#">AWS EBS volume type</a> , such as <b>io1</b> .                                                    |
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><br><code>kmsKeyARN:</code> | The Amazon Resource Name (key ARN) of a KMS key. This is required to encrypt operating system volumes of worker nodes with a specific KMS key.                                         | Valid <a href="#">key ID or the key ARN</a>                                                                         |
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><code>type:</code>                                          | The EC2 instance type for the compute machines.                                                                                                                                        | Valid AWS instance type, such as <b>m4.2xlarge</b> . See the <b>Supported AWS machine types</b> table that follows. |
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><code>zones:</code>                                         | The availability zones where the installation program creates machines for the compute machine pool. If you provide your own VPC, you must provide a subnet in that availability zone. | A list of valid AWS availability zones, such as <b>us-east-1c</b> , in a <a href="#">YAML sequence</a> .            |

| Parameter                                                                                                                       | Description                                                                                                                                                                                                                                                                | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>compute:</code><br><code>aws:</code><br><code>region:</code>                                                              | The AWS region that the installation program creates compute resources in.                                                                                                                                                                                                 | <p>Any valid <a href="#">AWS region</a>, such as <b>us-east-1</b>. You can use the AWS CLI to access the regions available based on your selected instance type. For example:</p> <pre>aws ec2 describe-instance-type-offerings --filters Name=instance-type,Values=c7g.xlarge</pre> <div>  <p><b>IMPORTANT</b></p> <p>When running on ARM based AWS instances, ensure that you enter a region where AWS Graviton processors are available. See <a href="#">Global availability</a> map in the AWS documentation. Currently, AWS Graviton3 processors are only available in some regions.</p> </div> |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><code>amiID:</code>                                | The AWS AMI used to boot control plane machines for the cluster. This is required for regions that require a custom RHCOS AMI.                                                                                                                                             | Any published or custom RHCOS AMI that belongs to the set AWS region. See <i>RHCOS AMIs for AWS infrastructure</i> for available AMI IDs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><code>iamRole:</code>                              | A pre-existing AWS IAM role applied to the control plane machine pool instance profiles. You can use these fields to match naming schemes and include predefined permissions boundaries for your IAM roles. If undefined, the installation program creates a new IAM role. | The name of a valid AWS IAM role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>iops:</code> | The Input/Output Operations Per Second (IOPS) that is reserved for the root volume on control plane machines.                                                                                                                                                              | Integer, for example <b>4000</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Parameter                                                                                                                                | Description                                                                                                                                           | Values                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>size:</code>          | The size in GiB of the root volume for control plane machines.                                                                                        | Integer, for example <b>500</b> .                                                                                   |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>type:</code>          | The type of the root volume for control plane machines.                                                                                               | Valid <a href="#">AWS EBS volume type</a> , such as <b>io1</b> .                                                    |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><br><code>kmsKeyARN:</code> | The Amazon Resource Name (key ARN) of a KMS key. This is required to encrypt operating system volumes of control plane nodes with a specific KMS key. | Valid <a href="#">key ID</a> and the <a href="#">key ARN</a>                                                        |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><code>type:</code>                                          | The EC2 instance type for the control plane machines.                                                                                                 | Valid AWS instance type, such as <b>m6i.xlarge</b> . See the <b>Supported AWS machine types</b> table that follows. |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><code>zones:</code>                                         | The availability zones where the installation program creates machines for the control plane machine pool.                                            | A list of valid AWS availability zones, such as <b>us-east-1c</b> , in a <a href="#">YAML sequence</a> .            |
| <code>controlPlane:</code><br><code>aws:</code><br><code>region:</code>                                                                  | The AWS region that the installation program creates control plane resources in.                                                                      | Valid <a href="#">AWS region</a> , such as <b>us-east-1</b> .                                                       |

| Parameter                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                            | Values                                                                                                                                    |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>platform:</b><br><b>aws:</b><br><b>amiID:</b>                               | The AWS AMI used to boot all machines for the cluster. If set, the AMI must belong to the same region as the cluster. This is required for regions that require a custom RHCOS AMI.                                                                                                                                                                                                                    | Any published or custom RHCOS AMI that belongs to the set AWS region. See <i>RHCOS AMIs for AWS infrastructure</i> for available AMI IDs. |
| <b>platform:</b><br><b>aws:</b><br><b>hostedZone:</b>                          | An existing Route 53 private hosted zone for the cluster. You can only use a pre-existing hosted zone when also supplying your own VPC. The hosted zone must already be associated with the user-provided VPC before installation. Also, the domain of the hosted zone must be the cluster domain or a parent of the cluster domain. If undefined, the installation program creates a new hosted zone. | String, for example <b>Z3URY6TWQ91KVV</b> .                                                                                               |
| <b>platform:</b><br><b>aws:</b><br><b>hostedZoneRole:</b>                      | An Amazon Resource Name (ARN) for an existing IAM role in the account containing the specified hosted zone. The installation program and cluster operators will assume this role when performing operations on the hosted zone. This parameter should only be used if you are installing a cluster into a shared VPC.                                                                                  | String, for example <b>arn:aws:iam::1234567890:role/shared-vpc-role</b> .                                                                 |
| <b>platform:</b><br><b>aws:</b><br><b>serviceEndpoints:</b><br>- name:<br>url: | The AWS service endpoint name and URL. Custom endpoints are only required for cases where alternative AWS endpoints, like FIPS, must be used. Custom API endpoints can be specified for EC2, S3, IAM, Elastic Load Balancing, Tagging, Route 53, and STS AWS services.                                                                                                                                 | Valid <a href="#">AWS service endpoint</a> name and valid <a href="#">AWS service endpoint</a> URL.                                       |

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>platform:</b><br><b>aws:</b><br><b>userTags:</b>          | <p>A map of keys and values that the installation program adds as tags to all resources that it creates.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <p>Any valid YAML map, such as key value pairs in the <b>&lt;key&gt;: &lt;value&gt;</b> format. For more information about AWS tags, see <a href="#">Tagging Your Amazon EC2 Resources</a> in the AWS documentation.</p> <div>  <div> <b>NOTE</b><br/>           You can add up to 25 user defined tags during installation. The remaining 25 tags are reserved for OpenShift Container Platform.         </div> </div> |
| <b>platform:</b><br><b>aws:</b><br><b>propagateUserTags:</b> | <p>A flag that directs in-cluster Operators to include the specified user tags in the tags of the AWS resources that the Operators create.</p>                                                                                                                                                                                                                                                                                                                                                                                                                      | <p>Boolean values, for example <b>true</b> or <b>false</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>platform:</b><br><b>aws:</b><br><b>subnets:</b>           | <p>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same <b>machineNetwork[].cidr</b> ranges that you specify.</p> <p>For a standard cluster, specify a public and a private subnet for each availability zone.</p> <p>For a private cluster, specify a private subnet for each availability zone.</p> <p>For clusters that use AWS Local Zones, you must add AWS Local Zone subnets to this list to ensure edge machine pool creation.</p> | <p>Valid subnet IDs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter                                                                           | Description                                                                  | Values                                                                                                          |
|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>platform:</b><br><b>aws:</b><br><br><b>preserveBoots</b><br><b>trapIgnition:</b> | Prevents the S3 bucket from being deleted after completion of bootstrapping. | <b>true</b> or <b>false</b> . The default value is <b>false</b> , which results in the S3 bucket being deleted. |

### 19.12.1.5. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 19.14. Additional RHOSP parameters**

| Parameter                                                                                           | Description                                                                                                                                       | Values                                                                                                            |
|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>compute:</b><br><b>platform:</b><br><b>openstack:</b><br><br><b>rootVolume:</b><br><b>size:</b>  | For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.                     | Integer, for example <b>30</b> .                                                                                  |
| <b>compute:</b><br><b>platform:</b><br><b>openstack:</b><br><br><b>rootVolume:</b><br><b>types:</b> | For compute machines, the root volume types.                                                                                                      | A list of strings, for example, <b>{performance-host1, performance-host2, performance-host3}</b> . <sup>[1]</sup> |
| <b>compute:</b><br><b>platform:</b><br><b>openstack:</b><br><br><b>rootVolume:</b><br><b>type:</b>  | For compute machines, the root volume's type. This property is deprecated and is replaced by <b>compute.platform.openstack.rootVolume.types</b> . | String, for example, <b>performance</b> . <sup>[2]</sup>                                                          |

| Parameter                                                                                                | Description                                                                                                                                                                                                                                                                       | Values                                                                                                            |
|----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>compute:</b><br><b>platform:</b><br><b>openstack:</b><br><br><b>rootVolume:</b><br><b>zones:</b>      | For compute machines, the Cinder availability zone to install root volumes on. If you do not set a value for this parameter, the installation program selects the default availability zone. This parameter is mandatory when <b>compute.platform.openstack.zones</b> is defined. | A list of strings, for example <b>["zone-1", "zone-2"]</b> .                                                      |
| <b>controlPlane:</b><br><b>platform:</b><br><b>openstack:</b><br><br><b>rootVolume:</b><br><b>size:</b>  | For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.                                                                                                                                               | Integer, for example <b>30</b> .                                                                                  |
| <b>controlPlane:</b><br><b>platform:</b><br><b>openstack:</b><br><br><b>rootVolume:</b><br><b>types:</b> | For control plane machines, the root volume types.                                                                                                                                                                                                                                | A list of strings, for example, <b>{performance-host1, performance-host2, performance-host3}</b> . <sup>[1]</sup> |
| <b>controlPlane:</b><br><b>platform:</b><br><b>openstack:</b><br><br><b>rootVolume:</b><br><b>type:</b>  | For control plane machines, the root volume's type. This property is deprecated and is replaced by <b>compute.platform.openstack.rootVolume.types</b> .                                                                                                                           | String, for example, <b>performance</b> . <sup>[2]</sup>                                                          |
| <b>controlPlane:</b><br><b>platform:</b><br><b>openstack:</b><br><br><b>rootVolume:</b><br><b>zones:</b> | For control plane machines, the Cinder availability zone to install root volumes on. If you do not set this value, the installation program selects the default availability zone. This parameter is mandatory when <b>controlPlane.platform.openstack.zones</b> is defined.      | A list of strings, for example <b>["zone-1", "zone-2"]</b> .                                                      |

| Parameter                                                            | Description                                                                                                                                                                                                                                                                                                                                                                          | Values                                 |
|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| <b>platform:</b><br><b>openstack:</b><br><b>cloud:</b>               | <p>The name of the RHOSP cloud to use from the list of clouds in the <b>clouds.yaml</b> file.</p> <p>In the cloud configuration in the <b>clouds.yaml</b> file, if possible, use application credentials rather than a user name and password combination. Using application credentials avoids disruptions from secret propagation that follow user name and password rotation.</p> | String, for example <b>MyCloud</b> .   |
| <b>platform:</b><br><b>openstack:</b><br><br><b>externalNetwork:</b> | The RHOSP external network name to be used for installation.                                                                                                                                                                                                                                                                                                                         | String, for example <b>external</b> .  |
| <b>platform:</b><br><b>openstack:</b><br><br><b>computeFlavor:</b>   | <p>The RHOSP flavor to use for control plane and compute machines.</p> <p>This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the <b>type</b> key in the <b>platform.openstack.defaultMachinePlatform</b> property. You can also set a flavor value for each machine pool individually.</p>                                    | String, for example <b>m1.xlarge</b> . |

1. If the machine pool defines **zones**, the count of types can either be a single item or match the number of items in **zones**. For example, the count of types cannot be 2 if there are 3 items in **zones**.
2. If you have any existing reference to this property, the installer populates the corresponding value in the **controlPlane.platform.openstack.rootVolume.types** field.

#### 19.12.1.6. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

**Table 19.15. Optional RHOSP parameters**

| Parameter                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Values                                                                                             |
|------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>compute:</code><br><code>platform:</code><br><code>openstack:</code><br><code>additionalNetworkIDs:</code>       | Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.                                                                                                                                                                                                                                                                                                                                                                         | A list of one or more UUIDs as strings. For example, <b>fa806b2f-ac49-4bce-b9db-124bc64209bf</b> . |
| <code>compute:</code><br><code>platform:</code><br><code>openstack:</code><br><code>additionalSecurityGroupIDs:</code> | Additional security groups that are associated with compute machines.                                                                                                                                                                                                                                                                                                                                                                                                                                 | A list of one or more UUIDs as strings. For example, <b>7ee219f3-d2e9-48a1-96c2-e7429f1b0da7</b> . |
| <code>compute:</code><br><code>platform:</code><br><code>openstack:</code><br><code>zones:</code>                      | <p>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installation program relies on the default settings for Nova that the RHOSP administrator configured.</p> <p>On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</p> | A list of strings. For example, <b>["zone-1", "zone-2"]</b> .                                      |

|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| <b>platform:</b><br><b>openstack:</b><br><b>apiFloatingIP:</b>  | An existing floating IP address to associate with the API load balancer. To use this property, you must also define the <b>platform.openstack.externalNetwork</b> property.                                                                                                                                                                                                                                                      | An IP address, for example <b>128.0.0.1</b> .                                        |
| <b>platform:</b><br><b>openstack:</b><br><b>externalDNS:</b>    | IP addresses for external DNS servers that cluster instances use for DNS resolution.                                                                                                                                                                                                                                                                                                                                             | A list of IP addresses as strings. For example, <b>["8.8.8.8", "192.168.1.12"]</b> . |
| <b>platform:</b><br><b>openstack:</b><br><b>loadbalancer:</b>   | Whether or not to use the default, internal load balancer. If the value is set to <b>UserManaged</b> , this default load balancer is disabled so that you can deploy a cluster that uses an external, user-managed load balancer. If the parameter is not set, or if the value is <b>OpenShiftManagedDefault</b> , the cluster uses the default load balancer.                                                                   | <b>UserManaged</b> or <b>OpenShiftManagedDefault</b> .                               |
| <b>platform:</b><br><b>openstack:</b><br><b>machinesSubnet:</b> | <p>The UUID of a RHOSP subnet that the cluster's nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</p> <p>The first item in <b>networking.machineNetwork</b> must match the value of <b>machinesSubnet</b>.</p> <p>If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, <a href="#">add DNS to the subnet in RHOSP</a>.</p> | A UUID as a string. For example, <b>fa806b2f-ac49-4bce-b9db-124bc64209bf</b> .       |

#### 19.12.1.7. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

**Table 19.16. Additional GCP parameters**

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                            | Values                                                      |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| <code>controlPlane.platform.gcp.osImage.project</code> | Optional. By default, the installation program downloads and installs the Red Hat Enterprise Linux CoreOS (RHCOS) image that is used to boot control plane machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for control plane machines only. | String. The name of GCP project where the image is located. |
| <code>controlPlane.platform.gcp.osImage.name</code>    | The name of the custom RHCOS image that the installation program is to use to boot control plane machines. If you use <b><code>controlPlane.platform.gcp.osImage.project</code></b> , this field is required.                                                                                                                          | String. The name of the RHCOS image.                        |

| Parameter                                             | Description                                                                                                                                                                                                                                                                              | Values                                                      |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| compute:<br>platform:<br>gcp:<br>osimage:<br>project: | Optional. By default, the installation program downloads and installs the RHCOS image that is used to boot compute machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for compute machines only. | String. The name of GCP project where the image is located. |
| compute:<br>platform:<br>gcp:<br>osimage:<br>name:    | The name of the custom RHCOS image that the installation program is to use to boot compute machines. If you use <b>compute.platform.gcp.osImage.project</b> , this field is required.                                                                                                    | String. The name of the RHCOS image.                        |

| Parameter                                     | Description                                                                                                                                                                                                                                                        | Values                                              |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| <code>platform: gcp: network:</code>          | The name of the existing Virtual Private Cloud (VPC) where you want to deploy your cluster. If you want to deploy your cluster into a shared VPC, you must set <b>platform.gcp.networkProjectID</b> with the name of the GCP project that contains the shared VPC. | String.                                             |
| <code>platform: gcp: networkProjectID:</code> | Optional. The name of the GCP project that contains the shared VPC where you want to deploy your cluster.                                                                                                                                                          | String.                                             |
| <code>platform: gcp: projectID:</code>        | The name of the GCP project where the installation program installs the cluster.                                                                                                                                                                                   | String.                                             |
| <code>platform: gcp: region:</code>           | The name of the GCP region that hosts your cluster.                                                                                                                                                                                                                | Any valid region name, such as <b>us-central1</b> . |

| Parameter                                       | Description                                                                           | Values           |
|-------------------------------------------------|---------------------------------------------------------------------------------------|------------------|
| <code>platform: gcp: controlPlaneSubnet:</code> | The name of the existing subnet where you want to deploy your control plane machines. | The subnet name. |
| <code>platform: gcp: computeSubnet:</code>      | The name of the existing subnet where you want to deploy your compute machines.       | The subnet name. |

| Parameter                                                  | Description                                                             | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform: gcp: defaultMachinePlatform: zones:</code> | The availability zones where the installation program creates machines. | <p>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</p> <div><div><b>IMPORTANT</b><br/><br/>When running your cluster on GCP 64-bit ARM infrastructure, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</div></div> |

| Parameter                                                                                                                               | Description                             | Values                               |
|-----------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|--------------------------------------|
| <code>platform:</code><br><code>gcp:</code><br><code>defaultMachinePlatform:</code><br><code>osDisk:</code><br><code>diskSizeGB:</code> | The size of the disk in gigabytes (GB). | Any size between 16 GB and 65536 GB. |

| Parameter                                                             | Description                                                                                                                                                                                                                                                                                                 | Values                                                                                                                                                                                             |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform: gcp: defaultMachinePlatform: osDisk: diskType:</code> | The <a href="#">GCP disk type</a> .                                                                                                                                                                                                                                                                         | The default disk type for all machines. Control plane nodes must use the <b>pd-ssd</b> disk type. Compute nodes can use the <b>pd-ssd</b> , <b>pd-balanced</b> , or <b>pd-standard</b> disk types. |
| <code>platform: gcp: defaultMachinePlatform: osImage: project:</code> | Optional. By default, the installation program downloads and installs the RHCOS image that is used to boot control plane and compute machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for both types of machines. | String. The name of GCP project where the image is located.                                                                                                                                        |

| Parameter                                                         | Description                                                                                                                                                                                                            | Values                                                 |
|-------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| platform:<br>gcp:<br>defaultMachinePlatform:<br>osImage:<br>name: | The name of the custom RHCOS image that the installation program is to use to boot control plane and compute machines. If you use <b>platform.gcp.defaultMachinePlatform.osImage.project</b> , this field is required. | String. The name of the RHCOS image.                   |
| platform:<br>gcp:<br>defaultMachinePlatform:<br>tags:             | Optional. Additional network tags to add to the control plane and compute machines.                                                                                                                                    | One or more strings, for example <b>network-tag1</b> . |

| Parameter                                     | Description                                                                  | Values                                                   |
|-----------------------------------------------|------------------------------------------------------------------------------|----------------------------------------------------------|
| platform: gcp: default MachinePlatform: type: | The <a href="#">GCP machine type</a> for control plane and compute machines. | The GCP machine type, for example <b>n1-standard-4</b> . |

| Parameter                                                                      | Description                                                                             | Values                   |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|--------------------------|
| platform: gcp default Machine Platform: os Disk: encryption Key: kmsKey: name: | The name of the customer managed encryption key to be used for machine disk encryption. | The encryption key name. |

| Parameter                                                                         | Description                                                                         | Values                 |
|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|------------------------|
| platform: gcp default Machine Platform: os Disk: encryption Key: kmsKey: keyRing: | The name of the Key Management Service (KMS) key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                                                          | Description                                                        | Values            |
|------------------------------------------------------------------------------------|--------------------------------------------------------------------|-------------------|
| platform: gcp default Machine Platform: os Disk: encryption Key: kmsKey: location: | The <a href="#">GCP location</a> in which the KMS key ring exists. | The GCP location. |

| Parameter              | Description                                                                                                                                               | Values              |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| platform.gcp.projectID | The ID of the project in which the KMS key ring exists. This value defaults to the value of the <b>platform.gcp.projectID</b> parameter if it is not set. | The GCP project ID. |

| Parameter                                                                                                                                   | Description                                                                                                                                                                                                                                                                      | Values                                                                                                                      |

If absent, the Compute Engine default service account is used. For more information about GCP service accounts, see Google's documentation on <a href="#">service accounts</a> . | The GCP service account email, for example <b>&lt;service_account_name&gt;@&lt;project_id&gt;.iam.gserviceaccount.com</b> . |

| Parameter                                                                | Description                                                                                                                                                                                                                                                                                                   | Values                                                                     |
|--------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <code>platform: gcp: defaultMachinePlatform: secureBoot:</code>          | Whether to enable Shielded VM secure boot for all machines in the cluster. Shielded VMs have additional security protocols such as secure boot, firmware and integrity monitoring, and rootkit protection. For more information on Shielded VMs, see Google's documentation on <a href="#">Shielded VMs</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |
| <code>platform: gcp: defaultMachinePlatform: confidentialCompute:</code> | Whether to use Confidential VMs for all machines in the cluster. Confidential VMs provide encryption for data during processing. For more information on Confidential computing, see Google's documentation on <a href="#">Confidential computing</a> .                                                       | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |

| Parameter                                                                     | Description                                                                                                                                                                                                                         | Values                                                                     |
|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <code>platform: gcp default Machine Plat form: on HostM aint ena nce :</code> | Specifies the behavior of all VMs during a host maintenance event, such as a software or hardware update. For Confidential VMs, this parameter must be set to <b>Terminate</b> . Confidential VMs do not support live VM migration. | <b>Terminate</b> or <b>Migrate</b> . The default value is <b>Migrate</b> . |

| Parameter                                                       | Description                                                                                           | Values                   |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|--------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKeyName: | The name of the customer managed encryption key to be used for control plane machine disk encryption. | The encryption key name. |

| Parameter                                                            | Description                                                                            | Values                 |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------|------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKey: keyRing: | For control plane machines, the name of the KMS key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                                             | Description                                                                                                                                                                              | Values                             |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKey: location: | For control plane machines, the GCP location in which the key ring exists. For more information about KMS locations, see Google's documentation on <a href="#">Cloud KMS locations</a> . | The GCP location for the key ring. |

| Parameter                                                                                | Description                                                                                                                              | Values              |
|------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| controlPlane:<br>platform:<br>gcp:<br>osDisk:<br>encryptionKey:<br>kmsKey:<br>projectId: | For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set. | The GCP project ID. |

| Parameter                                                              | Description                                                                                                                                                                                                                                                          | Values                                                                                                                      |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsServiceAccount: | The GCP service account used for the encryption request for control plane machines. If absent, the Compute Engine default service account is used. For more information about GCP service accounts, see Google’s documentation on <a href="#">service accounts</a> . | The GCP service account email, for example <b>&lt;service_account_name&gt;@&lt;project_id&gt;.iam.gserviceaccount.com</b> . |

| Parameter                                                       | Description                                                                           | Values                                                                             |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| control Plane:<br>platform:<br>gcp:<br>os Disk:<br>disk SizeGB: | The size of the disk in gigabytes (GB). This value applies to control plane machines. | Any integer between 16 and 65536.                                                  |
| control Plane:<br>platform:<br>gcp:<br>os Disk:<br>disk Type:   | The <a href="#">GCP disk type</a> for control plane machines.                         | Control plane machines must use the <b>pd-ssd</b> disk type, which is the default. |

| Parameter                                       | Description                                                                                                                                                                                        | Values                                                       |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <code>controlPlane: platform: gcp: tags:</code> | Optional. Additional network tags to add to the control plane machines. If set, this parameter overrides the <b>platform.gcp.defaultMachinePlatform.tags</b> parameter for control plane machines. | One or more strings, for example <b>control-plane-tag1</b> . |
| <code>controlPlane: platform: gcp: type:</code> | The <a href="#">GCP machine type</a> for control plane machines. If set, this parameter overrides the <b>platform.gcp.defaultMachinePlatform.type</b> parameter.                                   | The GCP machine type, for example <b>n1-standard-4</b> .     |

| Parameter                                                | Description                                                                           | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------------|---------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| controlPlane:<br><br>platform:<br><br>gcp:<br><br>zones: | The availability zones where the installation program creates control plane machines. | <p>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</p> <div><div><p><b>IMPORTANT</b></p><p>When running your cluster on GCP 64-bit ARM infrastructure, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</p></div></div> |

| Parameter                                       | Description                                                                                                                                                                                                                                                                                              | Values                                                                     |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| controlPlane:platform:gcps:secureBoot:          | Whether to enable Shielded VM secure boot for control plane machines. Shielded VMs have additional security protocols such as secure boot, firmware and integrity monitoring, and rootkit protection. For more information on Shielded VMs, see Google's documentation on <a href="#">Shielded VMs</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |
| controlPlane:platform:gcps:confidentialCompute: | Whether to enable Confidential VMs for control plane machines. Confidential VMs provide encryption for data while it is being processed. For more information on Confidential VMs, see Google's documentation on <a href="#">Confidential Computing</a> .                                                | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |

| Parameter                                                | Description                                                                                                                                                                                                                                   | Values                                                                     |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| controlPlanePlatform: gcp on HostMaintenance:            | Specifies the behavior of control plane VMs during a host maintenance event, such as a software or hardware update. For Confidential VMs, this parameter must be set to <b>Terminate</b> . Confidential VMs do not support live VM migration. | <b>Terminate</b> or <b>Migrate</b> . The default value is <b>Migrate</b> . |
| computePlatform: gcp os Disk: encryptionKey: kmsKeyName: | The name of the customer managed encryption key to be used for compute machine disk encryption.                                                                                                                                               | The encryption key name.                                                   |

| Parameter                                          | Description                                                                      | Values                 |
|----------------------------------------------------|----------------------------------------------------------------------------------|------------------------|
| compute:platform:gcp:osDisk:encryptionKey:keyRing: | For compute machines, the name of the KMS key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                                 | Description                                                                                                                                                                        | Values                             |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| compute:platform:gcp:osDisk:encryptionKey:kskey:location: | For compute machines, the GCP location in which the key ring exists. For more information about KMS locations, see Google's documentation on <a href="#">Cloud KMS locations</a> . | The GCP location for the key ring. |

| Parameter                                                   | Description                                                                                                                        | Values              |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| compute:platform:gcp:osDisk:encryptionKey:kmsKey:projectId: | For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set. | The GCP project ID. |

| Parameter                                                   | Description                                                                                                                                                                                                                                                                   | Values                                                                                                                      |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| compute:platform:gcp:osDisk:encryptionKey:kmServiceAccount: | The GCP service account used for the encryption request for compute machines. If this value is not set, the Compute Engine default service account is used. For more information about GCP service accounts, see Google's documentation on <a href="#">service accounts</a> . | The GCP service account email, for example <b>&lt;service_account_name&gt;@&lt;project_id&gt;.iam.gserviceaccount.com</b> . |
| compute:platform:gcp:osDisk:diskSizeGB:                     | The size of the disk in gigabytes (GB). This value applies to compute machines.                                                                                                                                                                                               | Any integer between 16 and 65536.                                                                                           |

| Parameter                            | Description                                                                                                                                                                            | Values                                                                                      |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| compute:platform:gcp:osDisk:diskType | The <a href="#">GCP disk type</a> for compute machines.                                                                                                                                | <b>pd-ssd</b> , <b>pd-standard</b> , or <b>pd-balanced</b> . The default is <b>pd-ssd</b> . |
| compute:platform:gcp:tags            | Optional. Additional network tags to add to the compute machines. If set, this parameter overrides the <b>platform.gcp.defaultMachinePlatform.tags</b> parameter for compute machines. | One or more strings, for example <b>compute-network-tag1</b> .                              |

| Parameter                                | Description                                                                                                                                                      | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>compute:platform:gcp:type:</code>  | The <a href="#">GCP machine type</a> for compute machines. If set, this parameter overrides the <code>platform.gcp.defaultMachinePlatform.type</code> parameter. | The GCP machine type, for example <b>n1-standard-4</b> .                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>compute:platform:gcp:zones:</code> | The availability zones where the installation program creates compute machines.                                                                                  | <div><div>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</div><div><div></div><div><b>IMPORTANT</b><br/><br/>When running your cluster on GCP 64-bit ARM infrastructure, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</div></div></div> |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                        | Values                                                                     |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| compute:platform:gcp:secureBoot:          | Whether to enable Shielded VM secure boot for compute machines. Shielded VMs have additional security protocols such as secure boot, firmware and integrity monitoring, and rootkit protection. For more information on Shielded VMs, see Google's documentation on <a href="#">Shielded VMs</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |
| compute:platform:gcp:confidentialCompute: | Whether to enable Confidential VMs for compute machines. Confidential VMs provide encryption for data while it is being processed. For more information on Confidential VMs, see Google's documentation on <a href="#">Confidential Computing</a> .                                                | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |

| Parameter                                           | Description                                                                                                                                                                                                                             | Values                                                                     |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| compute:<br>platform:<br>gcp:<br>onHostMaintenance: | Specifies the behavior of compute VMs during a host maintenance event, such as a software or hardware update. For Confidential VMs, this parameter must be set to <b>Terminate</b> . Confidential VMs do not support live VM migration. | <b>Terminate</b> or <b>Migrate</b> . The default value is <b>Migrate</b> . |

## CHAPTER 20. INSTALLING ON OCI

### 20.1. INSTALLING A CLUSTER ON ORACLE CLOUD INFRASTRUCTURE (OCI) BY USING THE ASSISTED INSTALLER

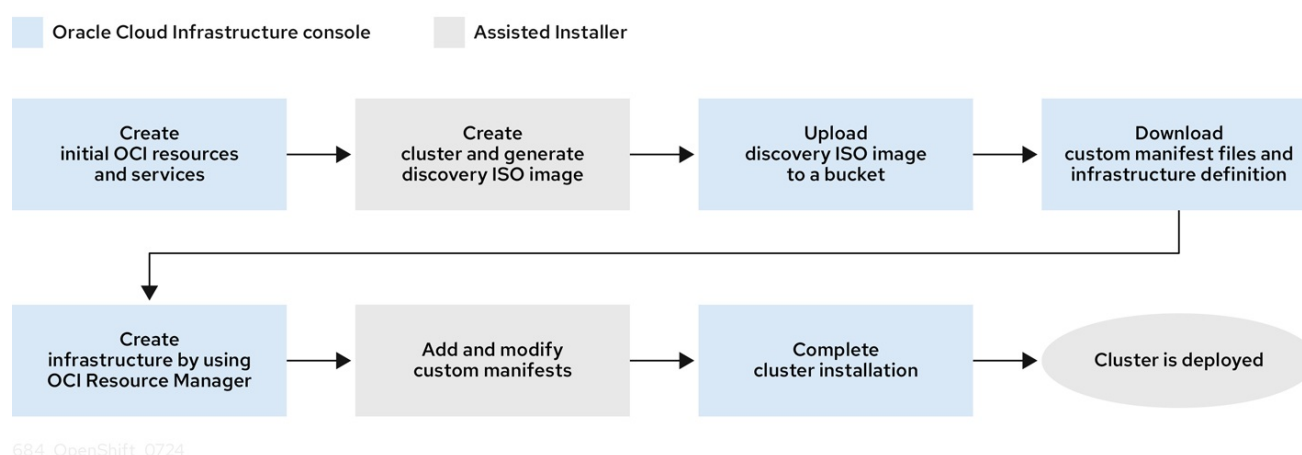

From OpenShift Container Platform 4.14 and later versions, you can use the Assisted Installer to install a cluster on Oracle® Cloud Infrastructure (OCI) by using infrastructure that you provide.

#### 20.1.1. The Assisted Installer and OCI overview

You can run cluster workloads on Oracle® Cloud Infrastructure (OCI) infrastructure that supports dedicated, hybrid, public, and multiple cloud environments. Both Red Hat and Oracle test, validate, and support running OCI in an OpenShift Container Platform cluster on OCI.

The Assisted Installer supports the OCI platform, and you can use the Assisted Installer to access an intuitive interactive workflow for the purposes of automating cluster installation tasks on OCI.

**Figure 20.1. Workflow for using the Assisted Installer in a connected environment to install a cluster on OCI**

684\_OpenShift\_0724

OCI provides services that can meet your needs for regulatory compliance, performance, and cost-effectiveness. You can access OCI Resource Manager configurations to provision and configure OCI resources.

#### IMPORTANT

The steps for provisioning OCI resources are provided as an example only. You can also choose to create the required resources through other methods; the scripts are just an example. Installing a cluster with infrastructure that you provide requires knowledge of the cloud provider and the installation process on OpenShift Container Platform. You can access OCI Resource Manager configurations to complete these steps, or use the configurations to model your own custom script.

Follow the steps in the *Installing a cluster on Oracle Cloud Infrastructure (OCI) by using the Assisted Installer* document to understand how to use the Assisted Installer to install a OpenShift Container Platform cluster on OCI. This document demonstrates the use of the OCI Cloud Controller Manager (CCM) and Oracle's Container Storage Interface (CSI) objects to link your OpenShift Container Platform cluster with the OCI API.

## IMPORTANT

To ensure the best performance conditions for your cluster workloads that operate on OCI, ensure that volume performance units (VPUs) for your block volume are sized for your workloads. The following list provides guidance for selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Basic environment: 500 GB, and 60 VPUs.
- Heavy production environment: More than 500 GB, and 100 or more VPUs.

Consider reserving additional VPUs to provide sufficient capacity for updates and scaling activities. For more information about VPUs, see [Volume Performance Units \(Oracle documentation\)](#).

If you are unfamiliar with the OpenShift Container Platform Assisted Installer, see "Assisted Installer for OpenShift Container Platform".

### Additional resources

- [Assisted Installer for OpenShift Container Platform](#)
- [Internet access for OpenShift Container Platform](#)
- [Volume Performance Units \(Oracle documentation\)](#)
- [Instance Sizing Recommendations for OpenShift Container Platform on OCI Nodes \(Oracle documentation\)](#)

## 20.1.2. Creating OCI resources and services

Create Oracle® Cloud Infrastructure (OCI) resources and services so that you can establish infrastructure with governance standards that meets your organization's requirements.

### Prerequisites

- You configured an OCI account to host the cluster. See [Prerequisites \(Oracle documentation\)](#).

### Procedure

1. Log in to your [Oracle Cloud Infrastructure \(OCI\)](#) account with administrator privileges.
2. Download an archive file from an Oracle resource. The archive file includes files for creating cluster resources and custom manifests. The archive file also includes a script, and when you run the script, the script creates OCI resources, such as DNS records, an instance, and so on. For more information, see [Configuration Files \(Oracle documentation\)](#).

## 20.1.3. Using the Assisted Installer to generate an OCI-compatible discovery ISO image

Generate a discovery ISO image and upload the image to Oracle® Cloud Infrastructure (OCI), so that the agent can perform hardware and network validation checks before you install an OpenShift Container Platform cluster on OCI.

From the OCI web console, you must create the following resources:

- A compartment for better organizing, restricting access, and setting usage limits to OCI resources.
- An object storage bucket for safely and securely storing the discovery ISO image. You can access the image at a later stage for the purposes of booting the instances, so that you can then create your cluster.

## Prerequisites

- You created a child compartment and an object storage bucket on OCI. See [Provisioning Cloud Infrastructure \(OCI Console\)](#) in the Oracle documentation.
- You reviewed details about the OpenShift Container Platform installation and update processes.
- If you use a firewall and you plan to use a Telemetry service, you configured your firewall to allow OpenShift Container Platform to access the sites required.
- Before you create a virtual machines (VM), see [Cloud instance types \(Red Hat Ecosystem Catalog portal\)](#) to identify the supported OCI VM shapes.

## Procedure

1. From the [Install OpenShift with the Assisted Installer](#) page on the Hybrid Cloud Console, generate the discovery ISO image by completing all the required Assisted Installer steps.
  - a. In the **Cluster Details** step, complete the following fields:

| Field                                     | Action required                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cluster name                              | Specify the name of your cluster, such as <b>ocidemo</b> .                                                                                                                                                                                                                                                                                                        |
| Base domain                               | Specify the base domain of the cluster, such as <b>splat-oci.devcluster.openshift.com</b> .<br>Provided you previously created a compartment on OCI, you can get this information by going to <b>DNS management</b> → <b>Zones</b> → <b>List scope</b> and then selecting the parent compartment. Your base domain should show under the <b>Public zones</b> tab. |
| OpenShift version                         | Specify <b>OpenShift 4.15</b> or a later version.                                                                                                                                                                                                                                                                                                                 |
| CPU architecture                          | Specify <b>x86_64</b> or <b>Arm64</b> .                                                                                                                                                                                                                                                                                                                           |
| Integrate with external partner platforms | Specify <b>Oracle Cloud Infrastructure</b> .<br><br>After you specify this value, the <b>Include custom manifests</b> checkbox is selected by default.                                                                                                                                                                                                            |

- b. On the **Operators** page, click **Next**.
- c. On the **Host Discovery** page, click **Add hosts**.
- d. For the **SSH public key** field, add your SSH key from your local system.

### TIP

You can create an SSH authentication key pair by using the **ssh-keygen** tool.

- e. Click **Generate Discovery ISO** to generate the discovery ISO image file.
  - f. Download the file to your local system.
2. Upload the discovery ISO image to the OCI bucket. See [Uploading an Object Storage Object to a Bucket \(Oracle documentation\)](#).
    - a. You must create a pre-authenticated request for your uploaded discovery ISO image. Ensure that you make note of the URL from the pre-authenticated request, because you must specify the URL at a later stage when you create an OCI stack.

### Additional resources

- [Installation and update](#)
- [Configuring your firewall](#)

## 20.1.4. Provisioning OCI infrastructure for your cluster

By using the Assisted Installer to create details for your OpenShift Container Platform cluster, you can specify these details in a stack. A stack is an OCI feature where you can automate the provisioning of all necessary OCI infrastructure resources, such as the custom image, that are required for installing an OpenShift Container Platform cluster on OCI.

The Oracle® Cloud Infrastructure (OCI) Compute Service creates a virtual machine (VM) instance on OCI. This instance can then automatically attach to a virtual network interface controller (vNIC) in the virtual cloud network (VCN) subnet. On specifying the IP address of your OpenShift Container Platform cluster in the custom manifest template files, the OCI instance can communicate with your cluster over the VCN.

### Prerequisites

- You uploaded the discovery ISO image to the OCI bucket. For more information, see "Using the Assisted Installer to generate an OCI-compatible discovery ISO image".

### Procedure

1. Complete the steps for provisioning OCI infrastructure for your OpenShift Container Platform cluster. See [Creating OpenShift Container Platform Infrastructure Using Resource Manager \(Oracle documentation\)](#).
2. Create a stack, and then edit the custom manifest files according to the steps in the [Editing the OpenShift Custom Manifests \(Oracle documentation\)](#).

## 20.1.5. Completing the remaining Assisted Installer steps

After you provision Oracle® Cloud Infrastructure (OCI) resources and upload OpenShift Container Platform custom manifest configuration files to OCI, you must complete the remaining cluster installation steps on the Assisted Installer before you can create an instance OCI.

### Prerequisites

- You created a resource stack on OCI that includes the custom manifest configuration files and OCI Resource Manager configuration resources. See "Provisioning OCI infrastructure for your cluster".

### Procedure

1. From the [Red Hat Hybrid Cloud Console](#) web console, go to the **Host discovery** page.
2. Under the **Role** column, select either **Control plane node** or **Worker** for each targeted hostname.

### IMPORTANT

Before, you can continue to the next steps, wait for each node to reach the **Ready** status.

3. Accept the default settings for the **Storage** and **Networking** steps, and then click **Next**.
4. On the **Custom manifests** page, in the **Folder** field, select **manifest**. This is the Assisted Installer folder where you want to save the custom manifest file.
  - a. In the **File name** field, enter a value such as **oci-ccm.yml**.
  - b. From the **Content** section, click **Browse**, and select the CCM manifest from your drive located in **custom\_manifest/manifests/oci-ccm.yml**.
5. Expand the next **Custom manifest** section and repeat the same steps for the following manifests:
  - CSI driver manifest: **custom\_manifest/manifests/oci-csi.yml**
  - CCM machine configuration: **custom\_manifest/openshift/machineconfig-ccm.yml**
  - CSI driver machine configuration: **custom\_manifest/openshift/machineconfig-csi.yml**
6. From the **Review and create** page, click **Install cluster** to create your OpenShift Container Platform cluster on OCI.

After the cluster installation and initialization operations, the Assisted Installer indicates the completion of the cluster installation operation. For more information, see "Completing the installation" section in the *Assisted Installer for OpenShift Container Platform* document.

### Additional resources

- [Assisted Installer for OpenShift Container Platform](#)

## 20.1.6. Verifying a successful cluster installation on OCI

Verify that your cluster was installed and is running effectively on Oracle® Cloud Infrastructure (OCI).

### Procedure

1. From the Hybrid Cloud Console, go to **Clusters > Assisted Clusters** and select your cluster's name.
2. Check that the Installation progress bar is at 100% and a message displays indicating "Installation completed successfully".
3. To access the OpenShift Container Platform web console, click the provided Web Console URL.
4. Go to the **Nodes** menu page.
5. Locate your node from the **Nodes** table.
6. From the **Overview** tab, check that your node has a **Ready** status.
7. Select the YAML tab.
8. Check the **labels** parameter, and verify that the listed labels apply to your configuration. For example, the **topology.kubernetes.io/region=us-sanjose-1** label indicates in what OCI region the node was deployed.

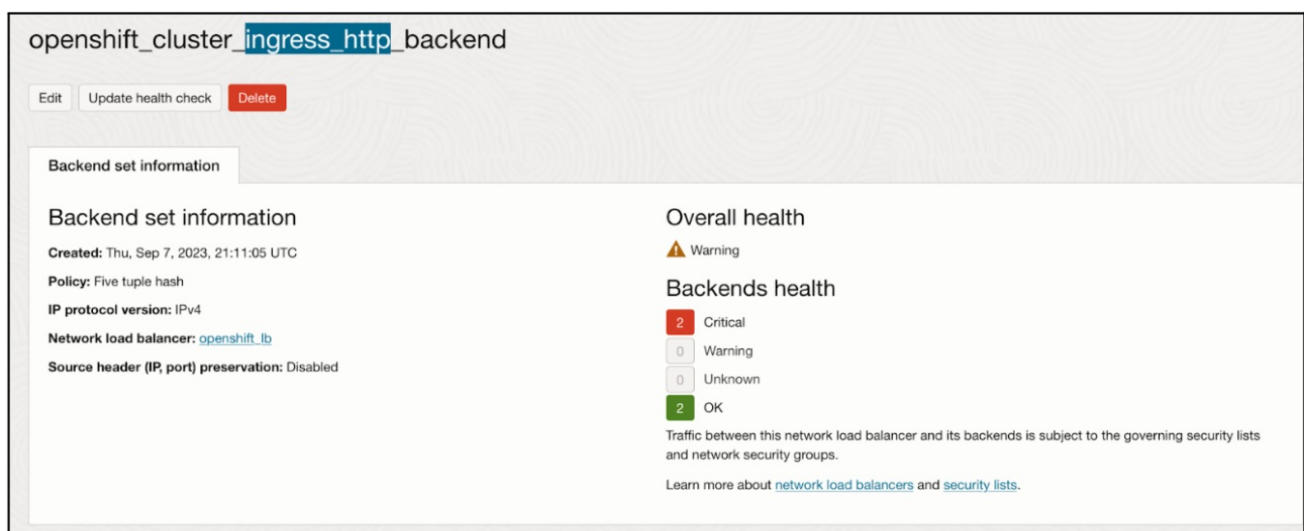

## 20.1.7. Troubleshooting the installation of a cluster on OCI

If you experience issues with using the Assisted Installer to install an OpenShift Container Platform cluster on Oracle® Cloud Infrastructure (OCI), read the following sections to troubleshoot common problems.

### The Ingress Load Balancer in OCI is not at a healthy status

This issue is classed as a **Warning** because by using the Resource Manager to create a stack, you created a pool of compute nodes, 3 by default, that are automatically added as backend listeners for the Ingress Load Balancer. By default, the OpenShift Container Platform deploys 2 router pods, which are based on the default values from the OpenShift Container Platform manifest files. The **Warning** is expected because a mismatch exists with the number of router pods available, two, to run on the three compute nodes.

Figure 20.2. Example of a **Warning** message that is under the Backend set information tab on OCI:

You do not need to modify the Ingress Load Balancer configuration. Instead, you can point the Ingress

Load Balancer to specific compute nodes that operate in your cluster on OpenShift Container Platform. To do this, use placement mechanisms, such as annotations, on OpenShift Container Platform to ensure router pods only run on the compute nodes that you originally configured on the Ingress Load Balancer as backend listeners.

### OCI create stack operation fails with an Error: 400-InvalidParameter message

On attempting to create a stack on OCI, you identified that the **Logs** section of the job outputs an error message. For example:

```
Error: 400-InvalidParameter, DNS Label oci-demo does not follow Oracle requirements
Suggestion: Please update the parameter(s) in the Terraform config as per error message DNS Label
oci-demo does not follow Oracle requirements
Documentation: https://registry.terraform.io/providers/oracle/oci/latest/docs/resources/core_vcn
```

Go to the [Install OpenShift with the Assisted Installer](#) page on the Hybrid Cloud Console, and check the **Cluster name** field on the **Cluster Details** step. Remove any special characters, such as a hyphen (-), from the name, because these special characters are not compatible with the OCI naming conventions. For example, change **oci-demo** to **ocidemo**.

- [Installing an on-premise cluster using the Assisted Installer](#)

## 20.2. INSTALLING A CLUSTER ON ORACLE CLOUD INFRASTRUCTURE (OCI) BY USING THE AGENT-BASED INSTALLER

In OpenShift Container Platform 4.14, you can use the Agent-based Installer to install a cluster on Oracle® Cloud Infrastructure (OCI), so that you can run cluster workloads on infrastructure that supports dedicated, hybrid, public, and multiple cloud environments.

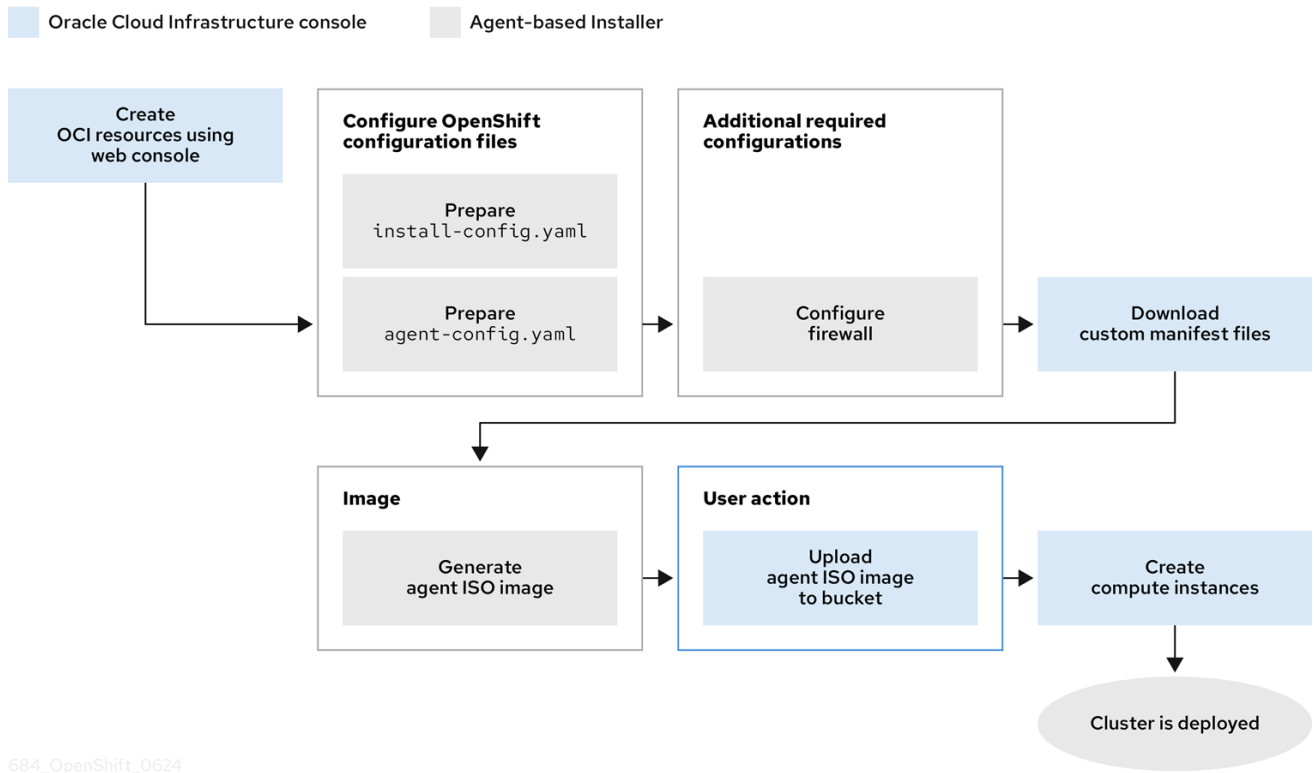

### 20.2.1. The Agent-based Installer and OCI overview

You can install an OpenShift Container Platform cluster on Oracle® Cloud Infrastructure (OCI) by using the Agent-based Installer. Both Red Hat and Oracle test, validate, and support running OCI and Oracle® Cloud VMware Solution (OCVS) workloads in an OpenShift Container Platform cluster on OCI.

The Agent-based installer provides the ease of use of the Assisted Installation service, but with the capability to install a cluster in either a connected or disconnected environment.

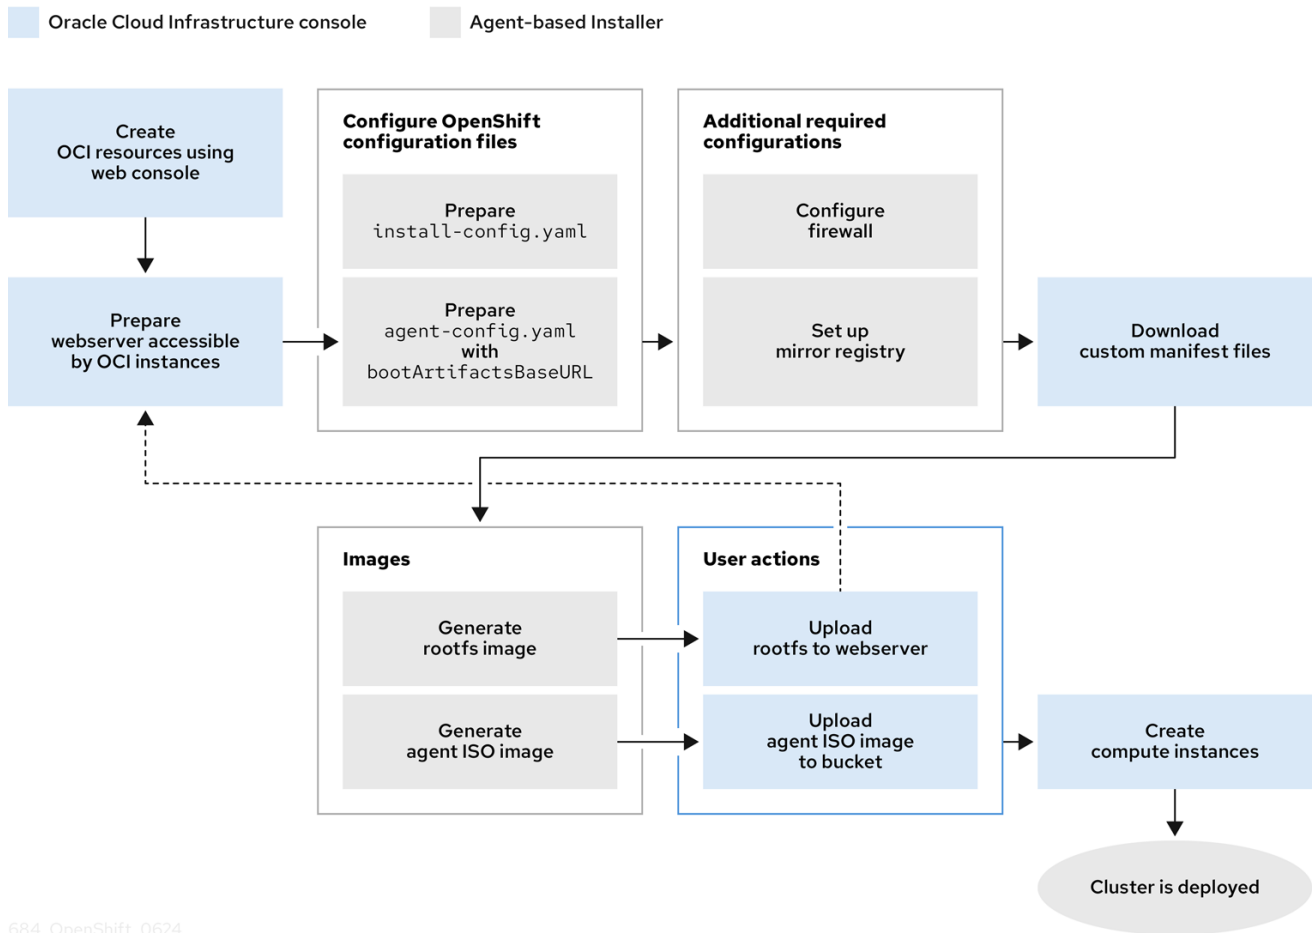

The following diagrams show workflows for connected and disconnected environments:

Figure 20.3. Workflow for using the Agent-based installer in a connected environment to install a cluster on OCI

684\_OpenShift\_0624

**Figure 20.4. Workflow for using the Agent-based installer in a disconnected environment to install a cluster on OCI**

684\_OpenShift\_0624

OCI provides services that can meet your regulatory compliance, performance, and cost-effectiveness needs. OCI supports 64-bit **x86** instances and 64-bit **ARM** instances. Additionally, OCI provides an OCVS service where you can move VMware workloads to OCI with minimal application re-architecture.

## NOTE

Consider selecting a nonvolatile memory express (NVMe) drive or a solid-state drive (SSD) for your boot disk, because these drives offer low latency and high throughput capabilities for your boot disk.

By running your OpenShift Container Platform cluster on OCI, you can access the following capabilities:

- Compute flexible shapes, where you can customize the number of Oracle® CPUs (OCPUs) and memory resources for your VM. With access to this capability, a cluster's workload can perform operations in a resource-balanced environment. You can find all RHEL-certified OCI shapes by going to the Oracle page on the Red Hat Ecosystem Catalog portal.
- Block Volume storage, where you can configure scaling and auto-tuning settings for your storage volume, so that the Block Volume service automatically adjusts the performance level to optimize performance.
- OCVS, where you can deploy a cluster in a public-cloud environment that operates on a VMware® vSphere software-defined data center (SDDC). You continue to retain full-administrative control over your VMware vSphere environment, but you can use OCI services to

improve your applications on flexible, scalable, and secure infrastructure.

## IMPORTANT

To ensure the best performance conditions for your cluster workloads that operate on OCI and on the OCVS service, ensure volume performance units (VPUs) for your block volume is sized for your workloads. The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Basic environment: 500 GB, and 60 VPUs.
- Heavy production environment: More than 500 GB, and 100 or more VPUs.

Consider reserving additional VPUs to provide sufficient capacity for updates and scaling activities. For more information about VPUs, see [Volume Performance Units \(Oracle documentation\)](#).

- [Volume Performance Units \(Oracle documentation\)](#)
- [Instance Sizing Recommendations for OpenShift Container Platform on OCI Nodes \(Oracle documentation\)](#)

### 20.2.2. Creating OCI infrastructure resources and services

You must create an OCI environment on your virtual machine (VM) shape. By creating this environment, you can install OpenShift Container Platform and deploy a cluster on an infrastructure that supports a wide range of cloud options and strong security policies. Having prior knowledge of OCI components can help you with understanding the concept of OCI resources and how you can configure them to meet your organizational needs.

The Agent-based installer method for installing an OpenShift Container Platform cluster on OCI requires that you manually create OCI resources and services.

## IMPORTANT

To ensure compatibility with OpenShift Container Platform, you must set **A** as the record type for each DNS record and name records as follows:

- **api.<cluster\_name>.<base\_domain>**, which targets the **apiVIP** parameter of the API load balancer.
- **api-int.<cluster\_name>.<base\_domain>**, which targets the **apiVIP** parameter of the API load balancer.
- **\*.apps.<cluster\_name>.<base\_domain>**, which targets the **ingressVIP** parameter of the Ingress load balancer.

The **api.\*** and **api-int.\*** DNS records relate to control plane machines, so you must ensure that all nodes in your installed OpenShift Container Platform cluster can access these DNS records.

## Prerequisites

- You configured an OCI account to host the OpenShift Container Platform cluster. See [Prerequisites \(Oracle documentation\)](#).

## Procedure

- Create the required OCI resources and services. See [OCI Resources Needed for Using the Agent-based Installer \(Oracle documentation\)](#).

## Additional resources

- [Learn About Oracle Cloud Basics \(Oracle documentation\)](#)

### 20.2.3. Creating configuration files for installing a cluster on OCI

You need to create the **install-config.yaml** and the **agent-config.yaml** configuration files so that you can use the Agent-based Installer to generate a bootable ISO image. The Agent-based installation comprises a bootable ISO that has the Assisted discovery agent and the Assisted Service. Both of these components are required to perform the cluster installation, but the latter component runs on only one of the hosts.

At a later stage, you must follow the steps in the Oracle documentation for uploading your generated agent ISO image to Oracle's default Object Storage bucket, which is the initial step for integrating your OpenShift Container Platform cluster on Oracle® Cloud Infrastructure (OCI).

## NOTE

You can also use the Agent-based Installer to generate or accept Zero Touch Provisioning (ZTP) custom resources.

## Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You read the documentation on selecting a cluster installation method and preparing the method for users.
- You have read the "Preparing to install with the Agent-based Installer" documentation.
- You downloaded the Agent-Based Installer and the command-line interface (CLI) from the Red Hat Hybrid Cloud Console.
- You have logged in to the OpenShift Container Platform with administrator privileges.

## Procedure

1. For a disconnected environment, mirror the Mirror registry for Red Hat OpenShift to your local container image registry.

### IMPORTANT

Check that your **openshift-install** binary version relates to your local image container registry and not a shared registry, such as Red Hat Quay.

```
$./openshift-install version
```

### Example output for a shared registry binary

```
./openshift-install 4.15.0
built from commit ae7977b7d1ca908674a0d45c5c243c766fa4b2ca
release image registry.ci.openshift.org/origin/release:4.15ocp-
release@sha256:0da6316466d60a3a4535d5fed3589feb0391989982fba59d47d
4c729912d6363
release architecture amd64
```

2. Configure the **install-config.yaml** configuration file to meet the needs of your organization.

### Example **install-config.yaml** configuration file that demonstrates setting an external platform

```
install-config.yaml
apiVersion: v1
baseDomain: <base_domain> ❶
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 network type: OVNKubernetes
 machineNetwork:
 - cidr: <ip_address_from_cidr> ❷
 serviceNetwork:
 - 172.30.0.0/16
compute:
 - architecture: amd64 ❸
 hyperthreading: Enabled
 name: worker
 replicas: 0
```

```

controlPlane:
 architecture: amd64 4
 hyperthreading: Enabled
 name: master
 replicas: 3
platform:
 external:
 platformName: oci 5
 cloudControllerManager: External
 sshKey: <public_ssh_key> 6
 pullSecret: '<pull_secret>' 7
...

```

- 1 The base domain of your cloud provider.
- 2 The IP address from the virtual cloud network (VCN) that the CIDR allocates to resources and components that operate on your network.
- 3 4 Depending on your infrastructure, you can select either **x86\_64**, or **amd64**.
- 5 Set **OCI** as the external platform, so that OpenShift Container Platform can integrate with OCI.
- 6 Specify your SSH public key.
- 7 The pull secret that you need for authenticate purposes when downloading container images for OpenShift Container Platform components and services, such as Quay.io. See [Install OpenShift Container Platform 4](#) from the Red Hat Hybrid Cloud Console.

3. Create a directory on your local system named **openshift**.

### IMPORTANT

Do not move the **install-config.yaml** and **agent-config.yaml** configuration files to the **openshift** directory.

4. Complete the steps in the "[Configuration Files](#)" section of the *Oracle* documentation to download Oracle Cloud Controller Manager (CCM) and Oracle Container Storage Interface (CSI) manifests as an archive file and save the archive file in your **openshift** directory. You need the Oracle CCM manifests for deploying the Oracle CCM during cluster installation so that OpenShift Container Platform can connect to the external OCI platform. You need the Oracle CSI custom manifests for deploying the Oracle CSI driver during cluster installation so that OpenShift Container Platform can claim required objects from OCI.
5. Access the custom manifest files that are provided in the "[Configuration Files](#)" section of the *Oracle* documentation.
  - a. Change the **oci-cloud-controller-manager** secret that is defined in the **oci-ccm.yml** configuration file to match your organization's region, compartment OCID, VCN OCID, and the subnet OCID from the load balancer.
6. Use the Agent-based Installer to generate a minimal ISO image, which excludes the rootfs image, by entering the following command in your OpenShift Container Platform CLI. You can use this image later in the process to boot all your cluster's nodes.

—

```
$./openshift-install agent create image --log-level debug
```

The command also completes the following actions:

- Creates a subdirectory, `./<installation_directory>/auth directory;` and places **kubeadmin-password** and **kubeconfig** files in the subdirectory.
- Creates a **rendezvousIP** file based on the IP address that you specified in the **agent-config.yaml** configuration file.
- Optional: Any modifications you made to **agent-config.yaml** and **install-config.yaml** configuration files get imported to the Zero Touch Provisioning (ZTP) custom resources.

### IMPORTANT

The Agent-based Installer uses Red Hat Enterprise Linux CoreOS (RHCOS). The rootfs image, which is mentioned in a later listed item, is required for booting, recovering, and repairing your operating system.

7. Configure the **agent-config.yaml** configuration file to meet your organization's requirements.

**Example `agent-config.yaml` configuration file that sets values for an IPv4 formatted network.**

```
apiVersion: v1alpha1
metadata:
 name: <cluster_name> 1
 namespace: <cluster_namespace> 2
rendezvousIP: <ip_address_from_CIDR> 3
bootArtifactsBaseURL: <server_URL> 4
...
```

- 1 The cluster name that you specified in your DNS record.
- 2 The namespace of your cluster on OpenShift Container Platform.
- 3 If you use IPv4 as the network IP address format, ensure that you set the **rendezvousIP** parameter to an IPv4 address that the VCN's Classless Inter-Domain Routing (CIDR) method allocates on your network. Also ensure that at least one instance from the pool of instances that you booted with the ISO matches the IP address value you set for **rendezvousIP**.
- 4 The URL of the server where you want to upload the rootfs image.

8. Apply one of the following two updates to your **agent-config.yaml** configuration file:

- For a disconnected network: After you run the command to generate a minimal ISO Image, the Agent-based installer saves the rootfs image into the `./<installation_directory>/boot-artifacts` directory on your local system. Use your preferred web server, such as any Hypertext Transfer Protocol daemon (**httpd**), to upload rootfs to the location stated in the **bootArtifactsBaseURL** parameter in the **agent-config.yaml** configuration file. For example, if the **bootArtifactsBaseURL** parameter states **http://192.168.122.20**, you would upload the generated rootfs image to this location, so that the Agent-based installer

can access the image from **[http://192.168.122.20/agent.x86\\_64-rootfs.img](http://192.168.122.20/agent.x86_64-rootfs.img)**. After the Agent-based installer boots the minimal ISO for the external platform, the Agent-based Installer downloads the rootfs image from the **[http://192.168.122.20/agent.x86\\_64-rootfs.img](http://192.168.122.20/agent.x86_64-rootfs.img)** location into the system memory.

#### NOTE

The Agent-based Installer also adds the value of the **bootArtifactsBaseURL** to the minimal ISO Image's configuration, so that when the Operator boots a cluster's node, the Agent-based Installer downloads the rootfs image into system memory.

- For a connected network: You do not need to specify the **bootArtifactsBaseURL** parameter in the **agent-config.yaml** configuration file. The default behavior of the Agent-based Installer reads the rootfs URL location from **<https://rhcos.mirror.openshift.com>**. After the Agent-based Installer boots the minimal ISO for the external platform, the Agent-based Installer then downloads the rootfs file into your system's memory from the default RHCOS URL.

#### IMPORTANT

Consider that the full ISO image, which is in excess of **1 GB**, includes the rootfs image. The image is larger than the minimal ISO Image, which is typically less than **150 MB**.

#### Additional resources

- [About OpenShift Container Platform installation](#)
- [Selecting a cluster installation type](#)
- [Preparing to install with the Agent-based Installer](#)
- [Downloading the Agent-based Installer](#)
- [Mirroring the OpenShift Container Platform image repository](#)
- [Optional: Using ZTP manifests](#)

### 20.2.4. Configuring your firewall for OpenShift Container Platform

Before you install OpenShift Container Platform, you must configure your firewall to grant access to the sites that OpenShift Container Platform requires. When using a firewall, make additional configurations to the firewall so that OpenShift Container Platform can access the sites that it requires to function.

For a disconnected environment, you must mirror content from both Red Hat and Oracle. This environment requires that you create firewall rules to expose your firewall to specific ports and registries.

#### NOTE

If your environment has a dedicated load balancer in front of your OpenShift Container Platform cluster, review the allowlists between your firewall and load balancer to prevent unwanted network restrictions to your cluster.

## Procedure

1. Set the following registry URLs for your firewall's allowlist:

| URL                               | Port | Function                                                                                                                                                                                                |
|-----------------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>registry.redhat.io</b>         | 443  | Provides core container images                                                                                                                                                                          |
| <b>access.redhat.com</b>          | 443  | Hosts a signature store that a container client requires for verifying images pulled from <b>registry.access.redhat.com</b> . In a firewall environment, ensure that this resource is on the allowlist. |
| <b>registry.access.redhat.com</b> | 443  | Hosts all the container images that are stored on the Red Hat Ecosystem Catalog, including core container images.                                                                                       |
| <b>quay.io</b>                    | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn.quay.io</b>                | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn01.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn02.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn03.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn04.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn05.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn06.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>sso.redhat.com</b>             | 443  | The <a href="https://console.redhat.com">https://console.redhat.com</a> site uses authentication from <b>sso.redhat.com</b>                                                                             |

- You can use the wildcards **\*.quay.io** and **\*.openshiftapps.com** instead of **cdn.quay.io** and **cdn0[1-6].quay.io** in your allowlist.
  - You can use the wildcard **\*.access.redhat.com** to simplify the configuration and ensure that all subdomains, including **registry.access.redhat.com**, are allowed.
  - When you add a site, such as **quay.io**, to your allowlist, do not add a wildcard entry, such as **\*.quay.io**, to your denylist. In most cases, image registries use a content delivery network (CDN) to serve images. If a firewall blocks access, image downloads are denied when the initial download request redirects to a hostname such as **cdn01.quay.io**.
2. Set your firewall's allowlist to include any site that provides resources for a language or framework that your builds require.

3. If you do not disable Telemetry, you must grant access to the following URLs to access Red Hat Insights:

| URL                               | Port | Function                                                |
|-----------------------------------|------|---------------------------------------------------------|
| <b>cert-api.access.redhat.com</b> | 443  | Required for Telemetry                                  |
| <b>api.access.redhat.com</b>      | 443  | Required for Telemetry                                  |
| <b>infogw.api.openshift.com</b>   | 443  | Required for Telemetry                                  |
| <b>console.redhat.com</b>         | 443  | Required for Telemetry and for <b>insights-operator</b> |

4. Set your firewall's allowlist to include the following registry URLs:

| URL                               | Port | Function                                                                                    |
|-----------------------------------|------|---------------------------------------------------------------------------------------------|
| <b>api.openshift.com</b>          | 443  | Required both for your cluster token and to check if updates are available for the cluster. |
| <b>rhcos.mirror.openshift.com</b> | 443  | Required to download Red Hat Enterprise Linux CoreOS (RHCOS) images.                        |

5. Set your firewall's allowlist to include the following external URLs. Each repository URL hosts OCI containers. Consider mirroring images to as few repositories as possible to reduce any performance issues.

| URL                           | Port | Function                                                                                                                                                                                  |
|-------------------------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>k8s.gcr.io</b>             | port | A Kubernetes registry that hosts container images for a community-based image registry. This image registry is hosted on a custom Google Container Registry (GCR) domain.                 |
| <b>ghcr.io</b>                | port | A GitHub image registry where you can store and manage Open Container Initiative images. Requires an access token to publish, install, and delete private, internal, and public packages. |
| <b>storage.googleapis.com</b> | 443  | A source of release image signatures, although the Cluster Version Operator needs only a single functioning source.                                                                       |

| URL                    | Port | Function                                                                                                                                 |
|------------------------|------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>registry.k8s.io</b> | port | Replaces the <b>k8s.gcr.io</b> image registry because the <b>k8s.gcr.io</b> image registry does not support other platforms and vendors. |

### 20.2.5. Running a cluster on OCI

To run a cluster on Oracle® Cloud Infrastructure (OCI), you must upload the generated agent ISO image to the default Object Storage bucket on OCI. Additionally, you must create a compute instance from the supplied base image, so that your OpenShift Container Platform and OCI can communicate with each other for the purposes of running the cluster on OCI.

#### NOTE

OCI supports the following OpenShift Container Platform cluster topologies:

- Installing an OpenShift Container Platform cluster on a single node.
- A highly available cluster that has a minimum of three control plane instances and two compute instances.
- A compact three-node cluster that has a minimum of three control plane instances.

#### Prerequisites

- You generated an agent ISO image. See the "Creating configuration files for installing a cluster on OCI" section.

#### Procedure

1. Upload the agent ISO image to Oracle's default Object Storage bucket and import the agent ISO image as a custom image to this bucket. Ensure you that you configure the custom image to boot in Unified Extensible Firmware Interface (UEFI) mode. For more information, see [Creating the OpenShift Container Platform ISO Image \(Oracle documentation\)](#).
2. Create a compute instance from the supplied base image for your cluster topology. See [Creating the OpenShift Container Platform cluster on OCI \(Oracle documentation\)](#).

#### IMPORTANT

Before you create the compute instance, check that you have enough memory and disk resources for your cluster. Additionally, ensure that at least one compute instance has the same IP address as the address stated under **rendezvousIP** in the **agent-config.yaml** file.

#### Additional resources

- [Recommended resources for topologies](#)

- [Instance Sizing Recommendations for OpenShift Container Platform on OCI Nodes \(Oracle documentation\)](#)
- [Troubleshooting OpenShift Container Platform on OCI \(Oracle documentation\)](#)

## 20.2.6. Verifying that your Agent-based cluster installation runs on OCI

Verify that your cluster was installed and is running effectively on Oracle® Cloud Infrastructure (OCI).

### Prerequisites

- You created all the required OCI resources and services. See the "Creating OCI infrastructure resources and services" section.
- You created **install-config.yaml** and **agent-config.yaml** configuration files. See the "Creating configuration files for installing a cluster on OCI" section.
- You uploaded the agent ISO image to Oracle's default Object Storage bucket, and you created a compute instance on OCI. For more information, see "Running a cluster on OCI".

### Procedure

After you deploy the compute instance on a self-managed node in your OpenShift Container Platform cluster, you can monitor the cluster's status by choosing one of the following options:

- From the OpenShift Container Platform CLI, enter the following command:

```
$./openshift-install agent wait-for install-complete --log-level debug
```

Check the status of the **rendezvous** host node that runs the bootstrap node. After the host reboots, the host forms part of the cluster.

- Use the **kubeconfig** API to check the status of various OpenShift Container Platform components. For the **KUBECONFIG** environment variable, set the relative path of the cluster's **kubeconfig** configuration file:

```
$ export KUBECONFIG=~/.kube/kubeconfig
```

Check the status of each of the cluster's self-managed nodes. CCM applies a label to each node to designate the node as running in a cluster on OCI.

```
$ oc get nodes -A
```

### Output example

| NAME                                   | STATUS | ROLES                 | AGE | VERSION         |
|----------------------------------------|--------|-----------------------|-----|-----------------|
| main-0.private.agenttest.oraclevcn.com | Ready  | control-plane, master | 7m  | v1.27.4+6eeca63 |
| main-1.private.agenttest.oraclevcn.com | Ready  | control-plane, master | 15m | v1.27.4+d7fa83f |
| main-2.private.agenttest.oraclevcn.com | Ready  | control-plane, master | 15m | v1.27.4+d7fa83f |

Check the status of each of the cluster's Operators, with the CCM Operator status being a good indicator that your cluster is running.

```
$ oc get co
```

### Truncated output example

```
NAME VERSION AVAILABLE PROGRESSING DEGRADED SINCE
MESSAGE
authentication 4.15.0-0 True False False 6m18s

## CHAPTER 21. INSTALLING ON VSPHERE

### 21.1. INSTALLATION METHODS

You can install an OpenShift Container Platform cluster on vSphere using a variety of different installation methods. Each method has qualities that can make them more suitable for different use cases, such as installing a cluster in a disconnected environment or installing a cluster with minimal configuration and provisioning.

#### 21.1.1. Assisted Installer

You can install OpenShift Container Platform with the [Assisted Installer](#). This method requires no setup for the installer and is ideal for connected environments like vSphere. Installing with the Assisted Installer also provides integration with vSphere, enabling autoscaling. See [Installing an on-premise cluster using the Assisted Installer](#) for additional details.

#### 21.1.2. Agent-based Installer

You can install an OpenShift Container Platform cluster on vSphere using the Agent-based Installer. The Agent-based Installer can be used to boot an on-premises server in a disconnected environment by using a bootable image. With the Agent-based Installer, users also have the flexibility to provision infrastructure, customize network configurations, and customize installations within a disconnected environment. See [Preparing to install with the Agent-based Installer](#) for additional details.

#### 21.1.3. Installer-provisioned infrastructure installation

You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure. Installer-provisioned infrastructure allows the installation program to preconfigure and automate the provisioning of resources required by OpenShift Container Platform. Installer-provisioned infrastructure is useful for installing in environments with disconnected networks, where the installation program provisions the underlying infrastructure for the cluster.

- [Installing a cluster on vSphere](#) You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure installation with no customization.
- [Installing a cluster on vSphere with customizations](#) You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure installation with the default customization options.
- [Installing a cluster on vSphere with network customizations](#) You can install OpenShift Container Platform on installer-provisioned vSphere infrastructure, with network customizations. You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.
- [Installing a cluster on vSphere in a restricted network](#) You can install a cluster on VMware vSphere infrastructure in a restricted network by creating an internal mirror of the installation release content. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

#### 21.1.4. User-provisioned infrastructure installation

You can install OpenShift Container Platform on vSphere by using user-provisioned infrastructure. User-provisioned infrastructure requires the user to provision all resources required by OpenShift

Container Platform. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

- [Installing a cluster on vSphere with user-provisioned infrastructure](#) You can install OpenShift Container Platform on VMware vSphere infrastructure that you provision.
- [Installing a cluster on vSphere with network customizations with user-provisioned infrastructure](#): You can install OpenShift Container Platform on VMware vSphere infrastructure that you provision with customized network configuration options.
- [Installing a cluster on vSphere in a restricted network with user-provisioned infrastructure](#) OpenShift Container Platform can be installed on VMware vSphere infrastructure that you provision in a restricted network.

### IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

#### 21.1.5. Additional resources

- [Installation process](#)

## 21.2. INSTALLER-PROVISIONED INFRASTRUCTURE

### 21.2.1. vSphere installation requirements

Before you begin an installation using installer-provisioned infrastructure, be sure that your vSphere environment meets the following installation requirements.

#### 21.2.1.1. VMware vSphere infrastructure requirements

You must install an OpenShift Container Platform cluster on one of the following versions of a VMware vSphere instance that meets the requirements for the components that you use:

- Version 7.0 Update 2 or later
- Version 8.0 Update 1 or later

Both of these releases support Container Storage Interface (CSI) migration, which is enabled by default on OpenShift Container Platform 4.14.

You can host the VMware vSphere infrastructure on-premise or on a [VMware Cloud Verified provider](#) that meets the requirements outlined in the following tables:

**Table 21.1. Version requirements for vSphere virtual environments**

| Virtual environment product | Required version |
|-----------------------------|------------------|
| VMware virtual hardware     | 15 or later      |

| Virtual environment product | Required version                             |
|-----------------------------|----------------------------------------------|
| vSphere ESXi hosts          | 7.0 Update 2 or later; 8.0 Update 1 or later |
| vCenter host                | 7.0 Update 2 or later; 8.0 Update 1 or later |

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.

**Table 21.2. Minimum supported vSphere version for VMware components**

| Component                    | Minimum supported versions                                                                          | Description                                                                                                                                                                                                                                                                                                            |
|------------------------------|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hypervisor                   | vSphere 7.0 Update 2 (or later) or vSphere 8.0 Update 1 (or later) with virtual hardware version 15 | This hypervisor version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see <a href="#">Hardware</a> on the Red Hat Customer Portal.               |
| Optional: Networking (NSX-T) | vSphere 7.0 Update 2 or later; vSphere 8.0 Update 1 or later                                        | At a minimum, vSphere 7.0 Update 2 or vSphere 8.0 Update 1 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware's <a href="#">NSX container plugin documentation</a> .                          |
| CPU micro-architecture       | x86-64-v2 or higher                                                                                 | OpenShift 4.13 and later are based on RHEL 9.2 host operating system which raised the microarchitecture requirements to x86-64-v2. See the <a href="#">RHEL Microarchitecture requirements documentation</a> . You can verify compatibility by following the procedures outlined in <a href="#">this KCS article</a> . |

**IMPORTANT**

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure (OCI) and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Base-production environment: 500 GB, and 60 VPUs.
- Heavy-use production environment: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See [Block Volume Performance Levels \(Oracle documentation\)](#).

**21.2.1.2. Network connectivity requirements**

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

**Table 21.3. Ports used for all-machine to all-machine communications**

| Protocol | Port               | Description                                                                                                                       |
|----------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| VRRP     | N/A                | Required for keepalived                                                                                                           |
| ICMP     | N/A                | Network reachability tests                                                                                                        |
| TCP      | <b>1936</b>        | Metrics                                                                                                                           |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> . |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                        |
|          | <b>10256</b>       | openshift-sdn                                                                                                                     |
| UDP      | <b>4789</b>        | virtual extensible LAN (VXLAN)                                                                                                    |
|          | <b>6081</b>        | Geneve                                                                                                                            |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                      |
|          | <b>500</b>         | IPsec IKE packets                                                                                                                 |

| Protocol | Port               | Description                                |
|----------|--------------------|--------------------------------------------|
|          | <b>4500</b>        | IPsec NAT-T packets                        |
| TCP/UDP  | <b>30000–32767</b> | Kubernetes node port                       |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP) |

**Table 21.4. Ports used for all-machine to control plane communications**

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

**Table 21.5. Ports used for control plane machine to control plane machine communications**

| Protocol | Port             | Description                |
|----------|------------------|----------------------------|
| TCP      | <b>2379–2380</b> | etcd server and peer ports |

### 21.2.1.3. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:

- VMware vSphere version: 7.0 Update 2 or later; 8.0 Update 1 or later
- vCenter version: 7.0 Update 2 or later; 8.0 Update 1 or later
- Virtual machines of hardware version 15 or later
- No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

#### NOTE

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with **platform: vsphere** in the installation manifest.

#### Additional resources

- To remove a third-party vSphere CSI driver, see [Removing a third-party vSphere CSI Driver](#).
- To update the hardware version for your vSphere nodes, see [Updating hardware on nodes running in vSphere](#).

### 21.2.1.4. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

### Required vCenter account privileges

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

#### Example 21.1. Roles and privileges required for installation in vSphere API

| vSphere object for role       | When required                              | Required privileges in vSphere API                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

Example 21.3. Required permissions and propagation settings

| vSphere object  | When required | Propagate to children | Permissions required       |
|-----------------|---------------|-----------------------|----------------------------|
| vSphere vCenter | Always        | False                 | Listed required privileges |

| vSphere object                         | When required                           | Propagate to children | Permissions required       |
|----------------------------------------|-----------------------------------------|-----------------------|----------------------------|
| vSphere vCenter Datacenter             | Existing folder                         | False                 | <b>ReadOnly</b> permission |
|                                        | Installation program creates the folder | True                  | Listed required privileges |
| vSphere vCenter Cluster                | Existing resource pool                  | False                 | <b>ReadOnly</b> permission |
|                                        | VMs in cluster root                     | True                  | Listed required privileges |
| vSphere vCenter Datastore              | Always                                  | False                 | Listed required privileges |
| vSphere Switch                         | Always                                  | False                 | <b>ReadOnly</b> permission |
| vSphere Port Group                     | Always                                  | False                 | Listed required privileges |
| vSphere vCenter Virtual Machine Folder | Existing folder                         | True                  | Listed required privileges |
| vSphere vCenter Resource Pool          | Existing resource pool                  | True                  | Listed required privileges |

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- Using Storage vMotion can cause issues and is not supported.
- Using VMware compute vMotion to migrate the workloads for both OpenShift Container Platform compute machines and control plane machines is generally supported, where *generally* implies that you meet all VMware best practices for vMotion.  
To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for [vMotion networking requirements](#) and [VM anti-affinity rules](#).

- If you are using VMware vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.
- OpenShift Container Platform does not support selective migration of VMDKs across

datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

## IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

## Cluster resources

When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

## Cluster limits

Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

## Networking requirements

Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

**NOTE**

You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.

Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

If you are installing to a restricted environment, the VM in your restricted network must have access to vCenter so that it can provision and manage nodes, persistent volume claims (PVCs), and other resources.

Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**

For a network that uses DHCP, an installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, **<cluster\_name>** is the cluster name and **<base\_domain>** is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: **<component>.<cluster\_name>.<base\_domain>..**

**Table 21.6. Required DNS records**

| Component | Record | Description |
|-----------|--------|-------------|
|-----------|--------|-------------|

| Component   | Record                                                  | Description                                                                                                                                                                                                                                                                                 |
|-------------|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| API VIP     | <b>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>    | This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.                                                                           |
| Ingress VIP | <b>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b> | A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster. |

### Static IP addresses for vSphere nodes

You can provision bootstrap, control plane, and compute nodes to be configured with static IP addresses in environments where Dynamic Host Configuration Protocol (DHCP) does not exist. To configure this environment, you must provide values to the **platform.vsphere.hosts.role** parameter in the **install-config.yaml** file.

### IMPORTANT

Static IP addresses for vSphere nodes is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

By default, the installation program is configured to use the DHCP for the network, but this network has limited configurable capabilities.

After you define one or more machine pools in your **install-config.yaml** file, you can define network definitions for nodes on your network. Ensure that the number of network definitions matches the number of machine pools that you configured for your cluster.

### Example network configuration that specifies different roles

```
...
```

```

platform:
vsphere:
 hosts:
 - role: bootstrap ❶
 networkDevice:
 ipAddrs:
 - 192.168.204.10/24 ❷
 gateway: 192.168.204.1 ❸
 nameservers: ❹
 - 192.168.204.1
 - role: control-plane
 networkDevice:
 ipAddrs:
 - 192.168.204.11/24
 gateway: 192.168.204.1
 nameservers:
 - 192.168.204.1
 - role: control-plane
 networkDevice:
 ipAddrs:
 - 192.168.204.12/24
 gateway: 192.168.204.1
 nameservers:
 - 192.168.204.1
 - role: control-plane
 networkDevice:
 ipAddrs:
 - 192.168.204.13/24
 gateway: 192.168.204.1
 nameservers:
 - 192.168.204.1
 - role: compute
 networkDevice:
 ipAddrs:
 - 192.168.204.14/24
 gateway: 192.168.204.1
 nameservers:
 - 192.168.204.1
...

```

- ❶ Valid network definition values include **bootstrap**, **control-plane**, and **compute**. You must list at least one **bootstrap** network definition in your **install-config.yaml** configuration file.
- ❷ Lists IPv4, IPv6, or both IP addresses that the installation program passes to the network interface. The machine API controller assigns all configured IP addresses to the default network interface.
- ❸ The default gateway for the network interface.
- ❹ Lists up to 3 DNS nameservers.

## IMPORTANT

To enable the Technology Preview feature of static IP addresses for vSphere nodes for your cluster, you must include **featureSet:TechPreviewNoUpgrade** as the initial entry in the **install-config.yaml** file.

After you deployed your cluster to run nodes with static IP addresses, you can scale a machine to use one of these static IP addresses. Additionally, you can use a machine set to configure a machine to use one of the configured static IP addresses.

#### Additional resources

- [Scaling machines to use static IP addresses](#)
- [Using a machine set to scale machines with configured static IP addresses](#)

### 21.2.2. Preparing to install a cluster using installer-provisioned infrastructure

You prepare to install an OpenShift Container Platform cluster on vSphere by completing the following steps:

- Downloading the installation program.

#### NOTE

If you are installing in a disconnected environment, you extract the installation program from the mirrored content. For more information, see [Mirroring images for a disconnected installation](#).

- Installing the OpenShift CLI (**oc**).

#### NOTE

If you are installing in a disconnected environment, install **oc** to the mirror host.

- Generating an SSH key pair. You can use this key pair to authenticate into the OpenShift Container Platform cluster's nodes after it is deployed.
- Adding your vCenter's trusted root CA certificates to your system trust.

#### 21.2.2.1. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 21.2.2.2. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**. To check your **PATH**, execute the following command:

```
$ echo $PATH
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

## Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

### 21.2.2.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **`./openshift-install gather`** command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

1

Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

#### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

#### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

#### 21.2.2.4. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter's API, you must add your vCenter's trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

## Procedure

1. From the vCenter home page, download the vCenter's root CA certificates. Click **Download trusted root CA certificates** in the vSphere Web Services SDK section. The **<vCenter>/certs/download.zip** file downloads.
2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

```

certs
├── lin
│ ├── 108f4d17.0
│ ├── 108f4d17.r1
│ ├── 7e757f6a.0
│ ├── 8e4f8471.0
│ └── 8e4f8471.r0
├── mac
│ ├── 108f4d17.0
│ ├── 108f4d17.r1
│ ├── 7e757f6a.0
│ ├── 8e4f8471.0
│ └── 8e4f8471.r0
└── win
 ├── 108f4d17.0.crt
 ├── 108f4d17.r1.crl
 ├── 7e757f6a.0.crt
 ├── 8e4f8471.0.crt
 └── 8e4f8471.r0.crl

```

3 directories, 15 files

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
update-ca-trust extract
```

### 21.2.3. Installing a cluster on vSphere

In OpenShift Container Platform version 4.14, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

**21.2.3.1. Prerequisites**

- You have completed the tasks in [Preparing to install a cluster using installer-provisioned infrastructure](#).
- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You provisioned [persistent storage](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

**21.2.3.2. Internet access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 21.2.3.3. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
- Optional: Before you create the cluster, configure an external load balancer in place of the default load balancer.

#### IMPORTANT

You do not need to specify API and Ingress static addresses for your installation program. If you choose this configuration, you must take additional actions to define network targets that accept an IP address from each referenced vSphere subnet. See the section "Configuring an external load balancer".

#### Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
  - The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GCLOUD\_KEYFILE\_JSON** environment variables
  - The `~/gcp/osServiceAccount.json` file
  - The **gcloud cli** default credentials
2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

3. Provide values at the prompts:

- a. Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- b. Select **aws** as the platform to target.

- c. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

#### NOTE

The AWS access key ID and secret access key are stored in **~/.aws/credentials** in the home directory of the current user on the installation host. You are prompted for the credentials by the installation program if the credentials for the exported profile are not present in the file. Any credentials that you provide to the installation program are stored in the file.

- d. Select the AWS region to deploy the cluster to.
- e. Select the base domain for the Route 53 service that you configured for your cluster.
- f. Select **gcp** as the platform to target.
- g. If you have not configured the service account key for your GCP account on your host, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
- h. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
- i. Select the region to deploy the cluster to.
- j. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
- k. Select **vsphere** as the platform to target.
- l. Specify the name of your vCenter instance.
- m. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

The installation program connects to your vCenter instance.

### IMPORTANT

Some VMware vCenter Single Sign-On (SSO) environments with Active Directory (AD) integration might primarily require you to use the traditional login method, which requires the `<domain>\` construct.

To ensure that vCenter account permission checks complete properly, consider using the User Principal Name (UPN) login method, such as `<username>@<fully_qualified_domainname>`.

- n. Select the data center in your vCenter instance to connect to.
- o. Select the default vCenter datastore to use.

### NOTE

Datastore and cluster names cannot exceed 60 characters; therefore, ensure the combined string length does not exceed the 60 character limit.

- p. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.
- q. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.
- r. Enter the virtual IP address that you configured for control plane API access.
- s. Enter the virtual IP address that you configured for cluster ingress.
- t. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.
- u. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

### NOTE

Datastore and cluster names cannot exceed 60 characters; therefore, ensure the combined string length does not exceed the 60 character limit.

If you provide a name that is longer than 6 characters, only the first 6 characters will be used in the infrastructure ID that is generated from the cluster name.

- v. Paste the [pull secret from Red Hat OpenShift Cluster Manager](#) .
4. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.

**NOTE**

The elevated permissions provided by the **AdministratorAccess** policy are required only during installation.

5. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
  - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

#### 21.2.3.4. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

##### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

##### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

##### Example output

```
system:admin
```

#### 21.2.3.5. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

##### 21.2.3.5.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**. When this has completed, you must configure storage.

##### 21.2.3.5.2. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

### 21.2.3.5.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

#### IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

#### IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

#### Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

#### NOTE

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

#### Example output

No resources found in openshift-image-registry namespace

#### NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

#### Example output

```
storage:
 pvc:
 claim: 1
```

- 1** Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

#### Example output

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED |
|----------------|---------|-----------|-------------|----------|
| image-registry | 4.7     | True      | False       | False    |

#### 21.2.3.5.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

#### IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

#### Procedure

1. Enter the following command to set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy, and runs with only **1** replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
  - a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: image-registry-storage ❶
 namespace: openshift-image-registry ❷
spec:
 accessModes:
 - ReadWriteOnce ❸
 resources:
 requests:
 storage: 100Gi ❹
```

- ❶ A unique name that represents the **PersistentVolumeClaim** object.
- ❷ The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
- ❸ The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
- ❹ The size of the persistent volume claim.

- b. Enter the following command to create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Enter the following command to edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

### Example output

```
storage:
 pvc:
 claim: ❶
```

- ❶ By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

## 21.2.3.6. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 21.2.3.7. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).
- Optional: [View the events from the vSphere Problem Detector Operator](#) to determine if the cluster has permission or storage configuration issues.

## 21.2.4. Installing a cluster on vSphere with customizations

In OpenShift Container Platform version 4.14, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

### NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

### 21.2.4.1. Prerequisites

- You have completed the tasks in [Preparing to install a cluster using installer-provisioned infrastructure](#).
- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You provisioned [persistent storage](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

#### 21.2.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

#### 21.2.4.3. VMware vSphere region and zone enablement

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

**IMPORTANT**

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature is only available on a newly installed cluster.

For a cluster that was upgraded from a previous release, you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default **install-config.yaml** file includes **vccenters** and **failureDomains** fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- **Failure domain:** Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- **Region:** Specifies a vCenter datacenter. You define a region by using a tag from the **openshift-region** tag category.
- **Zone:** Specifies a vCenter cluster. You define a zone by using a tag from the **openshift-zone** tag category.

## NOTE

If you plan on specifying more than one failure domain in your **install-config.yaml** file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster that runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
| us-east             | us-east-1      | us-east-1a |
|                     |                | us-east-1b |
|                     | us-east-2      | us-east-2a |
|                     |                | us-east-2b |
| us-west             | us-west-1      | us-west-1a |
|                     |                | us-west-1b |
|                     | us-west-2      | us-west-2a |
|                     |                | us-west-2b |

- [vSphere automatic migration](#)

- [VMware vSphere CSI Driver Operator](#)

#### 21.2.4.4. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS). Google Cloud Platform (GCP). VMware vSphere.

##### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

##### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

##### NOTE

Always delete the **~/powers** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powers
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

##### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **AWS** as the platform to target.
- iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.
- iv. Select the AWS region to deploy the cluster to.
- v. Select the base domain for the Route 53 service that you configured for your cluster.
- vi. Select **gcp** as the platform to target.
- vii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
- viii. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
- ix. Select the region to deploy the cluster to.
- x. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
- xi. Select **vsphere** as the platform to target.
- xii. Specify the name of your vCenter instance.
- xiii. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.  
The installation program connects to your vCenter instance.
- xiv. Select the data center in your vCenter instance to connect to.

#### NOTE

After you create the installation configuration file, you can modify the file to create a multiple vSphere datacenters environment. This means that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. For more information about creating this environment, see the section named *VMware vSphere region and zone enablement*.

- xv. Select the default vCenter datastore to use.

**WARNING**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

You cannot specify more than one datastore path. If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- xvi. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.
  - xvii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.
  - xviii. Enter the virtual IP address that you configured for control plane API access.
  - xix. Enter the virtual IP address that you configured for cluster ingress.
  - xx. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.
  - xxi. Enter a descriptive name for your cluster.  
The cluster name you enter must match the cluster name you specified when configuring the DNS records.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.

**NOTE**

If you are installing a three-node cluster, be sure to set the **compute.replicas** parameter to **0**. This ensures that the cluster's control planes are schedulable. For more information, see "Installing a three-node cluster on vSphere".

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

**IMPORTANT**

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- [Installation configuration parameters](#)

#### 21.2.4.4.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```

apiVersion: v1
baseDomain: example.com ❶
compute: ❷
- architecture: amd64
 name: <worker_node>
 platform: {}
 replicas: 3
controlPlane: ❸
 architecture: amd64
 name: <parent_node>
 platform: {}
 replicas: 3
metadata:
 creationTimestamp: null
 name: test ❹
platform:
 vsphere: ❺
 apiVIPs:
 - 10.0.0.1
 failureDomains: ❻
 - name: <failure_domain_name>
 region: <default_region_name>
 server: <fully_qualified_domain_name>
 topology:
 computeCluster: "/<datacenter>/host/<cluster>"
 datacenter: <datacenter>
 datastore: "/<datacenter>/datastore/<datastore>" ❼
 networks:
 - <VM_Network_name>
 resourcePool: "/<datacenter>/host/<cluster>/Resources/<resourcePool>" ❽
 folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>"
 zone: <default_zone_name>
 ingressVIPs:
 - 10.0.0.2
 vcenters:
 - datacenters:
 - <datacenter>
 password: <password>
 port: 443
 server: <fully_qualified_domain_name>
 user: administrator@vsphere.local
 diskType: thin ❾
 fips: false
 pullSecret: '{"auths": ...}'
 sshKey: 'ssh-ed25519 AAAA...'

```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
- 2 3 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 4 The cluster name that you specified in your DNS records.
- 5 Optional: Provides additional configuration for the machine pool parameters for the compute and control plane machines.
- 6 Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- 7 The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

### IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- 8 Optional: Provides an existing resource pool for machine creation. If you do not specify a value, the installation program uses the root resource pool of the vSphere cluster.
- 9 The vSphere disk provisioning method.

### NOTE

In OpenShift Container Platform 4.12 and later, the **apiVIP** and **ingressVIP** configuration settings are deprecated. Instead, use a list format to enter values in the **apiVIPs** and **ingressVIPs** configuration settings.

#### 21.2.4.4.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to

bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.
 <aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations. If you have added the Amazon **EC2**, **Elastic Load Balancing**, and **S3** VPC endpoints to your VPC, you must add these endpoints to the **noProxy** field. You must include vCenter's IP address and the IP range that you use for its machines.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 21.2.4.4.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default **install-config.yaml** file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the **openshift-installer** will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

**IMPORTANT**

The example uses the **govc** command. The **govc** command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the **govc** command. Instructions for downloading and installing **govc** are found on the VMware documentation website

### Prerequisites

- You have an existing **install-config.yaml** installation configuration file.

**IMPORTANT**

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

### Procedure

1. Enter the following **govc** command-line tool commands to create the **openshift-region** and **openshift-zone** vCenter tag categories:

### IMPORTANT

If you specify different names for the **openshift-region** and **openshift-zone** vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

```
$ govc tags.category.create -d "OpenShift region" openshift-region
```

```
$ govc tags.category.create -d "OpenShift zone" openshift-zone
```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

```
$ govc tags.create -c <region_tag_category> <region_tag>
```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
```

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

### Sample install-config.yaml file with multiple datacenters defined in a vSphere center

```

compute:

 vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

controlPlane:

 vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

```

```

platform:
 vsphere:
 vcenters:

 datacenters:
 - <datacenter1_name>
 - <datacenter2_name>
 failureDomains:
 - name: <machine_pool_zone_1>
 region: <region_tag_1>
 zone: <zone_tag_1>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter1>
 computeCluster: "/<datacenter1>/host/<cluster1>"
 networks:
 - <VM_Network1_name>
 datastore: "/<datacenter1>/datastore/<datastore1>"
 resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
 folder: "/<datacenter1>/vm/<folder1>"
 - name: <machine_pool_zone_2>
 region: <region_tag_2>
 zone: <zone_tag_2>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter2>
 computeCluster: "/<datacenter2>/host/<cluster2>"
 networks:
 - <VM_Network2_name>
 datastore: "/<datacenter2>/datastore/<datastore2>"
 resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
 folder: "/<datacenter2>/vm/<folder2>"

```

#### 21.2.4.5. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
- Optional: Before you create the cluster, configure an external load balancer in place of the default load balancer.

## IMPORTANT

You do not need to specify API and Ingress static addresses for your installation program. If you choose this configuration, you must take additional actions to define network targets that accept an IP address from each referenced vSphere subnet. See the section "Configuring an external load balancer".

## Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
  - The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GKLOUD\_KEYFILE\_JSON** environment variables
  - The `~/gcp/osServiceAccount.json` file
  - The **gcloud cli** default credentials
2. Change to the directory that contains the installation program and initialize the cluster deployment:
  - Change to the directory that contains the installation program and initialize the cluster deployment:
 

```
$./openshift-install create cluster --dir <installation_directory> \ 1
 --log-level=info 2
```

    - 1 For **<installation\_directory>**, specify the location of your customized `./install-config.yaml` file.
    - 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.
3. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.

## NOTE

The elevated permissions provided by the **AdministratorAccess** policy are required only during installation.

4. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
  - If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
  - If you included the **Service Account Key Admin** role, you can remove it.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

- Credential information also outputs to `<installation_directory>/openshift_install.log`.

## IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 21.2.4.6. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

### 21.2.4.7. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

#### 21.2.4.7.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**. When this has completed, you must configure storage.

#### 21.2.4.7.2. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

##### 21.2.4.7.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

**NOTE**

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

**Example output**

```
No resources found in openshift-image-registry namespace
```

**NOTE**

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

**Example output**

```
storage:
 pvc:
 claim: ❶
```

- ❶ Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

### Example output

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED |
|----------------|---------|-----------|-------------|----------|
| image-registry | 4.7     | True      | False       | False    |

#### 21.2.4.7.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

### IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

### Procedure

1. Enter the following command to set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy, and runs with only **1** replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
  - a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: image-registry-storage ❶
 namespace: openshift-image-registry ❷
spec:
 accessModes:
```

```
- ReadWriteOnce 3
resources:
 requests:
 storage: 100Gi 4
```

- 1** A unique name that represents the **PersistentVolumeClaim** object.
- 2** The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
- 3** The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
- 4** The size of the persistent volume claim.

b. Enter the following command to create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Enter the following command to edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

### Example output

```
storage:
 pvc:
 claim: 1
```

- 1** By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

#### 21.2.4.8. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

#### 21.2.4.9. Services for an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

## IMPORTANT

Configuring an external load balancer depends on your vendor's load balancer.

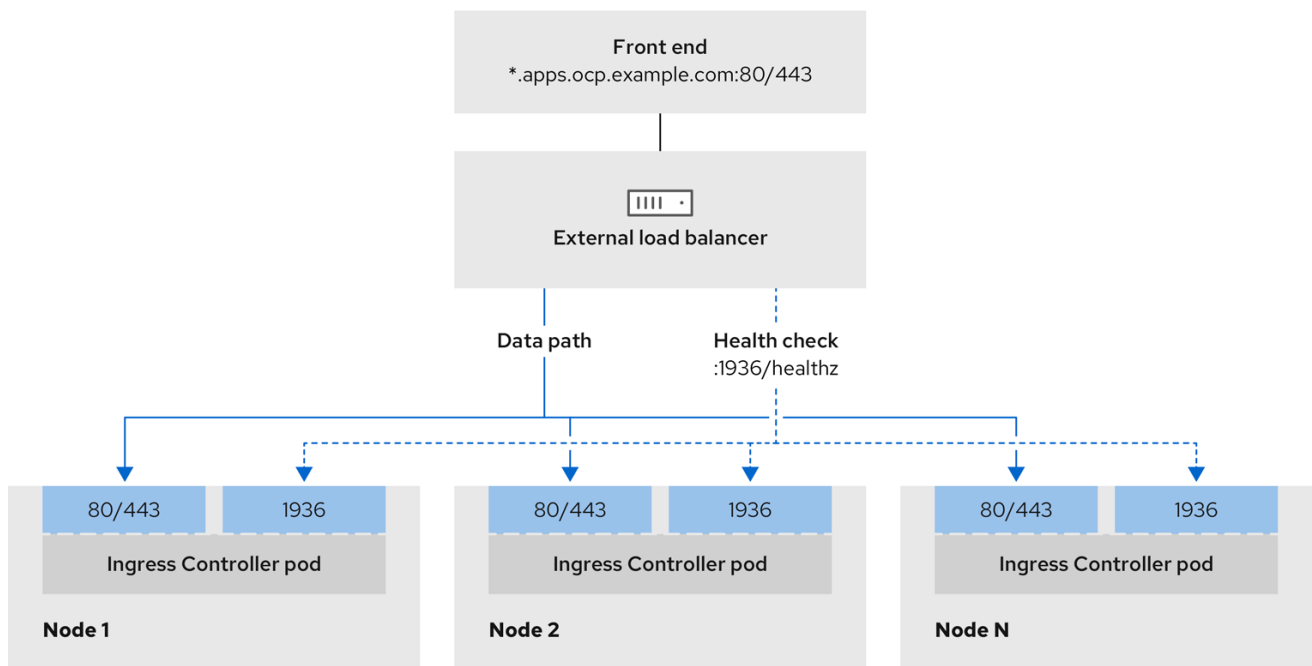

The information and examples in this section are for guideline purposes only. Consult the vendor documentation for more specific information about the vendor's load balancer.

Red Hat supports the following services for an external load balancer:

- Ingress Controller
- OpenShift API
- OpenShift MachineConfig API

You can choose whether you want to configure one or all of these services for an external load balancer. Configuring only the Ingress Controller service is a common configuration option. To better understand each service, view the following diagrams:

**Figure 21.1. Example network workflow that shows an Ingress Controller operating in an OpenShift Container Platform environment**

496\_OpenShift\_1223

Figure 21.2. Example network workflow that shows an OpenShift API operating in an OpenShift Container Platform environment

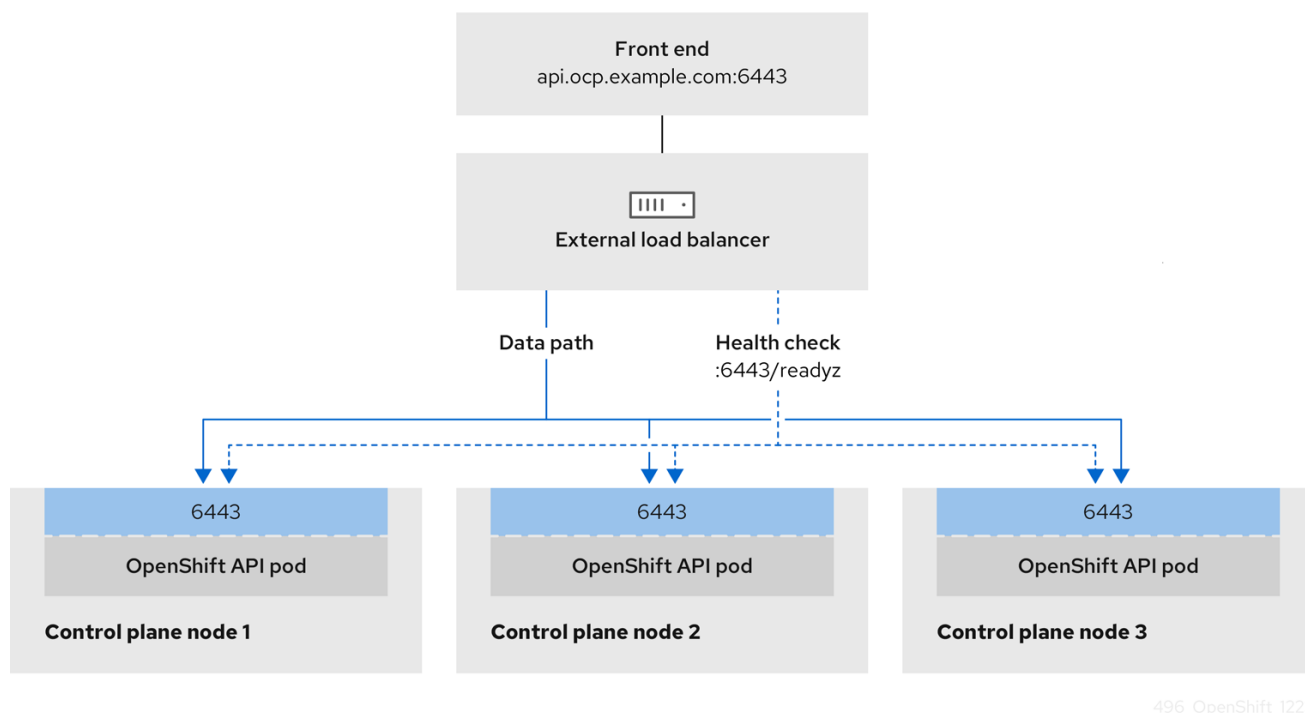

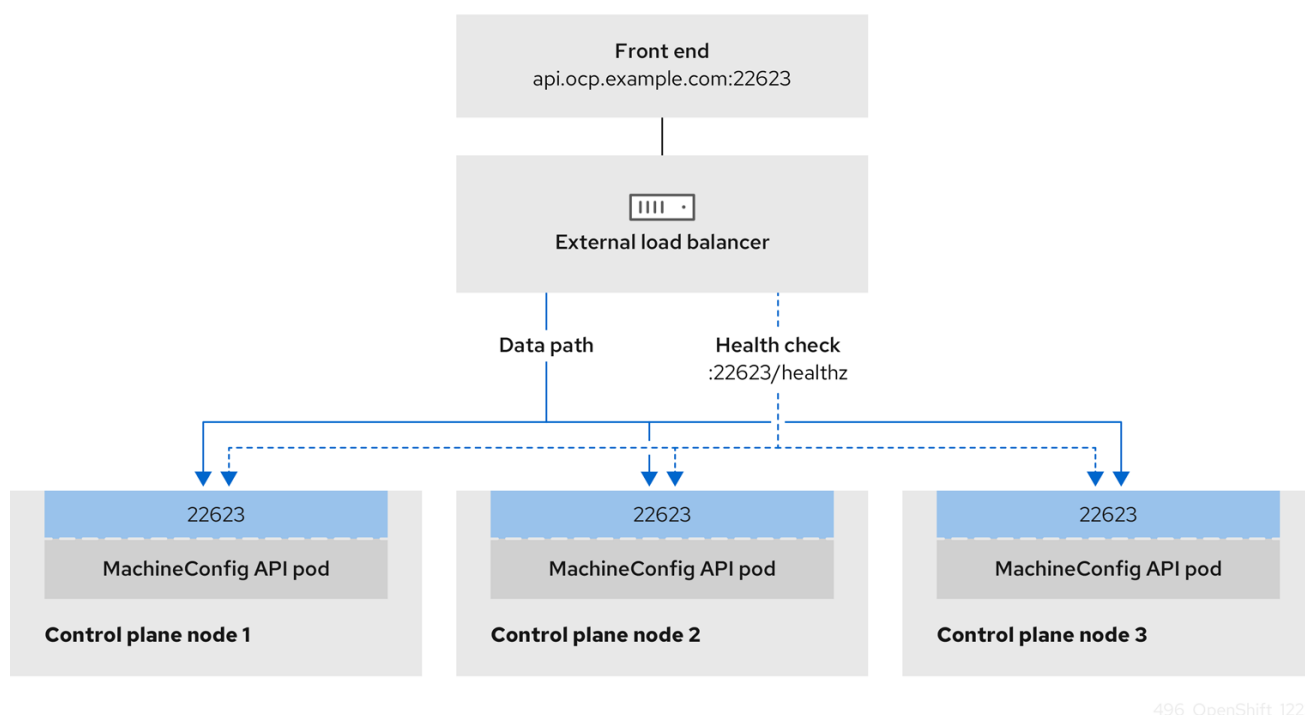

Figure 21.3. Example network workflow that shows an OpenShift MachineConfig API operating in an OpenShift Container Platform environment

The following configuration options are supported for external load balancers:

- Use a node selector to map the Ingress Controller to a specific set of nodes. You must assign a static IP address to each node in this set, or configure each node to receive the same IP address from the Dynamic Host Configuration Protocol (DHCP). Infrastructure nodes commonly receive this type of configuration.

- Target all IP addresses on a subnet. This configuration can reduce maintenance overhead, because you can create and destroy nodes within those networks without reconfiguring the load balancer targets. If you deploy your ingress pods by using a machine set on a smaller network, such as a /27 or /28, you can simplify your load balancer targets.

### TIP

You can list all IP addresses that exist in a network by checking the machine config pool's resources.

Before you configure an external load balancer for your OpenShift Container Platform cluster, consider the following information:

- For a front-end IP address, you can use the same IP address for the front-end IP address, the Ingress Controller's load balancer, and API load balancer. Check the vendor's documentation for this capability.
- For a back-end IP address, ensure that an IP address for an OpenShift Container Platform control plane node does not change during the lifetime of the external load balancer. You can achieve this by completing one of the following actions:
  - Assign a static IP address to each control plane node.
  - Configure each node to receive the same IP address from the DHCP every time the node requests a DHCP lease. Depending on the vendor, the DHCP lease might be in the form of an IP reservation or a static DHCP assignment.
- Manually define each node that runs the Ingress Controller in the external load balancer for the Ingress Controller back-end service. For example, if the Ingress Controller moves to an undefined node, a connection outage can occur.

#### 21.2.4.9.1. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

### IMPORTANT

Before you configure an external load balancer, ensure that you read the "Services for an external load balancer" section.

Read the following prerequisites that apply to the service that you want to configure for your external load balancer.

### NOTE

MetalLB, that runs on a cluster, functions as an external load balancer.

#### OpenShift API prerequisites

- You defined a front-end IP address.
- TCP ports 6443 and 22623 are exposed on the front-end IP address of your load balancer. Check the following items:

- Port 6443 provides access to the OpenShift API service.
- Port 22623 can provide ignition startup configurations to nodes.
- The front-end IP address and port 6443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address and port 22623 are reachable only by OpenShift Container Platform nodes.
- The load balancer backend can communicate with OpenShift Container Platform control plane nodes on port 6443 and 22623.

### Ingress Controller prerequisites

- You defined a front-end IP address.
- TCP ports 443 and 80 are exposed on the front-end IP address of your load balancer.
- The front-end IP address, port 80 and port 443 are be reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address, port 80 and port 443 are reachable to all nodes that operate in your OpenShift Container Platform cluster.
- The load balancer backend can communicate with OpenShift Container Platform nodes that run the Ingress Controller on ports 80, 443, and 1936.

### Prerequisite for health check URL specifications

You can configure most load balancers by setting health check URLs that determine if a service is available or unavailable. OpenShift Container Platform provides these health checks for the OpenShift API, Machine Configuration API, and Ingress Controller backend services.

The following examples demonstrate health check specifications for the previously listed backend services:

#### Example of a Kubernetes API health check specification

```
Path: HTTPS:6443/readyz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```

#### Example of a Machine Config API health check specification

```
Path: HTTPS:22623/healthz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```

#### Example of an Ingress Controller health check specification

```
Path: HTTP:1936/healthz/ready
```

Healthy threshold: 2  
 Unhealthy threshold: 2  
 Timeout: 5  
 Interval: 10

## Procedure

1. Configure the HAProxy Ingress Controller, so that you can enable access to the cluster from your load balancer on ports 6443, 443, and 80:

### Example HAProxy configuration

```
#...
listen my-cluster-api-6443
 bind 192.168.1.100:6443
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /readyz
 http-check expect status 200
 server my-cluster-master-2 192.168.1.101:6443 check inter 10s rise 2 fall 2
 server my-cluster-master-0 192.168.1.102:6443 check inter 10s rise 2 fall 2
 server my-cluster-master-1 192.168.1.103:6443 check inter 10s rise 2 fall 2

listen my-cluster-machine-config-api-22623
 bind 192.168.1.100:22623
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /healthz
 http-check expect status 200
 server my-cluster-master-2 192.168.1.101:22623 check inter 10s rise 2 fall 2
 server my-cluster-master-0 192.168.1.102:22623 check inter 10s rise 2 fall 2
 server my-cluster-master-1 192.168.1.103:22623 check inter 10s rise 2 fall 2

listen my-cluster-apps-443
 bind 192.168.1.100:443
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /healthz/ready
 http-check expect status 200
 server my-cluster-worker-0 192.168.1.111:443 check port 1936 inter 10s rise 2 fall 2
 server my-cluster-worker-1 192.168.1.112:443 check port 1936 inter 10s rise 2 fall 2
 server my-cluster-worker-2 192.168.1.113:443 check port 1936 inter 10s rise 2 fall 2

listen my-cluster-apps-80
 bind 192.168.1.100:80
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
```

```

http-check send meth GET uri /healthz/ready
http-check expect status 200
server my-cluster-worker-0 192.168.1.111:80 check port 1936 inter 10s rise 2 fall 2
server my-cluster-worker-1 192.168.1.112:80 check port 1936 inter 10s rise 2 fall 2
server my-cluster-worker-2 192.168.1.113:80 check port 1936 inter 10s rise 2 fall 2
...

```

2. Use the **curl** CLI command to verify that the external load balancer and its resources are operational:

- a. Verify that the cluster machine configuration API is accessible to the Kubernetes API server resource, by running the following command and observing the response:

```
$ curl https://<loadbalancer_ip_address>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```

{
 "major": "1",
 "minor": "11+",
 "gitVersion": "v1.11.0+ad103ed",
 "gitCommit": "ad103ed",
 "gitTreeState": "clean",
 "buildDate": "2019-01-09T06:44:10Z",
 "goVersion": "go1.10.3",
 "compiler": "gc",
 "platform": "linux/amd64"
}

```

- b. Verify that the cluster machine configuration API is accessible to the Machine config server resource, by running the following command and observing the output:

```
$ curl -v https://<loadbalancer_ip_address>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```

HTTP/1.1 200 OK
Content-Length: 0

```

- c. Verify that the controller is accessible to the Ingress Controller resource on port 80, by running the following command and observing the output:

```
$ curl -I -L -H "Host: console-openshift-console.apps.<cluster_name>.<base_domain>"
http://<load_balancer_front_end_IP_address>
```

If the configuration is correct, the output from the command shows the following response:

```

HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.ocp4.private.opequon.net/
cache-control: no-cache

```

- d. Verify that the controller is accessible to the Ingress Controller resource on port 443 by

- a. verify that the controller is accessible to the ingress Controller resource on port 443, by running the following command and observing the output:

```
$ curl -I -L --insecure --resolve console-openshift-console.apps.<cluster_name>.
<base_domain>:443:<Load Balancer Front End IP Address> https://console-openshift-
console.apps.<cluster_name>.<base_domain>
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-
token=UIYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG
LgaYO0nxzVERhiXt6QepA7g==; Path=/; Secure; SameSite=Lax
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Wed, 04 Oct 2023 16:29:38 GMT
content-type: text/html; charset=utf-8
set-cookie:
1e2670d92730b515ce3a1bb65da45062=1bf5e9573c9a2760c964ed1659cc1673; path=/
HttpOnly; Secure; SameSite=None
cache-control: private
```

3. Configure the DNS records for your cluster to target the front-end IP addresses of the external load balancer. You must update records to your DNS server for the cluster API and applications over the load balancer.

### Examples of modified DNS records

```
<load_balancer_ip_address> A api.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End
```

```
<load_balancer_ip_address> A apps.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End
```

### IMPORTANT

DNS propagation might take some time for each DNS record to become available. Ensure that each DNS record propagates before validating each record.

4. Use the **curl** CLI command to verify that the external load balancer and DNS record configuration are operational:
  - a. Verify that you can access the cluster API, by running the following command and observing the output:

```
$ curl https://api.<cluster_name>.<base_domain>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```
{
 "major": "1",
 "minor": "11+",
 "gitVersion": "v1.11.0+ad103ed",
 "gitCommit": "ad103ed",
 "gitTreeState": "clean",
 "buildDate": "2019-01-09T06:44:10Z",
 "goVersion": "go1.10.3",
 "compiler": "gc",
 "platform": "linux/amd64"
}
```

- b. Verify that you can access the cluster machine configuration, by running the following command and observing the output:

```
$ curl -v https://api.<cluster_name>.<base_domain>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

- c. Verify that you can access each cluster application on port, by running the following command and observing the output:

```
$ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.<cluster-name>.<base domain>/
cache-control: no-cacheHTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-
token=39HoZgztDnzjJkq/JuLJMeoKNXIfiVv2YgZc09c3TBOBU4NI6kDXaJH1LdicNhN1UsQ

cache-control: private
```

- d. Verify that you can access each cluster application on port 443, by running the following command and observing the output:

```
$ curl https://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-
token=UIYW0yQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG

#### 21.2.4.10. Next steps

- [Customize your cluster.](#)
- If necessary, you can [opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).
- Optional: [View the events from the vSphere Problem Detector Operator](#) to determine if the cluster has permission or storage configuration issues.

### 21.2.5. Installing a cluster on vSphere with network customizations

In OpenShift Container Platform version 4.14, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. To customize the installation, you modify parameters in the **install-config.yaml** file before you install the cluster.

You must set most of the network configuration parameters during installation, and you can modify only **kubeProxy** configuration parameters in a running cluster.

#### NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

#### 21.2.5.1. Prerequisites

- You have completed the tasks in [Preparing to install a cluster using installer-provisioned infrastructure](#).
- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.

- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You provisioned [persistent storage](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, confirm with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 21.2.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 21.2.5.3. VMware vSphere region and zone enablement

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

## IMPORTANT

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature is only available on a newly installed cluster.

For a cluster that was upgraded from a previous release, you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default **install-config.yaml** file includes **vcenters** and **failureDomains** fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- **Failure domain:** Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- **Region:** Specifies a vCenter datacenter. You define a region by using a tag from the **openshift-region** tag category.
- **Zone:** Specifies a vCenter cluster. You define a zone by using a tag from the **openshift-zone** tag category.

## NOTE

If you plan on specifying more than one failure domain in your **install-config.yaml** file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster that runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
| us-east             | us-east-1      | us-east-1a |
|                     |                | us-east-1b |
|                     | us-east-2      | us-east-2a |
|                     |                | us-east-2b |

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
| us-west             | us-west-1      | us-west-1a |
|                     |                | us-west-1b |
|                     | us-west-2      | us-west-2a |
|                     |                | us-west-2b |

#### 21.2.5.4. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS). Google Cloud Platform (GCP). VMware vSphere.

### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them

into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **AWS** as the platform to target.
- iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.
- iv. Select the AWS region to deploy the cluster to.
- v. Select the base domain for the Route 53 service that you configured for your cluster.
- vi. Select **gcp** as the platform to target.
- vii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
- viii. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
- ix. Select the region to deploy the cluster to.
- x. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
- xi. Select **vsphere** as the platform to target.
- xii. Specify the name of your vCenter instance.
- xiii. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.  
The installation program connects to your vCenter instance.
- xiv. Select the data center in your vCenter instance to connect to.

**NOTE**

After you create the installation configuration file, you can modify the file to create a multiple vSphere datacenters environment. This means that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. For more information about creating this environment, see the section named *VMware vSphere region and zone enablement*.

- xv. Select the default vCenter datastore to use.

**WARNING**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

You cannot specify more than one datastore path. If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- xvi. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.
  - xvii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.
  - xviii. Enter the virtual IP address that you configured for control plane API access.
  - xix. Enter the virtual IP address that you configured for cluster ingress.
  - xx. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.
  - xxi. Enter a descriptive name for your cluster.  
The cluster name you enter must match the cluster name you specified when configuring the DNS records.
2. Modify the **install-config.yaml** file. You can find more information about the available parameters in the "Installation configuration parameters" section.
  3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

## IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### Additional resources

- [Installation configuration parameters](#)

#### 21.2.5.4.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com ❶
compute: ❷
- architecture: amd64
 name: <worker_node>
 platform: {}
 replicas: 3
controlPlane: ❸
 architecture: amd64
 name: <parent_node>
 platform: {}
 replicas: 3
metadata:
 creationTimestamp: null
 name: test ❹
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 machineNetwork:
 - cidr: 10.0.0.0/16
 networkType: OVNKubernetes ❺
 serviceNetwork:
 - 172.30.0.0/16
platform:
 vsphere: ❻
 apiVIPs:
 - 10.0.0.1
 failureDomains: ❼
 - name: <failure_domain_name>
 region: <default_region_name>
 server: <fully_qualified_domain_name>
 topology:
 computeCluster: "/<datacenter>/host/<cluster>"
 datacenter: <datacenter>
 datastore: "/<datacenter>/datastore/<datastore>" ❽
 networks:
 - <VM_Network_name>
 resourcePool: "/<datacenter>/host/<cluster>/Resources/<resourcePool>" ❾
 folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>"
```

```

 zone: <default_zone_name>
 ingressVIPs:
 - 10.0.0.2
 vcenters:
 - datacenters:
 - <datacenter>
 password: <password>
 port: 443
 server: <fully_qualified_domain_name>
 user: administrator@vsphere.local
 diskType: thin 10
 fips: false
 pullSecret: '{"auths": ...}'
 sshKey: 'ssh-ed25519 AAAA...'

```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
- 2 3 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 4 The cluster name that you specified in your DNS records.
- 6 Optional: Provides additional configuration for the machine pool parameters for the compute and control plane machines.
- 7 Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- 8 The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

### IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- 9 Optional: Provides an existing resource pool for machine creation. If you do not specify a value, the installation program uses the root resource pool of the vSphere cluster.
- 10 The vSphere disk provisioning method.
- 5 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

## NOTE

In OpenShift Container Platform 4.12 and later, the **apiVIP** and **ingressVIP** configuration settings are deprecated. Instead, use a list format to enter values in the **apiVIPs** and **ingressVIPs** configuration settings.

### 21.2.5.4.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> ❶
 httpsProxy: https://<username>:<pswd>@<ip>:<port> ❷
 noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.
 <aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com ❸
 additionalTrustBundle: | ❹
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ❺
```

- ❶ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- ❷ A proxy URL to use for creating HTTPS connections outside the cluster.

- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 21.2.5.4.3. Optional: Deploying with dual-stack networking

For dual-stack networking in OpenShift Container Platform clusters, you can configure IPv4 and IPv6 address endpoints for cluster nodes. To configure IPv4 and IPv6 address endpoints for cluster nodes, edit the **machineNetwork**, **clusterNetwork**, and **serviceNetwork** configuration settings in the **install-config.yaml** file. Each setting must have two CIDR entries each. For a cluster with the IPv4 family as the primary address family, specify the IPv4 setting first. For a cluster with the IPv6 family as the primary address family, specify the IPv6 setting first.

```
machineNetwork:
- cidr: {{ extcidrnet }}
- cidr: {{ extcidrnet6 }}
clusterNetwork:
- cidr: 10.128.0.0/14
```

```

hostPrefix: 23
- cidr: fd02::/48
 hostPrefix: 64
serviceNetwork:
- 172.30.0.0/16
- fd03::/112

```

To provide an interface to the cluster for applications that use IPv4 and IPv6 addresses, configure IPv4 and IPv6 virtual IP (VIP) address endpoints for the Ingress VIP and API VIP services. To configure IPv4 and IPv6 address endpoints, edit the **apiVIPs** and **ingressVIPs** configuration settings in the **install-config.yaml** file. The **apiVIPs** and **ingressVIPs** configuration settings use a list format. The order of the list indicates the primary and secondary VIP address for each service.

```

platform:
 vsphere:
 apiVIPs:
 - <api_ipv4>
 - <api_ipv6>
 ingressVIPs:
 - <wildcard_ipv4>
 - <wildcard_ipv6>

```

#### NOTE

For a cluster with dual-stack networking configuration, you must assign both IPv4 and IPv6 addresses to the same interface.

#### 21.2.5.4.4. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default **install-config.yaml** file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the **openshift-installer** will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

#### IMPORTANT

The example uses the **govc** command. The **govc** command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the **govc** command. Instructions for downloading and installing **govc** are found on the VMware documentation website

#### Prerequisites

- You have an existing **install-config.yaml** installation configuration file.

## IMPORTANT

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

## Procedure

1. Enter the following **govc** command-line tool commands to create the **openshift-region** and **openshift-zone** vCenter tag categories:

## IMPORTANT

If you specify different names for the **openshift-region** and **openshift-zone** vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

```
$ govc tags.category.create -d "OpenShift region" openshift-region
```

```
$ govc tags.category.create -d "OpenShift zone" openshift-zone
```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

```
$ govc tags.create -c <region_tag_category> <region_tag>
```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
```

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

## Sample install-config.yaml file with multiple datacenters defined in a vSphere center

```

compute:

vsphere:
```

```

zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

controlPlane:

vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

platform:
 vsphere:
 vcenters:

 datacenters:
 - <datacenter1_name>
 - <datacenter2_name>
 failureDomains:
 - name: <machine_pool_zone_1>
 region: <region_tag_1>
 zone: <zone_tag_1>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter1>
 computeCluster: "/<datacenter1>/host/<cluster1>"
 networks:
 - <VM_Network1_name>
 datastore: "/<datacenter1>/datastore/<datastore1>"
 resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
 folder: "/<datacenter1>/vm/<folder1>"
 - name: <machine_pool_zone_2>
 region: <region_tag_2>
 zone: <zone_tag_2>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter2>
 computeCluster: "/<datacenter2>/host/<cluster2>"
 networks:
 - <VM_Network2_name>
 datastore: "/<datacenter2>/datastore/<datastore2>"
 resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
 folder: "/<datacenter2>/vm/<folder2>"

```

#### 21.2.5.5. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

##### Phase 1

You can customize the following network-related fields in the **install-config.yaml** file before you create the manifest files:

- **networking.networkType**

- **networking.clusterNetwork**
- **networking.serviceNetwork**
- **networking.machineNetwork**

For more information on these fields, refer to *Installation configuration parameters*.

#### NOTE

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

#### IMPORTANT

The CIDR range **172.17.0.0/16** is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

## Phase 2

After creating the manifest files by running **openshift-install create manifests**, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the **install-config.yaml** file during phase 2. However, you can further customize the network plugin during phase 2.

### 21.2.5.6. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

#### IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

## Prerequisites

- You have created the **install-config.yaml** file and completed any modifications to it.

## Procedure

1. Change to the directory that contains the installation program and create the manifests:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

**1**

**<installation\_directory>** specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yml** in the **<installation\_directory>/manifests/** directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
```

3. Specify the advanced network configuration for your cluster in the **cluster-network-03-config.yml** file, such as in the following examples:

#### Specify a different VXLAN port for the OpenShift SDN network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 openshiftSDNConfig:
 vxlanPort: 4800
```

#### Enable IPsec for the OVN-Kubernetes network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 ovnKubernetesConfig:
 ipsecConfig: {}
```

4. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program consumes the **manifests/** directory when you create the Ignition config files.
5. Remove the Kubernetes manifest files that define the control plane machines and compute machineSets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-
cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the MachineSet files to create compute machines by using the machine API, but you must update references to them to match your environment.

#### 21.2.5.7. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group:

#### **clusterNetwork**

IP address pools from which pod IP addresses are allocated.

#### **serviceNetwork**

IP address pool for services.

#### **defaultNetwork.type**

Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

#### 21.2.5.7.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 21.7. Cluster Network Operator configuration object**

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metadata.name</b>       | <b>string</b> | The name of the CNO object. This name is always <b>cluster</b> .                                                                                                                                                                                                                                                                                                                                    |
| <b>spec.clusterNetwork</b> | <b>array</b>  | <p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec:   clusterNetwork:     - cidr: 10.128.0.0/19       hostPrefix: 23     - cidr: 10.128.32.0/19       hostPrefix: 23</pre>                                                                          |
| <b>spec.serviceNetwork</b> | <b>array</b>  | <p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</p> <pre>spec:   serviceNetwork:     - 172.30.0.0/14</pre> <p>You can customize this field only in the <b>install-config.yaml</b> file before you create the manifests. The value is read-only in the manifest file.</p> |
| <b>spec.defaultNetwork</b> | <b>object</b> | Configures the network plugin for the cluster network.                                                                                                                                                                                                                                                                                                                                              |

| Field                        | Type          | Description                                                                                                                                                              |
|------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>spec.kubeProxy Config</b> | <b>object</b> | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect. |

### defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

**Table 21.8. defaultNetwork object**

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>type</b>                | <b>string</b> | <p>Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b>. The Red Hat OpenShift Networking network plugin is selected during installation. You can change this value by migrating from OpenShift SDN to OVN-Kubernetes.</p> <div>  <div> <b>NOTE</b><br/> OpenShift Container Platform uses the OVN-Kubernetes network plugin by default. </div> </div> |
| <b>openshiftSDNConfig</b>  | <b>object</b> | This object is only valid for the OpenShift SDN network plugin.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>ovnKubernetesConfig</b> | <b>object</b> | This object is only valid for the OVN-Kubernetes network plugin.                                                                                                                                                                                                                                                                                                                                                                       |

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

**Table 21.9. openshiftSDNConfig object**

| Field       | Type          | Description                                                                                                                                                                                                                                                                                                                         |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b> | <b>string</b> | <p>Configures the network isolation mode for OpenShift SDN. The default value is <b>NetworkPolicy</b>.</p> <p>The values <b>Multitenant</b> and <b>Subnet</b> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p> |

| Field            | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>       | <b>integer</b> | <p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>50</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1450</b>.</p> <p>This value cannot be changed after cluster installation.</p> |
| <b>vxlanPort</b> | <b>integer</b> | <p>The port to use for all VXLAN packets. The default value is <b>4789</b>. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port <b>9000</b> and port <b>9999</b>.</p>                                                                                                                                                                                                                            |

## Example OpenShift SDN configuration

```
defaultNetwork:
 type: OpenShiftSDN
 openshiftSDNConfig:
 mode: NetworkPolicy
 mtu: 1450
 vxlanPort: 4789
```

## Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

Table 21.10. `ovnKubernetesConfig` object

| Field | Type | Description |
|-------|------|-------------|
|-------|------|-------------|

| Field                    | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>               | <b>integer</b> | <p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>100</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1400</b>.</p> |
| <b>genevePort</b>        | <b>integer</b> | The port to use for all Geneve packets. The default value is <b>6081</b> . This value cannot be changed after cluster installation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipsecConfig</b>       | <b>object</b>  | Specify an empty object to enable IPsec encryption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>policyAuditConfig</b> | <b>object</b>  | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>gatewayConfig</b>     | <b>object</b>  | <p>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</p> <div>  <div> <p><b>NOTE</b></p> <p>While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.</p> </div> </div>                                                                                                                                                                                                                                                                                                                                                                                                        |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <b>v4InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>100.64.0.0/16</b> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <b>clusterNetwork.cidr</b> value is <b>10.128.0.0/14</b> and the <b>clusterNetwork.hostPrefix</b> value is <b>/23</b>, then the maximum number of nodes is <b><math>2^{(23-14)}=512</math></b>.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>100.64.0.0/16</b> . |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| <b>v6InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>fd98::/48</b> IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>fd98::/48</b> . |

Table 21.11. **policyAuditConfig** object

| Field              | Type    | Description                                                                                                           |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------|
| <b>rateLimit</b>   | integer | The maximum number of messages to generate every second per node. The default value is <b>20</b> messages per second. |
| <b>maxFileSize</b> | integer | The maximum size for the audit log in bytes. The default value is <b>50000000</b> or 50 MB.                           |
| <b>maxLogFiles</b> | integer | The maximum number of log files that are retained.                                                                    |

| Field                 | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination</b>    | string | <p>One of the following additional audit log targets:</p> <p><b>libc</b><br/>The libc <b>syslog()</b> function of the journald process on the host.</p> <p><b>udp:&lt;host&gt;:&lt;port&gt;</b><br/>A syslog server. Replace <b>&lt;host&gt;:&lt;port&gt;</b> with the host and port of the syslog server.</p> <p><b>unix:&lt;file&gt;</b><br/>A Unix Domain Socket file specified by <b>&lt;file&gt;</b>.</p> <p><b>null</b><br/>Do not send the audit logs to any additional target.</p> |
| <b>syslogFacility</b> | string | The syslog facility, such as <b>kern</b> , as defined by RFC5424. The default value is <b>local0</b> .                                                                                                                                                                                                                                                                                                                                                                                     |

Table 21.12. gatewayConfig object

| Field                 | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>routingViaHost</b> | <b>boolean</b> | <p>Set this field to <b>true</b> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <b>false</b>.</p> <p>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <b>true</b>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</p> |
| <b>ipForwarding</b>   | <b>object</b>  | You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <b>ipForwarding</b> specification in the <b>Network</b> resource. Specify <b>Restricted</b> to only allow IP forwarding for Kubernetes related traffic. Specify <b>Global</b> to allow forwarding of all IP traffic. For new installations, the default is <b>Restricted</b> . For updates to OpenShift Container Platform 4.14, the default is <b>Global</b> .                                                                                                                                                                                                                                                                                |

### Example OVN-Kubernetes configuration with IPsec enabled

```
defaultNetwork:
 type: OVNKubernetes
 ovnKubernetesConfig:
 mtu: 1400
 genevePort: 6081
 ipsecConfig: {}
```

**kubeProxyConfig object configuration (OpenShiftSDN container network interface only)**

The values for the **kubeProxyConfig** object are defined in the following table:

Table 21.13. **kubeProxyConfig** object

| Field                                          | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>iptablesSyncPeriod</b>                      | <b>string</b> | <p>The refresh period for <b>iptables</b> rules. The default value is <b>30s</b>. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a>. The default value is:</p> <pre>kubeProxyConfig:   proxyArguments:     iptables-min-sync-period:       - 0s</pre>                                                                                                                                                        |

**21.2.5.8. Deploying the cluster**

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
- Optional: Before you create the cluster, configure an external load balancer in place of the default load balancer.

## IMPORTANT

You do not need to specify API and Ingress static addresses for your installation program. If you choose this configuration, you must take additional actions to define network targets that accept an IP address from each referenced vSphere subnet. See the section "Configuring an external load balancer".

## Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:

- The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GKLOUD\_KEYFILE\_JSON** environment variables
- The `~/gcp/osServiceAccount.json` file
- The **gcloud cli** default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

**1** For **<installation\_directory>**, specify the location of your customized `./install-config.yaml` file.

**2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

3. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.

## NOTE

The elevated permissions provided by the **AdministratorAccess** policy are required only during installation.

4. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.

- If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
- If you included the **Service Account Key Admin** role, you can remove it.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

- Credential information also outputs to `<installation_directory>/openshift_install.log`.

## IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 21.2.5.9. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

#### Example output

```
system:admin
```

### 21.2.5.10. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

#### 21.2.5.10.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**. When this has completed, you must configure storage.

#### 21.2.5.10.2. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

##### 21.2.5.10.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

### IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

### IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

## Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

### NOTE

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

### Example output

```
No resources found in openshift-image-registry namespace
```

### NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

### Example output

```
storage:
 pvc:
 claim: 1
```

- 1** Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

### Example output

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED |
|----------------|---------|-----------|-------------|----------|
| image-registry | 4.7     | True      | False       | False    |

#### 21.2.5.10.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

### IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

### Procedure

1. Enter the following command to set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy, and runs with only **1** replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
  - a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: image-registry-storage 1
 namespace: openshift-image-registry 2
spec:
 accessModes:
```

```
- ReadWriteOnce 3
resources:
 requests:
 storage: 100Gi 4
```

- 1** A unique name that represents the **PersistentVolumeClaim** object.
- 2** The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
- 3** The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
- 4** The size of the persistent volume claim.

b. Enter the following command to create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Enter the following command to edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

### Example output

```
storage:
 pvc:
 claim: 1
```

- 1** By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

#### 21.2.5.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

#### 21.2.5.12. Services for an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

## IMPORTANT

Configuring an external load balancer depends on your vendor's load balancer.

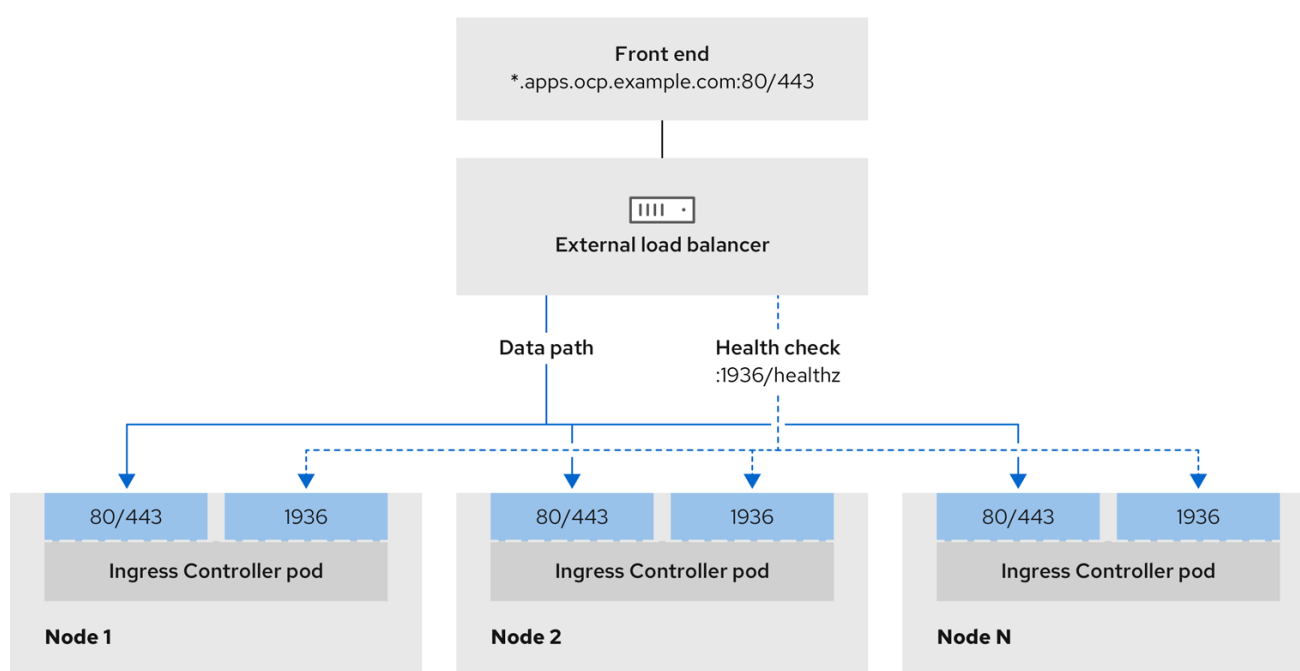

The information and examples in this section are for guideline purposes only. Consult the vendor documentation for more specific information about the vendor's load balancer.

Red Hat supports the following services for an external load balancer:

- Ingress Controller
- OpenShift API
- OpenShift MachineConfig API

You can choose whether you want to configure one or all of these services for an external load balancer. Configuring only the Ingress Controller service is a common configuration option. To better understand each service, view the following diagrams:

**Figure 21.4. Example network workflow that shows an Ingress Controller operating in an OpenShift Container Platform environment**

496\_OpenShift\_1223

Figure 21.5. Example network workflow that shows an OpenShift API operating in an OpenShift Container Platform environment

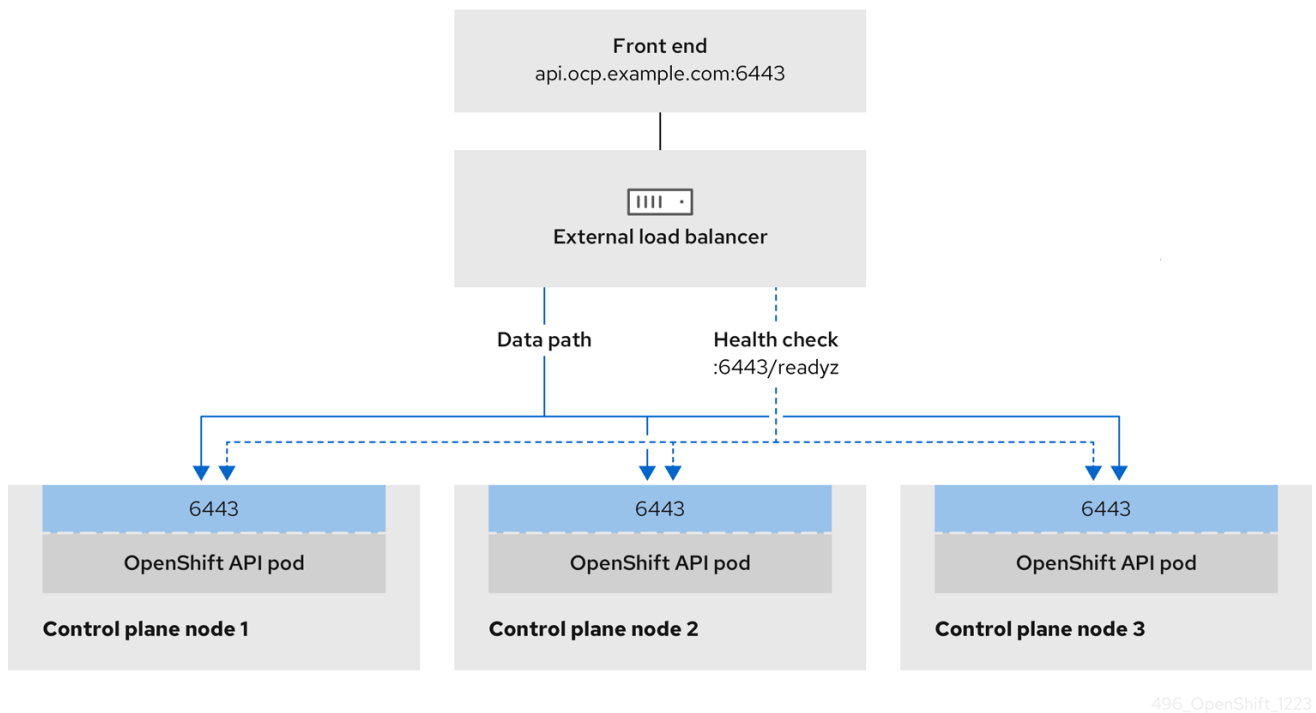

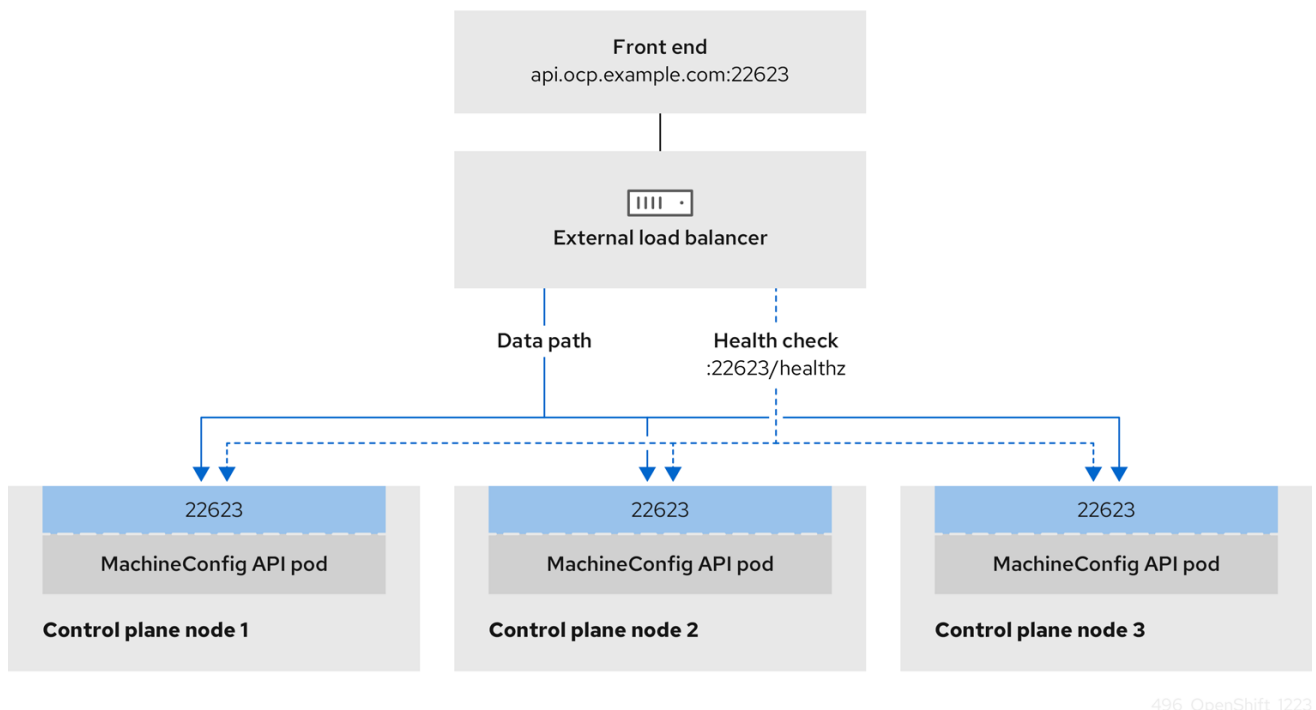

Figure 21.6. Example network workflow that shows an OpenShift MachineConfig API operating in an OpenShift Container Platform environment

The following configuration options are supported for external load balancers:

- Use a node selector to map the Ingress Controller to a specific set of nodes. You must assign a static IP address to each node in this set, or configure each node to receive the same IP address from the Dynamic Host Configuration Protocol (DHCP). Infrastructure nodes commonly receive this type of configuration.

- Target all IP addresses on a subnet. This configuration can reduce maintenance overhead, because you can create and destroy nodes within those networks without reconfiguring the load balancer targets. If you deploy your ingress pods by using a machine set on a smaller network, such as a `/27` or `/28`, you can simplify your load balancer targets.

### TIP

You can list all IP addresses that exist in a network by checking the machine config pool's resources.

Before you configure an external load balancer for your OpenShift Container Platform cluster, consider the following information:

- For a front-end IP address, you can use the same IP address for the front-end IP address, the Ingress Controller's load balancer, and API load balancer. Check the vendor's documentation for this capability.
- For a back-end IP address, ensure that an IP address for an OpenShift Container Platform control plane node does not change during the lifetime of the external load balancer. You can achieve this by completing one of the following actions:
  - Assign a static IP address to each control plane node.
  - Configure each node to receive the same IP address from the DHCP every time the node requests a DHCP lease. Depending on the vendor, the DHCP lease might be in the form of an IP reservation or a static DHCP assignment.
- Manually define each node that runs the Ingress Controller in the external load balancer for the Ingress Controller back-end service. For example, if the Ingress Controller moves to an undefined node, a connection outage can occur.

#### 21.2.5.12.1. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

### IMPORTANT

Before you configure an external load balancer, ensure that you read the "Services for an external load balancer" section.

Read the following prerequisites that apply to the service that you want to configure for your external load balancer.

### NOTE

MetalLB, that runs on a cluster, functions as an external load balancer.

#### OpenShift API prerequisites

- You defined a front-end IP address.
- TCP ports 6443 and 22623 are exposed on the front-end IP address of your load balancer. Check the following items:

- Port 6443 provides access to the OpenShift API service.
- Port 22623 can provide ignition startup configurations to nodes.
- The front-end IP address and port 6443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address and port 22623 are reachable only by OpenShift Container Platform nodes.
- The load balancer backend can communicate with OpenShift Container Platform control plane nodes on port 6443 and 22623.

### Ingress Controller prerequisites

- You defined a front-end IP address.
- TCP ports 443 and 80 are exposed on the front-end IP address of your load balancer.
- The front-end IP address, port 80 and port 443 are be reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address, port 80 and port 443 are reachable to all nodes that operate in your OpenShift Container Platform cluster.
- The load balancer backend can communicate with OpenShift Container Platform nodes that run the Ingress Controller on ports 80, 443, and 1936.

### Prerequisite for health check URL specifications

You can configure most load balancers by setting health check URLs that determine if a service is available or unavailable. OpenShift Container Platform provides these health checks for the OpenShift API, Machine Configuration API, and Ingress Controller backend services.

The following examples demonstrate health check specifications for the previously listed backend services:

#### Example of a Kubernetes API health check specification

```
Path: HTTPS:6443/readyz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```

#### Example of a Machine Config API health check specification

```
Path: HTTPS:22623/healthz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```

#### Example of an Ingress Controller health check specification

```
Path: HTTP:1936/healthz/ready
```

Healthy threshold: 2  
 Unhealthy threshold: 2  
 Timeout: 5  
 Interval: 10

## Procedure

1. Configure the HAProxy Ingress Controller, so that you can enable access to the cluster from your load balancer on ports 6443, 443, and 80:

### Example HAProxy configuration

```
#...
listen my-cluster-api-6443
 bind 192.168.1.100:6443
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /readyz
 http-check expect status 200
 server my-cluster-master-2 192.168.1.101:6443 check inter 10s rise 2 fall 2
 server my-cluster-master-0 192.168.1.102:6443 check inter 10s rise 2 fall 2
 server my-cluster-master-1 192.168.1.103:6443 check inter 10s rise 2 fall 2

listen my-cluster-machine-config-api-22623
 bind 192.168.1.100:22623
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /healthz
 http-check expect status 200
 server my-cluster-master-2 192.168.1.101:22623 check inter 10s rise 2 fall 2
 server my-cluster-master-0 192.168.1.102:22623 check inter 10s rise 2 fall 2
 server my-cluster-master-1 192.168.1.103:22623 check inter 10s rise 2 fall 2

listen my-cluster-apps-443
 bind 192.168.1.100:443
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /healthz/ready
 http-check expect status 200
 server my-cluster-worker-0 192.168.1.111:443 check port 1936 inter 10s rise 2 fall 2
 server my-cluster-worker-1 192.168.1.112:443 check port 1936 inter 10s rise 2 fall 2
 server my-cluster-worker-2 192.168.1.113:443 check port 1936 inter 10s rise 2 fall 2

listen my-cluster-apps-80
 bind 192.168.1.100:80
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
```

```

http-check send meth GET uri /healthz/ready
http-check expect status 200
server my-cluster-worker-0 192.168.1.111:80 check port 1936 inter 10s rise 2 fall 2
server my-cluster-worker-1 192.168.1.112:80 check port 1936 inter 10s rise 2 fall 2
server my-cluster-worker-2 192.168.1.113:80 check port 1936 inter 10s rise 2 fall 2
...

```

2. Use the **curl** CLI command to verify that the external load balancer and its resources are operational:

- a. Verify that the cluster machine configuration API is accessible to the Kubernetes API server resource, by running the following command and observing the response:

```
$ curl https://<loadbalancer_ip_address>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```

{
 "major": "1",
 "minor": "11+",
 "gitVersion": "v1.11.0+ad103ed",
 "gitCommit": "ad103ed",
 "gitTreeState": "clean",
 "buildDate": "2019-01-09T06:44:10Z",
 "goVersion": "go1.10.3",
 "compiler": "gc",
 "platform": "linux/amd64"
}

```

- b. Verify that the cluster machine configuration API is accessible to the Machine config server resource, by running the following command and observing the output:

```
$ curl -v https://<loadbalancer_ip_address>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```

HTTP/1.1 200 OK
Content-Length: 0

```

- c. Verify that the controller is accessible to the Ingress Controller resource on port 80, by running the following command and observing the output:

```
$ curl -I -L -H "Host: console-openshift-console.apps.<cluster_name>.<base_domain>"
http://<load_balancer_front_end_IP_address>
```

If the configuration is correct, the output from the command shows the following response:

```

HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.ocp4.private.opequon.net/
cache-control: no-cache

```

- d. Verify that the controller is accessible to the Ingress Controller resource on port 443 by

- a. verify that the controller is accessible to the ingress Controller resource on port 443, by running the following command and observing the output:

```
$ curl -I -L --insecure --resolve console-openshift-console.apps.<cluster_name>.
<base_domain>:443:<Load Balancer Front End IP Address> https://console-openshift-
console.apps.<cluster_name>.<base_domain>
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-
token=UIYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG
LgaYO0nxzVERhiXt6QepA7g==; Path=/; Secure; SameSite=Lax
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Wed, 04 Oct 2023 16:29:38 GMT
content-type: text/html; charset=utf-8
set-cookie:
1e2670d92730b515ce3a1bb65da45062=1bf5e9573c9a2760c964ed1659cc1673; path=/;
HttpOnly; Secure; SameSite=None
cache-control: private
```

3. Configure the DNS records for your cluster to target the front-end IP addresses of the external load balancer. You must update records to your DNS server for the cluster API and applications over the load balancer.

### Examples of modified DNS records

```
<load_balancer_ip_address> A api.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End
```

```
<load_balancer_ip_address> A apps.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End
```

### IMPORTANT

DNS propagation might take some time for each DNS record to become available. Ensure that each DNS record propagates before validating each record.

4. Use the **curl** CLI command to verify that the external load balancer and DNS record configuration are operational:
  - a. Verify that you can access the cluster API, by running the following command and observing the output:

```
$ curl https://api.<cluster_name>.<base_domain>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```
{
 "major": "1",
 "minor": "11+",
 "gitVersion": "v1.11.0+ad103ed",
 "gitCommit": "ad103ed",
 "gitTreeState": "clean",
 "buildDate": "2019-01-09T06:44:10Z",
 "goVersion": "go1.10.3",
 "compiler": "gc",
 "platform": "linux/amd64"
}
```

- b. Verify that you can access the cluster machine configuration, by running the following command and observing the output:

```
$ curl -v https://api.<cluster_name>.<base_domain>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

- c. Verify that you can access each cluster application on port, by running the following command and observing the output:

```
$ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.<cluster-name>.<base domain>/
cache-control: no-cacheHTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-

HttpOnly; Secure; SameSite=None
cache-control: private
```

### 21.2.5.13. Configuring network components to run on the control plane

You can configure networking components to run exclusively on the control plane nodes. By default, OpenShift Container Platform allows any node in the machine config pool to host the **ingressVIP** virtual IP address. However, some environments deploy worker nodes in separate subnets from the control plane nodes, which requires configuring the **ingressVIP** virtual IP address to run on the control plane nodes.

#### NOTE

You can scale the remote workers by creating a worker machineset in a separate subnet.

#### IMPORTANT

When deploying remote workers in separate subnets, you must place the **ingressVIP** virtual IP address exclusively with the control plane nodes.

## Internet access

## Procedure

1. Change to the directory storing the **install-config.yaml** file:

```
$ cd ~/clusterconfigs
```

2. Switch to the **manifests** subdirectory:

```
$ cd manifests
```

3. Create a file named **cluster-network-avoid-workers-99-config.yaml**:

```
$ touch cluster-network-avoid-workers-99-config.yaml
```

4. Open the **cluster-network-avoid-workers-99-config.yaml** file in an editor and enter a custom resource (CR) that describes the Operator configuration:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
 name: 50-worker-fix-ipi-rwn
 labels:
 machineconfiguration.openshift.io/role: worker
spec:
 config:
 ignition:
 version: 3.2.0
 storage:
 files:
 - path: /etc/kubernetes/manifests/keepalived.yaml
 mode: 0644
 contents:
 source: data;
```

This manifest places the **ingressVIP** virtual IP address on the control plane nodes. Additionally, this manifest deploys the following processes on the control plane nodes only:

- **openshift-ingress-operator**
- **keepalived**

5. Save the **cluster-network-avoid-workers-99-config.yaml** file.
6. Create a **manifests/cluster-ingress-default-ingresscontroller.yaml** file:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
 name: default
 namespace: openshift-ingress-operator
spec:
 nodePlacement:
 nodeSelector:
 matchLabels:
 node-role.kubernetes.io/master: ""
```

7. Consider backing up the **manifests** directory. The installer deletes the **manifests/** directory when creating the cluster.
8. Modify the **cluster-scheduler-02-config.yml** manifest to make the control plane nodes schedulable by setting the **mastersSchedulable** field to **true**. Control plane nodes are not schedulable by default. For example:

```
$ sed -i "s;mastersSchedulable: false;mastersSchedulable: true;g"
clusterconfigs/manifests/cluster-scheduler-02-config.yml
```

#### NOTE

If control plane nodes are not schedulable after completing this procedure, deploying the cluster will fail.

#### 21.2.5.14. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).
- Optional: [View the events from the vSphere Problem Detector Operator](#) to determine if the cluster has permission or storage configuration issues.

#### 21.2.6. Installing a cluster on vSphere in a restricted network

In OpenShift Container Platform 4.14, you can install a cluster on VMware vSphere infrastructure in a restricted network by creating an internal mirror of the installation release content.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

**21.2.6.1. Prerequisites**

- You have completed the tasks in [Preparing to install a cluster using installer-provisioned infrastructure](#).
- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [created a registry on your mirror host](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned [persistent storage](#) for your cluster. To deploy a private image registry, your storage must provide the ReadWriteMany access mode.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

**NOTE**

If you are configuring a proxy, be sure to also review this site list.

**21.2.6.2. About installations in restricted networks**

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the

OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

#### 21.2.6.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

#### 21.2.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### 21.2.6.4. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network VMware vSphere environment.

##### Prerequisites

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

##### Procedure

1. Log in to the Red Hat Customer Portal's [Product Downloads page](#).
2. Under **Version**, select the most recent release of OpenShift Container Platform 4.14 for RHEL 8.

##### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the **Red Hat Enterprise Linux CoreOS (RHCOS) - vSphere** image.

4. Upload the image you downloaded to a location that is accessible from the bastion server.

The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

### 21.2.6.5. VMware vSphere region and zone enablement

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

#### IMPORTANT

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature is only available on a newly installed cluster.

For a cluster that was upgraded from a previous release, you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default **install-config.yaml** file includes **vccenters** and **failureDomains** fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- **Failure domain:** Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- **Region:** Specifies a vCenter datacenter. You define a region by using a tag from the **openshift-region** tag category.
- **Zone:** Specifies a vCenter cluster. You define a zone by using a tag from the **openshift-zone** tag category.

#### NOTE

If you plan on specifying more than one failure domain in your **install-config.yaml** file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster that runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
| us-east             | us-east-1      | us-east-1a |
|                     |                | us-east-1b |
|                     | us-east-2      | us-east-2a |
|                     |                | us-east-2b |
| us-west             | us-west-1      | us-west-1a |
|                     |                | us-west-1b |
|                     | us-west-2      | us-west-2a |
|                     |                | us-west-2b |

- [VMware vSphere CSI Driver Operator](#)

### 21.2.6.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS). Google Cloud Platform (GCP). VMware vSphere.

### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the **imageContentSources** values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.

### Procedure

1. Create the **install-config.yaml** file.
  - a. Change to the directory that contains the installation program and run the following command:

```
$./openshift-install create install-config --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

#### NOTE

Always delete the **~/powers** directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powers
```

- b. At the prompts, provide the configuration details for your cloud:
  - i. Optional: Select an SSH key to use to access your cluster machines.

#### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- ii. Select **AWS** as the platform to target.
- iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.
- iv. Select the AWS region to deploy the cluster to.
- v. Select the base domain for the Route 53 service that you configured for your cluster.
- vi. Select **gcp** as the platform to target.
- vii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.
- viii. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.
- ix. Select the region to deploy the cluster to.

- x. Select the base domain to deploy the cluster to. The base domain corresponds to the

- x. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.
- xi. Select **vsphere** as the platform to target.
- xii. Specify the name of your vCenter instance.
- xiii. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.  
The installation program connects to your vCenter instance.
- xiv. Select the data center in your vCenter instance to connect to.

#### NOTE

After you create the installation configuration file, you can modify the file to create a multiple vSphere datacenters environment. This means that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. For more information about creating this environment, see the section named *VMware vSphere region and zone enablement*.

- xv. Select the default vCenter datastore to use.

#### WARNING

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

You cannot specify more than one datastore path. If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- xvi. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.
- xvii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.
- xviii. Enter the virtual IP address that you configured for control plane API access.
- xix. Enter the virtual IP address that you configured for cluster ingress.

- xx. Enter the base domain. This base domain must be the same one that you used in the

- xx. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.
  - xxi. Enter a descriptive name for your cluster.  
The cluster name you enter must match the cluster name you specified when configuring the DNS records.
2. In the **install-config.yaml** file, set the value of **platform.vsphere.clusterOSImage** to the image location or name. For example:

```
platform:
 vsphere:
 clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-vmware.x86_64.ova?
sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
```

3. Edit the **install-config.yaml** file to give the additional information that is required for an installation in a restricted network.
  - a. Update the **pullSecret** value to contain the authentication information for your registry:

```
pullSecret: '{"auths":{"<mirror_host_name>:5000":{"auth":"<credentials>","email":
"you@example.com"}}}'
```

For **<mirror\_host\_name>**, specify the registry domain name that you specified in the certificate for your mirror registry, and for **<credentials>**, specify the base64-encoded user name and password for your mirror registry.

- b. Add the **additionalTrustBundle** parameter and value.

[illegible]

The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority, or the self-signed certificate that you generated for the mirror registry.

- c. Define the subnets for the VPC to install the cluster in:

```
subnets:
- subnet-1
- subnet-2
- subnet-3
```

- d. Define the network and subnets for the VPC to install the cluster in under the parent **platform.qcp** field:

```
network: <existing_vpc>
controlPlaneSubnet: <control_plane_subnet>
computeSubnet: <compute_subnet>
```

For platform **non-network**, specify the name for the existing Google VPC. For

For **platform.gcp.network**, specify the name for the existing Google VPC. For **platform.gcp.controlPlaneSubnet** and **platform.gcp.computeSubnet**, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

- e. Add the image content resources, which resemble the following YAML excerpt:

```
imageContentSources:
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
 source: quay.io/openshift-release-dev/ocp-release
- mirrors:
 - <mirror_host_name>:5000/<repo_name>/release
 source: registry.redhat.io/ocp/release
```

For these values, use the **imageContentSources** that you recorded during mirror registry creation.

- f. Optional: Set the publishing strategy to **Internal**:

```
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

4. Make any other modifications to the **install-config.yaml** file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.
5. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### Additional resources

- [Installation configuration parameters](#)

#### 21.2.6.6.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com 1
compute: 2
- architecture: amd64
 name: <worker_node>
 platform: {}
 replicas: 3
controlPlane: 3
 architecture: amd64
 name: <parent_node>
 platform: {}
 replicas: 3
```

[illegible]

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
- 2 3 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

- 4 The cluster name that you specified in your DNS records.
- 5 Optional: Provides additional configuration for the machine pool parameters for the compute and control plane machines.
- 6 Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- 7 The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

### IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- 8 Optional: Provides an existing resource pool for machine creation. If you do not specify a value, the installation program uses the root resource pool of the vSphere cluster.
- 9 The vSphere disk provisioning method.
- 10 The location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that is accessible from the bastion server.
- 11 For **<local\_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example **registry.example.com** or **registry.example.com:5000**. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.
- 12 Provide the contents of the certificate file that you used for your mirror registry.
- 13 Provide the **imageContentSources** section from the output of the command to mirror the repository.

### NOTE

In OpenShift Container Platform 4.12 and later, the **apiVIP** and **ingressVIP** configuration settings are deprecated. Instead, use a list format to enter values in the **apiVIPs** and **ingressVIPs** configuration settings.

#### 21.2.6.6.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> ❶
 httpsProxy: https://<username>:<pswd>@<ip>:<port> ❷
 noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.
 <aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com ❸
 additionalTrustBundle: | ❹
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ❺
```

- ❶ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- ❷ A proxy URL to use for creating HTTPS connections outside the cluster.
- ❸ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations. If you have added the Amazon **EC2**, **Elastic Load Balancing**, and **S3** VPC endpoints to your VPC, you must add these endpoints to the **noProxy** field. You must include vCenter's IP address and the IP range that you use for its machines.
- ❹ If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.

- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 21.2.6.6.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default **install-config.yaml** file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the **openshift-installer** will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

**IMPORTANT**

The example uses the **govc** command. The **govc** command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the **govc** command. Instructions for downloading and installing **govc** are found on the VMware documentation website

### Prerequisites

- You have an existing **install-config.yaml** installation configuration file.

## IMPORTANT

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

## Procedure

1. Enter the following **govc** command-line tool commands to create the **openshift-region** and **openshift-zone** vCenter tag categories:

## IMPORTANT

If you specify different names for the **openshift-region** and **openshift-zone** vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

```
$ govc tags.category.create -d "OpenShift region" openshift-region
```

```
$ govc tags.category.create -d "OpenShift zone" openshift-zone
```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

```
$ govc tags.create -c <region_tag_category> <region_tag>
```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
```

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

## Sample install-config.yaml file with multiple datacenters defined in a vSphere center

```

compute:

vsphere:
```

```

 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

 controlPlane:

 vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

 platform:
 vsphere:
 vcenters:

 datacenters:
 - <datacenter1_name>
 - <datacenter2_name>
 failureDomains:
 - name: <machine_pool_zone_1>
 region: <region_tag_1>
 zone: <zone_tag_1>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter1>
 computeCluster: "/<datacenter1>/host/<cluster1>"
 networks:
 - <VM_Network1_name>
 datastore: "/<datacenter1>/datastore/<datastore1>"
 resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
 folder: "/<datacenter1>/vm/<folder1>"
 - name: <machine_pool_zone_2>
 region: <region_tag_2>
 zone: <zone_tag_2>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter2>
 computeCluster: "/<datacenter2>/host/<cluster2>"
 networks:
 - <VM_Network2_name>
 datastore: "/<datacenter2>/datastore/<datastore2>"
 resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
 folder: "/<datacenter2>/vm/<folder2>"

```

### 21.2.6.7. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

#### IMPORTANT

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
- Optional: Before you create the cluster, configure an external load balancer in place of the default load balancer.

### IMPORTANT

You do not need to specify API and Ingress static addresses for your installation program. If you choose this configuration, you must take additional actions to define network targets that accept an IP address from each referenced vSphere subnet. See the section "Configuring an external load balancer".

### Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
  - The **GOOGLE\_CREDENTIALS**, **GOOGLE\_CLOUD\_KEYFILE\_JSON**, or **GCPLOUD\_KEYFILE\_JSON** environment variables
  - The `~/gcp/osServiceAccount.json` file
  - The **gcloud cli** default credentials
2. Change to the directory that contains the installation program and initialize the cluster deployment:
  - Change to the directory that contains the installation program and initialize the cluster deployment:

```
$./openshift-install create cluster --dir <installation_directory> \ ❶
--log-level=info ❷
```

  - ❶ For **<installation\_directory>**, specify the location of your customized `./install-config.yaml` file.
  - ❷ To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.
3. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.

### NOTE

The elevated permissions provided by the **AdministratorAccess** policy are required only during installation.

4. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.

- If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.
- If you included the **Service Account Key Admin** role, you can remove it.

## Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

### IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

## Example output

```
...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-
console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## 21.2.6.8. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

## Example output

```
system:admin
```

### 21.2.6.9. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

## Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
 -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

## TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Configuration → OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

### 21.2.6.10. Creating registry storage

After you install the cluster, you must create storage for the Registry Operator.

#### 21.2.6.10.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**. When this has completed, you must configure storage.

#### 21.2.6.10.2. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

##### 21.2.6.10.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

#### IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

#### IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

#### Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

**NOTE**

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

**Example output**

```
No resources found in openshift-image-registry namespace
```

**NOTE**

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

**Example output**

```
storage:
 pvc:
 claim: 1
```

- 1 Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

**Example output**

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED |
|----------------|---------|-----------|-------------|----------|
| image-registry | 4.7     | True      | False       | False    |

### 21.2.6.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 21.2.6.12. Services for an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

#### IMPORTANT

Configuring an external load balancer depends on your vendor's load balancer.

The information and examples in this section are for guideline purposes only. Consult the vendor documentation for more specific information about the vendor's load balancer.

Red Hat supports the following services for an external load balancer:

- Ingress Controller
- OpenShift API
- OpenShift MachineConfig API

You can choose whether you want to configure one or all of these services for an external load balancer. Configuring only the Ingress Controller service is a common configuration option. To better understand each service, view the following diagrams:

Figure 21.7. Example network workflow that shows an Ingress Controller operating in an OpenShift Container Platform environment

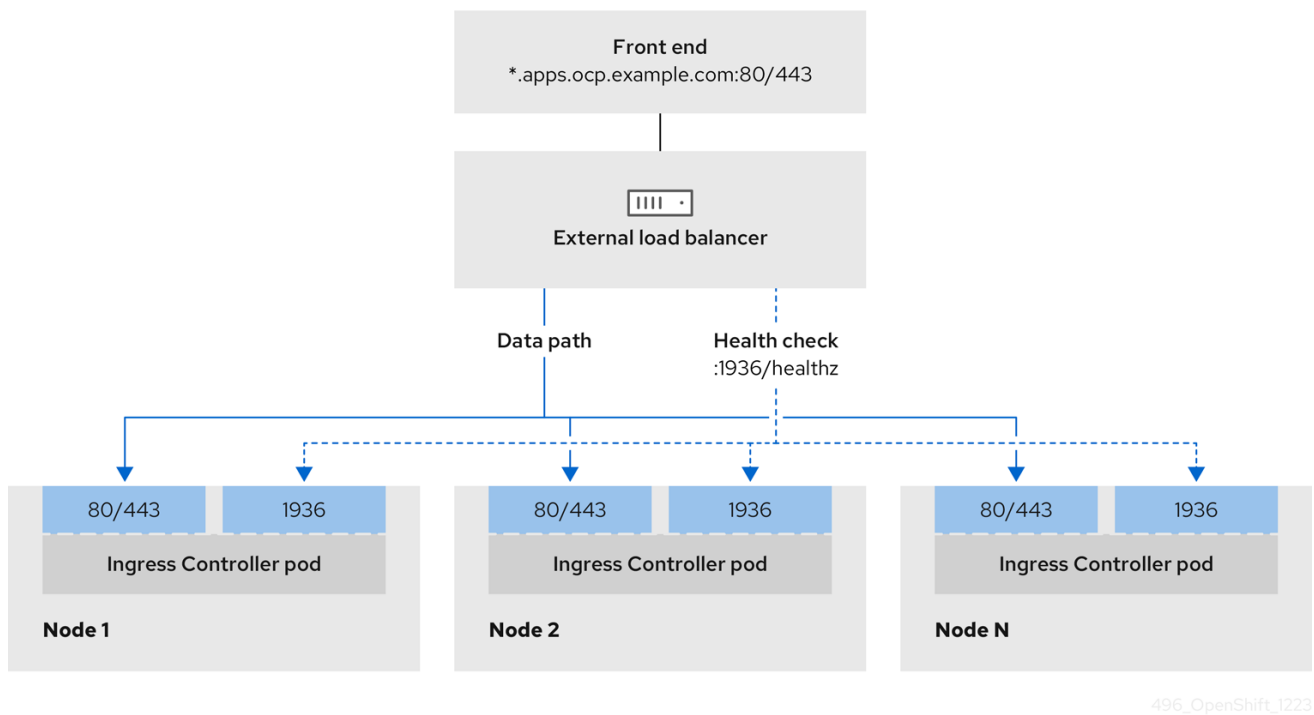

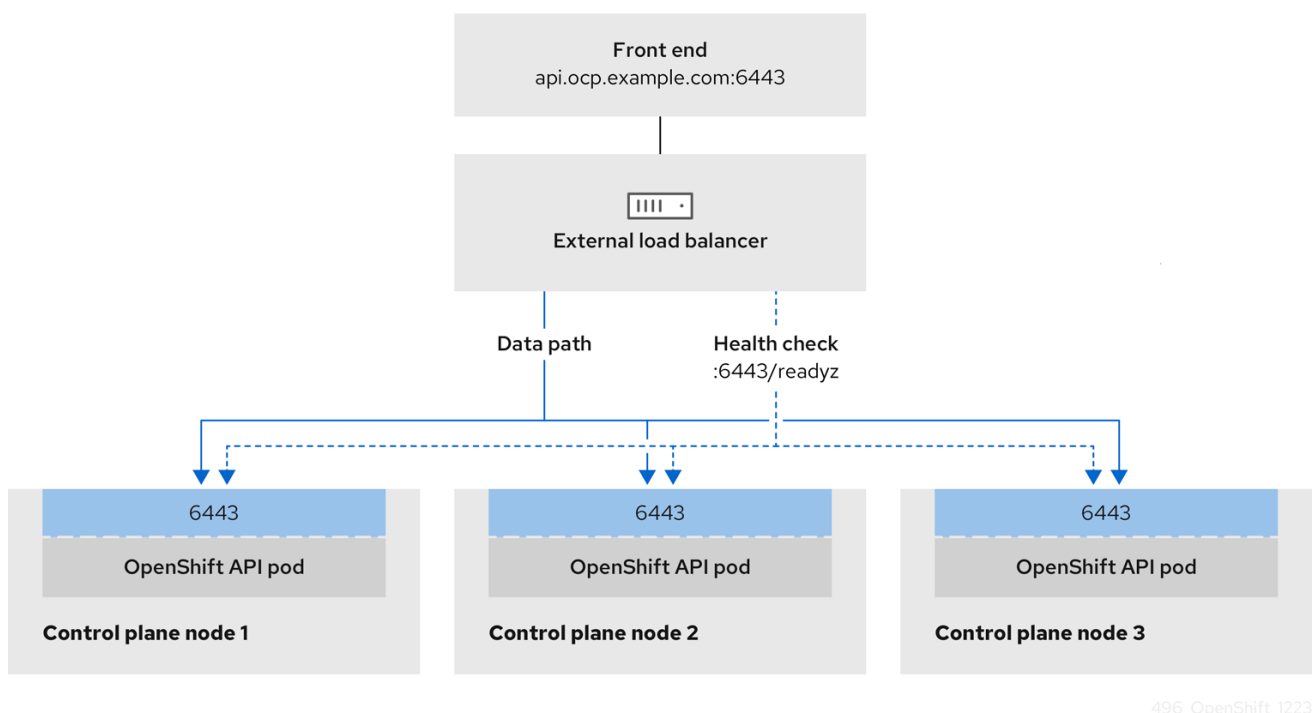

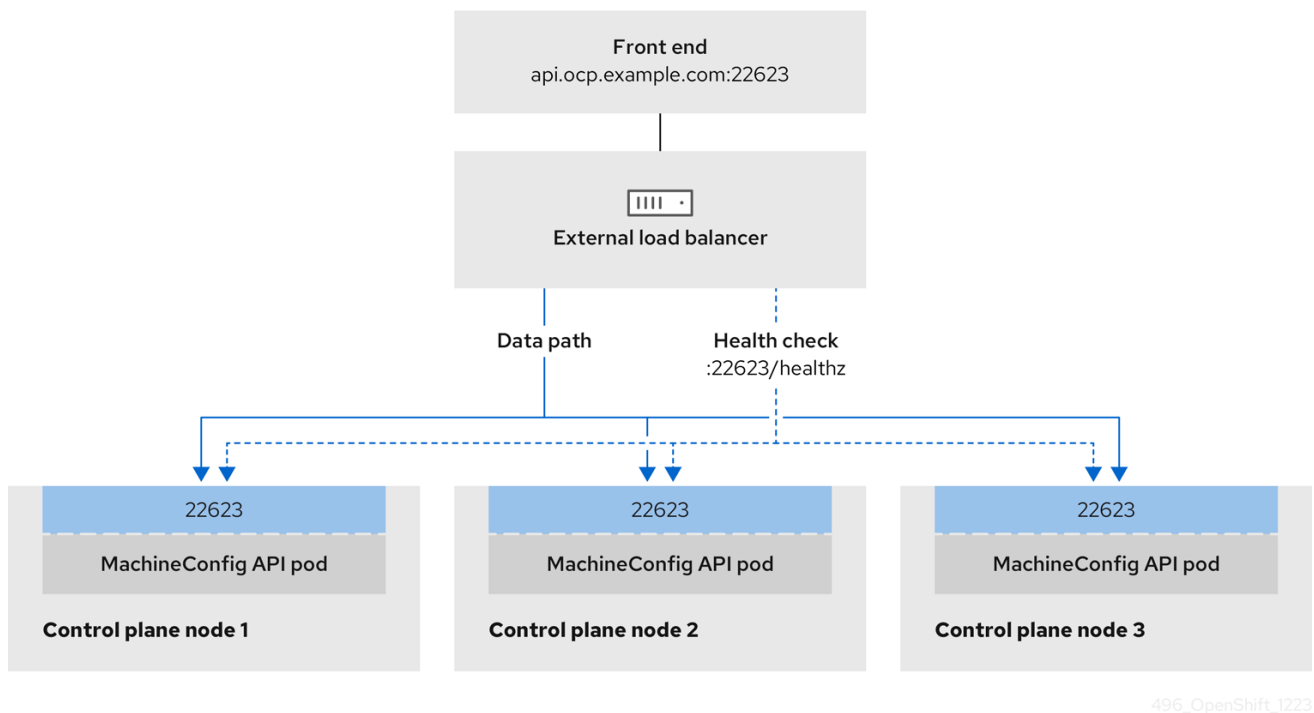

Figure 21.8. Example network workflow that shows an OpenShift API operating in an OpenShift Container Platform environment

**Figure 21.9. Example network workflow that shows an OpenShift MachineConfig API operating in an OpenShift Container Platform environment**

The following configuration options are supported for external load balancers:

- Use a node selector to map the Ingress Controller to a specific set of nodes. You must assign a static IP address to each node in this set, or configure each node to receive the same IP address from the Dynamic Host Configuration Protocol (DHCP). Infrastructure nodes commonly receive this type of configuration.
- Target all IP addresses on a subnet. This configuration can reduce maintenance overhead, because you can create and destroy nodes within those networks without reconfiguring the load balancer targets. If you deploy your ingress pods by using a machine set on a smaller network, such as a `/27` or `/28`, you can simplify your load balancer targets.

### TIP

You can list all IP addresses that exist in a network by checking the machine config pool's resources.

Before you configure an external load balancer for your OpenShift Container Platform cluster, consider the following information:

- For a front-end IP address, you can use the same IP address for the front-end IP address, the Ingress Controller's load balancer, and API load balancer. Check the vendor's documentation for this capability.
- For a back-end IP address, ensure that an IP address for an OpenShift Container Platform control plane node does not change during the lifetime of the external load balancer. You can achieve this by completing one of the following actions:
  - Assign a static IP address to each control plane node.

- Configure each node to receive the same IP address from the DHCP every time the node requests a DHCP lease. Depending on the vendor, the DHCP lease might be in the form of an IP reservation or a static DHCP assignment.
- Manually define each node that runs the Ingress Controller in the external load balancer for the Ingress Controller back-end service. For example, if the Ingress Controller moves to an undefined node, a connection outage can occur.

#### 21.2.6.12.1. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

#### IMPORTANT

Before you configure an external load balancer, ensure that you read the "Services for an external load balancer" section.

Read the following prerequisites that apply to the service that you want to configure for your external load balancer.

#### NOTE

MetalLB, that runs on a cluster, functions as an external load balancer.

#### OpenShift API prerequisites

- You defined a front-end IP address.
- TCP ports 6443 and 22623 are exposed on the front-end IP address of your load balancer. Check the following items:
  - Port 6443 provides access to the OpenShift API service.
  - Port 22623 can provide ignition startup configurations to nodes.
- The front-end IP address and port 6443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address and port 22623 are reachable only by OpenShift Container Platform nodes.
- The load balancer backend can communicate with OpenShift Container Platform control plane nodes on port 6443 and 22623.

#### Ingress Controller prerequisites

- You defined a front-end IP address.
- TCP ports 443 and 80 are exposed on the front-end IP address of your load balancer.
- The front-end IP address, port 80 and port 443 are be reachable by all users of your system with a location external to your OpenShift Container Platform cluster.

- The front-end IP address, port 80 and port 443 are reachable to all nodes that operate in your OpenShift Container Platform cluster.
- The load balancer backend can communicate with OpenShift Container Platform nodes that run the Ingress Controller on ports 80, 443, and 1936.

### Prerequisite for health check URL specifications

You can configure most load balancers by setting health check URLs that determine if a service is available or unavailable. OpenShift Container Platform provides these health checks for the OpenShift API, Machine Configuration API, and Ingress Controller backend services.

The following examples demonstrate health check specifications for the previously listed backend services:

#### Example of a Kubernetes API health check specification

```
Path: HTTPS:6443/readyz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```

#### Example of a Machine Config API health check specification

```
Path: HTTPS:22623/healthz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```

#### Example of an Ingress Controller health check specification

```
Path: HTTP:1936/healthz/ready
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 5
Interval: 10
```

### Procedure

1. Configure the HAProxy Ingress Controller, so that you can enable access to the cluster from your load balancer on ports 6443, 443, and 80:

#### Example HAProxy configuration

```
#...
listen my-cluster-api-6443
 bind 192.168.1.100:6443
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /readyz
 http-check expect status 200
```

```

server my-cluster-master-2 192.168.1.101:6443 check inter 10s rise 2 fall 2
server my-cluster-master-0 192.168.1.102:6443 check inter 10s rise 2 fall 2
server my-cluster-master-1 192.168.1.103:6443 check inter 10s rise 2 fall 2

listen my-cluster-machine-config-api-22623
 bind 192.168.1.100:22623
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /healthz
 http-check expect status 200
 server my-cluster-master-2 192.168.1.101:22623 check inter 10s rise 2 fall 2
 server my-cluster-master-0 192.168.1.102:22623 check inter 10s rise 2 fall 2
 server my-cluster-master-1 192.168.1.103:22623 check inter 10s rise 2 fall 2

listen my-cluster-apps-443
 bind 192.168.1.100:443
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /healthz/ready
 http-check expect status 200
 server my-cluster-worker-0 192.168.1.111:443 check port 1936 inter 10s rise 2 fall 2
 server my-cluster-worker-1 192.168.1.112:443 check port 1936 inter 10s rise 2 fall 2
 server my-cluster-worker-2 192.168.1.113:443 check port 1936 inter 10s rise 2 fall 2

listen my-cluster-apps-80
 bind 192.168.1.100:80
 mode tcp
 balance roundrobin
 option httpchk
 http-check connect
 http-check send meth GET uri /healthz/ready
 http-check expect status 200
 server my-cluster-worker-0 192.168.1.111:80 check port 1936 inter 10s rise 2 fall 2
 server my-cluster-worker-1 192.168.1.112:80 check port 1936 inter 10s rise 2 fall 2
 server my-cluster-worker-2 192.168.1.113:80 check port 1936 inter 10s rise 2 fall 2
...

```

2. Use the **curl** CLI command to verify that the external load balancer and its resources are operational:
  - a. Verify that the cluster machine configuration API is accessible to the Kubernetes API server resource, by running the following command and observing the response:

```
$ curl https://<loadbalancer_ip_address>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```
{
 "major": "1",
 "minor": "11+",
 "gitVersion": "v1.11.0+ad103ed",
 "gitCommit": "ad103ed",

```

```
"gitTreeState": "clean",
"buildDate": "2019-01-09T06:44:10Z",
"goVersion": "go1.10.3",
"compiler": "gc",
"platform": "linux/amd64"
}
```

- b. Verify that the cluster machine configuration API is accessible to the Machine config server resource, by running the following command and observing the output:

```
$ curl -v https://<loadbalancer_ip_address>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

- c. Verify that the controller is accessible to the Ingress Controller resource on port 80, by running the following command and observing the output:

```
$ curl -I -L -H "Host: console-openshift-console.apps.<cluster_name>.<base_domain>"
http://<load_balancer_front_end_IP_address>
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.ocp4.private.opequon.net/
cache-control: no-cache
```

- d. Verify that the controller is accessible to the Ingress Controller resource on port 443, by running the following command and observing the output:

```
$ curl -I -L --insecure --resolve console-openshift-console.apps.<cluster_name>.<base_domain>:443:<Load Balancer Front End IP Address> https://console-openshift-console.apps.<cluster_name>.<base_domain>
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-
token=UIYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG
LgaYO0nxzVERhiXt6QepA7g==; Path=/; Secure; SameSite=Lax
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Wed, 04 Oct 2023 16:29:38 GMT
content-type: text/html; charset=utf-8
set-cookie:
1e2670d92730b515ce3a1bb65da45062=1bf5e9573c9a2760c964ed1659cc1673; path=/;
HttpOnly; Secure; SameSite=None
cache-control: private
```

3. Configure the DNS records for your cluster to target the front-end IP addresses of the external load balancer. You must update records to your DNS server for the cluster API and applications over the load balancer.

### Examples of modified DNS records

```
<load_balancer_ip_address> A api.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End
```

```
<load_balancer_ip_address> A apps.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End
```

### IMPORTANT

DNS propagation might take some time for each DNS record to become available. Ensure that each DNS record propagates before validating each record.

4. Use the **curl** CLI command to verify that the external load balancer and DNS record configuration are operational:
  - a. Verify that you can access the cluster API, by running the following command and observing the output:

```
$ curl https://api.<cluster_name>.<base_domain>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```
{
 "major": "1",
 "minor": "11+",
 "gitVersion": "v1.11.0+ad103ed",
 "gitCommit": "ad103ed",
 "gitTreeState": "clean",
 "buildDate": "2019-01-09T06:44:10Z",
 "goVersion": "go1.10.3",
 "compiler": "gc",
 "platform": "linux/amd64"
}
```

- b. Verify that you can access the cluster machine configuration, by running the following command and observing the output:

```
$ curl -v https://api.<cluster_name>.<base_domain>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

- c. Verify that you can access each cluster application on port, by running the following command and observing the output:

```
$ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.<cluster-name>.<base domain>/
cache-control: no-cacheHTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-

```

### 21.2.6.13. Next steps

- [Customize your cluster.](#)

- If necessary, you can [opt out of remote health reporting](#) .
- If necessary, see [Registering your disconnected cluster](#) .
- [Set up your registry and configure registry storage](#) .

## 21.3. USER-PROVISIONED INFRASTRUCTURE

### 21.3.1. vSphere installation requirements for user-provisioned infrastructure

Before you begin an installation on infrastructure that you provision, be sure that your vSphere environment meets the following installation requirements.

#### 21.3.1.1. VMware vSphere infrastructure requirements

You must install an OpenShift Container Platform cluster on one of the following versions of a VMware vSphere instance that meets the requirements for the components that you use:

- Version 7.0 Update 2 or later
- Version 8.0 Update 1 or later

Both of these releases support Container Storage Interface (CSI) migration, which is enabled by default on OpenShift Container Platform 4.14.

You can host the VMware vSphere infrastructure on-premise or on a [VMware Cloud Verified provider](#) that meets the requirements outlined in the following tables:

**Table 21.14. Version requirements for vSphere virtual environments**

| Virtual environment product | Required version                             |
|-----------------------------|----------------------------------------------|
| VMware virtual hardware     | 15 or later                                  |
| vSphere ESXi hosts          | 7.0 Update 2 or later; 8.0 Update 1 or later |
| vCenter host                | 7.0 Update 2 or later; 8.0 Update 1 or later |

#### IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.

**Table 21.15. Minimum supported vSphere version for VMware components**

| Component | Minimum supported versions | Description |
|-----------|----------------------------|-------------|
|-----------|----------------------------|-------------|

| Component                    | Minimum supported versions                                                                                | Description                                                                                                                                                                                                                                                                                                            |
|------------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hypervisor                   | vSphere 7.0 Update 2 (or later)<br>or vSphere 8.0 Update 1 (or later)<br>with virtual hardware version 15 | This hypervisor version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see <a href="#">Hardware</a> on the Red Hat Customer Portal.               |
| Optional: Networking (NSX-T) | vSphere 7.0 Update 2 or later;<br>vSphere 8.0 Update 1 or later                                           | At a minimum, vSphere 7.0 Update 2 or vSphere 8.0 Update 1 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware's <a href="#">NSX container plugin documentation</a> .                          |
| CPU micro-architecture       | x86-64-v2 or higher                                                                                       | OpenShift 4.13 and later are based on RHEL 9.2 host operating system which raised the microarchitecture requirements to x86-64-v2. See the <a href="#">RHEL Microarchitecture requirements documentation</a> . You can verify compatibility by following the procedures outlined in <a href="#">this KCS article</a> . |

## IMPORTANT

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure (OCI) and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Base-production environment: 500 GB, and 60 VPUs.
- Heavy-use production environment: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See [Block Volume Performance Levels \(Oracle documentation\)](#).

### 21.3.1.2. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:

- VMware vSphere version: 7.0 Update 2 or later; 8.0 Update 1 or later
- vCenter version: 7.0 Update 2 or later; 8.0 Update 1 or later
- Virtual machines of hardware version 15 or later
- No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

#### NOTE

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with **platform: vsphere** in the installation manifest.

#### Additional resources

- To remove a third-party vSphere CSI driver, see [Removing a third-party vSphere CSI Driver](#).
- To update the hardware version for your vSphere nodes, see [Updating hardware on nodes running in vSphere](#).

### 21.3.1.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

#### 21.3.1.3.1. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

##### Required vCenter account privileges

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

#### Example 21.4. Roles and privileges required for installation in vSphere API

| vSphere object for role       | When required                              | Required privileges in vSphere API                                                                                                                                                                                                                                                                                                                                                                                                                           |

Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

#### Example 21.6. Required permissions and propagation settings

| vSphere object                         | When required                           | Propagate to children | Permissions required       |
|----------------------------------------|-----------------------------------------|-----------------------|----------------------------|
| vSphere vCenter                        | Always                                  | False                 | Listed required privileges |
| vSphere vCenter Datacenter             | Existing folder                         | False                 | <b>ReadOnly</b> permission |
|                                        | Installation program creates the folder | True                  | Listed required privileges |
| vSphere vCenter Cluster                | Existing resource pool                  | False                 | <b>ReadOnly</b> permission |
|                                        | VMs in cluster root                     | True                  | Listed required privileges |
| vSphere vCenter Datastore              | Always                                  | False                 | Listed required privileges |
| vSphere Switch                         | Always                                  | False                 | <b>ReadOnly</b> permission |
| vSphere Port Group                     | Always                                  | False                 | Listed required privileges |
| vSphere vCenter Virtual Machine Folder | Existing folder                         | True                  | Listed required privileges |

| vSphere object                | When required          | Propagate to children | Permissions required       |
|-------------------------------|------------------------|-----------------------|----------------------------|
| vSphere vCenter Resource Pool | Existing resource pool | True                  | Listed required privileges |

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- Using Storage vMotion can cause issues and is not supported.
- Using VMware compute vMotion to migrate the workloads for both OpenShift Container Platform compute machines and control plane machines is generally supported, where *generally* implies that you meet all VMware best practices for vMotion. To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for [vMotion networking requirements](#) and [VM anti-affinity rules](#).

- If you are using VMware vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.
- OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

### IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

### Cluster resources

When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder

- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

### Cluster limits

Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

### Networking requirements

Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

#### NOTE

You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.

Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

If you are installing to a restricted environment, the VM in your restricted network must have access to vCenter so that it can provision and manage nodes, persistent volume claims (PVCs), and other resources.

Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

#### NOTE

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

## Required IP Addresses

For a network that uses DHCP, an installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

## DNS records

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, **<cluster\_name>** is the cluster name and **<base\_domain>** is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: **<component>.<cluster\_name>.<base\_domain>..**

**Table 21.16. Required DNS records**

| Component   | Record                                                   | Description                                                                                                                                                                                                                                                                                 |
|-------------|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| API VIP     | <b>api.&lt;cluster_name&gt;.&lt;base_domain&gt;..</b>    | This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.                                                                           |
| Ingress VIP | <b>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;..</b> | A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster. |

### 21.3.1.3.2. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 21.17. Minimum required hosts**

| Hosts                                                                   | Description                                                                                                                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine                                         | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines                                            | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.                                                                                                             |

### IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

#### 21.3.1.3.3. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 21.18. Minimum resource requirements**

| Machine       | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS                         | 4        | 16 GB       | 100 GB  | 300                               |
| Compute       | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

## Additional resources

- [Optimizing storage](#)

### 21.3.1.3.4. Requirements for encrypting virtual machines

You can encrypt your virtual machines prior to installing OpenShift Container Platform 4.14 by meeting the following requirements.

- You have configured a Standard key provider in vSphere. For more information, see [Adding a KMS to vCenter Server](#).

## IMPORTANT

The Native key provider in vCenter is not supported. For more information, see [vSphere Native Key Provider Overview](#).

- You have enabled host encryption mode on all of the ESXi hosts that are hosting the cluster. For more information, see [Enabling host encryption mode](#).
- You have a vSphere account which has all cryptographic privileges enabled. For more information, see [Cryptographic Operations Privileges](#).

When you deploy the OVF template in the section titled "Installing RHCOS and starting the OpenShift Container Platform bootstrap process", select the option to "Encrypt this virtual machine" when you are

selecting storage for the OVF template. After completing cluster installation, create a storage class that uses the encryption storage policy you used to encrypt the virtual machines.

### Additional resources

- [Creating an encrypted storage class](#)

#### 21.3.1.3.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

#### 21.3.1.3.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

##### 21.3.1.3.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

##### 21.3.1.3.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

### IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 21.19. Ports used for all-machine to all-machine communications

| Protocol | Port | Description                |
|----------|------|----------------------------|
| ICMP     | N/A  | Network reachability tests |

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| TCP      | <b>1936</b>        | Metrics                                                                                                                                     |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> .           |

### 21.3.1.3.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

#### NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster\_name>** is the cluster name and **<base\_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster\_name>.<base\_domain>..**

Table 21.22. Required DNS records

| Component      | Record                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Kubernetes API | <b>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>     | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                            |
|                | <b>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b> | <div> A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster. </div> <div>  <h4>IMPORTANT</h4> <p>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</p> </div> |

| Component              | Record                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Routes                 | <b>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                         | <p>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</p> <p>For example, <b>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</b> is used as a wildcard route to the OpenShift Container Platform console.</p> |
| Bootstrap machine      | <b>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>                      | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                                |
| Control plane machines | <b>&lt;control_plane&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b> | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                 |
| Compute machines       | <b>&lt;compute&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>       | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                        |

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

**21.3.1.3.7.1. Example DNS configuration for user-provisioned clusters**

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

**Example 21.7. Sample DNS zone database**

```

$TTL 1W
@ IN SOA ns1.example.com. root (

```

- ❶ Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
- ❷ Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- ❸ Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- 4 Provides name resolution for the bootstrap machine.
- 5 6 7 Provides name resolution for the control plane machines.
- 8 9 Provides name resolution for the compute machines.

### Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

#### Example 21.8. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (
 2019070700 ; serial
 3H ; refresh (3 hours)
 30M ; retry (30 minutes)
 2W ; expiry (2 weeks)
 1W) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR control-plane0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR control-plane1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR control-plane2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR compute0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR compute1.ocp4.example.com. 8
;
;EOF
```

- 1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- 2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- 3 Provides reverse DNS resolution for the bootstrap machine.
- 4 5 6 Provides reverse DNS resolution for the control plane machines.
- 7 8 Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

**21.3.1.3.8. Load balancing requirements for user-provisioned infrastructure**

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
  - Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
  - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 21.23. API load balancer**

| Port         | Back-end machines (pool members)                                                                                                                                                                                                              | Internal | External | Description           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|-----------------------|
| <b>6443</b>  | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <b>/readyz</b> endpoint for the API server health check probe. | X        | X        | Kubernetes API server |
| <b>22623</b> | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.                                                                                       | X        |          | Machine config server |

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.
- Configure the following conditions:
- Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
  - A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 21.24. Application Ingress load balancer

| Port | Back-end machines (pool members)                                                   | Internal | External | Description   |
|------|------------------------------------------------------------------------------------|----------|----------|---------------|
| 443  | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTPS traffic |
| 80   | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTP traffic  |

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

21.3.1.3.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an **/etc/haproxy/haproxy.cfg** configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

## NOTE

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy\_connect\_any=1**.

### Example 21.9. Sample API and application Ingress load balancer configuration

```
global
 log 127.0.0.1 local2
 pidfile /var/run/haproxy.pid
 maxconn 4000
 daemon
defaults
 mode http
 log global
 option dontlognull
 option http-server-close
 option redispatch
 retries 3
 timeout http-request 10s
 timeout queue 1m
 timeout connect 10s
 timeout client 1m
 timeout server 1m
 timeout http-keep-alive 10s
 timeout check 10s
 maxconn 3000
listen api-server-6443 1
 bind *:6443
 mode tcp
 option httpchk GET /readyz HTTP/1.0
 option log-health-checks
 balance roundrobin
 server bootstrap bootstrap.ocp4.example.com:6443 verify none check check-ssl inter 10s fall 2
 rise 3 backup 2
 server master0 master0.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
 fall 2 rise 3
 server master1 master1.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
 fall 2 rise 3
 server master2 master2.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
 fall 2 rise 3
listen machine-config-server-22623 3
 bind *:22623
 mode tcp
 server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup 4
 server master0 master0.ocp4.example.com:22623 check inter 1s
 server master1 master1.ocp4.example.com:22623 check inter 1s
 server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443 5
```

```

bind *:443
mode tcp
balance source
server worker0 worker0.ocp4.example.com:443 check inter 1s
server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80 6
bind *:80
mode tcp
balance source
server worker0 worker0.ocp4.example.com:80 check inter 1s
server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- 1** Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- 2** **4** The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- 3** Port **22623** handles the machine config server traffic and points to the control plane machines.
- 5** Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 6** Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

#### NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

#### TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltp** on the HAProxy node.

### 21.3.2. Preparing to install a cluster using user-provisioned infrastructure

You prepare to install an OpenShift Container Platform cluster on vSphere by completing the following steps:

- Downloading the installation program.

#### NOTE

If you are installing in a disconnected environment, you extract the installation program from the mirrored content. For more information, see [Mirroring images for a disconnected installation](#).

- Installing the OpenShift CLI (**oc**).

**NOTE**

If you are installing in a disconnected environment, install **oc** to the mirror host.

- Generating an SSH key pair. You can use this key pair to authenticate into the OpenShift Container Platform cluster's nodes after it is deployed.
- Preparing the user-provisioned infrastructure.
- Validating DNS resolution.

### 21.3.2.1. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

#### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

#### Procedure

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 21.3.2.2. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

##### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.

To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

#### 21.3.2.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The **./openshift-install gather** command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as **~/.ssh/id\_ed25519**, of the new SSH key. If you have an existing key pair, ensure your public key is in the your **~/.ssh** directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the **~/.ssh/id\_ed25519.pub** public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the **./openshift-install gather** command.

### NOTE

On some distributions, default SSH private key identities such as **~/.ssh/id\_rsa** and **~/.ssh/id\_dsa** are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

#### Example output

```
Agent pid 31874
```

#### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

#### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

#### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 21.3.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

#### Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

#### Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
  - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
  - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

**NOTE**

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

**NOTE**

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.
3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.

**IMPORTANT**

By default, port **1936** is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
  - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
  - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.  
See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.

## 5. Validate your DNS configuration.

- a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
- b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

### NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

## 21.3.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

### IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

### Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

### Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
  - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- 1 Replace **<nameserver\_ip>** with the IP address of the nameserver, **<cluster\_name>** with your cluster name, and **<base\_domain>** with your base domain name.

### Example output

```
api.ocp4.example.com. 604800 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

#### Example output

```
api-int.ocp4.example.com. 604800 IN A 192.168.1.5
```

- c. Test an example **\*.apps.<cluster\_name>.<base\_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

#### Example output

```
random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

#### NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

#### Example output

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

#### Example output

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

- a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

### Example output

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
```

- 1** Provides the record name for the Kubernetes internal API.
- 2** Provides the record name for the Kubernetes API.

### NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

### Example output

```
96.1.168.192.in-addr.arpa. 604800 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

## 21.3.3. Installing a cluster on vSphere with user-provisioned infrastructure

In OpenShift Container Platform version 4.14, you can install a cluster on VMware vSphere infrastructure that you provision.

### NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

## IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

### 21.3.3.1. Prerequisites

- You have completed the tasks in [Preparing to install a cluster using user-provisioned infrastructure](#).
- You reviewed your VMware platform licenses. Red Hat does not place any restrictions on your VMware licenses, but some VMware infrastructure components require licensing.
- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You provisioned [persistent storage](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

## NOTE

Be sure to also review this site list if you are configuring a proxy.

### 21.3.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

## IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 21.3.3.3. VMware vSphere region and zone enablement

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

## IMPORTANT

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature is only available on a newly installed cluster.

For a cluster that was upgraded from a previous release, you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default **install-config.yaml** file includes **vccenters** and **failureDomains** fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- Failure domain: Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- Region: Specifies a vCenter datacenter. You define a region by using a tag from the **openshift-region** tag category.
- Zone: Specifies a vCenter cluster. You define a zone by using a tag from the **openshift-zone** tag category.

## NOTE

If you plan on specifying more than one failure domain in your **install-config.yaml** file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster than runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
| us-east             | us-east-1      | us-east-1a |
|                     |                | us-east-1b |
|                     | us-east-2      | us-east-2a |
|                     |                | us-east-2b |
| us-west             | us-west-1      | us-west-1a |
|                     |                | us-west-1b |
|                     | us-west-2      | us-west-2a |
|                     |                | us-west-2b |

#### Additional resources

- [Additional VMware vSphere configuration parameters](#)
- [Deprecated VMware vSphere configuration parameters](#)
- [vSphere automatic migration](#)
- [VMware vSphere CSI Driver Operator](#)

#### 21.3.3.4. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

### NOTE

You must name this configuration file **install-config.yaml**.

3. If you are installing a three-node cluster, modify the **install-config.yaml** file by setting the **compute.replicas** parameter to **0**. This ensures that the cluster's control planes are schedulable. For more information, see "Installing a three-node cluster on vSphere".
4. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

#### Additional resources

- [Installation configuration parameters](#)

#### 21.3.3.4.1. Sample **install-config.yaml** file for VMware vSphere

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
additionalTrustBundlePolicy: Proxyonly
apiVersion: v1
baseDomain: example.com ❶
compute: ❷
- architecture: amd64
 name: <worker_node>
 platform: {}
 replicas: 0 ❸
controlPlane: ❹
 architecture: amd64
 name: <parent_node>
 platform: {}
 replicas: 3 ❺
metadata:
```

```

creationTimestamp: null
name: test 6
networking:

platform:
 vsphere:
 failureDomains: 7
 - name: <failure_domain_name>
 region: <default_region_name>
 server: <fully_qualified_domain_name>
 topology:
 computeCluster: "/<datacenter>/host/<cluster>"
 datacenter: <datacenter> 8
 datastore: "/<datacenter>/datastore/<datastore>" 9
 networks:
 - <VM_Network_name>
 resourcePool: "/<datacenter>/host/<cluster>/Resources/<resourcePool>" 10
 folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>" 11
 zone: <default_zone_name>
 vcenters:
 - datacenters:
 - <datacenter>
 password: <password> 12
 port: 443
 server: <fully_qualified_domain_name> 13
 user: administrator@vsphere.local
 diskType: thin 14
 fips: false 15
 pullSecret: '{"auths": ...}' 16
 sshKey: 'ssh-ed25519 AAAA...' 17

```

- 1** The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
- 2** **4** The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Both sections define a single machine pool, so only one control plane is used. OpenShift Container Platform does not support defining multiple compute pools.
- 3** You must set the value of the **replicas** parameter to **0**. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.
- 5** The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 6** The cluster name that you specified in your DNS records.
- 7** Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

- 8 The vSphere datacenter.
- 9 The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

### IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- 10 Optional: For installer-provisioned infrastructure, the absolute path of an existing resource pool where the installation program creates the virtual machines, for example, `/<datacenter_name>/host/<cluster_name>/Resources/<resource_pool_name>/<optional_nested_resource_pool_name>`. If you do not specify a value, resources are installed in the root of the cluster `/example_datacenter/host/example_cluster/Resources`.
- 11 Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, `/<datacenter_name>/vm/<folder_name>/<subfolder_name>`. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster and you do not want to use the default **StorageClass** object, named **thin**, you can omit the **folder** parameter from the **install-config.yaml** file.
- 12 The password associated with the vSphere user.
- 13 The fully-qualified hostname or IP address of the vCenter server.

### IMPORTANT

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

- 14 The vSphere disk provisioning method.
- 15 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 16 The pull secret that you obtained from [OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
- 17 The public portion of the default SSH key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

### 21.3.3.4.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

- Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.
```

```

<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com 3
additionalTrustBundle: | 4
-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5

```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.
- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations. If you have added the Amazon **EC2**, **Elastic Load Balancing**, and **S3** VPC endpoints to your VPC, you must add these endpoints to the **noProxy** field. You must include vCenter's IP address and the IP range that you use for its machines.
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

**21.3.3.4.3. Configuring regions and zones for a VMware vCenter**

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default **install-config.yaml** file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the **openshift-installer** will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

**IMPORTANT**

The example uses the **govc** command. The **govc** command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the **govc** command. Instructions for downloading and installing **govc** are found on the VMware documentation website

**Prerequisites**

- You have an existing **install-config.yaml** installation configuration file.

**IMPORTANT**

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

**Procedure**

1. Enter the following **govc** command-line tool commands to create the **openshift-region** and **openshift-zone** vCenter tag categories:

**IMPORTANT**

If you specify different names for the **openshift-region** and **openshift-zone** vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

```
$ govc tags.category.create -d "OpenShift region" openshift-region
```

```
$ govc tags.category.create -d "OpenShift zone" openshift-zone
```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

```
$ govc tags.create -c <region_tag_category> <region_tag>
```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
```

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

### Sample install-config.yaml file with multiple datacenters defined in a vSphere center

```

compute:

vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

controlPlane:

vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

platform:
 vsphere:
 vcenters:

 datacenters:
 - <datacenter1_name>
 - <datacenter2_name>
 failureDomains:
 - name: <machine_pool_zone_1>
 region: <region_tag_1>
 zone: <zone_tag_1>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter1>
 computeCluster: "/<datacenter1>/host/<cluster1>"
 networks:
 - <VM_Network1_name>
 datastore: "/<datacenter1>/datastore/<datastore1>"
```

```

 resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
 folder: "/<datacenter1>/vm/<folder1>"
- name: <machine_pool_zone_2>
 region: <region_tag_2>
 zone: <zone_tag_2>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter2>
 computeCluster: "/<datacenter2>/host/<cluster2>"
 networks:
 - <VM_Network2_name>
 datastore: "/<datacenter2>/datastore/<datastore2>"
 resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
 folder: "/<datacenter2>/vm/<folder2>"

```

### 21.3.3.5. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

#### IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrap** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

#### Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

#### Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

### IMPORTANT

If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

5. Remove the Kubernetes manifest files that define the control plane machines, compute machine sets, and control plane machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the compute machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

### WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

## IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

6. Check that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
  - a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
  - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
7. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
 privateZone: ❶
 id: mycluster-100419-private-zone
 publicZone: ❷
 id: example.openshift.com
status: {}
```

- ❶ ❷ Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

8. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> ❶
```

- ❶ For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the `./<installation_directory>/auth` directory:

```
.
├── auth
│ ├── kubeadmin-password
│ └── kubeconfig
└── bootstrap.ign
```

### 21.3.3.6. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere (vSphere). The infrastructure name is also used to locate the appropriate vSphere resources during an OpenShift Container Platform installation. The provided {cp-template} templates contain references to this infrastructure name, so you must extract it.

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

#### Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

#### Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

#### Example output

```
openshift-vw9j6 1
```

- 1 The output of this command is your cluster name and a random string.

### 21.3.3.7. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

#### Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a [vSphere cluster](#).

## Procedure

1. Upload the bootstrap Ignition config file, which is named **<installation\_directory>/bootstrap.ign**, that the installation program created to your HTTP server. Note the URL of this file.
2. Save the following secondary Ignition config file for your bootstrap node to your computer as **<installation\_directory>/merge-bootstrap.ign**:

```
{
 "ignition": {
 "config": {
 "merge": [
 {
 "source": "<bootstrap_ignition_config_url>", 1
 "verification": {}
 }
]
 },
 "timeouts": {},
 "version": "3.2.0"
 },
 "networkd": {},
 "passwd": {},
 "storage": {},
 "systemd": {}
}
```

- 1** Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
  - **<installation\_directory>/master.ign**
  - **<installation\_directory>/worker.ign**
  - **<installation\_directory>/merge-bootstrap.ign**
4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter **guestinfo.ignition.config.data** in your VM. For example, if you use a Linux operating system, you can use the **base64** command to encode the files.

```
$ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
```

```
$ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
```

```
$ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
```

### IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the [RHCOS image mirror](#) page.

### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format **rhcos-vmware.<architecture>.ova**.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
  - a. Click the **VMs and Templates** view.
  - b. Right-click the name of your datacenter.
  - c. Click **New Folder → New VM and Template Folder**.
  - d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the **install-config.yaml** file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.
7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

### NOTE

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

- a. From the **Hosts and Clusters** tab, right-click your cluster name and select **Deploy OVF Template**.
- b. On the **Select an OVF** tab, specify the name of the RHCOS OVA file that you downloaded.
- c. On the **Select a name and folder** tab, set a **Virtual machine name** for your template, such as **Template-RHCOS**. Click the name of your vSphere cluster and select the folder you created in the previous step.

- d. On the **Select a compute resource** tab, click the name of your vSphere cluster.
- e. On the **Select storage** tab, configure the storage options for your VM.
  - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.
  - Select the datastore that you specified in your **install-config.yaml** file.
  - If you want to encrypt your virtual machines, select **Encrypt this virtual machine**. See the section titled "Requirements for encrypting virtual machines" for more information.
- f. On the **Select network** tab, specify the network that you configured for the cluster, if available.
- g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

### IMPORTANT

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that compute machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow [Upgrading a virtual machine to the latest hardware version](#) in the VMware documentation for more information.

### IMPORTANT

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.
  - a. Right-click the template name and click **Clone → Clone to Virtual Machine**
  - b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **control-plane-0** or **compute-1**.

### NOTE

Ensure that all virtual machine names across a vSphere installation are unique.

- c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

- d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
- e. On the **Select clone options** tab, select **Customize this virtual machine's hardware**
- f. On the **Customize hardware** tab, click **Advanced Parameters**.

### IMPORTANT

The following configuration suggestions are for example purposes only. As a cluster administrator, you must configure resources according to the resource demands placed on your cluster. To best manage cluster resources, consider creating a resource pool from the cluster's root resource pool.

- Optional: Override default DHCP networking in vSphere. To enable static IP networking:
  - Set your static IP configuration:

#### Example command

```
$ export IPCFG="ip=<ip>::<gateway>:<netmask>:<hostname>:<iface>:none
nameserver=svr1 [nameserver=svr2 [nameserver=svr3 [...]]]"
```

#### Example command

```
$ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0::none
nameserver=8.8.8.8"
```

- Set the **guestinfo.afterburn.initrd.network-kargs** property before you boot a VM from an OVA in vSphere:

#### Example command

```
$ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-
kargs=${IPCFG}"
```

- Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.
  - **guestinfo.ignition.config.data**: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
  - **disk.EnableUUID**: Specify **TRUE**.
  - **stealclock.enable**: If this parameter was not defined, add it and specify **TRUE**.
  - Create a child resource pool from the cluster's root resource pool. Perform resource allocation in this child resource pool.

- g. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.
- h. Complete the remaining configuration steps. On clicking the **Finish** button, you have completed the cloning operation.
- i. From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.
- j. Check the console output to verify that Ignition ran.

### Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

### Next steps

- Create the rest of the machines for your cluster by following the preceding steps for each machine.

### IMPORTANT

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

### 21.3.3.8. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

After your vSphere template deploys in your OpenShift Container Platform cluster, you can deploy a virtual machine (VM) for a machine in that cluster.

### NOTE

If you are installing a three-node cluster, skip this step. A three-node cluster consists of three control plane machines, which also act as compute machines.

### Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

### Procedure

1. Right-click the template's name and click **Clone → Clone to Virtual Machine**
2. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

**NOTE**

Ensure that all virtual machine names across a vSphere installation are unique.

3. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
4. On the **Select a compute resource** tab, select the name of a host in your datacenter.
5. On the **Select storage** tab, select storage for your configuration and disk files.
6. On the **Select clone options** tab, select **Customize this virtual machine's hardware**.
7. On the **Customize hardware** tab, click **Advanced Parameters**.
  - Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.
    - **guestinfo.ignition.config.data**: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
    - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
    - **disk.EnableUUID**: Specify **TRUE**.
8. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. If many networks exist, select **Add New Device > Network Adapter**, and then enter your network information in the fields provided by the **New Network** menu item.
9. Complete the remaining configuration steps. On clicking the **Finish** button, you have completed the cloning operation.
10. From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.

**Next steps**

- Continue to create more compute machines for your cluster.

**21.3.3.9. Disk partitioning**

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making **/var** or a subdirectory of **/var**, such as **/var/lib/etcd**, a separate partition, but not both.

**IMPORTANT**

For disk sizes larger than 100GB, and especially disk sizes larger than 1TB, create a separate **/var** partition. See "Creating a separate **/var** partition" and this [Red Hat Knowledgebase article](#) for more information.

**IMPORTANT**

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retain existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to **coreos-installer** that allow you to retain existing data partitions.

**Creating a separate /var partition**

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers:** Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd:** Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var:** Holds data that you might want to keep separate for purposes such as auditing.

**IMPORTANT**

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate **/var** partition.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
? SSH Public Key ...
$ ls $HOME/clusterconfig/openshift/
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

3. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
 labels:
 machineconfiguration.openshift.io/role: worker
 name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> ❶
 partitions:
 - label: var
 start_mib: <partition_start_offset> ❷
 size_mib: <partition_size> ❸
 number: 5
 filesystems:
 - device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] ❹
 with_mount_unit: true
```

- ❶ The storage device name of the disk that you want to partition.
- ❷ When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ❸ The size of the data partition in mebibytes.
- ❹ The **prjquota** mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

5. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 21.3.3.10. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

#### Procedure

1. Monitor the bootstrap process:

```
$./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 1
--log-level=info 2
```

**1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

**2** To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

### Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

### IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

#### 21.3.3.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

### Example output

```
system:admin
```

#### 21.3.3.12. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

## Prerequisites

- You added machines to your cluster.

## Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 63m v1.27.3
master-1 Ready master 63m v1.27.3
master-2 Ready master 64m v1.27.3
```

The output lists all of the machines that you created.

### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

```
NAME AGE REQUESTOR CONDITION
csr-8b2br 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
csr-8vnps 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrap** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

| NAME      | AGE   | REQUESTOR                                             | CONDITION |
|-----------|-------|-------------------------------------------------------|-----------|
| csr-bfd72 | 5m26s | system:node:ip-10-0-50-126.us-east-2.compute.internal | Pending   |
| csr-c57lv | 5m26s | system:node:ip-10-0-95-157.us-east-2.compute.internal | Pending   |
| ...       |       |                                                       |           |

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

### 21.3.3.13. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

### Prerequisites

- Your control plane has initialized.

### Procedure

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

| NAME                                     | VERSION | AVAILABLE | PROGRESSING | DEGRADED  |
|------------------------------------------|---------|-----------|-------------|-----------|
| SINCE                                    |         |           |             |           |
| authentication                           | 4.14.0  | True      | False       | False 19m |
| baremetal                                | 4.14.0  | True      | False       | False 37m |
| cloud-credential                         | 4.14.0  | True      | False       | False 40m |
| cluster-autoscaler                       | 4.14.0  | True      | False       | False 37m |
| config-operator                          | 4.14.0  | True      | False       | False 38m |
| console                                  | 4.14.0  | True      | False       | False 26m |
| csi-snapshot-controller                  | 4.14.0  | True      | False       | False 37m |
| dns                                      | 4.14.0  | True      | False       | False 37m |
| etcd                                     | 4.14.0  | True      | False       | False 36m |
| image-registry                           | 4.14.0  | True      | False       | False 31m |
| ingress                                  | 4.14.0  | True      | False       | False 30m |
| insights                                 | 4.14.0  | True      | False       | False 31m |
| kube-apiserver                           | 4.14.0  | True      | False       | False 26m |
| kube-controller-manager                  | 4.14.0  | True      | False       | False 36m |
| kube-scheduler                           | 4.14.0  | True      | False       | False 36m |
| kube-storage-version-migrator            | 4.14.0  | True      | False       | False 37m |
| machine-api                              | 4.14.0  | True      | False       | False 29m |
| machine-approver                         | 4.14.0  | True      | False       | False 37m |
| machine-config                           | 4.14.0  | True      | False       | False 36m |
| marketplace                              | 4.14.0  | True      | False       | False 37m |
| monitoring                               | 4.14.0  | True      | False       | False 29m |
| network                                  | 4.14.0  | True      | False       | False 38m |
| node-tuning                              | 4.14.0  | True      | False       | False 37m |
| openshift-apiserver                      | 4.14.0  | True      | False       | False 32m |
| openshift-controller-manager             | 4.14.0  | True      | False       | False 30m |
| openshift-samples                        | 4.14.0  | True      | False       | False 32m |
| operator-lifecycle-manager               | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-catalog       | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-packageserver | 4.14.0  | True      | False       | False 32m |
| service-ca                               | 4.14.0  | True      | False       | False 38m |
| storage                                  | 4.14.0  | True      | False       | False 37m |

2. Configure the Operators that are not available.

**21.3.3.13.1. Image registry removed during installation**

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**. When this has completed, you must configure storage.

**21.3.3.13.2. Image registry storage configuration**

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

### 21.3.3.13.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

#### IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

#### IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

#### Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

#### NOTE

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

### Example output

```
No resources found in openshift-image-registry namespace
```

### NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

### Example output

```
storage:
 pvc:
 claim: 1
```

- 1 Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

### Example output

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED |
|----------------|---------|-----------|-------------|----------|
| image-registry | 4.7     | True      | False       | False    |

#### 21.3.3.13.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

### Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 21.3.3.13.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. Enter the following command to set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy, and runs with only **1** replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
  - a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: image-registry-storage ❶
 namespace: openshift-image-registry ❷
spec:
 accessModes:
 - ReadWriteOnce ❸
 resources:
 requests:
 storage: 100Gi ❹
```

- ❶ A unique name that represents the **PersistentVolumeClaim** object.

- 2 The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
- 3 The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
- 4 The size of the persistent volume claim.

b. Enter the following command to create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Enter the following command to edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

### Example output

```
storage:
 pvc:
 claim: 1
```

- 1 By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 21.3.3.14. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

#### Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

#### Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

### Example output

| NAME<br>SINCE  | VERSION | AVAILABLE | PROGRESSING | DEGRADED  |
|----------------|---------|-----------|-------------|-----------|
| authentication | 4.14.0  | True      | False       | False 19m |

|                                          |        |      |       |       |     |
|------------------------------------------|--------|------|-------|-------|-----|
| baremetal                                | 4.14.0 | True | False | False | 37m |
| cloud-credential                         | 4.14.0 | True | False | False | 40m |
| cluster-autoscaler                       | 4.14.0 | True | False | False | 37m |
| config-operator                          | 4.14.0 | True | False | False | 38m |
| console                                  | 4.14.0 | True | False | False | 26m |
| csi-snapshot-controller                  | 4.14.0 | True | False | False | 37m |
| dns                                      | 4.14.0 | True | False | False | 37m |
| etcd                                     | 4.14.0 | True | False | False | 36m |
| image-registry                           | 4.14.0 | True | False | False | 31m |
| ingress                                  | 4.14.0 | True | False | False | 30m |
| insights                                 | 4.14.0 | True | False | False | 31m |
| kube-apiserver                           | 4.14.0 | True | False | False | 26m |
| kube-controller-manager                  | 4.14.0 | True | False | False | 36m |
| kube-scheduler                           | 4.14.0 | True | False | False | 36m |
| kube-storage-version-migrator            | 4.14.0 | True | False | False | 37m |
| machine-api                              | 4.14.0 | True | False | False | 29m |
| machine-approver                         | 4.14.0 | True | False | False | 37m |
| machine-config                           | 4.14.0 | True | False | False | 36m |
| marketplace                              | 4.14.0 | True | False | False | 37m |
| monitoring                               | 4.14.0 | True | False | False | 29m |
| network                                  | 4.14.0 | True | False | False | 38m |
| node-tuning                              | 4.14.0 | True | False | False | 37m |
| openshift-apiserver                      | 4.14.0 | True | False | False | 32m |
| openshift-controller-manager             | 4.14.0 | True | False | False | 30m |
| openshift-samples                        | 4.14.0 | True | False | False | 32m |
| operator-lifecycle-manager               | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-catalog       | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-packageserver | 4.14.0 | True | False | False | 32m |
| service-ca                               | 4.14.0 | True | False | False | 38m |
| storage                                  | 4.14.0 | True | False | False | 37m |

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

### Example output

| NAMESPACE                         | NAME                                          | READY | STATUS  |
|-----------------------------------|-----------------------------------------------|-------|---------|
| openshift-apiserver-operator      | openshift-apiserver-operator-85cb746d55-zqhs8 | 1/1   | Running |
| openshift-apiserver               | apiserver-67b9g                               | 1/1   | Running |
| openshift-apiserver               | apiserver-ljcmx                               | 1/1   | Running |
| openshift-apiserver               | apiserver-z25h4                               | 1/1   | Running |
| openshift-authentication-operator | authentication-operator-69d5d8bf84-vh2n8      | 1/1   | Running |

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> 1
```

- 1** Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the *Postinstallation machine configuration tasks* documentation for more information.

You can add extra compute machines after the cluster installation is completed by following [Adding compute machines to vSphere](#).

### 21.3.3.15. Configuring vSphere DRS anti-affinity rules for control plane nodes

vSphere Distributed Resource Scheduler (DRS) anti-affinity rules can be configured to support higher availability of OpenShift Container Platform Control Plane nodes. Anti-affinity rules ensure that the vSphere Virtual Machines for the OpenShift Container Platform Control Plane nodes are not scheduled to the same vSphere Host.

#### IMPORTANT

- The following information applies to compute DRS only and does not apply to storage DRS.
- The **govc** command is an open-source command available from VMware; it is not available from Red Hat. The **govc** command is not supported by the Red Hat support.
- Instructions for downloading and installing **govc** are found on the VMware documentation website.

Create an anti-affinity rule by running the following command:

#### Example command

```
$ govc cluster.rule.create \
-name openshift4-control-plane-group \
-dc MyDatacenter -cluster MyCluster \
-enable \
-anti-affinity master-0 master-1 master-2
```

After creating the rule, your control plane nodes are automatically migrated by vSphere so they are not running on the same hosts. This might take some time while vSphere reconciles the new rule. Successful command completion is shown in the following procedure.

#### NOTE

The migration occurs automatically and might cause brief OpenShift API outage or latency until the migration finishes.

The vSphere DRS anti-affinity rules need to be updated manually in the event of a control plane VM name change or migration to a new vSphere Cluster.

#### Procedure

1. Remove any existing DRS anti-affinity rule by running the following command:

```
$ govc cluster.rule.remove \
-name openshift4-control-plane-group \
-dc MyDatacenter -cluster MyCluster
```

#### Example Output

```
[13-10-22 09:33:24] Reconfigure /MyDatacenter/host/MyCluster...OK
```

2. Create the rule again with updated names by running the following command:

```
$ govc cluster.rule.create \
 -name openshift4-control-plane-group \
 -dc MyDatacenter -cluster MyOtherCluster \
 -enable \
 -anti-affinity master-0 master-1 master-2
```

### 21.3.3.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 21.3.3.17. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).
- Optional: [View the events from the vSphere Problem Detector Operator](#) to determine if the cluster has permission or storage configuration issues.
- Optional: if you created encrypted virtual machines, [create an encrypted storage class](#).

## 21.3.4. Installing a cluster on vSphere with network customizations

In OpenShift Container Platform version 4.14, you can install a cluster on VMware vSphere infrastructure that you provision with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

#### NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

You must set most of the network configuration parameters during installation, and you can modify only **kubeProxy** configuration parameters in a running cluster.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

**21.3.4.1. Prerequisites**

- You have completed the tasks in [Preparing to install a cluster using user-provisioned infrastructure](#).
- You reviewed your VMware platform licenses. Red Hat does not place any restrictions on your VMware licenses, but some VMware infrastructure components require licensing.
- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. Verify that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

**21.3.4.2. Internet access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

**21.3.4.3. VMware vSphere region and zone enablement**

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

## IMPORTANT

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature is only available on a newly installed cluster.

For a cluster that was upgraded from a previous release, you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default **install-config.yaml** file includes **vccenters** and **failureDomains** fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- **Failure domain:** Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- **Region:** Specifies a vCenter datacenter. You define a region by using a tag from the **openshift-region** tag category.
- **Zone:** Specifies a vCenter cluster. You define a zone by using a tag from the **openshift-zone** tag category.

## NOTE

If you plan on specifying more than one failure domain in your **install-config.yaml** file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster that runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
| us-east             | us-east-1      | us-east-1a |

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
|                     |                | us-east-1b |
|                     | us-east-2      | us-east-2a |
|                     |                | us-east-2b |
| us-west             | us-west-1      | us-west-1a |
|                     |                | us-west-1b |
|                     | us-west-2      | us-west-2a |
|                     |                | us-west-2b |

- [VMware vSphere CSI Driver Operator](#)

#### 21.3.4.4. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

### IMPORTANT

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

### NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

#### Additional resources

- [Installation configuration parameters](#)

#### 21.3.4.4.1. Sample **install-config.yaml** file for VMware vSphere

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
additionalTrustBundlePolicy: Proxyonly
apiVersion: v1
baseDomain: example.com 1
compute: 2
- architecture: amd64
 name: <worker_node>
 platform: {}
 replicas: 0 3
controlPlane: 4
 architecture: amd64
 name: <parent_node>
 platform: {}
 replicas: 3 5
metadata:
 creationTimestamp: null
 name: test 6
networking:

```

```

platform:
 vsphere:
 failureDomains: 7
 - name: <failure_domain_name>
 region: <default_region_name>
 server: <fully_qualified_domain_name>
 topology:
 computeCluster: "/<datacenter>/host/<cluster>"
 datacenter: <datacenter> 8
 datastore: "/<datacenter>/datastore/<datastore>" 9
 networks:
 - <VM_Network_name>
 resourcePool: "/<datacenter>/host/<cluster>/Resources/<resourcePool>" 10
 folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>" 11
 zone: <default_zone_name>
 vcenters:
 - datacenters:
 - <datacenter>
 password: <password> 12
 port: 443
 server: <fully_qualified_domain_name> 13
 user: administrator@vsphere.local
 diskType: thin 14
 fips: false 15
 pullSecret: '{"auths": ...}' 16
 sshKey: 'ssh-ed25519 AAAA...' 17

```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
- 2 4 The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Both sections define a single machine pool, so only one control plane is used. OpenShift Container Platform does not support defining multiple compute pools.
- 3 You must set the value of the **replicas** parameter to **0**. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.
- 5 The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 6 The cluster name that you specified in your DNS records.
- 7 Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- 8 The vSphere datacenter.
- 9 The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

## IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- 10 Optional: For installer-provisioned infrastructure, the absolute path of an existing resource pool where the installation program creates the virtual machines, for example, `/<datacenter_name>/host/<cluster_name>/Resources/<resource_pool_name>/<optional_nested_resource_pool_name>`. If you do not specify a value, resources are installed in the root of the cluster `/example_datacenter/host/example_cluster/Resources`.
- 11 Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, `/<datacenter_name>/vm/<folder_name>/<subfolder_name>`. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster and you do not want to use the default **StorageClass** object, named **thin**, you can omit the **folder** parameter from the **install-config.yaml** file.
- 12 The password associated with the vSphere user.
- 13 The fully-qualified hostname or IP address of the vCenter server.

## IMPORTANT

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

- 14 The vSphere disk provisioning method.
- 15 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

## IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 16 The pull secret that you obtained from [OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io,
- 17 The public portion of the default SSH key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

#### 21.3.4.4.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

#### NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

- Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.
 <aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.

- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

#### 21.3.4.4.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default **install-config.yaml** file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the **openshift-installer** will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

**IMPORTANT**

The example uses the **govc** command. The **govc** command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the **govc** command. Instructions for downloading and installing **govc** are found on the VMware documentation website

**Prerequisites**

- You have an existing **install-config.yaml** installation configuration file.

**IMPORTANT**

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

**Procedure**

1. Enter the following **govc** command-line tool commands to create the **openshift-region** and **openshift-zone** vCenter tag categories:

**IMPORTANT**

If you specify different names for the **openshift-region** and **openshift-zone** vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

```
$ govc tags.category.create -d "OpenShift region" openshift-region
```

```
$ govc tags.category.create -d "OpenShift zone" openshift-zone
```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

```
$ govc tags.create -c <region_tag_category> <region_tag>
```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-
workload-1
```

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

### Sample install-config.yaml file with multiple datacenters defined in a vSphere center

```

compute:

vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

controlPlane:

vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

platform:
 vsphere:
 vcenters:

 datacenters:
 - <datacenter1_name>
 - <datacenter2_name>
 failureDomains:
 - name: <machine_pool_zone_1>
 region: <region_tag_1>
 zone: <zone_tag_1>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter1>
 computeCluster: "/<datacenter1>/host/<cluster1>"
 networks:
 - <VM_Network1_name>
 datastore: "/<datacenter1>/datastore/<datastore1>"
 resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
 folder: "/<datacenter1>/vm/<folder1>"
 - name: <machine_pool_zone_2>
 region: <region_tag_2>
 zone: <zone_tag_2>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter2>
 computeCluster: "/<datacenter2>/host/<cluster2>"
 networks:
 - <VM_Network2_name>
 datastore: "/<datacenter2>/datastore/<datastore2>"
```

```
resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
folder: "/<datacenter2>/vm/<folder2>"

```

#### 21.3.4.5. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

##### Phase 1

You can customize the following network-related fields in the **install-config.yaml** file before you create the manifest files:

- **networking.networkType**
- **networking.clusterNetwork**
- **networking.serviceNetwork**
- **networking.machineNetwork**

For more information on these fields, refer to *Installation configuration parameters*.

#### NOTE

Set the **networking.machineNetwork** to match the CIDR that the preferred NIC resides in.

#### IMPORTANT

The CIDR range **172.17.0.0/16** is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

##### Phase 2

After creating the manifest files by running **openshift-install create manifests**, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the **install-config.yaml** file during phase 2. However, you can further customize the network plugin during phase 2.

#### 21.3.4.6. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

#### IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

## Prerequisites

- You have created the **install-config.yaml** file and completed any modifications to it.

## Procedure

1. Change to the directory that contains the installation program and create the manifests:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 **<installation\_directory>** specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yml** in the **<installation\_directory>/manifests/** directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
```

3. Specify the advanced network configuration for your cluster in the **cluster-network-03-config.yml** file, such as in the following examples:

### Specify a different VXLAN port for the OpenShift SDN network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 openshiftSDNConfig:
 vxlanPort: 4800
```

### Enable IPsec for the OVN-Kubernetes network provider

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
 name: cluster
spec:
 defaultNetwork:
 ovnKubernetesConfig:
 ipsecConfig: {}
```

4. Optional: Back up the **manifests/cluster-network-03-config.yml** file. The installation program consumes the **manifests/** directory when you create the Ignition config files.
5. Remove the Kubernetes manifest files that define the control plane machines and compute machineSets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the MachineSet files to create compute machines by using the machine API, but you must update references to them to match your environment.

### 21.3.4.7. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named **cluster**. The CR specifies the fields for the **Network** API in the **operator.openshift.io** API group.

The CNO configuration inherits the following fields during cluster installation from the **Network** API in the **Network.config.openshift.io** API group:

#### **clusterNetwork**

IP address pools from which pod IP addresses are allocated.

#### **serviceNetwork**

IP address pool for services.

#### **defaultNetwork.type**

Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

#### 21.3.4.7.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 21.25. Cluster Network Operator configuration object**

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                              |
|----------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metadata.name</b>       | <b>string</b> | The name of the CNO object. This name is always <b>cluster</b> .                                                                                                                                                                                                                                                         |
| <b>spec.clusterNetwork</b> | <b>array</b>  | <p>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</p> <pre>spec:   clusterNetwork:     - cidr: 10.128.0/19       hostPrefix: 23     - cidr: 10.128.32.0/19       hostPrefix: 23</pre> |

| Field                       | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>spec.serviceNetwork</b>  | <b>array</b>  | <p>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</p> <pre>spec:   serviceNetwork:   - 172.30.0.0/14</pre> <p>You can customize this field only in the <b>install-config.yaml</b> file before you create the manifests. The value is read-only in the manifest file.</p> |
| <b>spec.defaultNetwork</b>  | <b>object</b> | Configures the network plugin for the cluster network.                                                                                                                                                                                                                                                                                                                                            |
| <b>spec.kubeProxyConfig</b> | <b>object</b> | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.                                                                                                                                                                                                                          |

### defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

Table 21.26. **defaultNetwork** object

| Field                      | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>type</b>                | <b>string</b> | <p>Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b>. The Red Hat OpenShift Networking network plugin is selected during installation. You can change this value by migrating from OpenShift SDN to OVN-Kubernetes.</p> <div>  <div> <p><b>NOTE</b></p> <p>OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.</p> </div> </div> |
| <b>openshiftSDNConfig</b>  | <b>object</b> | This object is only valid for the OpenShift SDN network plugin.                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ovnKubernetesConfig</b> | <b>object</b> | This object is only valid for the OVN-Kubernetes network plugin.                                                                                                                                                                                                                                                                                                                                                                                 |

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

Table 21.27. openshiftSDNConfig object

| Field            | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b>      | <b>string</b>  | <p>Configures the network isolation mode for OpenShift SDN. The default value is <b>NetworkPolicy</b>.</p> <p>The values <b>Multitenant</b> and <b>Subnet</b> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>mtu</b>       | <b>integer</b> | <p>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>50</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1450</b>.</p> <p>This value cannot be changed after cluster installation.</p> |
| <b>vxlanPort</b> | <b>integer</b> | <p>The port to use for all VXLAN packets. The default value is <b>4789</b>. This value cannot be changed after cluster installation.</p> <p>If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.</p> <p>On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port <b>9000</b> and port <b>9999</b>.</p>                                                                                                                                                                                                                            |

### Example OpenShift SDN configuration

```
defaultNetwork:
 type: OpenShiftSDN
 openshiftSDNConfig:
 mode: NetworkPolicy
 mtu: 1450
 vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

Table 21.28. `ovnKubernetesConfig` object

| Field                    | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtu</b>               | <b>integer</b> | <p>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.</p> <p>If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.</p> <p>If your cluster requires different MTU values for different nodes, you must set this value to <b>100</b> less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of <b>9001</b>, and some have an MTU of <b>1500</b>, you must set this value to <b>1400</b>.</p> |
| <b>genevePort</b>        | <b>integer</b> | The port to use for all Geneve packets. The default value is <b>6081</b> . This value cannot be changed after cluster installation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipsecConfig</b>       | <b>object</b>  | Specify an empty object to enable IPsec encryption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>policyAuditConfig</b> | <b>object</b>  | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>gatewayConfig</b>     | <b>object</b>  | <p>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</p> <div>  <div> <p><b>NOTE</b></p> <p>While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.</p> </div> </div>                                                                                                                                                                                                                                                                                                                                                                                                        |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| <b>v4InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>100.64.0.0/16</b> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <b>clusterNetwork.cidr</b> value is <b>10.128.0.0/14</b> and the <b>clusterNetwork.hostPrefix</b> value is <b>/23</b>, then the maximum number of nodes is <b><math>2^{(23-14)}=512</math></b>.</p> <p>This field cannot be changed after installation.</p> | <p>The default value is <b>100.64.0.0/16</b>.</p> |

| Field                   | Type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| <b>v6InternalSubnet</b> | <p>If your existing network infrastructure overlaps with the <b>fd98::/48</b> IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.</p> <p>This field cannot be changed after installation.</p> | The default value is <b>fd98::/48</b> . |

Table 21.29. **policyAuditConfig** object

| Field              | Type    | Description                                                                                                           |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------|
| <b>rateLimit</b>   | integer | The maximum number of messages to generate every second per node. The default value is <b>20</b> messages per second. |
| <b>maxFileSize</b> | integer | The maximum size for the audit log in bytes. The default value is <b>50000000</b> or 50 MB.                           |
| <b>maxLogFiles</b> | integer | The maximum number of log files that are retained.                                                                    |

| Field                 | Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>destination</b>    | string | <p>One of the following additional audit log targets:</p> <p><b>libc</b><br/>The libc <b>syslog()</b> function of the journald process on the host.</p> <p><b>udp:&lt;host&gt;:&lt;port&gt;</b><br/>A syslog server. Replace <b>&lt;host&gt;:&lt;port&gt;</b> with the host and port of the syslog server.</p> <p><b>unix:&lt;file&gt;</b><br/>A Unix Domain Socket file specified by <b>&lt;file&gt;</b>.</p> <p><b>null</b><br/>Do not send the audit logs to any additional target.</p> |
| <b>syslogFacility</b> | string | The syslog facility, such as <b>kern</b> , as defined by RFC5424. The default value is <b>local0</b> .                                                                                                                                                                                                                                                                                                                                                                                     |

Table 21.30. gatewayConfig object

| Field                 | Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>routingViaHost</b> | <b>boolean</b> | <p>Set this field to <b>true</b> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <b>false</b>.</p> <p>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <b>true</b>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</p> |
| <b>ipForwarding</b>   | <b>object</b>  | You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <b>ipForwarding</b> specification in the <b>Network</b> resource. Specify <b>Restricted</b> to only allow IP forwarding for Kubernetes related traffic. Specify <b>Global</b> to allow forwarding of all IP traffic. For new installations, the default is <b>Restricted</b> . For updates to OpenShift Container Platform 4.14, the default is <b>Global</b> .                                                                                                                                                                                                                                                                                |

### Example OVN-Kubernetes configuration with IPsec enabled

```
defaultNetwork:
 type: OVNKubernetes
 ovnKubernetesConfig:
 mtu: 1400
 genevePort: 6081
 ipsecConfig: {}
```

**kubeProxyConfig object configuration (OpenShiftSDN container network interface only)**

The values for the **kubeProxyConfig** object are defined in the following table:

Table 21.31. **kubeProxyConfig** object

| Field                                          | Type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>iptablesSyncPeriod</b>                      | <b>string</b> | <p>The refresh period for <b>iptables</b> rules. The default value is <b>30s</b>. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a> documentation.</p> <div>  <div> <p><b>NOTE</b></p> <p>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the <b>iptablesSyncPeriod</b> parameter is no longer necessary.</p> </div> </div> |
| <b>proxyArguments.iptables-min-sync-period</b> | <b>array</b>  | <p>The minimum duration before refreshing <b>iptables</b> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <b>s</b>, <b>m</b>, and <b>h</b> and are described in the <a href="#">Go time package</a>. The default value is:</p> <div>  <pre>kubeProxyConfig:   proxyArguments:     iptables-min-sync-period:       - 0s</pre> </div>                                                              |

#### 21.3.4.8. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.

#### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

## Procedure

- Obtain the Ignition config files:

```
$./openshift-install create ignition-configs --dir <installation_directory> 1
```

- 1** For **<installation\_directory>**, specify the directory name to store the files that the installation program creates.

### IMPORTANT

If you created an **install-config.yaml** file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

The following files are generated in the directory:

### 21.3.4.9. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere (vSphere). The infrastructure name is also used to locate the appropriate vSphere resources during an OpenShift Container Platform installation. The provided {cp-template} templates contain references to this infrastructure name, so you must extract it.

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

## Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.

- You installed the **jq** package.

### Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

### Example output

```
openshift-vw9j6 1
```

- 1 The output of this command is your cluster name and a random string.

#### 21.3.4.10. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

### Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a [vSphere cluster](#).

### Procedure

1. Upload the bootstrap Ignition config file, which is named **<installation\_directory>/bootstrap.ign**, that the installation program created to your HTTP server. Note the URL of this file.
2. Save the following secondary Ignition config file for your bootstrap node to your computer as **<installation\_directory>/merge-bootstrap.ign**:

```
{
 "ignition": {
 "config": {
 "merge": [
 {
 "source": "<bootstrap_ignition_config_url>", 1
 }
]
 }
 }
}
```

```

 "verification": {}
 }
]
 },
 "timeouts": {},
 "version": "3.2.0"
},
"networkd": {},
"passwd": {},
"storage": {},
"systemd": {}
}

```

- 1 Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:

- **<installation\_directory>/master.ign**
- **<installation\_directory>/worker.ign**
- **<installation\_directory>/merge-bootstrap.ign**

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter **guestinfo.ignition.config.data** in your VM. For example, if you use a Linux operating system, you can use the **base64** command to encode the files.

```
$ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
```

```
$ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
```

```
$ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
```

### IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the [RHCOS image mirror](#) page.

### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format **rhcos-vmware.<architecture>.ova**.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
  - a. Click the **VMs and Templates** view.
  - b. Right-click the name of your datacenter.
  - c. Click **New Folder → New VM and Template Folder**.
  - d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the **install-config.yaml** file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.
7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

#### NOTE

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

- a. From the **Hosts and Clusters** tab, right-click your cluster name and select **Deploy OVF Template**.
- b. On the **Select an OVF** tab, specify the name of the RHCOS OVA file that you downloaded.
- c. On the **Select a name and folder** tab, set a **Virtual machine name** for your template, such as **Template-RHCOS**. Click the name of your vSphere cluster and select the folder you created in the previous step.
- d. On the **Select a compute resource** tab, click the name of your vSphere cluster.
- e. On the **Select storage** tab, configure the storage options for your VM.
  - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.
  - Select the datastore that you specified in your **install-config.yaml** file.
  - If you want to encrypt your virtual machines, select **Encrypt this virtual machine**. See the section titled "Requirements for encrypting virtual machines" for more information.
- f. On the **Select network** tab, specify the network that you configured for the cluster, if available.
- g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

### IMPORTANT

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that compute machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow [Upgrading a virtual machine to the latest hardware version](#) in the VMware documentation for more information.

### IMPORTANT

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.
  - a. Right-click the template name and click **Clone → Clone to Virtual Machine**
  - b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **control-plane-0** or **compute-1**.

### NOTE

Ensure that all virtual machine names across a vSphere installation are unique.

- c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
- d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
- e. On the **Select clone options** tab, select **Customize this virtual machine's hardware**
- f. On the **Customize hardware** tab, click **Advanced Parameters**.

### IMPORTANT

The following configuration suggestions are for example purposes only. As a cluster administrator, you must configure resources according to the resource demands placed on your cluster. To best manage cluster resources, consider creating a resource pool from the cluster's root resource pool.

- Optional: Override default DHCP networking in vSphere. To enable static IP networking:

- Set your static IP configuration:

#### Example command

```
$ export IPCFG="ip=<ip>::<gateway>:<netmask>:<hostname>:<iface>:none
nameserver=svr1 [nameserver=svr2 [nameserver=svr3 [...]]]"
```

#### Example command

```
$ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0::none
nameserver=8.8.8.8"
```

- Set the **guestinfo.afterburn.initrd.network-kargs** property before you boot a VM from an OVA in vSphere:

#### Example command

```
$ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-
kargs=${IPCFG}"
```

- Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.
  - **guestinfo.ignition.config.data**: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
  - **disk.EnableUUID**: Specify **TRUE**.
  - **stealclock.enable**: If this parameter was not defined, add it and specify **TRUE**.
  - Create a child resource pool from the cluster's root resource pool. Perform resource allocation in this child resource pool.
- g. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.
- h. Complete the remaining configuration steps. On clicking the **Finish** button, you have completed the cloning operation.
- i. From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.
- j. Check the console output to verify that Ignition ran.

#### Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

#### Next steps

- Create the rest of the machines for your cluster by following the preceding steps for each machine.

### IMPORTANT

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

#### 21.3.4.11. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

After your vSphere template deploys in your OpenShift Container Platform cluster, you can deploy a virtual machine (VM) for a machine in that cluster.

#### Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

#### Procedure

1. Right-click the template's name and click **Clone → Clone to Virtual Machine**
2. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

### NOTE

Ensure that all virtual machine names across a vSphere installation are unique.

3. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
4. On the **Select a compute resource** tab, select the name of a host in your datacenter.
5. On the **Select storage** tab, select storage for your configuration and disk files.
6. On the **Select clone options** tab, select **Customize this virtual machine's hardware**
7. On the **Customize hardware** tab, click **Advanced Parameters**.
  - Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.
    - **guestinfo.ignition.config.data**: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
    - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
    - **disk.EnableUUID**: Specify **TRUE**.

8. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. If many networks exist, select **Add New Device > Network Adapter**, and then enter your network information in the fields provided by the **New Network** menu item.
9. Complete the remaining configuration steps. On clicking the **Finish** button, you have completed the cloning operation.
10. From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.

### Next steps

- Continue to create more compute machines for your cluster.

#### 21.3.4.12. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- **Create separate partitions:** For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making **/var** or a subdirectory of **/var**, such as **/var/lib/etcd**, a separate partition, but not both.

#### IMPORTANT

For disk sizes larger than 100GB, and especially disk sizes larger than 1TB, create a separate **/var** partition. See "Creating a separate **/var** partition" and this [Red Hat Knowledgebase article](#) for more information.

#### IMPORTANT

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retain existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to **coreos-installer** that allow you to retain existing data partitions.

#### Creating a separate **/var** partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers:** Holds container-related content that can grow as more images and containers are added to a system.

- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

### IMPORTANT

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate **/var** partition.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

### Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
? SSH Public Key ...
$ ls $HOME/clusterconfig/openshift/
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

3. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
 labels:
 machineconfiguration.openshift.io/role: worker
 name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> 1
 partitions:
 - label: var
```

```

start_mib: <partition_start_offset> 2
size_mib: <partition_size> 3
number: 5
filesystems:
- device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] 4
 with_mount_unit: true

```

- 1 The storage device name of the disk that you want to partition.
- 2 When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- 3 The size of the data partition in mebibytes.
- 4 The **prjquota** mount option must be enabled for filesystems used for container storage.

#### NOTE

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

5. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

#### 21.3.4.13. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

## Procedure

1. Monitor the bootstrap process:

```
$./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

## IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 21.3.4.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

### Example output

```
system:admin
```

## 21.3.4.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

### Prerequisites

- You added machines to your cluster.

## Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 63m v1.27.3
master-1 Ready master 63m v1.27.3
master-2 Ready master 64m v1.27.3
```

The output lists all of the machines that you created.

### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

## Example output

| NAME      | AGE | REQUESTOR                                                                 | CONDITION |
|-----------|-----|---------------------------------------------------------------------------|-----------|
| csr-8b2br | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstrapper | Pending   |
| csr-8vnps | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstrapper | Pending   |
| ...       |     |                                                                           |           |

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

### NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

### NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

**1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

## Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

### 21.3.4.15.1. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

## Prerequisites

- Your control plane has initialized.

## Procedure

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

## Example output

| NAME                                     | VERSION | AVAILABLE | PROGRESSING | DEGRADED | SINCE |
|------------------------------------------|---------|-----------|-------------|----------|-------|
| authentication                           | 4.14.0  | True      | False       | False    | 19m   |
| baremetal                                | 4.14.0  | True      | False       | False    | 37m   |
| cloud-credential                         | 4.14.0  | True      | False       | False    | 40m   |
| cluster-autoscaler                       | 4.14.0  | True      | False       | False    | 37m   |
| config-operator                          | 4.14.0  | True      | False       | False    | 38m   |
| console                                  | 4.14.0  | True      | False       | False    | 26m   |
| csi-snapshot-controller                  | 4.14.0  | True      | False       | False    | 37m   |
| dns                                      | 4.14.0  | True      | False       | False    | 37m   |
| etcd                                     | 4.14.0  | True      | False       | False    | 36m   |
| image-registry                           | 4.14.0  | True      | False       | False    | 31m   |
| ingress                                  | 4.14.0  | True      | False       | False    | 30m   |
| insights                                 | 4.14.0  | True      | False       | False    | 31m   |
| kube-apiserver                           | 4.14.0  | True      | False       | False    | 26m   |
| kube-controller-manager                  | 4.14.0  | True      | False       | False    | 36m   |
| kube-scheduler                           | 4.14.0  | True      | False       | False    | 36m   |
| kube-storage-version-migrator            | 4.14.0  | True      | False       | False    | 37m   |
| machine-api                              | 4.14.0  | True      | False       | False    | 29m   |
| machine-approver                         | 4.14.0  | True      | False       | False    | 37m   |
| machine-config                           | 4.14.0  | True      | False       | False    | 36m   |
| marketplace                              | 4.14.0  | True      | False       | False    | 37m   |
| monitoring                               | 4.14.0  | True      | False       | False    | 29m   |
| network                                  | 4.14.0  | True      | False       | False    | 38m   |
| node-tuning                              | 4.14.0  | True      | False       | False    | 37m   |
| openshift-apiserver                      | 4.14.0  | True      | False       | False    | 32m   |
| openshift-controller-manager             | 4.14.0  | True      | False       | False    | 30m   |
| openshift-samples                        | 4.14.0  | True      | False       | False    | 32m   |
| operator-lifecycle-manager               | 4.14.0  | True      | False       | False    | 37m   |
| operator-lifecycle-manager-catalog       | 4.14.0  | True      | False       | False    | 37m   |
| operator-lifecycle-manager-packageserver | 4.14.0  | True      | False       | False    | 32m   |
| service-ca                               | 4.14.0  | True      | False       | False    | 38m   |
| storage                                  | 4.14.0  | True      | False       | False    | 37m   |

2. Configure the Operators that are not available.

#### 21.3.4.15.2. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**. When this has completed, you must configure storage.

#### 21.3.4.15.3. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

##### 21.3.4.15.3.1. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

#### IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

#### Procedure

1. Enter the following command to set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy, and runs with only **1** replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
  - a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: image-registry-storage ❶
 namespace: openshift-image-registry ❷
```

```
spec:
 accessModes:
 - ReadWriteOnce ❸
 resources:
 requests:
 storage: 100Gi ❹
```

- ❶ A unique name that represents the **PersistentVolumeClaim** object.
- ❷ The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
- ❸ The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
- ❹ The size of the persistent volume claim.

b. Enter the following command to create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Enter the following command to edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

### Example output

```
storage:
 pvc:
 claim: ❶
```

- ❶ By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 21.3.4.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

#### Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

#### Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

### Example output

| NAME                                     | VERSION | AVAILABLE | PROGRESSING | DEGRADED  |
|------------------------------------------|---------|-----------|-------------|-----------|
| SINCE                                    |         |           |             |           |
| authentication                           | 4.14.0  | True      | False       | False 19m |
| baremetal                                | 4.14.0  | True      | False       | False 37m |
| cloud-credential                         | 4.14.0  | True      | False       | False 40m |
| cluster-autoscaler                       | 4.14.0  | True      | False       | False 37m |
| config-operator                          | 4.14.0  | True      | False       | False 38m |
| console                                  | 4.14.0  | True      | False       | False 26m |
| csi-snapshot-controller                  | 4.14.0  | True      | False       | False 37m |
| dns                                      | 4.14.0  | True      | False       | False 37m |
| etcd                                     | 4.14.0  | True      | False       | False 36m |
| image-registry                           | 4.14.0  | True      | False       | False 31m |
| ingress                                  | 4.14.0  | True      | False       | False 30m |
| insights                                 | 4.14.0  | True      | False       | False 31m |
| kube-apiserver                           | 4.14.0  | True      | False       | False 26m |
| kube-controller-manager                  | 4.14.0  | True      | False       | False 36m |
| kube-scheduler                           | 4.14.0  | True      | False       | False 36m |
| kube-storage-version-migrator            | 4.14.0  | True      | False       | False 37m |
| machine-api                              | 4.14.0  | True      | False       | False 29m |
| machine-approver                         | 4.14.0  | True      | False       | False 37m |
| machine-config                           | 4.14.0  | True      | False       | False 36m |
| marketplace                              | 4.14.0  | True      | False       | False 37m |
| monitoring                               | 4.14.0  | True      | False       | False 29m |
| network                                  | 4.14.0  | True      | False       | False 38m |
| node-tuning                              | 4.14.0  | True      | False       | False 37m |
| openshift-apiserver                      | 4.14.0  | True      | False       | False 32m |
| openshift-controller-manager             | 4.14.0  | True      | False       | False 30m |
| openshift-samples                        | 4.14.0  | True      | False       | False 32m |
| operator-lifecycle-manager               | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-catalog       | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-packageserver | 4.14.0  | True      | False       | False 32m |
| service-ca                               | 4.14.0  | True      | False       | False 38m |
| storage                                  | 4.14.0  | True      | False       | False 37m |

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

## IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

### Example output

| NAMESPACE                         | NAME                                          | READY | STATUS  |
|-----------------------------------|-----------------------------------------------|-------|---------|
| openshift-apiserver-operator      | openshift-apiserver-operator-85cb746d55-zqhs8 | 1/1   | Running |
| openshift-apiserver               | apiserver-67b9g                               | 1/1   | Running |
| openshift-apiserver               | apiserver-ljcmx                               | 1/1   | Running |
| openshift-apiserver               | apiserver-z25h4                               | 1/1   | Running |
| openshift-authentication-operator | authentication-operator-69d5d8bf84-vh2n8      | 1/1   | Running |

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> 1
```

- 1 Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the *Postinstallation machine configuration tasks* documentation for more information.

You can add extra compute machines after the cluster installation is completed by following [Adding compute machines to vSphere](#).

### 21.3.4.17. Configuring vSphere DRS anti-affinity rules for control plane nodes

vSphere Distributed Resource Scheduler (DRS) anti-affinity rules can be configured to support higher availability of OpenShift Container Platform Control Plane nodes. Anti-affinity rules ensure that the vSphere Virtual Machines for the OpenShift Container Platform Control Plane nodes are not scheduled to the same vSphere Host.

#### IMPORTANT

- The following information applies to compute DRS only and does not apply to storage DRS.
- The **govc** command is an open-source command available from VMware; it is not available from Red Hat. The **govc** command is not supported by the Red Hat support.
- Instructions for downloading and installing **govc** are found on the VMware documentation website.

Create an anti-affinity rule by running the following command:

#### Example command

```
$ govc cluster.rule.create \
-name openshift4-control-plane-group \
-dc MyDatacenter -cluster MyCluster \
-enable \
-anti-affinity master-0 master-1 master-2
```

After creating the rule, your control plane nodes are automatically migrated by vSphere so they are not running on the same hosts. This might take some time while vSphere reconciles the new rule. Successful command completion is shown in the following procedure.

#### NOTE

The migration occurs automatically and might cause brief OpenShift API outage or latency until the migration finishes.

The vSphere DRS anti-affinity rules need to be updated manually in the event of a control plane VM name change or migration to a new vSphere Cluster.

#### Procedure

1. Remove any existing DRS anti-affinity rule by running the following command:

```
$ govc cluster.rule.remove \
-name openshift4-control-plane-group \
-dc MyDatacenter -cluster MyCluster
```

#### Example Output

```
[13-10-22 09:33:24] Reconfigure /MyDatacenter/host/MyCluster...OK
```

2. Create the rule again with updated names by running the following command:

```
$ govc cluster.rule.create \
-name openshift4-control-plane-group \
-dc MyDatacenter -cluster MyOtherCluster \
-enable \
-anti-affinity master-0 master-1 master-2
```

#### 21.3.4.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

#### 21.3.4.19. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).
- Optional: [View the events from the vSphere Problem Detector Operator](#) to determine if the cluster has permission or storage configuration issues.
- Optional: if you created encrypted virtual machines, [create an encrypted storage class](#).

### 21.3.5. Installing a cluster on vSphere in a restricted network with user-provisioned infrastructure

In OpenShift Container Platform version 4.14, you can install a cluster on VMware vSphere infrastructure that you provision in a restricted network.

#### NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

## IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

### 21.3.5.1. Prerequisites

- You have completed the tasks in [Preparing to install a cluster using user-provisioned infrastructure](#).
- You reviewed your VMware platform licenses. Red Hat does not place any restrictions on your VMware licenses, but some VMware infrastructure components require licensing.
- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You [created a registry on your mirror host](#) and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

## IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned [persistent storage](#) for your cluster. To deploy a private image registry, your storage must provide **ReadWriteMany** access modes.
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall and plan to use the Telemetry service, you [configured the firewall to allow the sites](#) that your cluster requires access to.

## NOTE

Be sure to also review this site list if you are configuring a proxy.

### 21.3.5.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

### IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

#### 21.3.5.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

#### 21.3.5.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### 21.3.5.4. VMware vSphere region and zone enablement

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

## IMPORTANT

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature is only available on a newly installed cluster.

For a cluster that was upgraded from a previous release, you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default **install-config.yaml** file includes **vcenters** and **failureDomains** fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- **Failure domain:** Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- **Region:** Specifies a vCenter datacenter. You define a region by using a tag from the **openshift-region** tag category.
- **Zone:** Specifies a vCenter cluster. You define a zone by using a tag from the **openshift-zone** tag category.

## NOTE

If you plan on specifying more than one failure domain in your **install-config.yaml** file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster that runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
| us-east             | us-east-1      | us-east-1a |
|                     |                | us-east-1b |
|                     | us-east-2      | us-east-2a |
|                     |                | us-east-2b |

| Datacenter (region) | Cluster (zone) | Tags       |
|---------------------|----------------|------------|
| us-west             | us-west-1      | us-west-1a |
|                     |                | us-west-1b |
|                     | us-west-2      | us-west-2a |
|                     |                | us-west-2b |

### Additional resources

- [VMware vSphere CSI Driver Operator](#)

### 21.3.5.5. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

#### IMPORTANT

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain the **imageContentSources** section from the output of the command to mirror the repository.
- Obtain the contents of the certificate for your mirror registry.

### Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

### NOTE

You must name this configuration file **install-config.yaml**.

- Unless you use a registry that RHCOS trusts by default, such as **docker.io**, you must provide the contents of the certificate for your mirror repository in the **additionalTrustBundle** section. In most cases, you must provide the certificate for your mirror.
- You must include the **imageContentSources** section from the output of the command to mirror the repository.

### IMPORTANT

- The **ImageContentSourcePolicy** file is generated as an output of **oc mirror** after the mirroring process is finished.
- The **oc mirror** command generates an **ImageContentSourcePolicy** file which contains the YAML needed to define **ImageContentSourcePolicy**. Copy the text from this file and paste it into your **install-config.yaml** file.
- You must run the 'oc mirror' command twice. The first time you run the **oc mirror** command, you get a full **ImageContentSourcePolicy** file. The second time you run the **oc mirror** command, you only get the difference between the first and second run. Because of this behavior, you must always keep a backup of these files in case you need to merge them into one complete **ImageContentSourcePolicy** file. Keeping a backup of these two output files ensures that you have a complete **ImageContentSourcePolicy** file.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

#### Additional resources

- [Installation configuration parameters](#)

#### 21.3.5.5.1. Sample **install-config.yaml** file for VMware vSphere

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

[illegible]

```

- <mirror_host_name>:<mirror_port>/<repo_name>/release
source: <source_image_1>
- mirrors:
- <mirror_host_name>:<mirror_port>/<repo_name>/release-images
source: <source_image_2>

```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
- 2 4 The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Both sections define a single machine pool, so only one control plane is used. OpenShift Container Platform does not support defining multiple compute pools.
- 3 You must set the value of the **replicas** parameter to **0**. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.
- 5 The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 6 The cluster name that you specified in your DNS records.
- 7 Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.
- 8 The vSphere datacenter.
- 9 The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

## IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a **datastore** object to specify a failure domain in your cluster's **install-config.yaml** configuration file. For more information, see "VMware vSphere region and zone enablement".

- 10 Optional: For installer-provisioned infrastructure, the absolute path of an existing resource pool where the installation program creates the virtual machines, for example, **/<datacenter\_name>/host/<cluster\_name>/Resources/<resource\_pool\_name>/<optional\_nested\_resource\_pool\_name>**. If you do not specify a value, resources are installed in the root of the cluster **/example\_datacenter/host/example\_cluster/Resources**.
- 11 Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, **/<datacenter\_name>/vm/<folder\_name>/<subfolder\_name>**. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster and you do

not want to use the default **StorageClass** object, named **thin**, you can omit the **folder** parameter from the **install-config.yaml** file.

- 12 The password associated with the vSphere user.
- 13 The fully-qualified hostname or IP address of the vCenter server.

### IMPORTANT

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

- 14 The vSphere disk provisioning method.
- 15 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 16 For **<local\_registry>**, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example **registry.example.com** or **registry.example.com:5000**. For **<credentials>**, specify the base64-encoded user name and password for your mirror registry.
- 17 The public portion of the default SSH key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

### NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

- 18 Provide the contents of the certificate file that you used for your mirror registry.
- 19 Provide the **imageContentSources** section from the output of the command to mirror the repository.

#### 21.3.5.5.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

## Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

## NOTE

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

## Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.
 <aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

**1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.

**2** A proxy URL to use for creating HTTPS connections outside the cluster.

**3** A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with **.** to match subdomains only. For example, **.y.com** matches **x.y.com**, but not **y.com**. Use **\*** to bypass the proxy for all destinations. If you have added the Amazon **EC2**, **Elastic Load Balancing**, and **S3** VPC endpoints to your VPC, you must add these endpoints to the **noProxy** field. You must include vCenter's IP address and the IP range that you use for its machines.

**4**

If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates

- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 21.3.5.5.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default **install-config.yaml** file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the **openshift-installer** will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

#### IMPORTANT

The example uses the **govc** command. The **govc** command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the **govc** command. Instructions for downloading and installing **govc** are found on the VMware documentation website

#### Prerequisites

- You have an existing **install-config.yaml** installation configuration file.

## IMPORTANT

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components. To enable regions and zones, you must define multiple failure domains for your OpenShift Container Platform cluster.

## Procedure

1. Enter the following **govc** command-line tool commands to create the **openshift-region** and **openshift-zone** vCenter tag categories:

## IMPORTANT

If you specify different names for the **openshift-region** and **openshift-zone** vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

```
$ govc tags.category.create -d "OpenShift region" openshift-region
```

```
$ govc tags.category.create -d "OpenShift zone" openshift-zone
```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

```
$ govc tags.create -c <region_tag_category> <region_tag>
```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
```

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

## Sample install-config.yaml file with multiple datacenters defined in a vSphere center

```

compute:

vsphere:
```

```

zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

controlPlane:

vsphere:
 zones:
 - "<machine_pool_zone_1>"
 - "<machine_pool_zone_2>"

platform:
 vsphere:
 vcenters:

 datacenters:
 - <datacenter1_name>
 - <datacenter2_name>
 failureDomains:
 - name: <machine_pool_zone_1>
 region: <region_tag_1>
 zone: <zone_tag_1>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter1>
 computeCluster: "/<datacenter1>/host/<cluster1>"
 networks:
 - <VM_Network1_name>
 datastore: "/<datacenter1>/datastore/<datastore1>"
 resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
 folder: "/<datacenter1>/vm/<folder1>"
 - name: <machine_pool_zone_2>
 region: <region_tag_2>
 zone: <zone_tag_2>
 server: <fully_qualified_domain_name>
 topology:
 datacenter: <datacenter2>
 computeCluster: "/<datacenter2>/host/<cluster2>"
 networks:
 - <VM_Network2_name>
 datastore: "/<datacenter2>/datastore/<datastore2>"
 resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
 folder: "/<datacenter2>/vm/<folder2>"

```

### 21.3.5.6. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

## IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the **install-config.yaml** installation configuration file.

## Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

## IMPORTANT

If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

5. Remove the Kubernetes manifest files that define the control plane machines, compute machine sets, and control plane machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the compute machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.
6. Check that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
    - a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
    - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
    - c. Save and exit the file.
  7. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
 privateZone: ❶
 id: mycluster-100419-private-zone
 publicZone: ❷
 id: example.openshift.com
status: {}
```

- ❶ ❷ Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

8. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> ❶
```

- ❶ For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

```
.
├── auth
│ ├── kubeadmin-password
│ └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

### 21.3.5.7. Configuring chrony time service

You must set the time server and related settings used by the chrony time service (**chronyd**) by modifying the contents of the **chrony.conf** file and passing those contents to your nodes as a machine config.

#### Procedure

1. Create a Butane config including the contents of the **chrony.conf** file. For example, to configure chrony on worker nodes, create a **99-worker-chrony.bu** file.

#### NOTE

See "Creating machine configs with Butane" for information about Butane.

```
variant: openshift
version: 4.14.0
metadata:
 name: 99-worker-chrony ❶
 labels:
 machineconfiguration.openshift.io/role: worker ❷
storage:
 files:
 - path: /etc/chrony.conf
 mode: 0644 ❸
 overwrite: true
 contents:
 inline: |
 pool 0.rhel.pool.ntp.org iburst ❹
 driftfile /var/lib/chrony/drift
 makestep 1.0 3
 rtcsync
 logdir /var/log/chrony
```

- ❶ ❷ On control plane nodes, substitute **master** for **worker** in both of these locations.

- 3 Specify an octal value mode for the **mode** field in the machine config file. After creating the file and applying the changes, the **mode** is converted to a decimal value. You can check
  - 4 Specify any valid, reachable time source, such as the one provided by your DHCP server.
2. Use Butane to generate a **MachineConfig** object file, **99-worker-chrony.yaml**, containing the configuration to be delivered to the nodes:

```
$ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
```

3. Apply the configurations in one of two ways:
  - If the cluster is not running yet, after you generate manifest files, add the **MachineConfig** object file to the **<installation\_directory>/openshift** directory, and then continue to create the cluster.
  - If the cluster is already running, apply the file:

```
$ oc apply -f ./99-worker-chrony.yaml
```

#### 21.3.5.8. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere (vSphere). The infrastructure name is also used to locate the appropriate vSphere resources during an OpenShift Container Platform installation. The provided {cp-template} templates contain references to this infrastructure name, so you must extract it.

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

#### Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

#### Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

#### Example output

openshift-vw9j6 **1**

- 1** The output of this command is your cluster name and a random string.

### 21.3.5.9. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

#### Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a [vSphere cluster](#).

#### Procedure

1. Upload the bootstrap Ignition config file, which is named **<installation\_directory>/bootstrap.ign**, that the installation program created to your HTTP server. Note the URL of this file.
2. Save the following secondary Ignition config file for your bootstrap node to your computer as **<installation\_directory>/merge-bootstrap.ign**:

```
{
 "ignition": {
 "config": {
 "merge": [
 {
 "source": "<bootstrap_ignition_config_url>", 1
 "verification": {}
 }
]
 },
 "timeouts": {},
 "version": "3.2.0"
 },
 "networkd": {},
 "passwd": {},
 "storage": {},
 "systemd": {}
}
```

- 1** Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
  - **<installation\_directory>/master.ign**
  - **<installation\_directory>/worker.ign**
  - **<installation\_directory>/merge-bootstrap.ign**
4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter **guestinfo.ignition.config.data** in your VM. For example, if you use a Linux operating system, you can use the **base64** command to encode the files.

```
$ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
```

```
$ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
```

```
$ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
```

#### IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the [RHCOS image mirror](#) page.

#### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format **rhcos-vmware.<architecture>.ova**.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
  - a. Click the **VMs and Templates** view.
  - b. Right-click the name of your datacenter.
  - c. Click **New Folder → New VM and Template Folder**.
  - d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the **install-config.yaml** file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

#### NOTE

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

- a. From the **Hosts and Clusters** tab, right-click your cluster name and select **Deploy OVF Template**.
- b. On the **Select an OVF** tab, specify the name of the RHCOS OVA file that you downloaded.
- c. On the **Select a name and folder** tab, set a **Virtual machine name** for your template, such as **Template-RHCOS**. Click the name of your vSphere cluster and select the folder you created in the previous step.
- d. On the **Select a compute resource** tab, click the name of your vSphere cluster.
- e. On the **Select storage** tab, configure the storage options for your VM.
  - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.
  - Select the datastore that you specified in your **install-config.yaml** file.
  - If you want to encrypt your virtual machines, select **Encrypt this virtual machine**. See the section titled "Requirements for encrypting virtual machines" for more information.
- f. On the **Select network** tab, specify the network that you configured for the cluster, if available.
- g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

#### IMPORTANT

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that compute machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow [Upgrading a virtual machine to the latest hardware version](#) in the VMware documentation for more information.

### IMPORTANT

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.
  - a. Right-click the template name and click **Clone → Clone to Virtual Machine**
  - b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **control-plane-0** or **compute-1**.

### NOTE

Ensure that all virtual machine names across a vSphere installation are unique.

- c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
  - d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
  - e. On the **Select clone options** tab, select **Customize this virtual machine's hardware**
  - f. On the **Customize hardware** tab, click **Advanced Parameters**.

### IMPORTANT

The following configuration suggestions are for example purposes only. As a cluster administrator, you must configure resources according to the resource demands placed on your cluster. To best manage cluster resources, consider creating a resource pool from the cluster's root resource pool.

- Optional: Override default DHCP networking in vSphere. To enable static IP networking:
  - Set your static IP configuration:

#### Example command

```
$ export IPCFG="ip=<ip>:<gateway>:<netmask>:<hostname>:<iface>:none
nameserver=svr1 [nameserver=svr2 [nameserver=svr3 [...]]]"
```

#### Example command

```
$ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0::none
nameserver=8.8.8.8"
```

- Set the **guestinfo.afterburn.initrd.network-kargs** property before you boot a VM from an OVA in vSphere:

### Example command

```
$ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
```

- Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.
  - **guestinfo.ignition.config.data**: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
  - **disk.EnableUUID**: Specify **TRUE**.
  - **stealclock.enable**: If this parameter was not defined, add it and specify **TRUE**.
  - Create a child resource pool from the cluster's root resource pool. Perform resource allocation in this child resource pool.
- g. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.
- h. Complete the remaining configuration steps. On clicking the **Finish** button, you have completed the cloning operation.
- i. From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.
- j. Check the console output to verify that Ignition ran.

### Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

### Next steps

- Create the rest of the machines for your cluster by following the preceding steps for each machine.

### IMPORTANT

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

### 21.3.5.10. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

After your vSphere template deploys in your OpenShift Container Platform cluster, you can deploy a virtual machine (VM) for a machine in that cluster.

## Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

## Procedure

1. Right-click the template's name and click **Clone → Clone to Virtual Machine**
2. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

### NOTE

Ensure that all virtual machine names across a vSphere installation are unique.

3. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
4. On the **Select a compute resource** tab, select the name of a host in your datacenter.
5. On the **Select storage** tab, select storage for your configuration and disk files.
6. On the **Select clone options** tab, select **Customize this virtual machine's hardware**
7. On the **Customize hardware** tab, click **Advanced Parameters**.
  - Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.
    - **guestinfo.ignition.config.data**: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
    - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
    - **disk.EnableUUID**: Specify **TRUE**.
8. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. If many networks exist, select **Add New Device > Network Adapter**, and then enter your network information in the fields provided by the **New Network** menu item.
9. Complete the remaining configuration steps. On clicking the **Finish** button, you have completed the cloning operation.
10. From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.

## Next steps

- Continue to create more compute machines for your cluster.

### 21.3.5.11. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- **Create separate partitions:** For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making **/var** or a subdirectory of **/var**, such as **/var/lib/etcd**, a separate partition, but not both.

#### IMPORTANT

For disk sizes larger than 100GB, and especially disk sizes larger than 1TB, create a separate **/var** partition. See "Creating a separate **/var** partition" and this [Red Hat Knowledgebase article](#) for more information.

#### IMPORTANT

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retain existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to **coreos-installer** that allow you to retain existing data partitions.

### Creating a separate **/var** partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** partition or a subdirectory of **/var**. For example:

- **/var/lib/containers:** Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd:** Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var:** Holds data that you might want to keep separate for purposes such as auditing.

#### IMPORTANT

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate **/var** partition.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as

needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because **/var** must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate **/var** partition by creating a machine config manifest that is inserted during the **openshift-install** preparation phases of an OpenShift Container Platform installation.

## Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run **openshift-install** to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
? SSH Public Key ...
$ ls $HOME/clusterconfig/openshift/
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

3. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
 labels:
 machineconfiguration.openshift.io/role: worker
 name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> ❶
 partitions:
 - label: var
 start_mib: <partition_start_offset> ❷
 size_mib: <partition_size> ❸
 number: 5
 filesystems:
 - device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] ❹
 with_mount_unit: true
```

- ❶ The storage device name of the disk that you want to partition.

- 2 When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to
- 3 The size of the data partition in mebibytes.
- 4 The **prjquota** mount option must be enabled for filesystems used for container storage.

#### NOTE

When creating a separate **/var** partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

5. Run **openshift-install** again to create Ignition configs from a set of files in the **manifest** and **openshift** subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

#### 21.3.5.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

#### Procedure

1. Monitor the bootstrap process:

```
$./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

### Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

### IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 21.3.5.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

## Example output

```
system:admin
```

### 21.3.5.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

#### Prerequisites

- You added machines to your cluster.

#### Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

## Example output

| NAME     | STATUS | ROLES  | AGE | VERSION |
|----------|--------|--------|-----|---------|
| master-0 | Ready  | master | 63m | v1.27.3 |
| master-1 | Ready  | master | 63m | v1.27.3 |
| master-2 | Ready  | master | 64m | v1.27.3 |

The output lists all of the machines that you created.

#### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

## Example output

| NAME      | AGE | REQUESTOR                                                              | CONDITION |
|-----------|-----|------------------------------------------------------------------------|-----------|
| csr-8b2br | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstrap | Pending   |
| csr-8vnps | 15m | system:serviceaccount:openshift-machine-config-operator:node-bootstrap | Pending   |
| ...       |     |                                                                        |           |

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

#### NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

#### NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

- 1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

#### NOTE

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

#### Example output

| NAME      | AGE   | REQUESTOR                                             | CONDITION |
|-----------|-------|-------------------------------------------------------|-----------|
| csr-bfd72 | 5m26s | system:node:ip-10-0-50-126.us-east-2.compute.internal | Pending   |

```
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

**1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

### 21.3.5.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

### Prerequisites

- Your control plane has initialized.

### Procedure

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

### Example output

| NAME                                     | VERSION | AVAILABLE | PROGRESSING | DEGRADED  |
|------------------------------------------|---------|-----------|-------------|-----------|
| SINCE                                    |         |           |             |           |
| authentication                           | 4.14.0  | True      | False       | False 19m |
| baremetal                                | 4.14.0  | True      | False       | False 37m |
| cloud-credential                         | 4.14.0  | True      | False       | False 40m |
| cluster-autoscaler                       | 4.14.0  | True      | False       | False 37m |
| config-operator                          | 4.14.0  | True      | False       | False 38m |
| console                                  | 4.14.0  | True      | False       | False 26m |
| csi-snapshot-controller                  | 4.14.0  | True      | False       | False 37m |
| dns                                      | 4.14.0  | True      | False       | False 37m |
| etcd                                     | 4.14.0  | True      | False       | False 36m |
| image-registry                           | 4.14.0  | True      | False       | False 31m |
| ingress                                  | 4.14.0  | True      | False       | False 30m |
| insights                                 | 4.14.0  | True      | False       | False 31m |
| kube-apiserver                           | 4.14.0  | True      | False       | False 26m |
| kube-controller-manager                  | 4.14.0  | True      | False       | False 36m |
| kube-scheduler                           | 4.14.0  | True      | False       | False 36m |
| kube-storage-version-migrator            | 4.14.0  | True      | False       | False 37m |
| machine-api                              | 4.14.0  | True      | False       | False 29m |
| machine-approver                         | 4.14.0  | True      | False       | False 37m |
| machine-config                           | 4.14.0  | True      | False       | False 36m |
| marketplace                              | 4.14.0  | True      | False       | False 37m |
| monitoring                               | 4.14.0  | True      | False       | False 29m |
| network                                  | 4.14.0  | True      | False       | False 38m |
| node-tuning                              | 4.14.0  | True      | False       | False 37m |
| openshift-apiserver                      | 4.14.0  | True      | False       | False 32m |
| openshift-controller-manager             | 4.14.0  | True      | False       | False 30m |
| openshift-samples                        | 4.14.0  | True      | False       | False 32m |
| operator-lifecycle-manager               | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-catalog       | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-packageserver | 4.14.0  | True      | False       | False 32m |
| service-ca                               | 4.14.0  | True      | False       | False 38m |
| storage                                  | 4.14.0  | True      | False       | False 37m |

2. Configure the Operators that are not available.

#### 21.3.5.15.1. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

#### Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
 -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

## TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Configuration → OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

### 21.3.5.15.2. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

#### 21.3.5.15.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

## Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

## IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

## IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

## Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

## NOTE

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

## Example output

```
No resources found in openshift-image-registry namespace
```

## NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

## Example output

```
storage:
 pvc:
 claim: 1
```

- 1 Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

#### Example output

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED    |
|----------------|---------|-----------|-------------|-------------|
| SINCE          | MESSAGE |           |             |             |
| image-registry | 4.7     | True      | False       | False 6h50m |

#### 21.3.5.15.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

#### Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

#### WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

#### 21.3.5.15.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

#### IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

#### Procedure

1. Enter the following command to set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy, and runs with only **1** replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

- a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: image-registry-storage 1
 namespace: openshift-image-registry 2
spec:
 accessModes:
 - ReadWriteOnce 3
 resources:
 requests:
 storage: 100Gi 4
```

- 1 A unique name that represents the **PersistentVolumeClaim** object.
- 2 The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
- 3 The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
- 4 The size of the persistent volume claim.

- b. Enter the following command to create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Enter the following command to edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

### Example output

```
storage:
 pvc:
 claim: 1
```

- 1 By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 21.3.5.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

#### Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

#### Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

#### Example output

| NAME                                     | VERSION | AVAILABLE | PROGRESSING | DEGRADED  |
|------------------------------------------|---------|-----------|-------------|-----------|
| SINCE                                    |         |           |             |           |
| authentication                           | 4.14.0  | True      | False       | False 19m |
| baremetal                                | 4.14.0  | True      | False       | False 37m |
| cloud-credential                         | 4.14.0  | True      | False       | False 40m |
| cluster-autoscaler                       | 4.14.0  | True      | False       | False 37m |
| config-operator                          | 4.14.0  | True      | False       | False 38m |
| console                                  | 4.14.0  | True      | False       | False 26m |
| csi-snapshot-controller                  | 4.14.0  | True      | False       | False 37m |
| dns                                      | 4.14.0  | True      | False       | False 37m |
| etcd                                     | 4.14.0  | True      | False       | False 36m |
| image-registry                           | 4.14.0  | True      | False       | False 31m |
| ingress                                  | 4.14.0  | True      | False       | False 30m |
| insights                                 | 4.14.0  | True      | False       | False 31m |
| kube-apiserver                           | 4.14.0  | True      | False       | False 26m |
| kube-controller-manager                  | 4.14.0  | True      | False       | False 36m |
| kube-scheduler                           | 4.14.0  | True      | False       | False 36m |
| kube-storage-version-migrator            | 4.14.0  | True      | False       | False 37m |
| machine-api                              | 4.14.0  | True      | False       | False 29m |
| machine-approver                         | 4.14.0  | True      | False       | False 37m |
| machine-config                           | 4.14.0  | True      | False       | False 36m |
| marketplace                              | 4.14.0  | True      | False       | False 37m |
| monitoring                               | 4.14.0  | True      | False       | False 29m |
| network                                  | 4.14.0  | True      | False       | False 38m |
| node-tuning                              | 4.14.0  | True      | False       | False 37m |
| openshift-apiserver                      | 4.14.0  | True      | False       | False 32m |
| openshift-controller-manager             | 4.14.0  | True      | False       | False 30m |
| openshift-samples                        | 4.14.0  | True      | False       | False 32m |
| operator-lifecycle-manager               | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-catalog       | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-packageserver | 4.14.0  | True      | False       | False 32m |
| service-ca                               | 4.14.0  | True      | False       | False 38m |
| storage                                  | 4.14.0  | True      | False       | False 37m |

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

Example output

| NAMESPACE                         | NAME                                          | READY | STATUS  |
|-----------------------------------|-----------------------------------------------|-------|---------|
| RESTARTS                          | AGE                                           |       |         |
| openshift-apiserver-operator      | openshift-apiserver-operator-85cb746d55-zqhs8 | 1/1   |         |
| Running                           | 1                                             | 9m    |         |
| openshift-apiserver               | apiserver-67b9g                               | 1/1   | Running |
| 3m                                |                                               |       | 0       |
| openshift-apiserver               | apiserver-ljcmx                               | 1/1   | Running |
| 1m                                |                                               |       | 0       |
| openshift-apiserver               | apiserver-z25h4                               | 1/1   | Running |
| 2m                                |                                               |       | 0       |
| openshift-authentication-operator | authentication-operator-69d5d8bf84-vh2n8      | 1/1   |         |
| Running                           | 0                                             | 5m    |         |
| ...                               |                                               |       |         |

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> 1
```

- 1 Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the *Postinstallation machine configuration tasks* documentation for more information.
4. Register your cluster on the [Cluster registration](#) page.

You can add extra compute machines after the cluster installation is completed by following [Adding compute machines to vSphere](#).

### 21.3.5.17. Configuring vSphere DRS anti-affinity rules for control plane nodes

vSphere Distributed Resource Scheduler (DRS) anti-affinity rules can be configured to support higher availability of OpenShift Container Platform Control Plane nodes. Anti-affinity rules ensure that the vSphere Virtual Machines for the OpenShift Container Platform Control Plane nodes are not scheduled to the same vSphere Host.

#### IMPORTANT

- The following information applies to compute DRS only and does not apply to storage DRS.
- The **govc** command is an open-source command available from VMware; it is not available from Red Hat. The **govc** command is not supported by the Red Hat support.
- Instructions for downloading and installing **govc** are found on the VMware documentation website.

Create an anti-affinity rule by running the following command:

#### Example command

```
$ govc cluster.rule.create \
-name openshift4-control-plane-group \
-dc MyDatacenter -cluster MyCluster \
-enable \
-anti-affinity master-0 master-1 master-2
```

After creating the rule, your control plane nodes are automatically migrated by vSphere so they are not running on the same hosts. This might take some time while vSphere reconciles the new rule. Successful command completion is shown in the following procedure.

**NOTE**

The migration occurs automatically and might cause brief OpenShift API outage or latency until the migration finishes.

The vSphere DRS anti-affinity rules need to be updated manually in the event of a control plane VM name change or migration to a new vSphere Cluster.

**Procedure**

1. Remove any existing DRS anti-affinity rule by running the following command:

```
$ govc cluster.rule.remove \
 -name openshift4-control-plane-group \
 -dc MyDatacenter -cluster MyCluster
```

**Example Output**

```
[13-10-22 09:33:24] Reconfigure /MyDatacenter/host/MyCluster...OK
```

2. Create the rule again with updated names by running the following command:

```
$ govc cluster.rule.create \
 -name openshift4-control-plane-group \
 -dc MyDatacenter -cluster MyOtherCluster \
 -enable \
 -anti-affinity master-0 master-1 master-2
```

**21.3.5.18. Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

**21.3.5.19. Next steps**

- [Customize your cluster](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by [configuring additional trust stores](#).
- If necessary, you can [opt out of remote health reporting](#).
- Optional: [View the events from the vSphere Problem Detector Operator](#) to determine if the cluster has permission or storage configuration issues.

- Optional: if you created encrypted virtual machines, [create an encrypted storage class](#) .

## 21.4. INSTALLING A CLUSTER ON VSPHERE USING THE ASSISTED INSTALLER

You can install OpenShift Container Platform on on-premise hardware or on-premise VMs by using the Assisted Installer. Installing OpenShift Container Platform by using the Assisted Installer supports **x86\_64**, **AArch64**, **ppc64le**, and **s390x** CPU architectures.

The Assisted Installer is a user-friendly installation solution offered on the Red Hat Hybrid Cloud Console. The Assisted Installer supports the various deployment platforms with a focus on the following infrastructures:

- Bare metal
- Nutanix
- vSphere

### 21.4.1. Additional resources

- [Installing OpenShift Container Platform with the Assisted Installer](#)

## 21.5. INSTALLING A CLUSTER ON VSPHERE USING THE AGENT-BASED INSTALLER

The Agent-based installation method provides the flexibility to boot your on-premises servers in any way that you choose. It combines the ease of use of the Assisted Installation service with the ability to run offline, including in air-gapped environments.

Agent-based installation is a subcommand of the OpenShift Container Platform installer. It generates a bootable ISO image containing all of the information required to deploy an OpenShift Container Platform cluster with an available release image.

### 21.5.1. Additional resources

- [Preparing to install with the Agent-based Installer](#)

## 21.6. INSTALLING A THREE-NODE CLUSTER ON VSPHERE

In OpenShift Container Platform version 4.14, you can install a three-node cluster on VMware vSphere. A three-node cluster consists of three control plane machines, which also act as compute machines. This type of cluster provides a smaller, more resource efficient cluster, for cluster administrators and developers to use for testing, development, and production.

You can install a three-node cluster using either installer-provisioned or user-provisioned infrastructure.

### 21.6.1. Configuring a three-node cluster

You configure a three-node cluster by setting the number of worker nodes to **0** in the **install-config.yaml** file before deploying the cluster. Setting the number of worker nodes to **0** ensures that the control plane machines are schedulable. This allows application workloads to be scheduled to run from the control plane nodes.

**NOTE**

Because application workloads run from control plane nodes, additional subscriptions are required, as the control plane nodes are considered to be compute nodes.

**Prerequisites**

- You have an existing **install-config.yaml** file.

**Procedure**

1. Set the number of compute replicas to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

**Example install-config.yaml file for a three-node cluster**

```
apiVersion: v1
baseDomain: example.com
compute:
- name: worker
 platform: {}
 replicas: 0
...
```

2. If you are deploying a cluster with user-provisioned infrastructure:
  - Configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. In a three-node cluster, the Ingress Controller pods run on the control plane nodes. For more information, see the "Load balancing requirements for user-provisioned infrastructure".
  - After you create the Kubernetes manifest files, make sure that the **spec.mastersSchedulable** parameter is set to **true** in **cluster-scheduler-02-config.yml** file. You can locate this file in **<installation\_directory>/manifests**. For more information, see "Creating the Kubernetes manifest and Ignition config files" in "Installing a cluster on vSphere with user-provisioned infrastructure".
  - Do not create additional worker nodes.

**Example cluster-scheduler-02-config.yml file for a three-node cluster**

```
apiVersion: config.openshift.io/v1
kind: Scheduler
metadata:
 creationTimestamp: null
 name: cluster
spec:
 mastersSchedulable: true
 policy:
 name: ""
status: {}
```

**21.6.2. Next steps**

- [Installing a cluster on vSphere with customizations](#)
- [Installing a cluster on vSphere with user-provisioned infrastructure](#)

## 21.7. UNINSTALLING A CLUSTER ON VSPHERE THAT USES INSTALLER-PROVISIONED INFRASTRUCTURE

You can remove a cluster that you deployed in your VMware vSphere instance by using installer-provisioned infrastructure.

### NOTE

When you run the **openshift-install destroy cluster** command to uninstall OpenShift Container Platform, vSphere volumes are not automatically deleted. The cluster administrator must manually find the vSphere volumes and delete them.

### 21.7.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

### NOTE

If you deployed your cluster to the AWS C2S Secret Region, the installation program does not support destroying the cluster; you must manually remove the cluster resources.

### NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access. For example, some Google Cloud resources require [IAM permissions](#) in shared VPC host projects, or there might be unused [health checks that must be deleted](#).

### Prerequisites

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

### Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$./openshift-install destroy cluster \
--dir <installation_directory> --log-level info 1 2
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.
- 2** To view different details, specify **warn**, **debug**, or **error** instead of **info**.

**NOTE**

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the **metadata.json** file in this directory to delete the cluster.

- Optional: Delete the **<installation\_directory>** directory and the OpenShift Container Platform installation program.

## 21.8. USING THE VSPHERE PROBLEM DETECTOR OPERATOR

### 21.8.1. About the vSphere Problem Detector Operator

The vSphere Problem Detector Operator checks clusters that are deployed on vSphere for common installation and misconfiguration issues that are related to storage.

The Operator runs in the **openshift-cluster-storage-operator** namespace and is started by the Cluster Storage Operator when the Cluster Storage Operator detects that the cluster is deployed on vSphere. The vSphere Problem Detector Operator communicates with the vSphere vCenter Server to determine the virtual machines in the cluster, the default datastore, and other information about the vSphere vCenter Server configuration. The Operator uses the credentials from the Cloud Credential Operator to connect to vSphere.

The Operator runs the checks according to the following schedule:

- The checks run every 8 hours.
- If any check fails, the Operator runs the checks again in intervals of 1 minute, 2 minutes, 4, 8, and so on. The Operator doubles the interval up to a maximum interval of 8 hours.
- When all checks pass, the schedule returns to an 8 hour interval.

The Operator increases the frequency of the checks after a failure so that the Operator can report success quickly after the failure condition is remedied. You can run the Operator manually for immediate troubleshooting information.

### 21.8.2. Running the vSphere Problem Detector Operator checks

You can override the schedule for running the vSphere Problem Detector Operator checks and run the checks immediately.

The vSphere Problem Detector Operator automatically runs the checks every 8 hours. However, when the Operator starts, it runs the checks immediately. The Operator is started by the Cluster Storage Operator when the Cluster Storage Operator starts and determines that the cluster is running on vSphere. To run the checks immediately, you can scale the vSphere Problem Detector Operator to **0** and back to **1** so that it restarts the vSphere Problem Detector Operator.

#### Prerequisites

- Access to the cluster as a user with the **cluster-admin** role.

#### Procedure

- Scale the Operator to **0**:

■

```
$ oc scale deployment/vsphere-problem-detector-operator --replicas=0 \
-n openshift-cluster-storage-operator
```

If the deployment does not scale to zero immediately, you can run the following command to wait for the pods to exit:

```
$ oc wait pods -l name=vsphere-problem-detector-operator \
--for=delete --timeout=5m -n openshift-cluster-storage-operator
```

2. Scale the Operator back to **1**:

```
$ oc scale deployment/vsphere-problem-detector-operator --replicas=1 \
-n openshift-cluster-storage-operator
```

3. Delete the old leader lock to speed up the new leader election for the Cluster Storage Operator:

```
$ oc delete -n openshift-cluster-storage-operator \
cm vsphere-problem-detector-lock
```

### Verification

- View the events or logs that are generated by the vSphere Problem Detector Operator. Confirm that the events or logs have recent timestamps.

### 21.8.3. Viewing the events from the vSphere Problem Detector Operator

After the vSphere Problem Detector Operator runs and performs the configuration checks, it creates events that can be viewed from the command line or from the OpenShift Container Platform web console.

#### Procedure

- To view the events by using the command line, run the following command:

```
$ oc get event -n openshift-cluster-storage-operator \
--sort-by={.metadata.creationTimestamp}
```

#### Example output

```
16m Normal Started pod/vsphere-problem-detector-operator-xxxxx Started
container vsphere-problem-detector
16m Normal Created pod/vsphere-problem-detector-operator-xxxxx Created
container vsphere-problem-detector
16m Normal LeaderElection configmap/vsphere-problem-detector-lock vsphere-
problem-detector-operator-xxxxx became leader
```

- To view the events by using the OpenShift Container Platform web console, navigate to **Home** → **Events** and select **openshift-cluster-storage-operator** from the **Project** menu.

### 21.8.4. Viewing the logs from the vSphere Problem Detector Operator

After the vSphere Problem Detector Operator runs and performs the configuration checks, it creates log records that can be viewed from the command line or from the OpenShift Container Platform web console.

Procedure

- To view the logs by using the command line, run the following command:

```
$ oc logs deployment/vsphere-problem-detector-operator \
-n openshift-cluster-storage-operator
```

Example output

```
I0108 08:32:28.445696 1 operator.go:209] ClusterInfo passed
I0108 08:32:28.451029 1 datastore.go:57] CheckStorageClasses checked 1 storage
classes, 0 problems found
I0108 08:32:28.451047 1 operator.go:209] CheckStorageClasses passed
I0108 08:32:28.452160 1 operator.go:209] CheckDefaultDatastore passed
I0108 08:32:28.480648 1 operator.go:271] CheckNodeDiskUUID:<host_name> passed
I0108 08:32:28.480685 1 operator.go:271] CheckNodeProviderID:<host_name> passed
```

- To view the Operator logs with the OpenShift Container Platform web console, perform the following steps:
  - Navigate to **Workloads → Pods**.
  - Select **openshift-cluster-storage-operator** from the **Projects** menu.
  - Click the link for the **vsphere-problem-detector-operator** pod.
  - Click the **Logs** tab on the **Pod details** page to view the logs.

21.8.5. Configuration checks run by the vSphere Problem Detector Operator

The following tables identify the configuration checks that the vSphere Problem Detector Operator runs. Some checks verify the configuration of the cluster. Other checks verify the configuration of each node in the cluster.

Table 21.32. Cluster configuration checks

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CheckDefaultDatastore | <p>Verifies that the default datastore name in the vSphere configuration is short enough for use with dynamic provisioning.</p> <p>If this check fails, you can expect the following:</p> <ul style="list-style-type: none"><li><b>systemd</b> logs errors to the journal such as <b>Failed to set up mount unit: Invalid argument</b>.</li><li><b>systemd</b> does not unmount volumes if the virtual machine is shut down or rebooted without draining all the pods from the node.</li></ul> <p>If this check fails, reconfigure vSphere with a shorter name for the default datastore.</p> |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CheckFolderPermissions</b> | <p>Verifies the permission to list volumes in the default datastore. This permission is required to create volumes. The Operator verifies the permission by listing the <code>/</code> and <code>/kubevols</code> directories. The root directory must exist. It is acceptable if the <code>/kubevols</code> directory does not exist when the check runs. The <code>/kubevols</code> directory is created when the datastore is used with dynamic provisioning if the directory does not already exist.</p> <p>If this check fails, review the required permissions for the vCenter account that was specified during the OpenShift Container Platform installation.</p> |
| <b>CheckStorageClasses</b>    | <p>Verifies the following:</p> <ul style="list-style-type: none"> <li>• The fully qualified path to each persistent volume that is provisioned by this storage class is less than 255 characters.</li> <li>• If a storage class uses a storage policy, the storage class must use one policy only and that policy must be defined.</li> </ul>                                                                                                                                                                                                                                                                                                                             |
| <b>CheckTaskPermissions</b>   | Verifies the permission to list recent tasks and datastores.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ClusterInfo</b>            | Collects the cluster version and UUID from vSphere vCenter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Table 21.33. Node configuration checks

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CheckNodeDiskUUID</b>      | <p>Verifies that all the vSphere virtual machines are configured with <b>disk.enableUUID=TRUE</b>.</p> <p>If this check fails, see the <a href="#">How to check 'disk.EnableUUID' parameter from VM in vSphere</a> Red Hat Knowledgebase solution.</p>                                                                                                                                                                                                                                     |
| <b>CheckNodeProviderID</b>    | <p>Verifies that all nodes are configured with the <b>ProviderID</b> from vSphere vCenter. This check fails when the output from the following command does not include a provider ID for each node.</p> <pre>\$ oc get nodes -o custom-columns=NAME:.metadata.name,PROVIDER_ID:.spec.providerID,UUID:.status.nodeInfo.systemUUID</pre> <p>If this check fails, refer to the vSphere product documentation for information about setting the provider ID for each node in the cluster.</p> |
| <b>CollectNodeESXiVersion</b> | Reports the version of the ESXi hosts that run nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Name                        | Description                                              |
|-----------------------------|----------------------------------------------------------|
| <b>CollectNodeHWVersion</b> | Reports the virtual machine hardware version for a node. |

### 21.8.6. About the storage class configuration check

The names for persistent volumes that use vSphere storage are related to the datastore name and cluster ID.

When a persistent volume is created, **systemd** creates a mount unit for the persistent volume. The **systemd** process has a 255 character limit for the length of the fully qualified path to the VDMK file that is used for the persistent volume.

The fully qualified path is based on the naming conventions for **systemd** and vSphere. The naming conventions use the following pattern:

```
/var/lib/kubelet/plugins/kubernetes.io/vsphere-volume/mounts/ [<datastore>] 00000000-0000-0000-0000-00000000000000/<cluster_id>-dynamic-pvc-00000000-0000-0000-0000-000000000000.vmdk
```

- The naming conventions require 205 characters of the 255 character limit.
- The datastore name and the cluster ID are determined from the deployment.
- The datastore name and cluster ID are substituted into the preceding pattern. Then the path is processed with the **systemd-escape** command to escape special characters. For example, a hyphen character uses four characters after it is escaped. The escaped value is **\x2d**.
- After processing with **systemd-escape** to ensure that **systemd** can access the fully qualified path to the VDMK file, the length of the path must be less than 255 characters.

### 21.8.7. Metrics for the vSphere Problem Detector Operator

The vSphere Problem Detector Operator exposes the following metrics for use by the OpenShift Container Platform monitoring stack.

Table 21.34. Metrics exposed by the vSphere Problem Detector Operator

| Name                                | Description                                                                                                                                                                 |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vsphere_cluster_check_total</b>  | Cumulative number of cluster-level checks that the vSphere Problem Detector Operator performed. This count includes both successes and failures.                            |
| <b>vsphere_cluster_check_errors</b> | Number of failed cluster-level checks that the vSphere Problem Detector Operator performed. For example, a value of <b>1</b> indicates that one cluster-level check failed. |
| <b>vsphere_esxi_version_total</b>   | Number of ESXi hosts with a specific version. Be aware that if a host runs more than one node, the host is counted only once.                                               |
| <b>vsphere_node_check_total</b>     | Cumulative number of node-level checks that the vSphere Problem Detector Operator performed. This count includes both successes and failures.                               |

| Name                                 | Description                                                                                                                                                           |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vsphere_node_check_errors</b>     | Number of failed node-level checks that the vSphere Problem Detector Operator performed. For example, a value of <b>1</b> indicates that one node-level check failed. |
| <b>vsphere_node_hw_version_total</b> | Number of vSphere nodes with a specific hardware version.                                                                                                             |
| <b>vsphere_vcenter_info</b>          | Information about the vSphere vCenter Server.                                                                                                                         |

### 21.8.8. Additional resources

- [Monitoring overview](#)

## 21.9. INSTALLATION CONFIGURATION PARAMETERS FOR VSPHERE

Before you deploy an OpenShift Container Platform cluster on vSphere, you provide parameters to customize your cluster and the platform that hosts it. When you create the **install-config.yaml** file, you provide values for the required parameters through the command line. You can then modify the **install-config.yaml** file to customize your cluster further.

### 21.9.1. Available installation configuration parameters for vSphere

The following tables specify the required, optional, and vSphere-specific installation configuration parameters that you can set as part of the installation process.

#### NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

#### 21.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 21.35. Required parameters

| Parameter          | Description                                                                                                                                                  | Values |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <b>apiVersion:</b> | The API version for the <b>install-config.yaml</b> content. The current version is <b>v1</b> . The installation program may also support older API versions. | String |

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                    | Values                                                                   |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| <b>baseDomain:</b>         | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <b>baseDomain</b> and <b>metadata.name</b> parameter values that uses the <b>&lt;metadata.name&gt;.&lt;baseDomain&gt;</b> format.                                                                                         | A fully-qualified domain or subdomain name, such as <b>example.com</b> . |
| <b>metadata:</b>           | Kubernetes resource <b>ObjectMeta</b> , from which only the <b>name</b> parameter is consumed.                                                                                                                                                                                                                                                                                                                                 | Object                                                                   |
| <b>metadata:<br/>name:</b> | The name of the cluster. DNS records for the cluster are all subdomains of <b>{{.metadata.name}}.{{.baseDomain}}</b> .                                                                                                                                                                                                                                                                                                         | String of lowercase letters and hyphens (-), such as <b>dev</b> .        |
| <b>platform:</b>           | The configuration for the specific platform upon which to perform the installation: <b>alibabacloud</b> , <b>aws</b> , <b>baremetal</b> , <b>azure</b> , <b>gcp</b> , <b>ibmcloud</b> , <b>nutanix</b> , <b>openstack</b> , <b>powervs</b> , <b>vsphere</b> , or <b>{}</b> . For additional information about <b>platform</b> . <b>&lt;platform&gt;</b> parameters, consult the table for your specific platform that follows. | Object                                                                   |

| Parameter                | Description                                                                                                                                                                                      | Values                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pullSecret:</code> | Get a <a href="#">pull secret from Red Hat OpenShift Cluster Manager</a> to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io. | <pre>{   "auths":{     "cloud.openshift.com":{       "auth":"b3Blb=",       "email":"you@example.com"     },     "quay.io":{       "auth":"b3Blb=",       "email":"you@example.com"     }   } }</pre> |

### 21.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

- If you use the Red Hat OpenShift Networking OVN-Kubernetes network plugin, both IPv4 and IPv6 address families are supported.
- If you use the Red Hat OpenShift Networking OpenShift SDN network plugin, only the IPv4 address family is supported.

#### NOTE

On VMware vSphere, dual-stack networking can specify either IPv4 or IPv6 as the primary address family.

If you configure your cluster to use both IP address families, review the following requirements:

- Both IP families must use the same network interface for the default gateway.
- Both IP families must have the default gateway.
- You must specify IPv4 and IPv6 addresses in the same order for all network configuration parameters. For example, in the following configuration IPv4 addresses are listed before IPv6 addresses.

```
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14
 hostPrefix: 23
 - cidr: fd00:10:128::/56
 hostPrefix: 64
 serviceNetwork:
 - 172.30.0.0/16
 - fd00:172:16::/112
```

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

**Table 21.36. Network parameters**

| Parameter                                                          | Description                                                                                                                                                                                                                                                                                   | Values                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>networking:</b>                                                 | The configuration for the cluster network.                                                                                                                                                                                                                                                    | Object<br><br> <b>NOTE</b><br>You cannot modify parameters specified by the <b>networking</b> object after installation.                                                                            |
| <b>networking:</b><br><b>networkType:</b>                          | The Red Hat OpenShift Networking network plugin to install.                                                                                                                                                                                                                                   | Either <b>OpenShiftSDN</b> or <b>OVNKubernetes</b> . <b>OpenShiftSDN</b> is a CNI plugin for all-Linux networks. <b>OVNKubernetes</b> is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is <b>OVNKubernetes</b> . |
| <b>networking:</b><br><b>clusterNetwork:</b>                       | The IP address blocks for pods.<br><br>The default value is <b>10.128.0.0/14</b> with a host prefix of <b>/23</b> .<br><br>If you specify multiple IP address blocks, the blocks must not overlap.                                                                                            | An array of objects. For example:<br><br> <b>networking:</b><br><b>clusterNetwork:</b><br>- cidr: <b>10.128.0.0/14</b><br><b>hostPrefix: 23</b>                                                    |
| <b>networking:</b><br><b>clusterNetwork:</b><br><b>cidr:</b>       | Required if you use <b>networking.clusterNetwork</b> . An IP address block.<br><br>An IPv4 network.                                                                                                                                                                                           | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between <b>0</b> and <b>32</b> .                                                                                                                                        |
| <b>networking:</b><br><b>clusterNetwork:</b><br><b>hostPrefix:</b> | The subnet prefix length to assign to each individual node. For example, if <b>hostPrefix</b> is set to <b>23</b> then each node is assigned a <b>/23</b> subnet out of the given <b>cidr</b> . A <b>hostPrefix</b> value of <b>23</b> provides 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. | A subnet prefix.<br><br>The default value is <b>23</b> .                                                                                                                                                                                                                              |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                         | Values                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>networking:<br/>serviceNetwork:</code>           | <p>The IP address block for services. The default value is <b>172.30.0.0/16</b>.</p> <p>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.</p>                                                                                                                    | <p>An array with an IP address block in CIDR format. For example:</p> <pre>networking:   serviceNetwork:     - 172.30.0.0/16</pre>                                                                                                                                                                            |
| <code>networking:<br/>machineNetwork:</code>           | <p>The IP address blocks for machines.</p> <p>If you specify multiple IP address blocks, the blocks must not overlap.</p>                                                                                                                                                                                                           | <p>An array of objects. For example:</p> <pre>networking:   machineNetwork:     - cidr: 10.0.0.0/16</pre>                                                                                                                                                                                                     |
| <code>networking:<br/>machineNetwork:<br/>cidr:</code> | <p>Required if you use <b>networking.machineNetwork</b>. An IP address block. The default value is <b>10.0.0.0/16</b> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <b>192.168.126.0/24</b>. For IBM Power® Virtual Server, the default value is <b>192.168.0.0/24</b>.</p> | <p>An IP network block in CIDR notation.</p> <p>For example, <b>10.0.0.0/16</b>.</p> <div>  <p><b>NOTE</b></p> <p>Set the <b>networking.machineNetwork</b> to match the CIDR that the preferred NIC resides in.</p> </div> |

### 21.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 21.37. Optional parameters**

| Parameter                           | Description                                                                                                                                                                                                                                                 | Values       |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <code>additionalTrustBundle:</code> | A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.                                                                                          | String       |
| <code>capabilities:</code>          | Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the "Cluster capabilities" page in <i>Installing</i> . | String array |

| Parameter                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Values                                                             |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| capabilities:<br>baselineCapabilitySet:         | Selects an initial set of optional capabilities to enable. Valid values are <b>None</b> , <b>v4.11</b> , <b>v4.12</b> and <b>vCurrent</b> . The default value is <b>vCurrent</b> .                                                                                                                                                                                                                                                                                                                                               | String                                                             |
| capabilities:<br>additionalEnabledCapabilities: | Extends the set of optional capabilities beyond what you specify in <b>baselineCapabilitySet</b> . You may specify multiple capabilities in this parameter.                                                                                                                                                                                                                                                                                                                                                                      | String array                                                       |
| cpuPartitioningMode:                            | Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <i>Workload partitioning</i> page in the <i>Scalability and Performance</i> section.                   | <b>None</b> or <b>AllNodes</b> . <b>None</b> is the default value. |
| compute:                                        | The configuration for the machines that comprise the compute nodes.                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Array of <b>MachinePool</b> objects.                               |
| compute:<br>architecture:                       | Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <b>amd64</b> and <b>arm64</b> . Not all installation options support the 64-bit ARM architecture. To verify if your installation option is supported on your platform, see <i>Supported installation methods for different platforms</i> in <i>Selecting a cluster installation method and preparing it for users</i> . | String                                                             |
| compute:<br>name:                               | Required if you use <b>compute</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <b>worker</b>                                                      |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Values                                                                                      |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>compute:</b><br><b>platform:</b>          | Required if you use <b>compute</b> . Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <b>controlPlane.platform</b> parameter value.                                                                                                                                                                                                                                                                                                                             | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |
| <b>compute:</b><br><b>replicas:</b>          | The number of compute machines, which are also known as worker machines, to provision.                                                                                                                                                                                                                                                                                                                                                                                                                                           | A positive integer greater than or equal to <b>2</b> . The default value is <b>3</b> .      |
| <b>featureSet:</b>                           | Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see "Enabling features using feature gates".                                                                                                                                                                                                                                                               | String. The name of the feature set to enable, such as <b>TechPreviewNoUpgrade</b> .        |
| <b>controlPlane:</b>                         | The configuration for the machines that comprise the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Array of <b>MachinePool</b> objects.                                                        |
| <b>controlPlane:</b><br><b>architecture:</b> | Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <b>amd64</b> and <b>arm64</b> . Not all installation options support the 64-bit ARM architecture. To verify if your installation option is supported on your platform, see <i>Supported installation methods for different platforms</i> in <i>Selecting a cluster installation method and preparing it for users</i> . | String                                                                                      |
| <b>controlPlane:</b><br><b>name:</b>         | Required if you use <b>controlPlane</b> . The name of the machine pool.                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <b>master</b>                                                                               |
| <b>controlPlane:</b><br><b>platform:</b>     | Required if you use <b>controlPlane</b> . Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <b>compute.platform</b> parameter value.                                                                                                                                                                                                                                                                                                                   | <b>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</b> |

| Parameter                                | Description                                                                                                                                                                                                                                  | Values                                                                                  |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <b>controlPlane:</b><br><b>replicas:</b> | The number of control plane machines to provision.                                                                                                                                                                                           | Supported values are <b>3</b> , or <b>1</b> when deploying single-node OpenShift.       |
| <b>credentialsMode:</b>                  | The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported. | <b>Mint, Passthrough, Manual</b> or an empty string ( <code>""</code> ). <sup>[1]</sup> |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Values                                                                                                                         |

| <b>fips:</b>                | <p>Enable or disable FIPS mode. The default is <b>false</b> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</p> <div>  <p><b>IMPORTANT</b></p> <p>To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see <a href="#">Installing the system in FIPS mode</a>. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.</p> </div> <div>  <p><b>NOTE</b></p> <p>If you are using Azure File storage, you cannot enable FIPS mode.</p> </div> | <b>false</b> or <b>true</b>                                                                                                    |
| <b>imageContentSources:</b> | Sources and repositories for the release-image content.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Array of objects. Includes a <b>source</b> and, optionally, <b>mirrors</b> , as described in the following rows of this table. |

| Parameter                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                              | Values                                                                                                                                                                                       |

| <code>imageContentSources:</code><br><code>source:</code>           | Required if you use <b>imageContentSources</b> . Specify the repository that users refer to, for example, in image pull specifications.                                                                                                                                                                                                                                                                  | String                                                                                                                                                                                       |
| <code>imageContentSources:</code><br><code>mirrors:</code>          | Specify one or more repositories that may also contain the same images.                                                                                                                                                                                                                                                                                                                                  | Array of strings                                                                                                                                                                             |
| <code>platform:</code><br><code>aws:</code><br><code>lbType:</code> | Required to set the NLB load balancer type in AWS. Valid values are <b>Classic</b> or <b>NLB</b> . If no value is specified, the installation program defaults to <b>Classic</b> . The installation program sets the value provided here in the ingress cluster configuration object. If you do not specify a load balancer type for other Ingress Controllers, they use the type set in this parameter. | <b>Classic</b> or <b>NLB</b> . The default value is <b>Classic</b> .                                                                                                                         |
| <code>publish:</code>                                               | How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.                                                                                                                                                                                                                                                                                        | <b>Internal</b> or <b>External</b> . To deploy a private cluster, which cannot be accessed from the internet, set <b>publish</b> to <b>Internal</b> . The default value is <b>External</b> . |
| <code>sshKey:</code>                                                | <p>The SSH key to authenticate access to your cluster machines.</p> <div>  <p><b>NOTE</b></p> <p>For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <b>ssh-agent</b> process uses.</p> </div>                | For example, <b>sshKey: ssh-ed25519 AAAA...</b>                                                                                                                                              |

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.

**NOTE**

If your AWS account has service control policies (SCP) enabled, you must configure the **credentialsMode** parameter to **Mint**, **Passthrough**, or **Manual**. If you are installing on GCP into a shared virtual private cloud (VPC), **credentialsMode** must be set to **Passthrough** or **Manual**.

**IMPORTANT**

Setting this parameter to **Manual** enables alternatives to storing administrator-level secrets in the **kube-system** project, which require additional configuration steps. For more information, see "Alternatives to storing administrator-level secrets in the kube-system project".

#### 21.9.1.4. Optional AWS configuration parameters

Optional AWS configuration parameters are described in the following table:

**Table 21.38. Optional AWS parameters**

| Parameter                                                                                | Description                                                                                                                                                                                                                                                          | Values                                                                                                                                    |
|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>compute:</b><br><b>platform:</b><br><b>aws:</b><br><b>amiID:</b>                      | The AWS AMI used to boot compute machines for the cluster. This is required for regions that require a custom RHCOS AMI.                                                                                                                                             | Any published or custom RHCOS AMI that belongs to the set AWS region. See <i>RHCOS AMIs for AWS infrastructure</i> for available AMI IDs. |
| <b>compute:</b><br><b>platform:</b><br><b>aws:</b><br><b>iamRole:</b>                    | A pre-existing AWS IAM role applied to the compute machine pool instance profiles. You can use these fields to match naming schemes and include predefined permissions boundaries for your IAM roles. If undefined, the installation program creates a new IAM role. | The name of a valid AWS IAM role.                                                                                                         |
| <b>compute:</b><br><b>platform:</b><br><b>aws:</b><br><b>rootVolume:</b><br><b>iops:</b> | The Input/Output Operations Per Second (IOPS) that is reserved for the root volume.                                                                                                                                                                                  | Integer, for example <b>4000</b> .                                                                                                        |

| Parameter                                                                                                                           | Description                                                                                                                                                                            | Values                                                                                                              |
|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>size:</code>          | The size in GiB of the root volume.                                                                                                                                                    | Integer, for example <b>500</b> .                                                                                   |
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>type:</code>          | The type of the root volume.                                                                                                                                                           | Valid <a href="#">AWS EBS volume type</a> , such as <b>io1</b> .                                                    |
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><br><code>kmsKeyARN:</code> | The Amazon Resource Name (key ARN) of a KMS key. This is required to encrypt operating system volumes of worker nodes with a specific KMS key.                                         | Valid <a href="#">key ID</a> or the <a href="#">key ARN</a>                                                         |
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><code>type:</code>                                          | The EC2 instance type for the compute machines.                                                                                                                                        | Valid AWS instance type, such as <b>m4.2xlarge</b> . See the <b>Supported AWS machine types</b> table that follows. |
| <code>compute:</code><br><code>platform:</code><br><code>aws:</code><br><code>zones:</code>                                         | The availability zones where the installation program creates machines for the compute machine pool. If you provide your own VPC, you must provide a subnet in that availability zone. | A list of valid AWS availability zones, such as <b>us-east-1c</b> , in a <a href="#">YAML sequence</a> .            |

| Parameter                                                                                                                       | Description                                                                                                                                                                                                                                                                | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>compute:</code><br><code>aws:</code><br><code>region:</code>                                                              | The AWS region that the installation program creates compute resources in.                                                                                                                                                                                                 | <p>Any valid <a href="#">AWS region</a>, such as <b>us-east-1</b>. You can use the AWS CLI to access the regions available based on your selected instance type. For example:</p> <pre>aws ec2 describe-instance-type-offerings --filters Name=instance-type,Values=c7g.xlarge</pre> <div>  <p><b>IMPORTANT</b></p> <p>When running on ARM based AWS instances, ensure that you enter a region where AWS Graviton processors are available. See <a href="#">Global availability</a> map in the AWS documentation. Currently, AWS Graviton3 processors are only available in some regions.</p> </div> |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><code>amiID:</code>                                | The AWS AMI used to boot control plane machines for the cluster. This is required for regions that require a custom RHCOS AMI.                                                                                                                                             | Any published or custom RHCOS AMI that belongs to the set AWS region. See <i>RHCOS AMIs for AWS infrastructure</i> for available AMI IDs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><code>iamRole:</code>                              | A pre-existing AWS IAM role applied to the control plane machine pool instance profiles. You can use these fields to match naming schemes and include predefined permissions boundaries for your IAM roles. If undefined, the installation program creates a new IAM role. | The name of a valid AWS IAM role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>iops:</code> | The Input/Output Operations Per Second (IOPS) that is reserved for the root volume on control plane machines.                                                                                                                                                              | Integer, for example <b>4000</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Parameter                                                                                                                                | Description                                                                                                                                           | Values                                                                                                              |

| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>size:</code>          | The size in GiB of the root volume for control plane machines.                                                                                        | Integer, for example <b>500</b> .                                                                                   |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><code>type:</code>          | The type of the root volume for control plane machines.                                                                                               | Valid <a href="#">AWS EBS volume type</a> , such as <b>io1</b> .                                                    |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><br><code>rootVolume:</code><br><br><code>kmsKeyARN:</code> | The Amazon Resource Name (key ARN) of a KMS key. This is required to encrypt operating system volumes of control plane nodes with a specific KMS key. | Valid <a href="#">key ID</a> and the <a href="#">key ARN</a>                                                        |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><code>type:</code>                                          | The EC2 instance type for the control plane machines.                                                                                                 | Valid AWS instance type, such as <b>m6i.xlarge</b> . See the <b>Supported AWS machine types</b> table that follows. |
| <code>controlPlane:</code><br><code>platform:</code><br><code>aws:</code><br><code>zones:</code>                                         | The availability zones where the installation program creates machines for the control plane machine pool.                                            | A list of valid AWS availability zones, such as <b>us-east-1c</b> , in a <a href="#">YAML sequence</a> .            |
| <code>controlPlane:</code><br><code>aws:</code><br><code>region:</code>                                                                  | The AWS region that the installation program creates control plane resources in.                                                                      | Valid <a href="#">AWS region</a> , such as <b>us-east-1</b> .                                                       |

| Parameter                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                            | Values                                                                                                                                    |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>platform:</b><br><b>aws:</b><br><b>amiID:</b>                               | The AWS AMI used to boot all machines for the cluster. If set, the AMI must belong to the same region as the cluster. This is required for regions that require a custom RHCOS AMI.                                                                                                                                                                                                                    | Any published or custom RHCOS AMI that belongs to the set AWS region. See <i>RHCOS AMIs for AWS infrastructure</i> for available AMI IDs. |
| <b>platform:</b><br><b>aws:</b><br><b>hostedZone:</b>                          | An existing Route 53 private hosted zone for the cluster. You can only use a pre-existing hosted zone when also supplying your own VPC. The hosted zone must already be associated with the user-provided VPC before installation. Also, the domain of the hosted zone must be the cluster domain or a parent of the cluster domain. If undefined, the installation program creates a new hosted zone. | String, for example <b>Z3URY6TWQ91KVV</b> .                                                                                               |
| <b>platform:</b><br><b>aws:</b><br><b>hostedZoneRole:</b>                      | An Amazon Resource Name (ARN) for an existing IAM role in the account containing the specified hosted zone. The installation program and cluster operators will assume this role when performing operations on the hosted zone. This parameter should only be used if you are installing a cluster into a shared VPC.                                                                                  | String, for example <b>arn:aws:iam::1234567890:role/shared-vpc-role</b> .                                                                 |
| <b>platform:</b><br><b>aws:</b><br><b>serviceEndpoints:</b><br>- name:<br>url: | The AWS service endpoint name and URL. Custom endpoints are only required for cases where alternative AWS endpoints, like FIPS, must be used. Custom API endpoints can be specified for EC2, S3, IAM, Elastic Load Balancing, Tagging, Route 53, and STS AWS services.                                                                                                                                 | Valid <a href="#">AWS service endpoint</a> name and valid <a href="#">AWS service endpoint</a> URL.                                       |

| Parameter                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>platform: aws:   userTags:</pre>                 | <p>A map of keys and values that the installation program adds as tags to all resources that it creates.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <p>Any valid YAML map, such as key value pairs in the <b>&lt;key&gt;: &lt;value&gt;</b> format. For more information about AWS tags, see <a href="#">Tagging Your Amazon EC2 Resources</a> in the AWS documentation.</p> <div>  <p><b>NOTE</b></p> <p>You can add up to 25 user defined tags during installation. The remaining 25 tags are reserved for OpenShift Container Platform.</p> </div> |
| <pre>platform: aws:   propagateUserTags:</pre>        | <p>A flag that directs in-cluster Operators to include the specified user tags in the tags of the AWS resources that the Operators create.</p>                                                                                                                                                                                                                                                                                                                                                                                                                      | <p>Boolean values, for example <b>true</b> or <b>false</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <pre>platform: aws:   subnets:</pre>                  | <p>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same <b>machineNetwork[].cidr</b> ranges that you specify.</p> <p>For a standard cluster, specify a public and a private subnet for each availability zone.</p> <p>For a private cluster, specify a private subnet for each availability zone.</p> <p>For clusters that use AWS Local Zones, you must add AWS Local Zone subnets to this list to ensure edge machine pool creation.</p> | <p>Valid subnet IDs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <pre>platform: aws:   preserveBootsrapIgnition:</pre> | <p>Prevents the S3 bucket from being deleted after completion of bootstrapping.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <p><b>true</b> or <b>false</b>. The default value is <b>false</b>, which results in the S3 bucket being deleted.</p>                                                                                                                                                                                                                                                                                                                                                               |

### 21.9.1.5. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

**Table 21.39. Additional GCP parameters**

| Parameter                                               | Description                                                                                                                                                                                                                                                                                                                            | Values                                                      |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| <code>controlPlane:platform:gcp:osImage:project:</code> | Optional. By default, the installation program downloads and installs the Red Hat Enterprise Linux CoreOS (RHCOS) image that is used to boot control plane machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for control plane machines only. | String. The name of GCP project where the image is located. |
| <code>controlPlane:platform:gcp:osImage:name:</code>    | The name of the custom RHCOS image that the installation program is to use to boot control plane machines. If you use <b><code>controlPlane.platform.gcp.osImage.project</code></b> , this field is required.                                                                                                                          | String. The name of the RHCOS image.                        |

| Parameter                                          | Description                                                                                                                                                                                                                                                                              | Values                                                      |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| <code>compute:platform:gcp:osimage:project:</code> | Optional. By default, the installation program downloads and installs the RHCOS image that is used to boot compute machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for compute machines only. | String. The name of GCP project where the image is located. |
| <code>compute:platform:gcp:osimage:name:</code>    | The name of the custom RHCOS image that the installation program is to use to boot compute machines. If you use <b><code>compute.platform.gcp.osimage.project</code></b> , this field is required.                                                                                       | String. The name of the RHCOS image.                        |
| <code>platform:gcp:network:</code>                 | The name of the existing Virtual Private Cloud (VPC) where you want to deploy your cluster. If you want to deploy your cluster into a shared VPC, you must set <b><code>platform.gcp.networkProjectID</code></b> with the name of the GCP project that contains the shared VPC.          | String.                                                     |

| Parameter                              | Description                                                                                               | Values                                              |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| platform:<br>gcp:<br>networkProjectID: | Optional. The name of the GCP project that contains the shared VPC where you want to deploy your cluster. | String.                                             |
| platform:<br>gcp:<br>projectId:        | The name of the GCP project where the installation program installs the cluster.                          | String.                                             |
| platform:<br>gcp:<br>region:           | The name of the GCP region that hosts your cluster.                                                       | Any valid region name, such as <b>us-central1</b> . |

| Parameter                          | Description                                                                           | Values           |
|------------------------------------|---------------------------------------------------------------------------------------|------------------|
| platform: gcp: controlPlaneSubnet: | The name of the existing subnet where you want to deploy your control plane machines. | The subnet name. |
| platform: gcp: computeSubnet:      | The name of the existing subnet where you want to deploy your compute machines.       | The subnet name. |

| Parameter                                                                                                  | Description                                                             | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform:</code><br><code>gcp:</code><br><code>defaultMachinePlatform:</code><br><code>zones:</code> | The availability zones where the installation program creates machines. | <p>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</p> <div><div><b>IMPORTANT</b><br/><br/>When running your cluster on GCP 64-bit ARM infrastructure, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</div></div> |

| Parameter                                                  | Description                             | Values                                                                                                                                                                                             |
|------------------------------------------------------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| platform: gcp: defaultMachinePlatform: osDisk: diskSizeGB: | The size of the disk in gigabytes (GB). | Any size between 16 GB and 65536 GB.                                                                                                                                                               |
| platform: gcp: defaultMachinePlatform: osDisk: diskType:   | The <a href="#">GCP disk type</a> .     | The default disk type for all machines. Control plane nodes must use the <b>pd-ssd</b> disk type. Compute nodes can use the <b>pd-ssd</b> , <b>pd-balanced</b> , or <b>pd-standard</b> disk types. |

| Parameter                                                            | Description                                                                                                                                                                                                                                                                                                 | Values                                                      |
|----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| platform:<br>gcp:<br>defaultMachinePlatform:<br>osImage:<br>project: | Optional. By default, the installation program downloads and installs the RHCOS image that is used to boot control plane and compute machines. You can override the default behavior by specifying the location of a custom RHCOS image that the installation program is to use for both types of machines. | String. The name of GCP project where the image is located. |
| platform:<br>gcp:<br>defaultMachinePlatform:<br>osImage:<br>name:    | The name of the custom RHCOS image that the installation program is to use to boot control plane and compute machines. If you use <b>platform.gcp.defaultMachinePlatform.osImage.project</b> , this field is required.                                                                                      | String. The name of the RHCOS image.                        |

| Parameter                                    | Description                                                                         | Values                                                   |
|----------------------------------------------|-------------------------------------------------------------------------------------|----------------------------------------------------------|
| platform: gcp: defaultMachinePlatform: tags: | Optional. Additional network tags to add to the control plane and compute machines. | One or more strings, for example <b>network-tag1</b> .   |
| platform: gcp: defaultMachinePlatform: type: | The <a href="#">GCP machine type</a> for control plane and compute machines.        | The GCP machine type, for example <b>n1-standard-4</b> . |

| Parameter                                                                       | Description                                                                             | Values                   |
|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|--------------------------|
| platform: gcp default Machine Plat form: os Disk: encryption Key: kmsKey: name: | The name of the customer managed encryption key to be used for machine disk encryption. | The encryption key name. |

| Parameter                                                                          | Description                                                                         | Values                 |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|------------------------|
| platform: gcp: default Machine Platform: os Disk: encryption Key: kmsKey: keyRing: | The name of the Key Management Service (KMS) key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                                                           | Description                                                        | Values            |
|-------------------------------------------------------------------------------------|--------------------------------------------------------------------|-------------------|
| platform: gcp: default Machine Platform: os Disk: encryption Key: kmsKey: location: | The <a href="#">GCP location</a> in which the KMS key ring exists. | The GCP location. |

| Parameter              | Description                                                                                                                                               | Values              |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| platform.gcp.projectID | The ID of the project in which the KMS key ring exists. This value defaults to the value of the <b>platform.gcp.projectID</b> parameter if it is not set. | The GCP project ID. |

| Parameter                                                                                                                                                       | Description                                                                                                                                                                                                                                                                      | Values                                                                                                                      |

The default value is <b>Migrate</b> . |

| Parameter                                                       | Description                                                                                           | Values                   |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|--------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKeyName: | The name of the customer managed encryption key to be used for control plane machine disk encryption. | The encryption key name. |

| Parameter                                                            | Description                                                                            | Values                 |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------|------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKey: keyRing: | For control plane machines, the name of the KMS key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                                             | Description                                                                                                                                                                              | Values                             |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKey: location: | For control plane machines, the GCP location in which the key ring exists. For more information about KMS locations, see Google’s documentation on <a href="#">Cloud KMS locations</a> . | The GCP location for the key ring. |

| Parameter                                                              | Description                                                                                                                              | Values              |
|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsKey: projectId: | For control plane machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set. | The GCP project ID. |

| Parameter                                                              | Description                                                                                                                                                                                                                                                          | Values                                                                                                                      |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| controlPlane: platform: gcp: osDisk: encryptionKey: kmsServiceAccount: | The GCP service account used for the encryption request for control plane machines. If absent, the Compute Engine default service account is used. For more information about GCP service accounts, see Google’s documentation on <a href="#">service accounts</a> . | The GCP service account email, for example <b>&lt;service_account_name&gt;@&lt;project_id&gt;.iam.gserviceaccount.com</b> . |

| Parameter                                    | Description                                                                           | Values                                                                             |
|----------------------------------------------|---------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| controlPlane:platform:gcp:osDisk:diskSizeGB: | The size of the disk in gigabytes (GB). This value applies to control plane machines. | Any integer between 16 and 65536.                                                  |
| controlPlane:platform:gcp:osDisk:diskType:   | The <a href="#">GCP disk type</a> for control plane machines.                         | Control plane machines must use the <b>pd-ssd</b> disk type, which is the default. |

| Parameter                          | Description                                                                                                                                                                                        | Values                                                       |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| controlPlane: platform: gcp: tags: | Optional. Additional network tags to add to the control plane machines. If set, this parameter overrides the <b>platform.gcp.defaultMachinePlatform.tags</b> parameter for control plane machines. | One or more strings, for example <b>control-plane-tag1</b> . |
| controlPlane: platform: gcp: type: | The <a href="#">GCP machine type</a> for control plane machines. If set, this parameter overrides the <b>platform.gcp.defaultMachinePlatform.type</b> parameter.                                   | The GCP machine type, for example <b>n1-standard-4</b> .     |

| Parameter                                                | Description                                                                           | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------|---------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| controlPlane:<br><br>platform:<br><br>gcp:<br><br>zones: | The availability zones where the installation program creates control plane machines. | <p>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</p> <div><div><b>IMPORTANT</b><br/><br/>When running your cluster on GCP 64-bit ARM infrastructure, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</div></div> |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                              | Values                                                                     |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| controlPlane:platform:gcp:secureBoot:          | Whether to enable Shielded VM secure boot for control plane machines. Shielded VMs have additional security protocols such as secure boot, firmware and integrity monitoring, and rootkit protection. For more information on Shielded VMs, see Google's documentation on <a href="#">Shielded VMs</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |
| controlPlane:platform:gcp:confidentialCompute: | Whether to enable Confidential VMs for control plane machines. Confidential VMs provide encryption for data while it is being processed. For more information on Confidential VMs, see Google's documentation on <a href="#">Confidential Computing</a> .                                                | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |

| Parameter                                                | Description                                                                                                                                                                                                                                   | Values                                                                     |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <code>controlPlanePlatform:gcp.onHostMaintenance:</code> | Specifies the behavior of control plane VMs during a host maintenance event, such as a software or hardware update. For Confidential VMs, this parameter must be set to <b>Terminate</b> . Confidential VMs do not support live VM migration. | <b>Terminate</b> or <b>Migrate</b> . The default value is <b>Migrate</b> . |

| Parameter                                                | Description                                                                                     | Values                   |
|----------------------------------------------------------|-------------------------------------------------------------------------------------------------|--------------------------|
| computePlatform: gcp: osDisk: encryptionKey: kmsKeyName: | The name of the customer managed encryption key to be used for compute machine disk encryption. | The encryption key name. |

| Parameter                                          | Description                                                                      | Values                 |
|----------------------------------------------------|----------------------------------------------------------------------------------|------------------------|
| compute:platform:gcp:osDisk:encryptionKey:keyRing: | For compute machines, the name of the KMS key ring to which the KMS key belongs. | The KMS key ring name. |

| Parameter                                              | Description                                                                                                                                                                        | Values                             |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| computePlatform.gcp.osDiskEncryptionKey.kmsKeyLocation | For compute machines, the GCP location in which the key ring exists. For more information about KMS locations, see Google's documentation on <a href="#">Cloud KMS locations</a> . | The GCP location for the key ring. |

| Parameter                                                  | Description                                                                                                                        | Values              |
|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| compute:platform:gcp:osDisk:encryptionKey:ksKey:projectId: | For compute machines, the ID of the project in which the KMS key ring exists. This value defaults to the VM project ID if not set. | The GCP project ID. |

| Parameter                                                       | Description                                                                                                                                                                                                                                                                   | Values                                                                                                                      |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| computePlatform: gcp: osDisk: encryptionKey: kmsServiceAccount: | The GCP service account used for the encryption request for compute machines. If this value is not set, the Compute Engine default service account is used. For more information about GCP service accounts, see Google’s documentation on <a href="#">service accounts</a> . | The GCP service account email, for example <b>&lt;service_account_name&gt;@&lt;project_id&gt;.iam.gserviceaccount.com</b> . |

| Parameter                          | Description                                                                     | Values                                                                                      |
|------------------------------------|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| compute:platform:gcp:osDiskSizeGB: | The size of the disk in gigabytes (GB). This value applies to compute machines. | Any integer between 16 and 65536.                                                           |
| compute:platform:gcp:osDiskType:   | The <a href="#">GCP disk type</a> for compute machines.                         | <b>pd-ssd</b> , <b>pd-standard</b> , or <b>pd-balanced</b> . The default is <b>pd-ssd</b> . |

| Parameter                               | Description                                                                                                                                                                                         | Values                                                                      |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <code>compute:platform:gcp:tags:</code> | Optional. Additional network tags to add to the compute machines. If set, this parameter overrides the <b><code>platform.gcp.defaultMachinePlatform.tags</code></b> parameter for compute machines. | One or more strings, for example <b><code>compute-network-tag1</code></b> . |
| <code>compute:platform:gcp:type:</code> | The <a href="#">GCP machine type</a> for compute machines. If set, this parameter overrides the <b><code>platform.gcp.defaultMachinePlatform.type</code></b> parameter.                             | The GCP machine type, for example <b><code>n1-standard-4</code></b> .       |

| Parameter                                                                                                    | Description                                                                                                                                                                                                                                                                                        | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>compute:</code><br><br><code>platform:</code><br><br><code>gcp:</code><br><br><code>zones:</code>      | The availability zones where the installation program creates compute machines.                                                                                                                                                                                                                    | <p>A list of valid <a href="#">GCP availability zones</a>, such as <b>us-central1-a</b>, in a <a href="#">YAML sequence</a>.</p> <div><div><b>IMPORTANT</b><br/><br/>When running your cluster on GCP 64-bit ARM infrastructure, ensure that you use a zone where Ampere Altra Arm CPU's are available. You can find which zones are compatible with 64-bit ARM processors in the "GCP availability zones" link.</div></div> |
| <code>compute:</code><br><br><code>platform:</code><br><br><code>gcp:</code><br><br><code>secureBoot:</code> | Whether to enable Shielded VM secure boot for compute machines. Shielded VMs have additional security protocols such as secure boot, firmware and integrity monitoring, and rootkit protection. For more information on Shielded VMs, see Google's documentation on <a href="#">Shielded VMs</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Parameter                                 | Description                                                                                                                                                                                                                                         | Values                                                                     |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| compute.platform.gcp.confidentialCompute: | Whether to enable Confidential VMs for compute machines. Confidential VMs provide encryption for data while it is being processed. For more information on Confidential VMs, see Google's documentation on <a href="#">Confidential Computing</a> . | <b>Enabled</b> or <b>Disabled</b> . The default value is <b>Disabled</b> . |
| compute.platform.gcp.onHostMaintenance:   | Specifies the behavior of compute VMs during a host maintenance event, such as a software or hardware update. For Confidential VMs, this parameter must be set to <b>Terminate</b> . Confidential VMs do not support live VM migration.             | <b>Terminate</b> or <b>Migrate</b> . The default value is <b>Migrate</b> . |

21.9.1.6. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

Table 21.40. Additional VMware vSphere cluster parameters

| Parameter                                                           | Description                                                                                                                                                                                                                                                                                                                                                      | Values                                                                     |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <code>platform:<br/>vsphere:</code>                                 | Describes your account on the cloud platform that hosts your cluster. You can use the parameter to customize the platform. If you provide additional configuration settings for compute and control plane machines in the machine pool, the parameter is not required. You can only specify one vCenter server for your OpenShift Container Platform cluster.    | A dictionary of vSphere configuration objects                              |
| <code>platform:<br/>vsphere:<br/>apiVIPs:</code>                    | <p>Virtual IP (VIP) addresses that you configured for control plane API access.</p> <div>  <div> <p><b>NOTE</b></p> <p>This parameter applies only to installer-provisioned infrastructure.</p> </div> </div>                                                                   | Multiple IP addresses                                                      |
| <code>platform:<br/>vsphere:<br/>diskType:</code>                   | Optional: The disk provisioning method. This value defaults to the vSphere default storage policy if not set.                                                                                                                                                                                                                                                    | Valid values are <b>thin</b> , <b>thick</b> , or <b>eagerZeroedThick</b> . |
| <code>platform:<br/>vsphere:<br/>failureDomains:</code>             | Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a <b>datastore</b> object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.                                                                                                                  | An array of failure domain configuration objects.                          |
| <code>platform:<br/>vsphere:<br/>failureDomains:<br/>name:</code>   | The name of the failure domain.                                                                                                                                                                                                                                                                                                                                  | String                                                                     |
| <code>platform:<br/>vsphere:<br/>failureDomains:<br/>region:</code> | If you define multiple failure domains for your cluster, you must attach the tag to each vCenter datacenter. To define a region, use a tag from the <b>openshift-region</b> tag category. For a single vSphere datacenter environment, you do not need to attach a tag, but you must enter an alphanumeric value, such as <b>datacenter</b> , for the parameter. | String                                                                     |
| <code>platform:<br/>vsphere:<br/>failureDomains:<br/>server:</code> | Specifies the fully-qualified hostname or IP address of the VMware vCenter server, so that a client can access failure domain resources. You must apply the <b>server</b> role to the vSphere vCenter server location.                                                                                                                                           | String                                                                     |

| Parameter                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Values |
|--------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <pre>platform: vsphere: failureDomains: zone:</pre>                      | If you define multiple failure domains for your cluster, you must attach a tag to each vCenter cluster. To define a zone, use a tag from the <b>openshift-zone</b> tag category. For a single vSphere datacenter environment, you do not need to attach a tag, but you must enter an alphanumeric value, such as <b>cluster</b> , for the parameter.                                                                                                                                                                                                                                                    | String |
| <pre>platform: vsphere: failureDomains: topology:  computeCluster:</pre> | The path to the vSphere compute cluster.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | String |
| <pre>platform: vsphere: failureDomains: topology: datacenter:</pre>      | Lists and defines the datacenters where OpenShift Container Platform virtual machines (VMs) operate. The list of datacenters must match the list of datacenters specified in the <b>vcenters</b> field.                                                                                                                                                                                                                                                                                                                                                                                                 | String |
| <pre>platform: vsphere: failureDomains: topology: datastore:</pre>       | Specifies the path to a vSphere datastore that stores virtual machines files for a failure domain. You must apply the <b>datastore</b> role to the vSphere vCenter datastore location.                                                                                                                                                                                                                                                                                                                                                                                                                  | String |
| <pre>platform: vsphere: failureDomains: topology: folder:</pre>          | Optional: The absolute path of an existing folder where the user creates the virtual machines, for example, <b>/&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;sub folder_name&gt;</b> . If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster and you do not want to use the default <b>StorageClass</b> object, named <b>thin</b> , you can omit the <b>folder</b> parameter from the <b>install-config.yaml</b> file. | String |
| <pre>platform: vsphere: failureDomains: topology: networks:</pre>        | Lists any network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | String |

| Parameter                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Values                                     |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| platform:<br>vsphere:<br>failureDomains:<br>topology:<br>resourcePool: | Optional: The absolute path of an existing resource pool where the installation program creates the virtual machines, for example, <b>/&lt;datacenter_name&gt;/host/&lt;cluster_name&gt;/Resources/&lt;resource_pool_name&gt;/&lt;optional_nested_resource_pool_name&gt;</b> . If you do not specify a value, the installation program installs the resources in the root of the cluster under <b>/&lt;datacenter_name&gt;/host/&lt;cluster_name&gt;/Resources</b> . | String                                     |
| platform:<br>vsphere:<br>failureDomains:<br>topology<br>template:      | Specifies the absolute path to a pre-existing Red Hat Enterprise Linux CoreOS (RHCOS) image template or virtual machine. The installation program can use the image template or virtual machine to quickly install RHCOS on vSphere hosts. Consider using this parameter as an alternative to uploading an RHCOS image on vSphere hosts. This parameter is available for use only on installer-provisioned infrastructure.                                           | String                                     |
| platform:<br>vsphere:<br>ingressVIPs:                                  | <p>Virtual IP (VIP) addresses that you configured for cluster Ingress.</p>  <p><b>NOTE</b></p> <p>This parameter applies only to installer-provisioned infrastructure.</p>                                                                                                                                                                                                        | Multiple IP addresses                      |
| platform:<br>vsphere:<br>vcenters:                                     | Configures the connection details so that services can communicate with a vCenter server. Currently, only a single vCenter server is supported.                                                                                                                                                                                                                                                                                                                      | An array of vCenter configuration objects. |
| platform:<br>vsphere:<br>vcenters:<br>datacenters:                     | Lists and defines the datacenters where OpenShift Container Platform virtual machines (VMs) operate. The list of datacenters must match the list of datacenters specified in the <b>failureDomains</b> field.                                                                                                                                                                                                                                                        | String                                     |
| platform:<br>vsphere:<br>vcenters:<br>password:                        | The password associated with the vSphere user.                                                                                                                                                                                                                                                                                                                                                                                                                       | String                                     |

| Parameter                                     | Description                                                               | Values  |
|-----------------------------------------------|---------------------------------------------------------------------------|---------|
| platform:<br>vsphere:<br>vcenters:<br>port:   | The port number used to communicate with the vCenter server.              | Integer |
| platform:<br>vsphere:<br>vcenters:<br>server: | The fully qualified host name (FQHN) or IP address of the vCenter server. | String  |
| platform:<br>vsphere:<br>vcenters:<br>user:   | The username associated with the vSphere user.                            | String  |

### 21.9.1.7. Deprecated VMware vSphere configuration parameters

In OpenShift Container Platform 4.13, the following vSphere configuration parameters are deprecated. You can continue to use these parameters, but the installation program does not automatically specify these parameters in the **install-config.yaml** file.

The following table lists each deprecated vSphere configuration parameter:

**Table 21.41. Deprecated VMware vSphere cluster parameters**

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                             | Values                                        |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| platform:<br>vsphere:<br>apiVIP:  | <p>The virtual IP (VIP) address that you configured for control plane API access.</p> <div>  <p><b>NOTE</b></p> <p>In OpenShift Container Platform 4.12 and later, the <b>apiVIP</b> configuration setting is deprecated. Instead, use a <b>List</b> format to enter a value in the <b>apiVIPs</b> configuration setting.</p> </div> | An IP address, for example <b>128.0.0.1</b> . |
| platform:<br>vsphere:<br>cluster: | The vCenter cluster to install the OpenShift Container Platform cluster in.                                                                                                                                                                                                                                                                                                                                             | String                                        |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                          | Values                                                                                               |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| platform:<br>vsphere:<br>datacenter:           | Defines the datacenter where OpenShift Container Platform virtual machines (VMs) operate.                                                                                                                                                                                                                                                                                                                            | String                                                                                               |
| platform:<br>vsphere:<br><br>defaultDatastore: | The name of the default datastore to use for provisioning volumes.                                                                                                                                                                                                                                                                                                                                                   | String                                                                                               |
| platform:<br>vsphere:<br>folder:               | Optional: The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the data center virtual machine folder.                                                                                                                                       | String, for example, <b>/&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;</b> . |
| platform:<br>vsphere:<br>ingressVIP:           | <p>Virtual IP (VIP) addresses that you configured for cluster Ingress.</p> <div>  <p><b>NOTE</b></p> <p>In OpenShift Container Platform 4.12 and later, the <b>ingressVIP</b> configuration setting is deprecated. Instead, use a <b>List</b> format to enter a value in the <b>ingressVIPs</b> configuration setting.</p> </div> | An IP address, for example <b>128.0.0.1</b> .                                                        |
| platform:<br>vsphere:<br>network:              | The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.                                                                                                                                                                                                                                                                                                      | String                                                                                               |
| platform:<br>vsphere:<br>password:             | The password for the vCenter user name.                                                                                                                                                                                                                                                                                                                                                                              | String                                                                                               |

| Parameter                                             | Description                                                                                                                                                                                                                                                                                                              | Values                                                                                                                                                                        |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform:<br/>vsphere:<br/>resourcePool:</code> | Optional: The absolute path of an existing resource pool where the installation program creates the virtual machines. If you do not specify a value, the installation program installs the resources in the root of the cluster under <b><code>/&lt;datacenter_name&gt;/host/&lt;cluster_name&gt;/Resources</code></b> . | String, for example, <b><code>/&lt;datacenter_name&gt;/host/&lt;cluster_name&gt;/Resources/&lt;resource_pool_name&gt;/&lt;optional_nested_resource_pool_name&gt;</code></b> . |
| <code>platform:<br/>vsphere:<br/>username:</code>     | The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for <a href="#">static or dynamic persistent volume provisioning</a> in vSphere.                                                                                                   | String                                                                                                                                                                        |
| <code>platform:<br/>vsphere:<br/>vCenter:</code>      | The fully-qualified hostname or IP address of a vCenter server.                                                                                                                                                                                                                                                          | String                                                                                                                                                                        |

#### 21.9.1.8. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

**Table 21.42. Optional VMware vSphere machine pool parameters**

| Parameter                                                       | Description                                                                                                                                                                                                                                                                                                                                                 | Values                                                                                                                                                                                 |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>platform:<br/>vsphere:<br/>clusterOSImage:</code>         | The location from which the installation program downloads the Red Hat Enterprise Linux CoreOS (RHCOS) image. Before setting a path value for this parameter, ensure that the default RHCOS boot image in the OpenShift Container Platform release matches the RHCOS image template or virtual machine version; otherwise, cluster installation might fail. | An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <b><code>https://mirror.openshift.com/images/rhcos-&lt;version&gt;-vmware.&lt;architecture&gt;.ova</code></b> . |
| <code>platform:<br/>vsphere:<br/>osDisk:<br/>diskSizeGB:</code> | The size of the disk in gigabytes.                                                                                                                                                                                                                                                                                                                          | Integer                                                                                                                                                                                |
| <code>platform:<br/>vsphere:<br/>cpus:</code>                   | The total number of virtual processor cores to assign a virtual machine. The value of <b><code>platform.vsphere.cpus</code></b> must be a multiple of <b><code>platform.vsphere.coresPerSocket</code></b> value.                                                                                                                                            | Integer                                                                                                                                                                                |

| Parameter                                | Description                                                                                                                                                                                                                                                                     | Values  |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| platform:<br>vsphere:<br>coresPerSocket: | The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is <b>platform.vsphere.cpus/platform.vsphere.coresPerSocket</b> . The default value for control plane nodes and worker nodes is <b>4</b> and <b>2</b> , respectively. | Integer |
| platform:<br>vsphere:<br>memoryMB:       | The size of a virtual machine's memory in megabytes.                                                                                                                                                                                                                            | Integer |

## 21.10. MULTIPLE REGIONS AND ZONES CONFIGURATION FOR A CLUSTER ON VSPHERE

As an administrator, you can specify multiple regions and zones for your OpenShift Container Platform cluster that runs on a VMware vSphere instance. This configuration reduces the risk of a hardware failure or network outage causing your cluster to fail.

A failure domain configuration lists parameters that create a topology. The following list states some of these parameters:

- **computeCluster**
- **datacenter**
- **datastore**
- **networks**
- **resourcePool**

After you define multiple regions and zones for your OpenShift Container Platform cluster, you can create or migrate nodes to another failure domain.

### IMPORTANT

If you want to migrate pre-existing OpenShift Container Platform cluster compute nodes to a failure domain, you must define a new compute machine set for the compute node. This new machine set can scale up a compute node according to the topology of the failure domain, and scale down the pre-existing compute node.

The cloud provider adds **topology.kubernetes.io/zone** and **topology.kubernetes.io/region** labels to any compute node provisioned by a machine set resource.

For more information, see [Creating a compute machine set](#).

### 21.10.1. Specifying multiple regions and zones for your cluster on vSphere

You can configure the **infrastructures.config.openshift.io** configuration resource to specify multiple regions and zones for your OpenShift Container Platform cluster that runs on a VMware vSphere instance.

Topology-aware features for the cloud controller manager and the vSphere Container Storage Interface (CSI) Operator Driver require information about the vSphere topology where you host your OpenShift Container Platform cluster. This topology information exists in the **infrastructures.config.openshift.io** configuration resource.

Before you specify regions and zones for your cluster, you must ensure that all datacenters and compute clusters contain tags, so that the cloud provider can add labels to your node. For example, if **datacenter-1** represents **region-a** and **compute-cluster-1** represents **zone-1**, the cloud provider adds an **openshift-region** category label with a value of **region-a** to **datacenter-1**. Additionally, the cloud provider adds an **openshift-zone** category tag with a value of **zone-1** to **compute-cluster-1**.

## NOTE

You can migrate control plane nodes with vMotion capabilities to a failure domain. After you add these nodes to a failure domain, the cloud provider adds **topology.kubernetes.io/zone** and **topology.kubernetes.io/region** labels to these nodes.

## Prerequisites

- You created the **openshift-region** and **openshift-zone** tag categories on the vCenter server.
- You ensured that each datacenter and compute cluster contains tags that represent the name of their associated region or zone, or both.
- Optional: If you defined **API** and **Ingress** static IP addresses to the installation program, you must ensure that all regions and zones share a common layer 2 network. This configuration ensures that API and Ingress Virtual IP (VIP) addresses can interact with your cluster.

## IMPORTANT

If you do not supply tags to all datacenters and compute clusters before you create a node or migrate a node, the cloud provider cannot add the **topology.kubernetes.io/zone** and **topology.kubernetes.io/region** labels to the node. This means that services cannot route traffic to your node.

## Procedure

1. Edit the **infrastructures.config.openshift.io** custom resource definition (CRD) of your cluster to specify multiple regions and zones in the **failureDomains** section of the resource by running the following command:

```
$ oc edit infrastructures.config.openshift.io cluster
```

**Example **infrastructures.config.openshift.io** CRD for a instance named **cluster** with multiple regions and zones defined in its configuration**

```
spec:
 cloudConfig:
 key: config
```

```

name: cloud-provider-config
platformSpec:
 type: vSphere
 vsphere:
 vcenters:
 - datacenters:
 - <region_a_datacenter>
 - <region_b_datacenter>
 port: 443
 server: <your_vcenter_server>
 failureDomains:
 - name: <failure_domain_1>
 region: <region_a>
 zone: <zone_a>
 server: <your_vcenter_server>
 topology:
 datacenter: <region_a_dc>
 computeCluster: "</region_a_dc/host/zone_a_cluster>"
 resourcePool: "</region_a_dc/host/zone_a_cluster/Resources/resource_pool>"
 datastore: "</region_a_dc/datastore/datastore_a>"
 networks:
 - port-group
 - name: <failure_domain_2>
 region: <region_a>
 zone: <zone_b>
 server: <your_vcenter_server>
 topology:
 computeCluster: </region_a_dc/host/zone_b_cluster>
 datacenter: <region_a_dc>
 datastore: </region_a_dc/datastore/datastore_a>
 networks:
 - port-group
 - name: <failure_domain_3>
 region: <region_b>
 zone: <zone_a>
 server: <your_vcenter_server>
 topology:
 computeCluster: </region_b_dc/host/zone_a_cluster>
 datacenter: <region_b_dc>
 datastore: </region_b_dc/datastore/datastore_b>
 networks:
 - port-group
 nodeNetworking:
 external: {}
 internal: {}

```

## IMPORTANT

After you create a failure domain and you define it in a CRD for a VMware vSphere cluster, you must not modify or delete the failure domain. Doing any of these actions with this configuration can impact the availability and fault tolerance of a control plane machine.

2. Save the resource file to apply the changes.

### Additional resources

- [Parameters for the cluster-wide infrastructure CRD](#)

## 21.10.2. Enabling a multiple layer 2 network for your cluster

You can configure your cluster to use a multiple layer 2 network configuration so that data transfer among nodes can span across multiple networks.

### Prerequisites

- You configured network connectivity among machines so that cluster components can communicate with each other.

### Procedure

- If you installed your cluster with installer-provisioned infrastructure, you must ensure that all control plane nodes share a common layer 2 network. Additionally, ensure compute nodes that are configured for Ingress pod scheduling share a common layer 2 network.
  - If you need compute nodes to span multiple layer 2 networks, you can create infrastructure nodes that can host Ingress pods.
  - If you need to provision workloads across additional layer 2 networks, you can create compute machine sets on vSphere and then move these workloads to your target layer 2 networks.
- If you installed your cluster on infrastructure that you provided, which is defined as a user-provisioned infrastructure, complete the following actions to meet your needs:
  - Configure your API load balancer and network so that the load balancer can reach the API and Machine Config Server on the control plane nodes.
  - Configure your Ingress load balancer and network so that the load balancer can reach the Ingress pods on the compute or infrastructure nodes.

### Additional resources

- [Installing a cluster on vSphere with network customizations](#)
- [Creating infrastructure machine sets for production environments](#)
- [Creating a compute machine set](#)

## 21.10.3. Parameters for the cluster-wide infrastructure CRD

You must set values for specific parameters in the cluster-wide infrastructure, **infrastructures.config.openshift.io**, Custom Resource Definition (CRD) to define multiple regions and zones for your OpenShift Container Platform cluster that runs on a VMware vSphere instance.

The following table lists mandatory parameters for defining multiple regions and zones for your OpenShift Container Platform cluster:

| Parameter             | Description                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>vcenters</b>       | The vCenter server for your OpenShift Container Platform cluster. You can only specify one vCenter for your cluster.       |
| <b>datacenters</b>    | vCenter datacenters where VMs associated with the OpenShift Container Platform cluster will be created or presently exist. |
| <b>port</b>           | The TCP port of the vCenter server.                                                                                        |
| <b>server</b>         | The fully qualified domain name (FQDN) of the vCenter server.                                                              |
| <b>failureDomains</b> | The list of failure domains.                                                                                               |
| <b>name</b>           | The name of the failure domain.                                                                                            |
| <b>region</b>         | The value of the <b>openshift-region</b> tag assigned to the topology for the failure failure domain.                      |
| <b>zone</b>           | The value of the <b>openshift-zone</b> tag assigned to the topology for the failure failure domain.                        |
| <b>topology</b>       | The vCenter resources associated with the failure domain.                                                                  |
| <b>datacenter</b>     | The datacenter associated with the failure domain.                                                                         |
| <b>computeCluster</b> | The full path of the compute cluster associated with the failure domain.                                                   |
| <b>resourcePool</b>   | The full path of the resource pool associated with the failure domain.                                                     |
| <b>datastore</b>      | The full path of the datastore associated with the failure domain.                                                         |
| <b>networks</b>       | A list of port groups associated with the failure domain. Only one portgroup may be defined.                               |

## 21.11. ENABLING ENCRYPTION ON A VSPHERE CLUSTER

You can encrypt your virtual machines after installing OpenShift Container Platform 4.14 on vSphere by draining and shutting down your nodes one at a time. While each virtual machine is shutdown, you can enable encryption in the vCenter web interface.

### 21.11.1. Encrypting virtual machines

You can encrypt your virtual machines with the following process. You can drain your virtual machines, power them down and encrypt them using the vCenter interface. Finally, you can create a storage class to use the encrypted storage.

### Prerequisites

- You have configured a Standard key provider in vSphere. For more information, see [Adding a KMS to vCenter Server](#).

#### IMPORTANT

The Native key provider in vCenter is not supported. For more information, see [vSphere Native Key Provider Overview](#).

- You have enabled host encryption mode on all of the ESXi hosts that are hosting the cluster. For more information, see [Enabling host encryption mode](#).
- You have a vSphere account which has all cryptographic privileges enabled. For more information, see [Cryptographic Operations Privileges](#).

### Procedure

1. Drain and cordon one of your nodes. For detailed instructions on node management, see "Working with Nodes".
2. Shutdown the virtual machine associated with that node in the vCenter interface.
3. Right-click on the virtual machine in the vCenter interface and select **VM Policies** → **Edit VM Storage Policies**.
4. Select an encrypted storage policy and select **OK**.
5. Start the encrypted virtual machine in the vCenter interface.
6. Repeat steps 1-5 for all nodes that you want to encrypt.
7. Configure a storage class that uses the encrypted storage policy. For more information about configuring an encrypted storage class, see "VMware vSphere CSI Driver Operator".

## 21.12. CONFIGURING THE VSPHERE CONNECTION SETTINGS AFTER AN INSTALLATION

After installing an OpenShift Container Platform cluster on vSphere with the platform integration feature enabled, you might need to update the vSphere connection settings manually, depending on the installation method.

For installations using the Assisted Installer, you must update the connection settings. This is because the Assisted Installer adds default connection settings to the **vSphere connection configuration** wizard as placeholders during the installation.

For installer-provisioned or user-provisioned infrastructure installations, you should have entered valid connection settings during the installation. You can use the **vSphere connection configuration** wizard at any time to validate or modify the connection settings, but this is not mandatory for completing the installation.

### 21.12.1. Configuring the vSphere connection settings

Modify the following vSphere configuration settings as required:

- vCenter address
- vCenter cluster
- vCenter username
- vCenter password
- vCenter address
- vSphere data center
- vSphere datastore
- Virtual machine folder

#### Prerequisites

- The Assisted Installer has finished installing the cluster successfully.
- The cluster is connected to <https://console.redhat.com>.

#### Procedure

1. In the Administrator perspective, navigate to **Home → Overview**.
2. Under **Status**, click **vSphere connection** to open the **vSphere connection configuration** wizard.
3. In the **vCenter** field, enter the network address of the vSphere vCenter server. This can be either a domain name or an IP address. It appears in the vSphere web client URL; for example **https://[your\_vCenter\_address]/ui**.
4. In the **vCenter cluster** field, enter the name of the vSphere vCenter cluster where OpenShift Container Platform is installed.

#### IMPORTANT

This step is mandatory if you installed OpenShift Container Platform 4.13 or later.

5. In the **Username** field, enter your vSphere vCenter username.
6. In the **Password** field, enter your vSphere vCenter password.

**WARNING**

The system stores the username and password in the **vsphere-creds** secret in the **kube-system** namespace of the cluster. An incorrect vCenter username or password makes the cluster nodes unschedulable.

7. In the **Datacenter** field, enter the name of the vSphere data center that contains the virtual machines used to host the cluster; for example, **SDDC-Datacenter**.
8. In the **Default data store** field, enter the path and name of the vSphere data store that stores the persistent data volumes; for example, **/SDDC-Datacenter/datastore/datastorename**.

**WARNING**

Updating the vSphere data center or default data store after the configuration has been saved detaches any active vSphere **PersistentVolumes**.

9. In the **Virtual Machine Folder** field, enter the data center folder that contains the virtual machine of the cluster; for example, **/SDDC-Datacenter/vm/ci-ln-hjg4vg2-c61657-t2gzs**. For the OpenShift Container Platform installation to succeed, all virtual machines comprising the cluster must be located in a single data center folder.
10. Click **Save Configuration**. This updates the **cloud-provider-config** ConfigMap resource in the **openshift-config** namespace, and starts the configuration process.
11. Reopen the **vSphere connection configuration** wizard and expand the **Monitored operators** panel. Check that the status of the operators is either **Progressing** or **Healthy**.

### 21.12.2. Verifying the configuration

The connection configuration process updates operator statuses and control plane nodes. It takes approximately an hour to complete. During the configuration process, the nodes will reboot. Previously bound **PersistentVolumeClaims** objects might become disconnected.

#### Prerequisites

- You have saved the configuration settings in the **vSphere connection configuration** wizard.

#### Procedure

1. Check that the configuration process completed successfully:
  - a. In the OpenShift Container Platform Administrator perspective, navigate to **Home → Overview**.

- b. Under **Status** click **Operators**. Wait for all operator statuses to change from **Progressing** to **All succeeded**. A **Failed** status indicates that the configuration failed.
- c. Under **Status**, click **Control Plane**. Wait for the response rate of all Control Plane components to return to 100%. A **Failed** control plane component indicates that the configuration failed.

A failure indicates that at least one of the connection settings is incorrect. Change the settings in the **vSphere connection configuration** wizard and save the configuration again.

2. Check that you are able to bind **PersistentVolumeClaims** objects by performing the following steps:

- a. Create a **StorageClass** object using the following YAML:

```
kind: StorageClass
apiVersion: storage.k8s.io/v1
metadata:
 name: vsphere-sc
provisioner: kubernetes.io/vsphere-volume
parameters:
 datastore: YOURVCENTERDATASTORE
 diskformat: thin
 reclaimPolicy: Delete
 volumeBindingMode: Immediate
```

- b. Create a **PersistentVolumeClaims** object using the following YAML:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: test-pvc
 namespace: openshift-config
 annotations:
 volume.beta.kubernetes.io/storage-provisioner: kubernetes.io/vsphere-volume
 finalizers:
 - kubernetes.io/pvc-protection
spec:
 accessModes:
 - ReadWriteOnce
 resources:
 requests:
 storage: 10Gi
 storageClassName: vsphere-sc
 volumeMode: Filesystem
```

If you are unable to create a **PersistentVolumeClaims** object, you can troubleshoot by navigating to **Storage → PersistentVolumeClaims** in the **Administrator** perspective of the OpenShift Container Platform web console.

For instructions on creating storage objects, see [Dynamic provisioning](#).

## CHAPTER 22. INSTALLING ON ANY PLATFORM

### 22.1. INSTALLING A CLUSTER ON ANY PLATFORM

In OpenShift Container Platform version 4.14, you can install a cluster on any infrastructure that you provision, including virtualization and cloud environments.

#### IMPORTANT

Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you attempt to install an OpenShift Container Platform cluster in virtualized or cloud environments.

#### 22.1.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update](#) processes.
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- If you use a firewall, you [configured it to allow the sites](#) that your cluster requires access to.

#### NOTE

Be sure to also review this site list if you are configuring a proxy.

#### 22.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

#### IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

#### 22.1.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

### 22.1.3.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 22.1. Minimum required hosts**

| Hosts                                                                   | Description                                                                                                                                                                                            |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| One temporary bootstrap machine                                         | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster. |
| Three control plane machines                                            | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.                                                                                   |
| At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.                                                                                                             |

#### IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

### 22.1.3.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 22.2. Minimum resource requirements**

| Machine       | Operating System | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------------|------------------|----------|-------------|---------|-----------------------------------|
| Bootstrap     | RHCOS            | 4        | 16 GB       | 100 GB  | 300                               |
| Control plane | RHCOS            | 4        | 16 GB       | 100 GB  | 300                               |

| Machine | Operating System              | vCPU [1] | Virtual RAM | Storage | Input/Output Per Second (IOPS)[2] |
|---------|-------------------------------|----------|-------------|---------|-----------------------------------|
| Compute | RHCOS, RHEL 8.6 and later [3] | 2        | 8 GB        | 100 GB  | 300                               |

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or Hyper-Threading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

## NOTE

As of OpenShift Container Platform version 4.13, RHCOS is based on RHEL version 9.2, which updates the micro-architecture requirements. The following list contains the minimum instruction set architectures (ISA) that each architecture requires:

- x86-64 architecture requires x86-64-v2 ISA
- ARM64 architecture requires ARMv8.0-A ISA
- IBM Power architecture requires Power 9 ISA
- s390x architecture requires z14 ISA

For more information, see [RHEL Architectures](#).

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### 22.1.3.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 22.1.3.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

#### 22.1.3.4.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as **localhost** or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

#### 22.1.3.4.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

#### IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 22.3. Ports used for all-machine to all-machine communications

| Protocol | Port               | Description                                                                                                                       |
|----------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| ICMP     | N/A                | Network reachability tests                                                                                                        |
| TCP      | <b>1936</b>        | Metrics                                                                                                                           |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> and the Cluster Version Operator on port <b>9099</b> . |
|          | <b>10250-10259</b> | The default ports that Kubernetes reserves                                                                                        |
|          | <b>10256</b>       | openshift-sdn                                                                                                                     |
| UDP      | <b>4789</b>        | VXLAN                                                                                                                             |
|          | <b>6081</b>        | Geneve                                                                                                                            |
|          | <b>9000-9999</b>   | Host level services, including the node exporter on ports <b>9100-9101</b> .                                                      |
|          |                    |                                                                                                                                   |

| Protocol | Port               | Description                                                                                                                                 |
|----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
|          | <b>500</b>         | IPsec IKE packets                                                                                                                           |
|          | <b>4500</b>        | IPsec NAT-T packets                                                                                                                         |
|          | <b>123</b>         | Network Time Protocol (NTP) on UDP port <b>123</b><br><br>If an external NTP time server is configured, you must open UDP port <b>123</b> . |
| TCP/UDP  | <b>30000–32767</b> | Kubernetes node port                                                                                                                        |
| ESP      | N/A                | IPsec Encapsulating Security Payload (ESP)                                                                                                  |

Table 22.4. Ports used for all-machine to control plane communications

| Protocol | Port        | Description    |
|----------|-------------|----------------|
| TCP      | <b>6443</b> | Kubernetes API |

Table 22.5. Ports used for control plane machine to control plane machine communications

| Protocol | Port             | Description                |

### 22.1.3.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, **<cluster\_name>** is the cluster name and **<base\_domain>** is the base domain that you specify in the **install-config.yaml** file. A complete DNS record takes the form: **<component>.<cluster\_name>.<base\_domain>..**

**Table 22.6. Required DNS records**

| Component         | Record                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Kubernetes API    | <b>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>       | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                              |
|                   | <b>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>   | <p>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</p> <div>  <div> <b>IMPORTANT</b> <p>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</p> </div> </div>              |
| Routes            | <b>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b>    | <p>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</p> <p>For example, <b>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</b> is used as a wildcard route to the OpenShift Container Platform console.</p> |
| Bootstrap machine | <b>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</b> | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.                                                                                                                                                                                                                                                                                                                                                                                                                |

| Component              | Record                                                                                    | Description                                                                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Control plane machines | <b>&lt;control_plane&gt;&lt;n&gt;.<br/>&lt;cluster_name&gt;.<br/>&lt;base_domain&gt;.</b> | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster. |
| Compute machines       | <b>&lt;compute&gt;&lt;n&gt;.<br/>&lt;cluster_name&gt;.<br/>&lt;base_domain&gt;.</b>       | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.        |

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

**22.1.3.5.1. Example DNS configuration for user-provisioned clusters**

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

**Example 22.1. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root (
 2019070700 ; serial
 3H ; refresh (3 hours)
 30M ; retry (30 minutes)
 2W ; expiry (2 weeks)
 1W) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
;
ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
;
helper.example.com. IN A 192.168.1.5
```

```

helper.ocp4.example.com. IN A 192.168.1.5
;
api.ocp4.example.com. IN A 192.168.1.5 1
api-int.ocp4.example.com. IN A 192.168.1.5 2
;
*.apps.ocp4.example.com. IN A 192.168.1.5 3
;
bootstrap.ocp4.example.com. IN A 192.168.1.96 4
;
control-plane0.ocp4.example.com. IN A 192.168.1.97 5
control-plane1.ocp4.example.com. IN A 192.168.1.98 6
control-plane2.ocp4.example.com. IN A 192.168.1.99 7
;
compute0.ocp4.example.com. IN A 192.168.1.11 8
compute1.ocp4.example.com. IN A 192.168.1.7 9
;
;EOF

```

- 1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
- 2 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
- 3 Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

#### NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

- 4 Provides name resolution for the bootstrap machine.
- 5 6 7 Provides name resolution for the control plane machines.
- 8 9 Provides name resolution for the compute machines.

### Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

#### Example 22.2. Sample DNS zone database for reverse records

```

$TTL 1W
@ IN SOA ns1.example.com. root (
 2019070700 ; serial

```

```

3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR control-plane0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR control-plane1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR control-plane2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR compute0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR compute1.ocp4.example.com. 8
;
;EOF

```

- 1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
- 2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
- 3 Provides reverse DNS resolution for the bootstrap machine.
- 4 5 6 Provides reverse DNS resolution for the control plane machines.
- 7 8 Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

### 22.1.3.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
- A stateless load balancing algorithm. The options vary based on the load balancer implementation.

### IMPORTANT

Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 22.7. API load balancer**

| Port         | Back-end machines (pool members)                                                                                                                                                                                                              | Internal | External | Description           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|-----------------------|
| <b>6443</b>  | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <b>/readyz</b> endpoint for the API server health check probe. | X        | X        | Kubernetes API server |
| <b>22623</b> | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.                                                                                       | X        |          | Machine config server |

### NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the **/readyz** endpoint to the removal of the API server instance from the pool. Within the time frame after **/readyz** returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer.** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP or SSL Passthrough mode.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 22.8. Application Ingress load balancer**

| Port       | Back-end machines (pool members)                                                   | Internal | External | Description   |
|------------|------------------------------------------------------------------------------------|----------|----------|---------------|
| <b>443</b> | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTPS traffic |
| <b>80</b>  | The machines that run the Ingress Controller pods, compute, or worker, by default. | X        | X        | HTTP traffic  |

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

### 22.1.3.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running **setsebool -P haproxy\_connect\_any=1**.

### Example 22.3. Sample API and application Ingress load balancer configuration

```
global
 log 127.0.0.1 local2
 pidfile /var/run/haproxy.pid
 maxconn 4000
 daemon
defaults
```

```

mode http
log global
option dontlognull
option http-server-close
option redispatch
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
timeout server 1m
timeout http-keep-alive 10s
timeout check 10s
maxconn 3000
listen api-server-6443 ①
bind *:6443
mode tcp
option httpchk GET /readyz HTTP/1.0
option log-health-checks
balance roundrobin
server bootstrap bootstrap.ocp4.example.com:6443 verify none check check-ssl inter 10s fall 2
rise 3 backup ②
server master0 master0.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
server master1 master1.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
server master2 master2.ocp4.example.com:6443 weight 1 verify none check check-ssl inter 10s
fall 2 rise 3
listen machine-config-server-22623 ③
bind *:22623
mode tcp
server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup ④

listen ingress-router-80 ⑥
bind *:80
mode tcp
balance source
server worker0 worker0.ocp4.example.com:80 check inter 1s
server worker1 worker1.ocp4.example.com:80 check inter 1s

```

- ① Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
- ② ④ The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.
- ③ Port **22623** handles the machine config server traffic and points to the control plane machines.

- 5 Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
- 6 Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

#### NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

#### TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443**, **22623**, **443**, and **80** by running **netstat -nltp** on the HAProxy node.

### 22.1.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

#### Prerequisites

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

#### Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
  - a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
  - b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

**NOTE**

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

- c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

**NOTE**

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.
3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.

**IMPORTANT**

By default, port **1936** is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
  - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
  - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.  
See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.
5. Validate your DNS configuration.
  - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
  - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

#### NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

### 22.1.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

#### IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

#### Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

#### Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
  - a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
```

- 1 Replace **<nameserver\_ip>** with the IP address of the nameserver, **<cluster\_name>** with your cluster name, and **<base\_domain>** with your base domain name.

#### Example output

```
api.ocp4.example.com. 604800 IN A 192.168.1.5
```

- b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

#### Example output

```
api-int.ocp4.example.com. 604800 IN A 192.168.1.5
```

- c. Test an example **\*.apps.<cluster\_name>.<base\_domain>** DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

### Example output

```
random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

### NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace **random** with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

### Example output

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

- d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

### Example output

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

- e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.
    - a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

### Example output

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
```

- 1 Provides the record name for the Kubernetes internal API.
- 2 Provides the record name for the Kubernetes API.

#### NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

- b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

#### Example output

```
96.1.168.192.in-addr.arpa. 604800 IN PTR bootstrap.ocp4.example.com.
```

- c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

### 22.1.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

#### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

#### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as [AWS key pairs](#).

## Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

- 1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

### NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86\_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

### NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

- a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

### Example output

```
Agent pid 31874
```

### NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

- 1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

### Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

### Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

## 22.1.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

### Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

### Procedure

- Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
- Select your infrastructure provider.
- Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

#### IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

#### IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

- Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation [pull secret from Red Hat OpenShift Cluster Manager](#) . This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 22.1.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

#### IMPORTANT

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the **oc** binary in a directory that is on your **PATH**.  
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

##### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

##### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the **oc** binary to a directory that is on your **PATH**.  
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

### Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

#### Procedure

1. Navigate to the [OpenShift Container Platform downloads page](#) on the Red Hat Customer Portal.
2. Select the appropriate version from the **Version** drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

#### NOTE

For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your PATH.  
To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification

- Verify your installation by using an **oc** command:

```
$ oc <command>
```

## 22.1.9. Manually creating the installation configuration file

### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

## Procedure

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

### IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample **install-config.yaml** file template that is provided and save it in the **<installation\_directory>**.

### NOTE

You must name this configuration file **install-config.yaml**.

3. Back up the **install-config.yaml** file so that you can use it to install multiple clusters.

### IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

## 22.1.9.1. Sample install-config.yaml file for other platforms

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com 1
compute: 2
- hyperthreading: Enabled 3
 name: worker
 replicas: 0 4
controlPlane: 5
 hyperthreading: Enabled 6
 name: master
 replicas: 3 7
metadata:
 name: test 8
networking:
 clusterNetwork:
 - cidr: 10.128.0.0/14 9
```

```

hostPrefix: 23 10
networkType: OVNKubernetes 11
serviceNetwork: 12
- 172.30.0.0/16
platform:
 none: {} 13
fips: false 14
pullSecret: '{"auths": ...}' 15
sshKey: 'ssh-ed25519 AAAA...' 16

```

- 1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
- 2 5 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.
- 3 6 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

#### NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

#### IMPORTANT

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

- 4 You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

#### NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

- 7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.
- 8 The cluster name that you specified in your DNS records.
- 9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to

manage the traffic.

#### NOTE

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

- 10 The subnet prefix length to assign to each individual node. For example, if **hostPrefix** is set to **23**, then each node is assigned a **/23** subnet out of the given **cidr**, which allows for 510 ( $2^{(32 - 23)} - 2$ ) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.
- 11 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.
- 12 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
- 13 You must set the platform to **none**. You cannot provide additional platform configuration variables for your platform.

#### IMPORTANT

Clusters that are installed with the platform type **none** are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

- 14 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

#### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86\_64, ppc64le, and s390x architectures.

- 15 The [pull secret from Red Hat OpenShift Cluster Manager](#). This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
- 16 The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 22.1.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object's **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (**169.254.169.254**).

#### Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
 httpProxy: http://<username>:<pswd>@<ip>:<port> 1
 httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
 noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.
 <aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com 3
 additionalTrustBundle: | 4
 -----BEGIN CERTIFICATE-----
 <MY_TRUSTED_CA_CERT>
 -----END CERTIFICATE-----
 additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

- 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
- 2 A proxy URL to use for creating HTTPS connections outside the cluster.

- 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For
- 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.
- 5 Optional: The policy to determine the configuration of the **Proxy** object to reference the **user-ca-bundle** config map in the **trustedCA** field. The allowed values are **Proxyonly** and **Always**. Use **Proxyonly** to reference the **user-ca-bundle** config map only when **http/https** proxy is configured. Use **Always** to always reference the **user-ca-bundle** config map. The default value is **Proxyonly**.

#### NOTE

The installation program does not support the proxy **readinessEndpoints** field.

#### NOTE

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

#### NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 22.1.9.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

#### Prerequisites

- You have an existing **install-config.yaml** file.

#### Procedure

- Ensure that the number of compute replicas is set to **0** in your **install-config.yaml** file, as shown in the following **compute** stanza:

```
compute:
- name: worker
 platform: {}
 replicas: 0
```

#### NOTE

You must set the value of the **replicas** parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.
- When you create the Kubernetes manifest files in the following procedure, ensure that the **mastersSchedulable** parameter in the **<installation\_directory>/manifests/cluster-scheduler-02-config.yml** file is set to **true**. This enables your application workloads to run on the control plane nodes.
- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

### 22.1.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

## IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

## Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the **install-config.yaml** installation configuration file.

## Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
```

By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

```
$ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
```

4. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

```
$ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

**IMPORTANT**

If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

Because you create and manage the worker machines yourself, you do not need to initialize these machines.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

5. Check that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
  - a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
  - b. Locate the **mastersSchedulable** parameter and ensure that it is set to **false**.
  - c. Save and exit the file.
6. Optional: If you do not want [the Ingress Operator](#) to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

```
apiVersion: config.openshift.io/v1
kind: DNS
metadata:
 creationTimestamp: null
 name: cluster
spec:
 baseDomain: example.openshift.com
 privateZone: ❶
 id: mycluster-100419-private-zone
 publicZone: ❷
 id: example.openshift.com
status: {}
```

- ❶ ❷ Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

7. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$./openshift-install create ignition-configs --dir <installation_directory> 1
```

- 1 For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The **kubeadmin-password** and **kubeconfig** files are created in the **./<installation\_directory>/auth** directory:

```
.
├── auth
│ ├── kubeadmin-password
│ └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

### 22.1.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

#### NOTE

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Only RHEL 8 compute machines are supported.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments:** You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the **APPEND** parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special **coreos.inst.\*** arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- Ignition configs: OpenShift Container Platform Ignition config files (**\*.ign**) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the **coreos-installer** to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.
- **coreos-installer**: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the **coreos-installer** command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

#### NOTE

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

### 22.1.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

#### Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your **bootstrap.ign** Ignition config file:

```
$ sha512sum <installation_directory>/bootstrap.ign
```

The digests are provided to the **coreos-installer** in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

## IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

- From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign 1
```

### Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"},"passwd":{"users":[{"name":"core","sshAuthorizedKeys":["ssh-rsa...
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

- Although it is possible to obtain the RHCOS images that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page, the recommended way to obtain the correct version of your RHCOS images are from the output of **openshift-install** command:

```
$ openshift-install coreos print-stream-json | grep "\.iso[^\.]"
```

### Example output

```
"location": "<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-
<release>-live.aarch64.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-
<release>-live.ppc64le.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-
live.s390x.iso",
"location": "<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-
live.x86_64.iso",
```

## IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

**rhcos-<version>-live.<architecture>.iso**

- Use the ISO to start the RHCOS installation. Use one of the following installation options:

- Burn the ISO image to a disk and boot it directly.
  - Use ISO redirection by using a lights-out management (LOM) interface.
6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

**NOTE**

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the **coreos-installer** command as outlined in the following steps, instead of adding kernel arguments.

7. Run the **coreos-installer** command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>
--ignition-hash=sha512-<digest> 1 2
```

- 1 You must run the **coreos-installer** command by using **sudo**, because the **core** user does not have the required root privileges to perform the installation.
- 2 The **--ignition-hash** option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. **<digest>** is the Ignition config file SHA512 digest obtained in a preceding step.

**NOTE**

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running **coreos-installer**.

The following example initializes a bootstrap node installation to the **/dev/sda** device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-
url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=sha512-
a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf011
6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, you must reboot the system. During the system reboot, it applies the Ignition config file that you specified.
10. Check the console output to verify that Ignition ran.

### Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

11. Continue to create the other machines for your cluster.

### IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

### NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster\_name>.<base\_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install\_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

#### 22.1.11.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

#### Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the *Advanced RHCOS installation configuration* section for different ways to configure features, such as networking and disk partitioning.

#### Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

### IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

```
$ curl -k http://<HTTP_server>/bootstrap.ign 1
```

### Example output

```
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
 0 0 0 0 0 0 0 0 0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"},"passwd":{"users":[{"name":"core","sshAuthorizedKeys":["ssh-rsa...
```

Replace **bootstrap.ign** with **master.ign** or **worker.ign** in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Although it is possible to obtain the RHCOS **kernel**, **initramfs** and **rootfs** files that are required for your preferred method of installing operating system instances from the [RHCOS image mirror](#) page, the recommended way to obtain the correct version of your RHCOS files are from the output of **openshift-install** command:

```
$ openshift-install coreos print-stream-json | grep -Eo "https.*(kernel-|initramfs-|rootfs-)\w+(\.img)?"
```

### Example output

```
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
kernel-aarch64"
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
initramfs.aarch64.img"
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-
rootfs.aarch64.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/49.84.202110081256-0/ppc64le/rhcos-
<release>-live-kernel-ppc64le"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-
initramfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-
rootfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-kernel-
s390x"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-
initramfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-
rootfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-kernel-
```

```
x86_64"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-
initramfs.x86_64.img"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-
rootfs.x86_64.img"
```

## IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel:** `rhcos-<version>-live-kernel-<architecture>`
- **initramfs:** `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs:** `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

## IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.
6. Configure PXE or iPXE installation for the RHCOS images and begin the installation. Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE (**x86\_64**):

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
 KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> ❶
 APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.
<architecture>.img coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-
rootfs.<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign ❷ ❸
```

- ❶ Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

- ❷ If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named `enp1`, set `ip=enp1:dhcp`.

DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.

- 3 Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.rootfs\_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition\_url** parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.

#### NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **APPEND** line. For example, add **console=tty0 console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#) and "Enabling the serial console for PXE and ISO installation" in the "Advanced RHCOS installation configuration" section.

- For iPXE (**x86\_64** + **aarch64**):

```
kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-rootfs.
<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign 1 2
initrd --name main http://<HTTP_server>/rhcos-<version>-live-initramfs.
<architecture>.img 3
boot
```

- 1 Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **kernel** parameter value is the location of the **kernel** file, the **initrd=main** argument is needed for booting on UEFI systems, the **coreos.live.rootfs\_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition\_url** parameter value is the location of the bootstrap Ignition config file.
- 2 If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
- 3 Specify the location of the **initramfs** file that you uploaded to your HTTP server.

#### NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more **console=** arguments to the **kernel** line. For example, add **console=tty0 console=ttyS0** to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see [How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?](#) and "Enabling the serial console for PXE and ISO installation" in the "Advanced RHCOS installation configuration" section.

**NOTE**

To network boot the CoreOS **kernel** on **aarch64** architecture, you need to use a version of iPXE build with the **IMAGE\_GZIP** option enabled. See [IMAGE\\_GZIP option in iPXE](#).

- For PXE (with UEFI and Grub as second stage) on **aarch64**:

```
menuentry 'Install CoreOS' {
 linux rhcos-<version>-live-kernel-<architecture>
 coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-rootfs.
 <architecture>.img coreos.inst.install_dev=/dev/sda
 coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign 1 2
 initrd rhcos-<version>-live-initramfs.<architecture>.img 3
}
```

- 1** Specify the locations of the RHCOS files that you uploaded to your HTTP/TFTP server. The **kernel** parameter value is the location of the **kernel** file on your TFTP server. The **coreos.live.rootfs\_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition\_url** parameter value is the location of the bootstrap Ignition config file on your HTTP Server.
- 2** If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named **eno1**, set **ip=eno1:dhcp**.
- 3** Specify the location of the **initramfs** file that you uploaded to your TFTP server.

7. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.
9. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

#### NOTE

RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running **ssh core@<node>.<cluster\_name>.<base\_domain>** as a user with access to the SSH private key that is paired to the public key that you specified in your **install\_config.yaml** file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 22.1.11.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running **coreos-installer** manually from the live system
- Customizing a live ISO or PXE boot image

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

#### 22.1.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

#### Procedure

1. Boot the ISO installer.
2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as **nmcli** or **nmtui**.
3. Run the **coreos-installer** command to install the system, adding the **--copy-network** option to copy networking configuration. For example:

```
$ sudo coreos-installer install --copy-network \
 --ignition-url=http://host/worker.ign /dev/disk/by-id/scsi-<serial_number>
```

### IMPORTANT

The **--copy-network** option only copies networking configuration found under **/etc/NetworkManager/system-connections**. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

### Additional resources

- See [Getting started with nmcli](#) and [Getting started with nmtui](#) in the RHEL 8 documentation for more information about the **nmcli** and **nmtui** tools.

#### 22.1.11.3.2. Disk partitioning

Disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless you override the default partitioning configuration. During the RHCOS installation, the size of the root file system is increased to use any remaining available space on the target device.

### IMPORTANT

The use of a custom partition scheme on your node might result in OpenShift Container Platform not monitoring or alerting on some node partitions. If you override the default partitioning, see [Understanding OpenShift File System Monitoring \(eviction conditions\)](#) for more information about how OpenShift Container Platform monitors your host file systems.

OpenShift Container Platform monitors the following two filesystem identifiers:

- **nodefs**, which is the filesystem that contains **/var/lib/kubelet**
- **imagefs**, which is the filesystem that contains **/var/lib/containers**

For the default partition scheme, **nodefs** and **imagefs** monitor the same root filesystem, **/**.

To override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node, you must create separate partitions. Consider a situation where you want to add a separate storage partition for your containers and container images. For example, by mounting **/var/lib/containers** in a separate partition, the kubelet separately monitors **/var/lib/containers** as the **imagefs** directory and the root file system as the **nodefs** directory.

**IMPORTANT**

If you have resized your disk size to host a larger file system, consider creating a separate **/var/lib/containers** partition. Consider resizing a disk that has an **xfs** format to reduce CPU time issues caused by a high number of allocation groups.

**22.1.11.3.2.1. Creating a separate /var partition**

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the **/var** directory or a subdirectory of **/var**. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

**IMPORTANT**

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate **/var** partition.

Storing the contents of a **/var** directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the **/var** directory or a subdirectory of **/var** also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate **/var** partition by adding a machine config manifest that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

**Procedure**

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ openshift-install create manifests --dir <installation_directory>
```

2. Create a Butane config that configures the additional partition. For example, name the file **\$HOME/clusterconfig/98-var-partition.bu**, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the **/var** directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
 labels:
```

```

machineconfiguration.openshift.io/role: worker
name: 98-var-partition
storage:
 disks:
 - device: /dev/disk/by-id/<device_name> ❶
 partitions:
 - label: var
 start_mib: <partition_start_offset> ❷
 size_mib: <partition_size> ❸
 number: 5
 filesystems:
 - device: /dev/disk/by-partlabel/var
 path: /var
 format: xfs
 mount_options: [defaults, prjquota] ❹
 with_mount_unit: true

```

- ❶ The storage device name of the disk that you want to partition.
- ❷ When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
- ❸ The size of the data partition in mebibytes.
- ❹ The **prjquota** mount option must be enabled for filesystems used for container storage.

#### NOTE

When creating a separate **/var** partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create a manifest from the Butane config and save it to the **clusterconfig/openshift** directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

4. Create the Ignition config files:

```
$ openshift-install create ignition-configs --dir <installation_directory> ❶
```

- ❶ For **<installation\_directory>**, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

```

.
├── auth

```

The files in the `<installation_directory>/manifest` and `<installation_directory>/openshift` directories are wrapped into the Ignition config files, including the file that contains the **98-var-partition** custom **MachineConfig** object.

## Next steps

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

### 22.1.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the **coreos-installer** command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add **coreos.inst.\*** options to the **APPEND** parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

#### NOTE

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

### Retaining existing partitions during an ISO installation

This example preserves any partition in which the partition label begins with **data** (**data\***):

```
coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
 --save-partlabel 'data*' /dev/disk/by-id/scsi-<serial_number>
```

The following example illustrates running the **coreos-installer** in a way that preserves the sixth (6) partition on the disk:

```
coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
 --save-partindex 6 /dev/disk/by-id/scsi-<serial_number>
```

This example preserves partitions 5 and higher:

```
coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
 --save-partindex 5- /dev/disk/by-id/scsi-<serial_number>
```

In the previous examples where partition saving is used, **coreos-installer** recreates the partition immediately.

### Retaining existing partitions during a PXE installation

This **APPEND** option preserves any partition in which the partition label begins with 'data' ('data\*'):

```
coreos.inst.save_partlabel=data*
```

This **APPEND** option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This **APPEND** option preserves partition 6:

```
coreos.inst.save_partindex=6
```

### 22.1.11.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config:** Every manual RHCOS installation needs to pass one of the Ignition config files generated by **openshift-installer**, such as **bootstrap.ign**, **master.ign** and **worker.ign**, to carry out the installation.

#### IMPORTANT

It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

For PXE installations, you pass the Ignition configs on the **APPEND** line using the **coreos.inst.ignition\_url=** option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the **coreos-installer** command line with the **--ignition-url=** option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config:** This type can be created by using the **coreos-installer customize** subcommand and its various options. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

For PXE or ISO boots, you can create the Ignition config and **APPEND** the **ignition.config.url=** option to identify the location of the Ignition config. You also need to append **ignition.firstboot** **ignition.platform.id=metal** or the **ignition.config.url** option will be ignored.

### 22.1.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the **coreos-installer** command.

#### 22.1.11.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the **rd.neednet=1** kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the **ip=**, **nameserver=**, and **bond=** kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: **ip=**, **nameserver=**, and then **bond=**.

The networking options are passed to the **dracut** tool during system boot. For more information about the networking options supported by **dracut**, see the [dracut.cmdline manual page](#).

The following examples are the networking options for ISO installation.

Configuring DHCP or static IP addresses

To configure an IP address, either use DHCP (**ip=dhcp**) or set an individual static IP address (**ip=<host\_ip>**). If setting a static IP, you must then identify the DNS server IP address (**nameserver=<dns\_ip>**) on each node. The following example sets:

- The node's IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The hostname to **core0.example.com**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```

**NOTE**

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Configuring an IP address without a static hostname

You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node's IP address to **10.10.10.2**

- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0::enp1s0:none
nameserver=4.4.4.41
```

#### Specifying multiple network interfaces

You can specify multiple network interfaces by setting multiple **ip=** entries.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

#### Configuring default gateway and route

Optional: You can configure routes to additional networks by setting an **rd.route=** value.

#### NOTE

When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

- Run the following command to configure the default gateway:

```
ip=::10.10.10.254:::
```

- Enter the following command to configure the route for the additional network:

```
rd.route=20.20.20.0/24:20.20.20.254:enp2s0
```

#### Disabling DHCP on a single interface

You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the **enp1s0** interface has a static networking configuration and DHCP is disabled for **enp2s0**, which is not used:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=::::core0.example.com:enp2s0:none
```

#### Combining DHCP and static IP configurations

You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
ip=enp1s0:dhcp
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

#### Configuring VLANs on individual interfaces

Optional: You can configure VLANs on individual interfaces by using the **vlan=** parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0
```

- To configure a VLAN on a network interface and to use DHCP, run the following command:

```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

#### Providing multiple DNS servers

You can provide multiple DNS servers by adding a **nameserver=** entry for each server, for example:

```
nameserver=1.1.1.1
nameserver=8.8.8.8
```

#### Bonding multiple network interfaces to a single interface

Optional: You can bond multiple network interfaces to a single interface by using the **bond=** option. Refer to the following examples:

- The syntax for configuring a bonded interface is: **bond=<name>[:<network\_interfaces>][:options]**  
**<name>** is the bonding device name (**bond0**), **<network\_interfaces>** represents a comma-separated list of physical (ethernet) interfaces (**em1,em2**), and **options** is a comma-separated list of bonding options. Enter **modinfo bonding** to see available options.
- When you create a bonded interface using **bond=**, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond's IP address to **dhcp**. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp
```

- To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

#### Bonding multiple SR-IOV network interfaces to a dual port NIC interface

## IMPORTANT

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Optional: You can bond multiple SR-IOV network interfaces to a dual port NIC interface by using the **bond=** option.

On each node, you must perform the following tasks:

1. Create the SR-IOV virtual functions (VFs) following the guidance in [Managing SR-IOV devices](#). Follow the procedure in the "Attaching SR-IOV networking devices to virtual machines" section.
2. Create the bond, attach the desired VFs to the bond and set the bond link state up following the guidance in [Configuring network bonding](#). Follow any of the described procedures to create the bond.

The following examples illustrate the syntax you must use:

- The syntax for configuring a bonded interface is **bond=<name>[:<network\_interfaces>][:options]**. **<name>** is the bonding device name (**bond0**), **<network\_interfaces>** represents the virtual functions (VFs) by their known name in the kernel and shown in the output of the **ip link** command (**eno1f0**, **eno2f0**), and **options** is a comma-separated list of bonding options. Enter **modinfo bonding** to see available options.
- When you create a bonded interface using **bond=**, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond's IP address to **dhcp**. For example:

```
bond=bond0:eno1f0,eno2f0:mode=active-backup
ip=bond0:dhcp
```

- To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:eno1f0,eno2f0:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

Using network teaming

Optional: You can use a network teaming as an alternative to bonding by using the **team=** parameter:

- The syntax for configuring a team interface is: **team=name[:network\_interfaces]**. **name** is the team device name (**team0**) and **network\_interfaces** represents a comma-separated list of physical (ethernet) interfaces (**em1**, **em2**).

**NOTE**

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this [Red Hat Knowledgebase Article](#).

Use the following example to configure a network team:

```
team=team0:em1,em2
ip=team0:dhcp
```

#### 22.1.11.3.4.2. coreos-installer options for ISO and PXE installations

You can install RHCOS by running **coreos-installer install <options> <device>** at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the **coreos-installer** command.

**Table 22.9. coreos-installer subcommands, command-line options, and arguments**

| coreos-installer install subcommand                               |                                                                                                                                                                                                   |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Subcommand</i>                                                 | <i>Description</i>                                                                                                                                                                                |
| <b>\$ coreos-installer install &lt;options&gt; &lt;device&gt;</b> | Embed an Ignition config in an ISO image.                                                                                                                                                         |
| coreos-installer install subcommand options                       |                                                                                                                                                                                                   |
| <i>Option</i>                                                     | <i>Description</i>                                                                                                                                                                                |
| <b>-u, --image-url &lt;url&gt;</b>                                | Specify the image URL manually.                                                                                                                                                                   |
| <b>-f, --image-file &lt;path&gt;</b>                              | Specify a local image file manually. Used for debugging.                                                                                                                                          |
| <b>-i, --ignition-file &lt;path&gt;</b>                           | Embed an Ignition config from a file.                                                                                                                                                             |
| <b>-l, --ignition-url &lt;URL&gt;</b>                             | Embed an Ignition config from a URL.                                                                                                                                                              |
| <b>--ignition-hash &lt;digest&gt;</b>                             | Digest <b>type-value</b> of the Ignition config.                                                                                                                                                  |
| <b>-p, --platform &lt;name&gt;</b>                                | Override the Ignition platform ID for the installed system.                                                                                                                                       |
| <b>--console &lt;spec&gt;</b>                                     | Set the kernel and bootloader console for the installed system. For more information about the format of <b>&lt;spec&gt;</b> , see the <a href="#">Linux kernel serial console</a> documentation. |

|                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>--append-karg &lt;arg&gt;...</b>                                        | Append a default kernel argument to the installed system.                                                                                                                                                                                                                                                                                                                                            |
| <b>--delete-karg &lt;arg&gt;...</b>                                        | Delete a default kernel argument from the installed system.                                                                                                                                                                                                                                                                                                                                          |
| <b>-n, --copy-network</b>                                                  | Copy the network configuration from the install environment.<br><br><div>  <div> <p><b>IMPORTANT</b></p> <p>The <b>--copy-network</b> option only copies networking configuration found under <b>/etc/NetworkManager/system-connections</b>. In particular, it does not copy the system hostname.</p> </div> </div> |
| <b>--network-dir &lt;path&gt;</b>                                          | For use with <b>-n</b> . Default is <b>/etc/NetworkManager/system-connections/</b> .                                                                                                                                                                                                                                                                                                                 |
| <b>--save-partlabel &lt;lx&gt;..</b>                                       | Save partitions with this label glob.                                                                                                                                                                                                                                                                                                                                                                |
| <b>--save-partindex &lt;id&gt;...</b>                                      | Save partitions with this number or range.                                                                                                                                                                                                                                                                                                                                                           |
| <b>--insecure</b>                                                          | Skip RHCOS image signature verification.                                                                                                                                                                                                                                                                                                                                                             |

| <b>-h, --help</b>                                                              | Print help information.                                                                                |
| coreos-installer PXE subcommands                                               |                                                                                                        |
| <i>Subcommand</i>                                                              | <i>Description</i>                                                                                     |
| Note that not all of these options are accepted by all subcommands.            |                                                                                                        |
| <b>coreos-installer pxe customize &lt;options&gt; &lt;path&gt;</b>             | Customize a RHCOS live PXE boot config.                                                                |
| <b>coreos-installer pxe ignition wrap &lt;options&gt;</b>                      | Wrap an Ignition config in an image.                                                                   |
| <b>coreos-installer pxe ignition unwrap &lt;options&gt; &lt;image_name&gt;</b> | Show the wrapped Ignition config in an image.                                                          |
| coreos-installer PXE customize subcommand options                              |                                                                                                        |
| <i>Option</i>                                                                  | <i>Description</i>                                                                                     |
| Note that not all of these options are accepted by all subcommands.            |                                                                                                        |
| <b>--dest-ignition &lt;path&gt;</b>                                            | Merge the specified Ignition config file into a new configuration fragment for the destination system. |
| <b>--dest-console &lt;spec&gt;</b>                                             | Specify the kernel and bootloader console for the destination system.                                  |
| <b>--dest-device &lt;path&gt;</b>                                              | Install and overwrite the specified destination device.                                                |
| <b>--network-keyfile &lt;path&gt;</b>                                          | Configure networking by using the specified NetworkManager keyfile for live and destination systems.   |
| <b>--ignition-ca &lt;path&gt;</b>                                              | Specify an additional TLS certificate authority to be trusted by Ignition.                             |
| <b>--pre-install &lt;path&gt;</b>                                              | Run the specified script before installation.                                                          |
| <b>post-install &lt;path&gt;</b>                                               | Run the specified script after installation.                                                           |
| <b>--installer-config &lt;path&gt;</b>                                         | Apply the specified installer configuration file.                                                      |

|                                     |                                                                                                                                                                                                                                                                                                     |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>--live-ignition &lt;path&gt;</b> | Merge the specified Ignition config file into a new configuration fragment for the live environment.                                                                                                                                                                                                |
| <b>-o, --output &lt;path&gt;</b>    | Write the initramfs to a new output file.<br><br><div data-bbox="815 333 922 468" data-label="Image"></div> <div data-bbox="997 338 1091 369" data-label="Section-Header"><b>NOTE</b></div> <div data-bbox="997 405 1353 463" data-label="Text">This option is required for PXE environments.</div> |
| <b>-h, --help</b>                   | Print help information.                                                                                                                                                                                                                                                                             |

#### 22.1.11.3.4.3. **coreos.inst** boot options for ISO or PXE installations

You can automatically invoke **coreos-installer** options at boot time by passing **coreos.inst** boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the **coreos.inst** options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing **TAB** while the **RHEL CoreOS (Live)** menu option is highlighted.
- For PXE or iPXE installations, the **coreos.inst** options must be added to the **APPEND** line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer **coreos.inst** boot options for ISO and PXE installations.

**Table 22.10. **coreos.inst** boot options**

| Argument                          | Description                                                                                                                                                                                                     |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>coreos.inst.install_dev</b>    | Required. The block device on the system to install to. It is recommended to use the full path, such as <b>/dev/sda</b> , although <b>sda</b> is allowed.                                                       |
| <b>coreos.inst.ignition_url</b>   | Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.                               |
| <b>coreos.inst.save_partlabel</b> | Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.                                               |
| <b>coreos.inst.save_partindex</b> | Optional: Comma-separated indexes of partitions to preserve during the install. Ranges <b>m-n</b> are permitted, and either <b>m</b> or <b>n</b> can be omitted. The specified partitions do not need to exist. |

| Argument                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>coreos.inst.insecure</b>    | Optional: Permits the OS image that is specified by <b>coreos.inst.image_url</b> to be unsigned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>coreos.inst.image_url</b>   | <p>Optional: Download and install the specified RHCOS image.</p> <ul style="list-style-type: none"> <li>• This argument should not be used in production environments and is intended for debugging purposes only.</li> <li>• While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</li> <li>• If you are using <b>coreos.inst.image_url</b>, you must also use <b>coreos.inst.insecure</b>. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</li> <li>• Only HTTP and HTTPS protocols are supported.</li> </ul> |
| <b>coreos.inst.skip_reboot</b> | Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>coreos.inst.platform_id</b> | <p>Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is <b>metal</b>. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example:</p> <p><b>coreos.inst.platform_id=vmware.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ignition.config.url</b>     | Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how <b>coreos-installer</b> is invoked, or to run code before or after the installation. This is different from <b>coreos.inst.ignition_url</b> , which is the Ignition config for the installed system.                                                                                                                                                                                                                                                                                                                                                                                      |

### 22.1.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

## Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

## Procedure

1. Monitor the bootstrap process:

```
$./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 1
--log-level=info 2
```

- 1 For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

- 2 To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.

## Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

### IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

## 22.1.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

## Prerequisites

- You deployed an OpenShift Container Platform cluster.

- You installed the **oc** CLI.

## Procedure

1. Export the **kubeadmin** credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

```
$ oc whoami
```

### Example output

```
system:admin
```

## 22.1.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

### Prerequisites

- You added machines to your cluster.

## Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

### Example output

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 63m v1.27.3
master-1 Ready master 63m v1.27.3
master-2 Ready master 64m v1.27.3
```

The output lists all of the machines that you created.

### NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

### Example output

```
NAME AGE REQUESTOR CONDITION
csr-8b2br 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
csr-8vnps 15m system:serviceaccount:openshift-machine-config-operator:node-
bootstrapper Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

- If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

#### NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

#### NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

**1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

- Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME AGE REQUESTOR CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
```

- If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

**1** **<csr\_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
```

- After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME STATUS ROLES AGE VERSION
master-0 Ready master 73m v1.27.3
master-1 Ready master 73m v1.27.3
master-2 Ready master 74m v1.27.3
worker-0 Ready worker 11m v1.27.3
worker-1 Ready worker 11m v1.27.3
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

## Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

## 22.1.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

### Prerequisites

- Your control plane has initialized.

### Procedure

- Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

### Example output

| NAME                                     | VERSION | AVAILABLE | PROGRESSING | DEGRADED  |
|------------------------------------------|---------|-----------|-------------|-----------|
| SINCE                                    |         |           |             |           |
| authentication                           | 4.14.0  | True      | False       | False 19m |
| baremetal                                | 4.14.0  | True      | False       | False 37m |
| cloud-credential                         | 4.14.0  | True      | False       | False 40m |
| cluster-autoscaler                       | 4.14.0  | True      | False       | False 37m |
| config-operator                          | 4.14.0  | True      | False       | False 38m |
| console                                  | 4.14.0  | True      | False       | False 26m |
| csi-snapshot-controller                  | 4.14.0  | True      | False       | False 37m |
| dns                                      | 4.14.0  | True      | False       | False 37m |
| etcd                                     | 4.14.0  | True      | False       | False 36m |
| image-registry                           | 4.14.0  | True      | False       | False 31m |
| ingress                                  | 4.14.0  | True      | False       | False 30m |
| insights                                 | 4.14.0  | True      | False       | False 31m |
| kube-apiserver                           | 4.14.0  | True      | False       | False 26m |
| kube-controller-manager                  | 4.14.0  | True      | False       | False 36m |
| kube-scheduler                           | 4.14.0  | True      | False       | False 36m |
| kube-storage-version-migrator            | 4.14.0  | True      | False       | False 37m |
| machine-api                              | 4.14.0  | True      | False       | False 29m |
| machine-approver                         | 4.14.0  | True      | False       | False 37m |
| machine-config                           | 4.14.0  | True      | False       | False 36m |
| marketplace                              | 4.14.0  | True      | False       | False 37m |
| monitoring                               | 4.14.0  | True      | False       | False 29m |
| network                                  | 4.14.0  | True      | False       | False 38m |
| node-tuning                              | 4.14.0  | True      | False       | False 37m |
| openshift-apiserver                      | 4.14.0  | True      | False       | False 32m |
| openshift-controller-manager             | 4.14.0  | True      | False       | False 30m |
| openshift-samples                        | 4.14.0  | True      | False       | False 32m |
| operator-lifecycle-manager               | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-catalog       | 4.14.0  | True      | False       | False 37m |
| operator-lifecycle-manager-packageserver | 4.14.0  | True      | False       | False 32m |
| service-ca                               | 4.14.0  | True      | False       | False 38m |
| storage                                  | 4.14.0  | True      | False       | False 37m |

2. Configure the Operators that are not available.

### 22.1.15.1. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

#### Procedure

- Disable the sources for the default catalogs by adding **disableAllDefaultSources: true** to the **OperatorHub** object:

```
$ oc patch OperatorHub cluster --type json \
 -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```

#### TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Configuration → OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

### 22.1.15.2. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**. When this has completed, you must configure storage.

### 22.1.15.3. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

#### 22.1.15.3.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.

- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

### IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

### Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.

### NOTE

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

### Example output

```
No resources found in openshift-image-registry namespace
```

### NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

### Example output

```
storage:
 pvc:
 claim:
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

```
$ oc get clusteroperator image-registry
```

**Example output**

| NAME           | VERSION | AVAILABLE | PROGRESSING | DEGRADED | SINCE |
|----------------|---------|-----------|-------------|----------|-------|
| image-registry | 4.14    | True      | False       | False    | 6h50m |

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

**22.1.15.3.2. Configuring storage for the image registry in non-production clusters**

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

**22.1.15.3.3. Configuring block registry storage for bare metal**

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

## IMPORTANT

Block storage volumes, or block persistent volumes, are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

If you choose to use a block storage volume with the image registry, you must use a filesystem persistent volume claim (PVC).

## Procedure

1. Enter the following command to set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy, and runs with only one ( **1** ) replica:

```
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate", "replicas": 1}}'
```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
  - a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: image-registry-storage ❶
 namespace: openshift-image-registry ❷
spec:
 accessModes:
 - ReadWriteOnce ❸
 resources:
 requests:
 storage: 100Gi ❹
```

- ❶ A unique name that represents the **PersistentVolumeClaim** object.
- ❷ The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
- ❸ The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
- ❹ The size of the persistent volume claim.

- b. Enter the following command to create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Enter the following command to edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

## Example output

```
storage:
pvc:
claim: 1
```

- 1 By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

## 22.1.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

### Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

### Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

## Example output

| NAME                          | VERSION | AVAILABLE | PROGRESSING | DEGRADED | SINCE |
|-------------------------------|---------|-----------|-------------|----------|-------|
| authentication                | 4.14.0  | True      | False       | False    | 19m   |
| baremetal                     | 4.14.0  | True      | False       | False    | 37m   |
| cloud-credential              | 4.14.0  | True      | False       | False    | 40m   |
| cluster-autoscaler            | 4.14.0  | True      | False       | False    | 37m   |
| config-operator               | 4.14.0  | True      | False       | False    | 38m   |
| console                       | 4.14.0  | True      | False       | False    | 26m   |
| csi-snapshot-controller       | 4.14.0  | True      | False       | False    | 37m   |
| dns                           | 4.14.0  | True      | False       | False    | 37m   |
| etcd                          | 4.14.0  | True      | False       | False    | 36m   |
| image-registry                | 4.14.0  | True      | False       | False    | 31m   |
| ingress                       | 4.14.0  | True      | False       | False    | 30m   |
| insights                      | 4.14.0  | True      | False       | False    | 31m   |
| kube-apiserver                | 4.14.0  | True      | False       | False    | 26m   |
| kube-controller-manager       | 4.14.0  | True      | False       | False    | 36m   |
| kube-scheduler                | 4.14.0  | True      | False       | False    | 36m   |
| kube-storage-version-migrator | 4.14.0  | True      | False       | False    | 37m   |
| machine-api                   | 4.14.0  | True      | False       | False    | 29m   |
| machine-approver              | 4.14.0  | True      | False       | False    | 37m   |
| machine-config                | 4.14.0  | True      | False       | False    | 36m   |
| marketplace                   | 4.14.0  | True      | False       | False    | 37m   |
| monitoring                    | 4.14.0  | True      | False       | False    | 29m   |
| network                       | 4.14.0  | True      | False       | False    | 38m   |
| node-tuning                   | 4.14.0  | True      | False       | False    | 37m   |

|                                          |        |      |       |       |     |
|------------------------------------------|--------|------|-------|-------|-----|
| openshift-apiserver                      | 4.14.0 | True | False | False | 32m |
| openshift-controller-manager             | 4.14.0 | True | False | False | 30m |
| openshift-samples                        | 4.14.0 | True | False | False | 32m |
| operator-lifecycle-manager               | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-catalog       | 4.14.0 | True | False | False | 37m |
| operator-lifecycle-manager-packageserver | 4.14.0 | True | False | False | 32m |
| service-ca                               | 4.14.0 | True | False | False | 38m |
| storage                                  | 4.14.0 | True | False | False | 37m |

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$./openshift-install --dir <installation_directory> wait-for install-complete 1
```

- 1** For **<installation\_directory>**, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

- a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

### Example output

| NAMESPACE                    | NAME                                          | READY | STATUS |
|------------------------------|-----------------------------------------------|-------|--------|
| RESTARTS                     | AGE                                           |       |        |
| openshift-apiserver-operator | openshift-apiserver-operator-85cb746d55-zqhs8 | 1/1   |        |
| Running                      | 1                                             | 9m    |        |

```

openshift-apiserver apiserver-67b9g 1/1 Running 0
3m
openshift-apiserver apiserver-ljcmx 1/1 Running 0
1m
openshift-apiserver apiserver-z25h4 1/1 Running 0
2m
openshift-authentication-operator authentication-operator-69d5d8bf84-vh2n8 1/1
Running 0 5m
...

```

- b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace> ❶
```

- ❶ Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the *Postinstallation machine configuration tasks* documentation for more information.

### 22.1.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, [use subscription watch](#) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 22.1.18. Next steps

- [Customize your cluster](#).
- If necessary, you can [opt out of remote health reporting](#).
- [Set up your registry and configure registry storage](#).

## CHAPTER 23. INSTALLATION CONFIGURATION

### 23.1. CUSTOMIZING NODES

OpenShift Container Platform supports both cluster-wide and per-machine configuration via Ignition, which allows arbitrary partitioning and file content changes to the operating system. In general, if a configuration file is documented in Red Hat Enterprise Linux (RHEL), then modifying it via Ignition is supported.

There are two ways to deploy machine config changes:

- Creating machine configs that are included in manifest files to start up a cluster during **openshift-install**.
- Creating machine configs that are passed to running OpenShift Container Platform nodes via the Machine Config Operator.

Additionally, modifying the reference config, such as the Ignition config that is passed to **coreos-installer** when installing bare-metal nodes allows per-machine configuration. These changes are currently not visible to the Machine Config Operator.

The following sections describe features that you might want to configure on your nodes in this way.

#### 23.1.1. Creating machine configs with Butane

Machine configs are used to configure control plane and worker machines by instructing machines how to create users and file systems, set up the network, install systemd units, and more.

Because modifying machine configs can be difficult, you can use Butane configs to create machine configs for you, thereby making node configuration much easier.

##### 23.1.1.1. About Butane

Butane is a command-line utility that OpenShift Container Platform uses to provide convenient, short-hand syntax for writing machine configs, as well as for performing additional validation of machine configs. The format of the Butane config file that Butane accepts is defined in the [OpenShift Butane config spec](#).

##### 23.1.1.2. Installing Butane

You can install the Butane tool (**butane**) to create OpenShift Container Platform machine configs from a command-line interface. You can install **butane** on Linux, Windows, or macOS by downloading the corresponding binary file.

#### TIP

Butane releases are backwards-compatible with older releases and with the Fedora CoreOS Config Transpiler (FCCT).

#### Procedure

1. Navigate to the Butane image download page at <https://mirror.openshift.com/pub/openshift-v4/clients/butane/>.

## 2. Get the **butane** binary:

- a. For the newest version of Butane, save the latest **butane** image to your current directory:

```
$ curl https://mirror.openshift.com/pub/openshift-v4/clients/butane/latest/butane --output butane
```

- b. Optional: For a specific type of architecture you are installing Butane on, such as aarch64 or ppc64le, indicate the appropriate URL. For example:

```
$ curl https://mirror.openshift.com/pub/openshift-v4/clients/butane/latest/butane-aarch64 --output butane
```

## 3. Make the downloaded binary file executable:

```
$ chmod +x butane
```

## 4. Move the **butane** binary file to a directory on your **PATH**.

To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

### Verification steps

- You can now use the Butane tool by running the **butane** command:

```
$ butane <butane_file>
```

### 23.1.1.3. Creating a MachineConfig object by using Butane

You can use Butane to produce a **MachineConfig** object so that you can configure worker or control plane nodes at installation time or via the Machine Config Operator.

#### Prerequisites

- You have installed the **butane** utility.

#### Procedure

1. Create a Butane config file. The following example creates a file named **99-worker-custom.bu** that configures the system console to show kernel debug messages and specifies custom settings for the chrony time service:

```
variant: openshift
version: 4.14.0
metadata:
 name: 99-worker-custom
labels:
 machineconfiguration.openshift.io/role: worker
openshift:
 kernel_arguments:
 - loglevel=7
storage:
```

```
files:
 - path: /etc/chrony.conf
 mode: 0644
 overwrite: true
 contents:
 inline: |
 pool 0.rhel.pool.ntp.org iburst
 driftfile /var/lib/chrony/drift
 makestep 1.0 3
 rtcsync
 logdir /var/log/chrony
```

## NOTE

The **99-worker-custom.bu** file is set to create a machine config for worker nodes. To deploy on control plane nodes, change the role from **worker** to **master**. To do both, you could repeat the whole procedure using different file names for the two types of deployments.

2. Create a **MachineConfig** object by giving Butane the file that you created in the previous step:

```
$ butane 99-worker-custom.bu -o ./99-worker-custom.yaml
```

A **MachineConfig** object YAML file is created for you to finish configuring your machines.

3. Save the Butane config in case you need to update the **MachineConfig** object in the future.
4. If the cluster is not running yet, generate manifest files and add the **MachineConfig** object YAML file to the **openshift** directory. If the cluster is already running, apply the file as follows:

```
$ oc create -f 99-worker-custom.yaml
```

## Additional resources

- [Adding kernel modules to nodes](#)
- [Encrypting and mirroring disks during installation](#)

## 23.1.2. Adding day-1 kernel arguments

Although it is often preferable to modify kernel arguments as a day-2 activity, you might want to add kernel arguments to all master or worker nodes during initial cluster installation. Here are some reasons you might want to add kernel arguments during cluster installation so they take effect before the systems first boot up:

- You need to do some low-level network configuration before the systems start.
- You want to disable a feature, such as SELinux, so it has no impact on the systems when they first come up.

**WARNING**

Disabling SELinux on RHCOS in production is not supported. Once SELinux has been disabled on a node, it must be re-provisioned before re-inclusion in a production cluster.

To add kernel arguments to master or worker nodes, you can create a **MachineConfig** object and inject that object into the set of manifest files used by Ignition during cluster setup.

For a listing of arguments you can pass to a RHEL 8 kernel at boot time, see [Kernel.org kernel parameters](https://kernel.org/doc/Documentation/kernel-parameters.txt). It is best to only add kernel arguments with this procedure if they are needed to complete the initial OpenShift Container Platform installation.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory>
```

2. Decide if you want to add kernel arguments to worker or control plane nodes.
3. In the **openshift** directory, create a file (for example, **99-openshift-machineconfig-master-kargs.yaml**) to define a **MachineConfig** object to add the kernel settings. This example adds a **loglevel=7** kernel argument to control plane nodes:

```
$ cat << EOF > 99-openshift-machineconfig-master-kargs.yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
 labels:
 machineconfiguration.openshift.io/role: master
 name: 99-openshift-machineconfig-master-kargs
spec:
 kernelArguments:
 - loglevel=7
EOF
```

You can change **master** to **worker** to add kernel arguments to worker nodes instead. Create a separate YAML file to add to both master and worker nodes.

You can now continue on to create the cluster.

**23.1.3. Adding kernel modules to nodes**

For most common hardware, the Linux kernel includes the device driver modules needed to use that hardware when the computer starts up. For some hardware, however, modules are not available in Linux. Therefore, you must find a way to provide those modules to each host computer. This procedure describes how to do that for nodes in an OpenShift Container Platform cluster.

When a kernel module is first deployed by following these instructions, the module is made available for the current kernel. If a new kernel is installed, the `kmods-via-containers` software will rebuild and deploy the module so a compatible version of that module is available with the new kernel.

The way that this feature is able to keep the module up to date on each node is by:

- Adding a `systemd` service to each node that starts at boot time to detect if a new kernel has been installed and
- If a new kernel is detected, the service rebuilds the module and installs it to the kernel

For information on the software needed for this procedure, see the [kmods-via-containers](#) github site.

A few important issues to keep in mind:

- This procedure is Technology Preview.
- Software tools and examples are not yet available in official RPM form and can only be obtained for now from unofficial **github.com** sites noted in the procedure.
- Third-party kernel modules you might add through these procedures are not supported by Red Hat.
- In this procedure, the software needed to build your kernel modules is deployed in a RHEL 8 container. Keep in mind that modules are rebuilt automatically on each node when that node gets a new kernel. For that reason, each node needs access to a **yum** repository that contains the kernel and related packages needed to rebuild the module. That content is best provided with a valid RHEL subscription.

### 23.1.3.1. Building and testing the kernel module container

Before deploying kernel modules to your OpenShift Container Platform cluster, you can test the process on a separate RHEL system. Gather the kernel module's source code, the KVC framework, and the `kmod-via-containers` software. Then build and test the module. To do that on a RHEL 8 system, do the following:

#### Procedure

1. Register a RHEL 8 system:

```
subscription-manager register
```

2. Attach a subscription to the RHEL 8 system:

```
subscription-manager attach --auto
```

3. Install software that is required to build the software and container:

```
yum install podman make git -y
```

4. Clone the **kmod-via-containers** repository:

- a. Create a folder for the repository:

```
$ mkdir kmods; cd kmods
```

- b. Clone the repository:

```
$ git clone https://github.com/kmods-via-containers/kmods-via-containers
```

5. Install a KVC framework instance on your RHEL 8 build host to test the module. This adds a **kmods-via-container** systemd service and loads it:

- a. Change to the **kmod-via-containers** directory:

```
$ cd kmods-via-containers/
```

- b. Install the KVC framework instance:

```
$ sudo make install
```

- c. Reload the systemd manager configuration:

```
$ sudo systemctl daemon-reload
```

6. Get the kernel module source code. The source code might be used to build a third-party module that you do not have control over, but is supplied by others. You will need content similar to the content shown in the **kvc-simple-kmod** example that can be cloned to your system as follows:

```
$ cd .. ; git clone https://github.com/kmods-via-containers/kvc-simple-kmod
```

7. Edit the configuration file, **simple-kmod.conf** file, in this example, and change the name of the Dockerfile to **Dockerfile.rhel**:

- a. Change to the **kvc-simple-kmod** directory:

```
$ cd kvc-simple-kmod
```

- b. Rename the Dockerfile:

```
$ cat simple-kmod.conf
```

### Example Dockerfile

```
KMOD_CONTAINER_BUILD_CONTEXT="https://github.com/kmods-via-containers/kvc-
simple-kmod.git"
KMOD_CONTAINER_BUILD_FILE=Dockerfile.rhel
KMOD_SOFTWARE_VERSION=dd1a7d4
KMOD_NAMES="simple-kmod simple-procfs-kmod"
```

8. Create an instance of **kmods-via-containers@.service** for your kernel module, **simple-kmod** in this example:

```
$ sudo make install
```

9. Enable the **kmods-via-containers@.service** instance:

```
$ sudo kmods-via-containers build simple-kmod $(uname -r)
```

10. Enable and start the systemd service:

```
$ sudo systemctl enable kmods-via-containers@simple-kmod.service --now
```

- a. Review the service status:

```
$ sudo systemctl status kmods-via-containers@simple-kmod.service
```

#### Example output

- kmods-via-containers@simple-kmod.service - Kmods Via Containers - simple-kmod  
Loaded: loaded (/etc/systemd/system/kmods-via-containers@.service;  
enabled; vendor preset: disabled)  
Active: active (exited) since Sun 2020-01-12 23:49:49 EST; 5s ago...

11. To confirm that the kernel modules are loaded, use the **lsmod** command to list the modules:

```
$ lsmod | grep simple_
```

#### Example output

```
simple_procfs_kmod 16384 0
simple_kmod 16384 0
```

12. Optional. Use other methods to check that the **simple-kmod** example is working:

- Look for a "Hello world" message in the kernel ring buffer with **dmesg**:

```
$ dmesg | grep 'Hello world'
```

#### Example output

```
[6420.761332] Hello world from simple_kmod.
```

- Check the value of **simple-procfs-kmod** in **/proc**:

```
$ sudo cat /proc/simple-procfs-kmod
```

#### Example output

```
simple-procfs-kmod number = 0
```

- Run the **spkut** command to get more information from the module:

```
$ sudo spkut 44
```

#### Example output

```
KVC: wrapper simple-kmod for 4.18.0-147.3.1.el8_1.x86_64
Running userspace wrapper using the kernel module container...
+ podman run -i --rm --privileged
 simple-kmod-dd1a7d4:4.18.0-147.3.1.el8_1.x86_64 spkut 44
simple-procfs-kmod number = 0
simple-procfs-kmod number = 44
```

Going forward, when the system boots this service will check if a new kernel is running. If there is a new kernel, the service builds a new version of the kernel module and then loads it. If the module is already built, it will just load it.

### 23.1.3.2. Provisioning a kernel module to OpenShift Container Platform

Depending on whether or not you must have the kernel module in place when OpenShift Container Platform cluster first boots, you can set up the kernel modules to be deployed in one of two ways:

- **Provision kernel modules at cluster install time (day-1)** You can create the content as a **MachineConfig** object and provide it to **openshift-install** by including it with a set of manifest files.
- **Provision kernel modules via Machine Config Operator (day-2)** If you can wait until the cluster is up and running to add your kernel module, you can deploy the kernel module software via the Machine Config Operator (MCO).

In either case, each node needs to be able to get the kernel packages and related software packages at the time that a new kernel is detected. There are a few ways you can set up each node to be able to obtain that content.

- Provide RHEL entitlements to each node.
- Get RHEL entitlements from an existing RHEL host, from the **/etc/pki/entitlement** directory and copy them to the same location as the other files you provide when you build your Ignition config.
- Inside the Dockerfile, add pointers to a **yum** repository containing the kernel and other packages. This must include new kernel packages as they are needed to match newly installed kernels.

#### 23.1.3.2.1. Provision kernel modules via a MachineConfig object

By packaging kernel module software with a **MachineConfig** object, you can deliver that software to worker or control plane nodes at installation time or via the Machine Config Operator.

#### Procedure

1. Register a RHEL 8 system:

```
subscription-manager register
```

2. Attach a subscription to the RHEL 8 system:

```
subscription-manager attach --auto
```

3. Install software needed to build the software:

```
-
```

```
yum install podman make git -y
```

4. Create a directory to host the kernel module and tooling:

```
$ mkdir kmods; cd kmods
```

5. Get the **kmods-via-containers** software:

- a. Clone the **kmods-via-containers** repository:

```
$ git clone https://github.com/kmods-via-containers/kmods-via-containers
```

- b. Clone the **kvc-simple-kmod** repository:

```
$ git clone https://github.com/kmods-via-containers/kvc-simple-kmod
```

6. Get your module software. In this example, **kvc-simple-kmod** is used.

7. Create a fakeroot directory and populate it with files that you want to deliver via Ignition, using the repositories cloned earlier:

- a. Create the directory:

```
$ FAKEROOT=$(mktemp -d)
```

- b. Change to the **kmod-via-containers** directory:

```
$ cd kmods-via-containers
```

- c. Install the KVC framework instance:

```
$ make install DESTDIR=${FAKEROOT}/usr/local CONFDIR=${FAKEROOT}/etc/
```

- d. Change to the **kvc-simple-kmod** directory:

```
$ cd ../kvc-simple-kmod
```

- e. Create the instance:

```
$ make install DESTDIR=${FAKEROOT}/usr/local CONFDIR=${FAKEROOT}/etc/
```

8. Clone the fakeroot directory, replacing any symbolic links with copies of their targets, by running the following command:

```
$ cd .. && rm -rf kmod-tree && cp -Lpr ${FAKEROOT} kmod-tree
```

9. Create a Butane config file, **99-simple-kmod.bu**, that embeds the kernel module tree and enables the systemd service.

#### NOTE

See "Creating machine configs with Butane" for information about Butane.

```

variant: openshift
version: 4.14.0
metadata:
 name: 99-simple-kmod
 labels:
 machineconfiguration.openshift.io/role: worker 1
storage:
 trees:
 - local: kmod-tree
systemd:
 units:
 - name: kmods-via-containers@simple-kmod.service
 enabled: true

```

- 1** To deploy on control plane nodes, change **worker** to **master**. To deploy on both control plane and worker nodes, perform the remainder of these instructions once for each node type.

10. Use Butane to generate a machine config YAML file, **99-simple-kmod.yaml**, containing the files and configuration to be delivered:

```
$ butane 99-simple-kmod.bu --files-dir . -o 99-simple-kmod.yaml
```

11. If the cluster is not up yet, generate manifest files and add this file to the **openshift** directory. If the cluster is already running, apply the file as follows:

```
$ oc create -f 99-simple-kmod.yaml
```

Your nodes will start the **kmods-via-containers@simple-kmod.service** service and the kernel modules will be loaded.

12. To confirm that the kernel modules are loaded, you can log in to a node (using **oc debug node/<openshift-node>**, then **chroot /host**). To list the modules, use the **lsmod** command:

```
$ lsmod | grep simple_
```

### Example output

```

simple_procfs_kmod 16384 0
simple_kmod 16384 0

```

## 23.1.4. Encrypting and mirroring disks during installation

During an OpenShift Container Platform installation, you can enable boot disk encryption and mirroring on the cluster nodes.

### 23.1.4.1. About disk encryption

You can enable encryption for the boot disks on the control plane and compute nodes at installation time. OpenShift Container Platform supports the Trusted Platform Module (TPM) v2 and Tang encryption modes.

## TPM v2

This is the preferred mode. TPM v2 stores passphrases in a secure cryptoprocessor on the server. You can use this mode to prevent decryption of the boot disk data on a cluster node if the disk is removed from the server.

## Tang

Tang and Clevis are server and client components that enable network-bound disk encryption (NBDE). You can bind the boot disk data on your cluster nodes to one or more Tang servers. This prevents decryption of the data unless the nodes are on a secure network where the Tang servers are accessible. Clevis is an automated decryption framework used to implement decryption on the client side.

### IMPORTANT

The use of the Tang encryption mode to encrypt your disks is only supported for bare metal and vSphere installations on user-provisioned infrastructure.

In earlier versions of Red Hat Enterprise Linux CoreOS (RHCOS), disk encryption was configured by specifying `/etc/clevis.json` in the Ignition config. That file is not supported in clusters created with OpenShift Container Platform 4.7 or later. Configure disk encryption by using the following procedure.

When the TPM v2 or Tang encryption modes are enabled, the RHCOS boot disks are encrypted using the LUKS2 format.

This feature:

- Is available for installer-provisioned infrastructure, user-provisioned infrastructure, and Assisted Installer deployments
- For Assisted installer deployments:
  - Each cluster can only have a single encryption method, Tang or TPM
  - Encryption can be enabled on some or all nodes
  - There is no Tang threshold; all servers must be valid and operational
  - Encryption applies to the installation disks only, not to the workload disks
- Is supported on Red Hat Enterprise Linux CoreOS (RHCOS) systems only
- Sets up disk encryption during the manifest installation phase, encrypting all data written to disk, from first boot forward
- Requires no user intervention for providing passphrases
- Uses AES-256-XTS encryption, or AES-256-CBC if FIPS mode is enabled

### 23.1.4.1.1. Configuring an encryption threshold

In OpenShift Container Platform, you can specify a requirement for more than one Tang server. You can also configure the TPM v2 and Tang encryption modes simultaneously. This enables boot disk data decryption only if the TPM secure cryptoprocessor is present and the Tang servers are accessible over a secure network.

You can use the **threshold** attribute in your Butane configuration to define the minimum number of TPM v2 and Tang encryption conditions required for decryption to occur.

The threshold is met when the stated value is reached through any combination of the declared conditions. In the case of offline provisioning, the offline server is accessed using an included advertisement, and only uses that supplied advertisement if the number of online servers do not meet the set threshold.

For example, the **threshold** value of **2** in the following configuration can be reached by accessing two Tang servers, with the offline server available as a backup, or by accessing the TPM secure cryptoprocessor and one of the Tang servers:

### Example Butane configuration for disk encryption

```
variant: openshift
version: 4.14.0
metadata:
 name: worker-storage
 labels:
 machineconfiguration.openshift.io/role: worker
boot_device:
 layout: x86_64 ❶
 luks:
 tpm2: true ❷
 tang: ❸
 - url: http://tang1.example.com:7500
 thumbprint: jwGN5tRFK-kF6pIX89ssF3khxxX
 - url: http://tang2.example.com:7500
 thumbprint: VCJsvZFjBSIHSlDw78rOrq7h2ZF
 - url: http://tang3.example.com:7500
 thumbprint: PLjNyRdGw03zIRoGjQYMahSZGu9
 advertisement: "{\"payload\": \"...\", \"protected\": \"...\", \"signature\": \"...\"}" ❹
 threshold: 2 ❺
openshift:
 fips: true
```

- ❶ Set this field to the instruction set architecture of the cluster nodes. Some examples include, **x86\_64**, **aarch64**, or **ppc64le**.
- ❷ Include this field if you want to use a Trusted Platform Module (TPM) to encrypt the root file system.
- ❸ Include this section if you want to use one or more Tang servers.
- ❹ Optional: Include this field for offline provisioning. Ignition will provision the Tang server binding rather than fetching the advertisement from the server at runtime. This lets the server be unavailable at provisioning time.
- ❺ Specify the minimum number of TPM v2 and Tang encryption conditions required for decryption to occur.

### IMPORTANT

The default **threshold** value is **1**. If you include multiple encryption conditions in your configuration but do not specify a threshold, decryption can occur if any of the conditions are met.

### NOTE

If you require TPM v2 *and* Tang for decryption, the value of the **threshold** attribute must equal the total number of stated Tang servers plus one. If the **threshold** value is lower, it is possible to reach the threshold value by using a single encryption mode. For example, if you set **tpm2** to **true** and specify two Tang servers, a threshold of **2** can be met by accessing the two Tang servers, even if the TPM secure cryptoprocessor is not available.

#### 23.1.4.2. About disk mirroring

During OpenShift Container Platform installation on control plane and worker nodes, you can enable mirroring of the boot and other disks to two or more redundant storage devices. A node continues to function after storage device failure provided one device remains available.

Mirroring does not support replacement of a failed disk. Reprovision the node to restore the mirror to a pristine, non-degraded state.

### NOTE

For user-provisioned infrastructure deployments, mirroring is available only on RHCOS systems. Support for mirroring is available on **x86\_64** nodes booted with BIOS or UEFI and on **ppc64le** nodes.

#### 23.1.4.3. Configuring disk encryption and mirroring

You can enable and configure encryption and mirroring during an OpenShift Container Platform installation.

#### Prerequisites

- You have downloaded the OpenShift Container Platform installation program on your installation node.
- You installed Butane on your installation node.

### NOTE

Butane is a command-line utility that OpenShift Container Platform uses to offer convenient, short-hand syntax for writing and validating machine configs. For more information, see "Creating machine configs with Butane".

- You have access to a Red Hat Enterprise Linux (RHEL) 8 machine that can be used to generate a thumbprint of the Tang exchange key.

#### Procedure

1. If you want to use TPM v2 to encrypt your cluster, check to see if TPM v2 encryption needs to be enabled in the host firmware for each node. This is required on most Dell systems. Check the manual for your specific system.
2. If you want to use Tang to encrypt your cluster, follow these preparatory steps:
  - a. Set up a Tang server or access an existing one. See [Network-bound disk encryption](#) for instructions.
  - b. Install the **clevis** package on a RHEL 8 machine, if it is not already installed:

```
$ sudo yum install clevis
```

- c. On the RHEL 8 machine, run the following command to generate a thumbprint of the exchange key. Replace **http://tang1.example.com:7500** with the URL of your Tang server:

```
$ clevis-encrypt-tang '{"url":"http://tang1.example.com:7500"}' < /dev/null > /dev/null 1
```

**1** In this example, **tangd.socket** is listening on port **7500** on the Tang server.

#### NOTE

The **clevis-encrypt-tang** command generates a thumbprint of the exchange key. No data passes to the encryption command during this step; **/dev/null** exists here as an input instead of plain text. The encrypted output is also sent to **/dev/null**, because it is not required for this procedure.

#### Example output

```
The advertisement contains the following signing keys:
```

```
PLjNyRdGw03zlRoGjQYMahSZGu9 1
```

**1** The thumbprint of the exchange key.

When the **Do you wish to trust these keys? [ynYN]** prompt displays, type **Y**.

- d. Optional: For offline Tang provisioning:
  - i. Obtain the advertisement from the server using the **curl** command. Replace **http://tang2.example.com:7500** with the URL of your Tang server:

```
$ curl -f http://tang2.example.com:7500/adv > adv.jws && cat adv.jws
```

#### Expected output

```
{"payload": "eyJrZXlzljogW3siYWxnljogIkV", "protected":
"eyJhbGciOiJIUzUxMiIsImN0eSI", "signature": "ADLgk7fZdE3Yt4FyYsm0pHiau7Q"}
```

- ii. Provide the advertisement file to Clevis for encryption:

```
$ clevis-encrypt-tang '{"url":"http://tang2.example.com:7500","adv":"adv.jws"}' < /dev/null > /dev/null
```

- e. If the nodes are configured with static IP addressing, run **coreos-installer iso customize --dest-karg-append** or use the **coreos-installer --append-karg** option when installing RHCOS nodes to set the IP address of the installed system. Append the **ip=** and other arguments needed for your network.

## IMPORTANT

Some methods for configuring static IPs do not affect the initramfs after the first boot and will not work with Tang encryption. These include the **coreos-installer --copy-network** option, the **coreos-installer iso customize --network-keyfile** option, and the **coreos-installer pxe customize --network-keyfile** option, as well as adding **ip=** arguments to the kernel command line of the live ISO or PXE image during installation. Incorrect static IP configuration causes the second boot of the node to fail.

3. On your installation node, change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$./openshift-install create manifests --dir <installation_directory> ❶
```

- ❶ Replace **<installation\_directory>** with the path to the directory that you want to store the installation files in.

4. Create a Butane config that configures disk encryption, mirroring, or both. For example, to configure storage for compute nodes, create a **\$HOME/clusterconfig/worker-storage.bu** file.

## Butane config example for a boot device

```
variant: openshift
version: 4.14.0
metadata:
 name: worker-storage ❶
 labels:
 machineconfiguration.openshift.io/role: worker ❷
boot_device:

openshift:
 fips: true 13
```

- 1 2** For control plane configurations, replace **worker** with **master** in both of these locations.
- 3** Set this field to the instruction set architecture of the cluster nodes. Some examples include, **x86\_64**, **aarch64**, or **ppc64le**.
- 4** Include this section if you want to encrypt the root file system. For more details, see "About disk encryption".
- 5** Include this field if you want to use a Trusted Platform Module (TPM) to encrypt the root file system.
- 6** Include this section if you want to use one or more Tang servers.
- 7** Specify the URL of a Tang server. In this example, **tangd.socket** is listening on port **7500** on the Tang server.
- 8** Specify the exchange key thumbprint, which was generated in a preceding step.
- 9** Optional: Specify the advertisement for your offline Tang server in valid JSON format.
- 10** Specify the minimum number of TPM v2 and Tang encryption conditions that must be met for decryption to occur. The default value is **1**. For more information about this topic, see "Configuring an encryption threshold".
- 11** Include this section if you want to mirror the boot disk. For more details, see "About disk mirroring".
- 12** List all disk devices that should be included in the boot disk mirror, including the disk that RHCOS will be installed onto.
- 13** Include this directive to enable FIPS mode on your cluster.

## IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). If you are configuring nodes to use both disk encryption and mirroring, both features must be configured in the same Butane configuration file. If you are configuring disk encryption on a node with FIPS mode enabled, you must include the **fips** directive in the same Butane configuration file, even if FIPS mode is also enabled in a separate manifest.

5. Create a control plane or compute node manifest from the corresponding Butane configuration file and save it to the **<installation\_directory>/openshift** directory. For example, to create a manifest for the compute nodes, run the following command:

```
$ butane $HOME/clusterconfig/worker-storage.bu -o <installation_directory>/openshift/99-
worker-storage.yaml
```

- Repeat this step for each node type that requires disk encryption or mirroring.
6. Save the Butane configuration file in case you need to update the manifests in the future.
  7. Continue with the remainder of the OpenShift Container Platform installation.

## TIP

You can monitor the console log on the RHCOS nodes during installation for error messages relating to disk encryption or mirroring.

## IMPORTANT

If you configure additional data partitions, they will not be encrypted unless encryption is explicitly requested.

## Verification

After installing OpenShift Container Platform, you can verify if boot disk encryption or mirroring is enabled on the cluster nodes.

1. From the installation host, access a cluster node by using a debug pod:
  - a. Start a debug pod for the node, for example:
- b. Set **/host** as the root directory within the debug shell. The debug pod mounts the root file system of the node in **/host** within the pod. By changing the root directory to **/host**, you can run binaries contained in the executable paths on the node:

```
$ oc debug node/compute-1
```

```
chroot /host
```

## NOTE

OpenShift Container Platform cluster nodes running Red Hat Enterprise Linux CoreOS (RHCOS) are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes using SSH is not recommended. However, if the OpenShift Container Platform API is not available, or **kubelet** is not properly functioning on the target node, **oc** operations will be impacted. In such situations, it is possible to access nodes using **ssh core@<node>.<cluster\_name>.<base\_domain>** instead.

2. If you configured boot disk encryption, verify if it is enabled:
  - a. From the debug shell, review the status of the root mapping on the node:

```
cryptsetup status root
```

## Example output

```
/dev/mapper/root is active and is in use.
type: LUKS2 1
```

```

cipher: aes-xts-plain64 ❷
keysize: 512 bits
key location: keyring
device: /dev/sda4 ❸
sector size: 512
offset: 32768 sectors
size: 15683456 sectors
mode: read/write

```

- ❶ The encryption format. When the TPM v2 or Tang encryption modes are enabled, the RHCOS boot disks are encrypted using the LUKS2 format.
- ❷ The encryption algorithm used to encrypt the LUKS2 volume. The **aes-cbc-essiv:sha256** cipher is used if FIPS mode is enabled.
- ❸ The device that contains the encrypted LUKS2 volume. If mirroring is enabled, the value will represent a software mirror device, for example **/dev/md126**.

b. List the Clevis plugins that are bound to the encrypted device:

```
clevis luks list -d /dev/sda4 ❶
```

- ❶ Specify the device that is listed in the **device** field in the output of the preceding step.

### Example output

```
1: sss '{"t":1,"pins":{"tang":{"url":"http://tang.example.com:7500"}}}' ❶
```

- ❶ In the example output, the Tang plugin is used by the Shamir's Secret Sharing (SSS) Clevis plugin for the **/dev/sda4** device.

3. If you configured mirroring, verify if it is enabled:

a. From the debug shell, list the software RAID devices on the node:

```
cat /proc/mdstat
```

### Example output

```

Personalities : [raid1]
md126 : active raid1 sdb3[1] sda3[0] ❶
 393152 blocks super 1.0 [2/2] [UU]

md127 : active raid1 sda4[0] sdb4[1] ❷
 51869632 blocks super 1.2 [2/2] [UU]

unused devices: <none>

```

- ❶ The **/dev/md126** software RAID mirror device uses the **/dev/sda3** and **/dev/sdb3** disk devices on the cluster node.

- 2** The **/dev/md127** software RAID mirror device uses the **/dev/sda4** and **/dev/sdb4** disk devices on the cluster node.

- b. Review the details of each of the software RAID devices listed in the output of the preceding command. The following example lists the details of the **/dev/md126** device:

```
mdadm --detail /dev/md126
```

### Example output

```
/dev/md126:
 Version : 1.0
 Creation Time : Wed Jul 7 11:07:36 2021
 Raid Level : raid1 1
 Array Size : 393152 (383.94 MiB 402.59 MB)
 Used Dev Size : 393152 (383.94 MiB 402.59 MB)
 Raid Devices : 2
 Total Devices : 2
 Persistence : Superblock is persistent

 Update Time : Wed Jul 7 11:18:24 2021
 State : clean 2
 Active Devices : 2 3
 Working Devices : 2 4
 Failed Devices : 0 5
 Spare Devices : 0

 Consistency Policy : resync

 Name : any:md-boot 6
 UUID : cdfa3801:c520e0b5:2bee2755:69043055
 Events : 19

 Number Major Minor RaidDevice State
 0 252 3 0 active sync /dev/sda3 7
 1 252 19 1 active sync /dev/sdb3 8
```

- 1** Specifies the RAID level of the device. **raid1** indicates RAID 1 disk mirroring.
- 2** Specifies the state of the RAID device.
- 3 4** States the number of underlying disk devices that are active and working.
- 5** States the number of underlying disk devices that are in a failed state.
- 6** The name of the software RAID device.
- 7 8** Provides information about the underlying disk devices used by the software RAID device.

- c. List the file systems mounted on the software RAID devices:

```
mount | grep /dev/md
```

### Example output

```
/dev/md127 on / type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /etc type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /usr type xfs
(ro,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /sysroot type xfs
(ro,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/containers/storage/overlay type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-
subpaths/etc/tuned/1 type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-
subpaths/etc/tuned/2 type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-
subpaths/etc/tuned/3 type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-
subpaths/etc/tuned/4 type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-
subpaths/etc/tuned/5 type xfs
(rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md126 on /boot type ext4 (rw,relatime,seclabel)
```

In the example output, the **/boot** file system is mounted on the **/dev/md126** software RAID device and the root file system is mounted on **/dev/md127**.

4. Repeat the verification steps for each OpenShift Container Platform node type.

### Additional resources

- For more information about the TPM v2 and Tang encryption modes, see [Configuring automated unlocking of encrypted volumes using policy-based decryption](#).

#### 23.1.4.4. Configuring a RAID-enabled data volume

You can enable software RAID partitioning to provide an external data volume. OpenShift Container Platform supports RAID 0, RAID 1, RAID 4, RAID 5, RAID 6, and RAID 10 for data protection and fault tolerance. See "About disk mirroring" for more details.

### Prerequisites

- You have downloaded the OpenShift Container Platform installation program on your installation node.

- You have installed Butane on your installation node.

## NOTE

Butane is a command-line utility that OpenShift Container Platform uses to provide convenient, short-hand syntax for writing machine configs, as well as for performing additional validation of machine configs. For more information, see the *Creating machine configs with Butane* section.

## Procedure

1. Create a Butane config that configures a data volume by using software RAID.
  - To configure a data volume with RAID 1 on the same disks that are used for a mirrored boot disk, create a **\$HOME/clusterconfig/raid1-storage.bu** file, for example:

### RAID 1 on mirrored boot disk

```
variant: openshift
version: 4.14.0
metadata:
 name: raid1-storage
 labels:
 machineconfiguration.openshift.io/role: worker
boot_device:
 mirror:
 devices:
 - /dev/disk/by-id/scsi-3600508b400105e210000900000490000
 - /dev/disk/by-id/scsi-SSEAGATE_ST373453LW_3HW1RHM6
storage:
 disks:
 - device: /dev/disk/by-id/scsi-3600508b400105e210000900000490000
 partitions:
 - label: root-1
 size_mib: 25000 1
 - label: var-1
 - device: /dev/disk/by-id/scsi-SSEAGATE_ST373453LW_3HW1RHM6
 partitions:
 - label: root-2
 size_mib: 25000 2
 - label: var-2
 raid:
 - name: md-var
 level: raid1
 devices:
 - /dev/disk/by-partlabel/var-1
 - /dev/disk/by-partlabel/var-2
 filesystems:
 - device: /dev/md/md-var
 path: /var
 format: xfs
 wipe_filesystem: true
 with_mount_unit: true
```

**1 2** When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. If no value is specified, or if the specified value is smaller than the

- To configure a data volume with RAID 1 on secondary disks, create a **\$HOME/clusterconfig/raid1-alt-storage.bu** file, for example:

#### RAID 1 on secondary disks

```
variant: openshift
version: 4.14.0
metadata:
 name: raid1-alt-storage
 labels:
 machineconfiguration.openshift.io/role: worker
storage:
 disks:
 - device: /dev/sdc
 wipe_table: true
 partitions:
 - label: data-1
 - device: /dev/sdd
 wipe_table: true
 partitions:
 - label: data-2
 raid:
 - name: md-var-lib-containers
 level: raid1
 devices:
 - /dev/disk/by-partlabel/data-1
 - /dev/disk/by-partlabel/data-2
 filesystems:
 - device: /dev/md/md-var-lib-containers
 path: /var/lib/containers
 format: xfs
 wipe_filesystem: true
 with_mount_unit: true
```

2. Create a RAID manifest from the Butane config you created in the previous step and save it to the **<installation\_directory>/openshift** directory. For example, to create a manifest for the compute nodes, run the following command:

```
$ butane $HOME/clusterconfig/<butane_config>.bu -o
<installation_directory>/openshift/<manifest_name>.yaml 1
```

- 1** Replace **<butane\_config>** and **<manifest\_name>** with the file names from the previous step. For example, **raid1-alt-storage.bu** and **raid1-alt-storage.yaml** for secondary disks.

3. Save the Butane config in case you need to update the manifest in the future.
4. Continue with the remainder of the OpenShift Container Platform installation.

#### 23.1.4.5. Configuring an Intel® Virtual RAID on CPU (VROC) data volume

Intel® VROC is a type of hybrid RAID, where some of the maintenance is offloaded to the hardware, but appears as software RAID to the operating system.

## IMPORTANT

Support for Intel® VROC is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

The following procedure configures an Intel® VROC-enabled RAID1.

## Prerequisites

- You have a system with Intel® Volume Management Device (VMD) enabled.

## Procedure

1. Create the Intel® Matrix Storage Manager (IMSM) RAID container by running the following command:

```
$ mdadm -CR /dev/md/imsmd0 -e \
 imsm -n2 /dev/nvme0n1 /dev/nvme1n1 1
```

- 1** The RAID device names. In this example, there are two devices listed. If you provide more than two device names, you must adjust the **-n** flag. For example, listing three devices would use the flag **-n3**.

2. Create the RAID1 storage inside the container:

- a. Create a dummy RAID0 volume in front of the real RAID1 volume by running the following command:

```
$ mdadm -CR /dev/md/dummy -l0 -n2 /dev/imsmd0 -z10m --assume-clean
```

- b. Create the real RAID1 array by running the following command:

```
$ mdadm -CR /dev/md/coreos -l1 -n2 /dev/imsmd0
```

- c. Stop both RAID0 and RAID1 member arrays and delete the dummy RAID0 array with the following commands:

```
$ mdadm -S /dev/md/dummy \
 mdadm -S /dev/md/coreos \
 mdadm --kill-subarray=0 /dev/md/imsmd0
```

- d. Restart the RAID1 arrays by running the following command:

```
$ mdadm -A /dev/md/coreos /dev/md/ims0
```

### 3. Install RHCOS on the RAID1 device:

- a. Get the UUID of the IMSM container by running the following command:

```
$ mdadm --details --export /dev/md/ims0
```

- b. Install RHCOS and include the **rd.md.uuid** kernel argument by running the following command:

```
$ coreos-installer install /dev/md/coreos \
 --append-karg rd.md.uuid=<md_UUID> ❶
...
```

❶ The UUID of the IMSM container.

Include any additional **coreos-installer** arguments you need to install RHCOS.

## 23.1.5. Configuring chrony time service

You can set the time server and related settings used by the chrony time service (**chronyd**) by modifying the contents of the **chrony.conf** file and passing those contents to your nodes as a machine config.

### Procedure

1. Create a Butane config including the contents of the **chrony.conf** file. For example, to configure chrony on worker nodes, create a **99-worker-chrony.bu** file.

### NOTE

See "Creating machine configs with Butane" for information about Butane.

```
variant: openshift
version: 4.14.0
metadata:
 name: 99-worker-chrony ❶
 labels:
 machineconfiguration.openshift.io/role: worker ❷
storage:
 files:
 - path: /etc/chrony.conf
 mode: 0644 ❸
 overwrite: true
 contents:
 inline: |
 pool 0.rhel.pool.ntp.org iburst ❹
 driftfile /var/lib/chrony/drift
 makestep 1.0 3
 rtsync
 logdir /var/log/chrony
```

- 1 2 On control plane nodes, substitute **master** for **worker** in both of these locations.
  - 3 Specify an octal value mode for the **mode** field in the machine config file. After creating the file and applying the changes, the **mode** is converted to a decimal value. You can check the YAML file with the command **oc get mc <mc-name> -o yaml**.
  - 4 Specify any valid, reachable time source, such as the one provided by your DHCP server. Alternately, you can specify any of the following NTP servers: **1.rhel.pool.ntp.org**, **2.rhel.pool.ntp.org**, or **3.rhel.pool.ntp.org**.
2. Use Butane to generate a **MachineConfig** object file, **99-worker-chrony.yaml**, containing the configuration to be delivered to the nodes:

```
$ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
```

3. Apply the configurations in one of two ways:
  - If the cluster is not running yet, after you generate manifest files, add the **MachineConfig** object file to the **<installation\_directory>/openshift** directory, and then continue to create the cluster.
  - If the cluster is already running, apply the file:

```
$ oc apply -f ./99-worker-chrony.yaml
```

### 23.1.6. Additional resources

- For information on Butane, see [Creating machine configs with Butane](#).
- For information on FIPS support, see [Support for FIPS cryptography](#).

## 23.2. CONFIGURING YOUR FIREWALL

If you use a firewall, you must configure it so that OpenShift Container Platform can access the sites that it requires to function. You must always grant access to some sites, and you grant access to more if you use Red Hat Insights, the Telemetry service, a cloud to host your cluster, and certain build strategies.

### 23.2.1. Configuring your firewall for OpenShift Container Platform

Before you install OpenShift Container Platform, you must configure your firewall to grant access to the sites that OpenShift Container Platform requires. When using a firewall, make additional configurations to the firewall so that OpenShift Container Platform can access the sites that it requires to function.

There are no special configuration considerations for services running on only controller nodes compared to worker nodes.

#### NOTE

If your environment has a dedicated load balancer in front of your OpenShift Container Platform cluster, review the allowlists between your firewall and load balancer to prevent unwanted network restrictions to your cluster.

## Procedure

1. Set the following registry URLs for your firewall's allowlist:

| URL                               | Port | Function                                                                                                                                                                                                |
|-----------------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>registry.redhat.io</b>         | 443  | Provides core container images                                                                                                                                                                          |
| <b>access.redhat.com</b>          | 443  | Hosts a signature store that a container client requires for verifying images pulled from <b>registry.access.redhat.com</b> . In a firewall environment, ensure that this resource is on the allowlist. |
| <b>registry.access.redhat.com</b> | 443  | Hosts all the container images that are stored on the Red Hat Ecosystem Catalog, including core container images.                                                                                       |
| <b>quay.io</b>                    | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn.quay.io</b>                | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn01.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn02.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn03.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn04.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn05.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>cdn06.quay.io</b>              | 443  | Provides core container images                                                                                                                                                                          |
| <b>sso.redhat.com</b>             | 443  | The <a href="https://console.redhat.com">https://console.redhat.com</a> site uses authentication from <b>sso.redhat.com</b>                                                                             |

- You can use the wildcards **\*.quay.io** and **\*.openshiftapps.com** instead of **cdn.quay.io** and **cdn0[1-6].quay.io** in your allowlist.
  - You can use the wildcard **\*.access.redhat.com** to simplify the configuration and ensure that all subdomains, including **registry.access.redhat.com**, are allowed.
  - When you add a site, such as **quay.io**, to your allowlist, do not add a wildcard entry, such as **\*.quay.io**, to your denylist. In most cases, image registries use a content delivery network (CDN) to serve images. If a firewall blocks access, image downloads are denied when the initial download request redirects to a hostname such as **cdn01.quay.io**.
2. Set your firewall's allowlist to include any site that provides resources for a language or framework that your builds require.

3. If you do not disable Telemetry, you must grant access to the following URLs to access Red Hat Insights:

| URL                               | Port | Function                                                |
|-----------------------------------|------|---------------------------------------------------------|
| <b>cert-api.access.redhat.com</b> | 443  | Required for Telemetry                                  |
| <b>api.access.redhat.com</b>      | 443  | Required for Telemetry                                  |
| <b>infogw.api.openshift.com</b>   | 443  | Required for Telemetry                                  |
| <b>console.redhat.com</b>         | 443  | Required for Telemetry and for <b>insights-operator</b> |

4. If you use Alibaba Cloud, Amazon Web Services (AWS), Microsoft Azure, or Google Cloud Platform (GCP) to host your cluster, you must grant access to the URLs that offer the cloud provider API and DNS for that cloud:

| Cloud   | URL                                                                                                                                                   | Port | Function                                                                                                                                                                                    |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Alibaba | <b>*.aliyuncs.com</b>                                                                                                                                 | 443  | Required to access Alibaba Cloud services and resources. Review the <a href="#">Alibaba endpoints_config.go</a> file to find the exact endpoints to allow for the regions that you use.     |
| AWS     | <b>aws.amazon.com</b>                                                                                                                                 | 443  | Used to install and manage clusters in an AWS environment.                                                                                                                                  |
|         | <b>*.amazonaws.com</b><br><br>Alternatively, if you choose to not use a wildcard for AWS APIs, you must include the following URLs in your allowlist: | 443  | Required to access AWS services and resources. Review the <a href="#">AWS Service Endpoints</a> in the AWS documentation to find the exact endpoints to allow for the regions that you use. |
|         | <b>ec2.amazonaws.com</b>                                                                                                                              | 443  | Used to install and manage clusters in an AWS environment.                                                                                                                                  |
|         | <b>events.amazonaws.com</b>                                                                                                                           | 443  | Used to install and manage clusters in an AWS environment.                                                                                                                                  |
|         | <b>iam.amazonaws.com</b>                                                                                                                              | 443  | Used to install and manage clusters in an AWS environment.                                                                                                                                  |
|         | <b>route53.amazonaws.com</b>                                                                                                                          | 443  | Used to install and manage clusters in an AWS environment.                                                                                                                                  |
|         | <b>*.s3.amazonaws.com</b>                                                                                                                             | 443  | Used to install and manage clusters in an AWS environment.                                                                                                                                  |

| Cloud | URL                                                               | Port | Function                                                                                                                                                     |
|-------|-------------------------------------------------------------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <b>*.s3.<br/>&lt;aws_region&gt;.amazonaws.com</b>                 | 443  | Used to install and manage clusters in an AWS environment.                                                                                                   |

|       | <b>sts.amazonaws.com</b>                                          | 443  | Used to install and manage clusters in an AWS environment.                                                                                                   |
|       | <b>sts.<br/>&lt;aws_region&gt;.amazonaws.com</b>                  | 443  | Used to install and manage clusters in an AWS environment.                                                                                                   |
|       | <b>tagging.us-east-1.amazonaws.com</b>                            | 443  | Used to install and manage clusters in an AWS environment. This endpoint is always <b>us-east-1</b> , regardless of the region the cluster is deployed in.   |
|       | <b>ec2.<br/>&lt;aws_region&gt;.amazonaws.com</b>                  | 443  | Used to install and manage clusters in an AWS environment.                                                                                                   |
|       | <b>elasticloadbalancing.<br/>&lt;aws_region&gt;.amazonaws.com</b> | 443  | Used to install and manage clusters in an AWS environment.                                                                                                   |
|       | <b>servicequotas.<br/>&lt;aws_region&gt;.amazonaws.com</b>        | 443  | Required. Used to confirm quotas for deploying the service.                                                                                                  |
|       | <b>tagging.<br/>&lt;aws_region&gt;.amazonaws.com</b>              | 443  | Allows the assignment of metadata about AWS resources in the form of tags.                                                                                   |
|       | <b>*.cloudfront.net</b>                                           | 443  | Used to provide access to CloudFront. If you use the AWS Security Token Service (STS) and the private S3 bucket, you must provide access to CloudFront.      |
| GCP   | <b>*.googleapis.com</b>                                           | 443  | Required to access GCP services and resources. Review <a href="#">Cloud Endpoints</a> in the GCP documentation to find the endpoints to allow for your APIs. |
|       | <b>accounts.google.com</b>                                        | 443  | Required to access your GCP account.                                                                                                                         |

| Cloud           | URL                              | Port | Function                                                                                                                                                                                                    |
|-----------------|----------------------------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Microsoft Azure | <b>management.azure.com</b>      | 443  | Required to access Microsoft Azure services and resources. Review the <a href="#">Microsoft Azure REST API reference</a> in the Microsoft Azure documentation to find the endpoints to allow for your APIs. |
|                 | <b>*.blob.core.windows.net</b>   | 443  | Required to download Ignition files.                                                                                                                                                                        |
|                 | <b>login.microsoftonline.com</b> | 443  | Required to access Microsoft Azure services and resources. Review the <a href="#">Azure REST API reference</a> in the Microsoft Azure documentation to find the endpoints to allow for your APIs.           |

5. Allowlist the following URLs:

| URL                                                    | Port | Function                                                                                                                                                                                           |
|--------------------------------------------------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mirror.openshift.com</b>                            | 443  | Required to access mirrored installation content and images. This site is also a source of release image signatures, although the Cluster Version Operator needs only a single functioning source. |
| <b>storage.googleapis.com/openshift-release</b>        | 443  | A source of release image signatures, although the Cluster Version Operator needs only a single functioning source.                                                                                |
| <b>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</b> | 443  | Required to access the default cluster routes unless you set an ingress wildcard during installation.                                                                                              |
| <b>quayio-production-s3.s3.amazonaws.com</b>           | 443  | Required to access Quay image content in AWS.                                                                                                                                                      |
| <b>api.openshift.com</b>                               | 443  | Required both for your cluster token and to check if updates are available for the cluster.                                                                                                        |
| <b>rhcos.mirror.openshift.com</b>                      | 443  | Required to download Red Hat Enterprise Linux CoreOS (RHCOS) images.                                                                                                                               |
| <b>console.redhat.com</b>                              | 443  | Required for your cluster token.                                                                                                                                                                   |

| URL                   | Port | Function                                                                                                                    |
|-----------------------|------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>sso.redhat.com</b> | 443  | The <a href="https://console.redhat.com">https://console.redhat.com</a> site uses authentication from <b>sso.redhat.com</b> |

Operators require route access to perform health checks. Specifically, the authentication and web console Operators connect to two routes to verify that the routes work. If you are the cluster administrator and do not want to allow **\*.apps.<cluster\_name>.<base\_domain>**, then allow these routes:

- **oauth-openshift.apps.<cluster\_name>.<base\_domain>**
- **console-openshift-console.apps.<cluster\_name>.<base\_domain>**, or the hostname that is specified in the **spec.route.hostname** field of the **consoles.operator/cluster** object if the field is not empty.

6. Allowlist the following URLs for optional third-party content:

| URL                                                                                                        | Port | Function                                                                         |
|------------------------------------------------------------------------------------------------------------|------|----------------------------------------------------------------------------------|
| <b>registry.connect.redhat.com</b>                                                                         | 443  | Required for all third-party images and certified operators.                     |
| <b>rhc4tp-prod-z8cxf-image-registry-us-east-1-evenkyleffocxqvofrk.s3.dualstack.us-east-1.amazonaws.com</b> | 443  | Provides access to container images hosted on <b>registry.connect.redhat.com</b> |
| <b>oso-rhc4tp-docker-registry.s3-us-west-2.amazonaws.com</b>                                               | 443  | Required for Sonatype Nexus, F5 Big IP operators.                                |

7. If you use a default Red Hat Network Time Protocol (NTP) server allow the following URLs:

- **1.rhel.pool.ntp.org**
- **2.rhel.pool.ntp.org**
- **3.rhel.pool.ntp.org**

#### NOTE

If you do not use a default Red Hat NTP server, verify the NTP server for your platform and allow it in your firewall.

#### Additional resources

- [OpenID Connect requirements for AWS STS](#)

## 23.3. ENABLING LINUX CONTROL GROUP VERSION 1 (CGROUP V1)

As of OpenShift Container Platform 4.14, OpenShift Container Platform uses [Linux control group version 2](#) (cgroup v2) in your cluster. If you are using cgroup v1 on OpenShift Container Platform 4.13 or earlier, migrating to OpenShift Container Platform 4.14 will not automatically update your cgroup configuration to version 2. A fresh installation of OpenShift Container Platform 4.14 will use cgroup v2 by default. However, you can enable [Linux control group version 1](#) (cgroup v1) upon installation. Enabling cgroup v1 in OpenShift Container Platform disables all cgroup v2 controllers and hierarchies in your cluster.

cgroup v2 is the current version of the Linux cgroup API. cgroup v2 offers several improvements over cgroup v1, including a unified hierarchy, safer sub-tree delegation, new features such as [Pressure Stall Information](#), and enhanced resource management and isolation. However, cgroup v2 has different CPU, memory, and I/O management characteristics than cgroup v1. Therefore, some workloads might experience slight differences in memory or CPU usage on clusters that run cgroup v2.

You can switch between cgroup v1 and cgroup v2, as needed, by editing the **node.config** object. For more information, see "Configuring the Linux cgroup on your nodes" in the "Additional resources" of this section.

### 23.3.1. Enabling Linux cgroup v1 during installation

You can enable Linux control group version 1 (cgroup v1) when you install a cluster by creating installation manifests.

#### Procedure

1. Create or edit the **node.config** object to specify the **v1** cgroup:

```
apiVersion: config.openshift.io/v1
kind: Node
metadata:
 name: cluster
spec:
 cgroupMode: "v2"
```

2. Proceed with the installation as usual.

#### Additional resources

- [OpenShift Container Platform installation overview](#)
- [Configuring the Linux cgroup on your nodes](#)

## CHAPTER 24. VALIDATION AND TROUBLESHOOTING

### 24.1. VALIDATING AN INSTALLATION

You can check the status of an OpenShift Container Platform cluster after an installation by following the procedures in this document.

/validating-an-installation.adoc

#### 24.1.1. Reviewing the installation log

You can review a summary of an installation in the OpenShift Container Platform installation log. If an installation succeeds, the information required to access the cluster is included in the log.

##### Prerequisites

- You have access to the installation host.

##### Procedure

- Review the **.openshift\_install.log** log file in the installation directory on your installation host:

```
$ cat <install_dir>/openshift_install.log
```

##### Example output

Cluster credentials are included at the end of the log if the installation is successful, as outlined in the following example:

```
...
time="2020-12-03T09:50:47Z" level=info msg="Install complete!"
time="2020-12-03T09:50:47Z" level=info msg="To access the cluster as the system:admin
user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'"
time="2020-12-03T09:50:47Z" level=info msg="Access the OpenShift web-console here:
https://console-openshift-console.apps.mycluster.example.com"
time="2020-12-03T09:50:47Z" level=info msg="Login to the console with user: \"kubeadmin\",
and password: \"password\""
time="2020-12-03T09:50:47Z" level=debug msg="Time elapsed per stage:"
time="2020-12-03T09:50:47Z" level=debug msg=" Infrastructure: 6m45s"
time="2020-12-03T09:50:47Z" level=debug msg="Bootstrap Complete: 11m30s"
time="2020-12-03T09:50:47Z" level=debug msg="Bootstrap Destroy: 1m5s"
time="2020-12-03T09:50:47Z" level=debug msg="Cluster Operators: 17m31s"
time="2020-12-03T09:50:47Z" level=info msg="Time elapsed: 37m26s"
```

/validating-an-installation.adoc

#### 24.1.2. Viewing the image pull source

For clusters with unrestricted network connectivity, you can view the source of your pulled images by using a command on a node, such as **crictl images**.

However, for disconnected installations, to view the source of pulled images, you must review the CRI-O logs to locate the **Trying to access** log entry, as shown in the following procedure. Other methods to

view the image pull source, such as the **crictl images** command, show the non-mirrored image name, even though the image is pulled from the mirrored location.

## Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.

## Procedure

- Review the CRI-O logs for a master or worker node:

```
$ oc adm node-logs <node_name> -u crio
```

## Example output

The **Trying to access** log entry indicates where the image is being pulled from.

```
...
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1366]: time="2021-08-05
10:33:21.594930907Z" level=info msg="Pulling image: quay.io/openshift-release-dev/ocp-
release:4.10.0-ppc64le" id=abcd713b-d0e1-4844-ac1c-474c5b60c07c
name=/runtime.v1alpha2.ImageService/PullImage
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1484]: time="2021-03-17
02:52:50.194341109Z" level=info msg="Trying to access \"li0317gcp1.mirror-
registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec
98b00628970e974284b6ddaf9a6a086cb9af7a6c31\""
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1484]: time="2021-03-17
02:52:50.226788351Z" level=info msg="Trying to access \"li0317gcp1.mirror-
registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec
98b00628970e974284b6ddaf9a6a086cb9af7a6c31\""
...
```

The log might show the image pull source twice, as shown in the preceding example.

If your **ImageContentSourcePolicy** object lists multiple mirrors, OpenShift Container Platform attempts to pull the images in the order listed in the configuration, for example:

```
Trying to access \"li0317gcp1.mirror-
registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec
98b00628970e974284b6ddaf9a6a086cb9af7a6c31\"
Trying to access \"li0317gcp2.mirror-
registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec
98b00628970e974284b6ddaf9a6a086cb9af7a6c31\"
```

/validating-an-installation.adoc

## 24.1.3. Getting cluster version, status, and update details

You can view the cluster version and status by running the **oc get clusterversion** command. If the status shows that the installation is still progressing, you can review the status of the Operators for more information.

You can also list the current update channel and review the available cluster updates.

## Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have installed the OpenShift CLI (**oc**).

## Procedure

1. Obtain the cluster version and overall status:

```
$ oc get clusterversion
```

### Example output

```
NAME VERSION AVAILABLE PROGRESSING SINCE STATUS
version 4.6.4 True False 6m25s Cluster version is 4.6.4
```

The example output indicates that the cluster has been installed successfully.

2. If the cluster status indicates that the installation is still progressing, you can obtain more detailed progress information by checking the status of the Operators:

```
$ oc get clusteroperators.config.openshift.io
```

3. View a detailed summary of cluster specifications, update availability, and update history:

```
$ oc describe clusterversion
```

4. List the current update channel:

```
$ oc get clusterversion -o jsonpath='{.items[0].spec}{"\n"}'
```

### Example output

```
{"channel":"stable-4.6","clusterID":"245539c1-72a3-41aa-9cec-72ed8cf25c5c"}
```

5. Review the available cluster updates:

```
$ oc adm upgrade
```

### Example output

```
Cluster version is 4.6.4
```

```
Updates:
```

```
VERSION IMAGE
```

```
4.6.6 quay.io/openshift-release-dev/ocp-
release@sha256:c7e8f18e8116356701bd23ae3a23fb9892dd5ea66c8300662ef30563d7104f3
9
```

## Additional resources

- See [Querying Operator status after installation](#) for more information about querying Operator status if your installation is still progressing.
- See [Troubleshooting Operator issues](#) for information about investigating issues with Operators.
- See [Updating a cluster using the web console](#) for more information on updating your cluster.
- See [Understanding update channels and releases](#) for an overview about update release channels.

/validating-an-installation.adoc

### 24.1.4. Verifying that a cluster uses short-term credentials

You can verify that a cluster uses short-term security credentials for individual components by checking the Cloud Credential Operator (CCO) configuration and other values in the cluster.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster using the Cloud Credential Operator utility (**ccoctl**) to implement short-term credentials.
- You installed the OpenShift CLI (**oc**).
- You are logged in as a user with **cluster-admin** privileges.

#### Procedure

- Verify that the CCO is configured to operate in manual mode by running the following command:

```
$ oc get cloudcredentials cluster \
 -o=jsonpath={.spec.credentialsMode}
```

The following output confirms that the CCO is operating in manual mode:

#### Example output

```
Manual
```

- Verify that the cluster does not have **root** credentials by running the following command:

```
$ oc get secrets \
 -n kube-system <secret_name>
```

where **<secret\_name>** is the name of the root secret for your cloud provider.

| Platform                  | Secret name              |
|---------------------------|--------------------------|
| Amazon Web Services (AWS) | <b>aws-creds</b>         |
| Microsoft Azure           | <b>azure-credentials</b> |

| Platform                    | Secret name            |
|-----------------------------|------------------------|
| Google Cloud Platform (GCP) | <b>gcp-credentials</b> |

An error confirms that the root secret is not present on the cluster.

### Example output for an AWS cluster

Error from server (NotFound): secrets "aws-creds" not found

- Verify that the components are using short-term security credentials for individual components by running the following command:

```
$ oc get authentication cluster \
 -o jsonpath \
 --template='{ .spec.serviceAccountIssuer }'
```

This command displays the value of the **.spec.serviceAccountIssuer** parameter in the cluster **Authentication** object. An output of a URL that is associated with your cloud provider indicates that the cluster is using manual mode with short-term credentials that are created and managed from outside of the cluster.

- Azure clusters: Verify that the components are assuming the Azure client ID that is specified in the secret manifests by running the following command:

```
$ oc get secrets \
 -n openshift-image-registry installer-cloud-credentials \
 -o jsonpath='{.data}'
```

An output that contains the **azure\_client\_id** and **azure\_federated\_token\_file** fields confirms that the components are assuming the Azure client ID.

- Azure clusters: Verify that the pod identity webhook is running by running the following command:

```
$ oc get pods \
 -n openshift-cloud-credential-operator
```

### Example output

```
NAME READY STATUS RESTARTS AGE
cloud-credential-operator-59cf744f78-r8pbq 2/2 Running 2 71m
pod-identity-webhook-548f977b4c-859lz 1/1 Running 1 70m
```

/validating-an-installation.adoc

## 24.1.5. Querying the status of the cluster nodes by using the CLI

You can verify the status of the cluster nodes after an installation.

### Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have installed the OpenShift CLI (**oc**).

## Procedure

1. List the status of the cluster nodes. Verify that the output lists all of the expected control plane and compute nodes and that each node has a **Ready** status:

```
$ oc get nodes
```

### Example output

| NAME                        | STATUS | ROLES  | AGE | VERSION |
|-----------------------------|--------|--------|-----|---------|
| compute-1.example.com       | Ready  | worker | 33m | v1.27.3 |
| control-plane-1.example.com | Ready  | master | 41m | v1.27.3 |
| control-plane-2.example.com | Ready  | master | 45m | v1.27.3 |
| compute-2.example.com       | Ready  | worker | 38m | v1.27.3 |
| compute-3.example.com       | Ready  | worker | 33m | v1.27.3 |
| control-plane-3.example.com | Ready  | master | 41m | v1.27.3 |

2. Review CPU and memory resource availability for each cluster node:

```
$ oc adm top nodes
```

### Example output

| NAME                        | CPU(cores) | CPU% | MEMORY(bytes) | MEMORY% |
|-----------------------------|------------|------|---------------|---------|
| compute-1.example.com       | 128m       | 8%   | 1132Mi        | 16%     |
| control-plane-1.example.com | 801m       | 22%  | 3471Mi        | 23%     |
| control-plane-2.example.com | 1718m      | 49%  | 6085Mi        | 40%     |
| compute-2.example.com       | 935m       | 62%  | 5178Mi        | 75%     |
| compute-3.example.com       | 111m       | 7%   | 1131Mi        | 16%     |
| control-plane-3.example.com | 942m       | 26%  | 4100Mi        | 27%     |

## Additional resources

- See [Verifying node health](#) for more details about reviewing node health and investigating node issues.

/validating-an-installation.adoc

## 24.1.6. Reviewing the cluster status from the OpenShift Container Platform web console

You can review the following information in the **Overview** page in the OpenShift Container Platform web console:

- The general status of your cluster
- The status of the control plane, cluster Operators, and storage
- CPU, memory, file system, network transfer, and pod availability

- The API address of the cluster, the cluster ID, and the name of the provider
- Cluster version information
- Cluster update status, including details of the current update channel and available updates
- A cluster inventory detailing node, pod, storage class, and persistent volume claim (PVC) information
- A list of ongoing cluster activities and recent events

### Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.

### Procedure

- In the **Administrator** perspective, navigate to **Home → Overview**.

/validating-an-installation.adoc

## 24.1.7. Reviewing the cluster status from Red Hat OpenShift Cluster Manager

From the OpenShift Container Platform web console, you can review detailed information about the status of your cluster on OpenShift Cluster Manager.

### Prerequisites

- You are logged in to [OpenShift Cluster Manager](#).
- You have access to the cluster as a user with the **cluster-admin** role.

### Procedure

1. Go to the **Clusters** list in [OpenShift Cluster Manager](#) and locate your OpenShift Container Platform cluster.
2. Click the **Overview** tab for your cluster.
3. Review the following information about your cluster:
  - vCPU and memory availability and resource usage
  - The cluster ID, status, type, region, and the provider name
  - Node counts by node type
  - Cluster version details, the creation date of the cluster, and the name of the cluster owner
  - The life cycle support status of the cluster
  - Subscription information, including the service level agreement (SLA) status, the subscription unit type, the production status of the cluster, the subscription obligation, and the service level

**TIP**

To view the history for your cluster, click the **Cluster history** tab.

4. Navigate to the **Monitoring** page to review the following information:
  - A list of any issues that have been detected
  - A list of alerts that are firing
  - The cluster Operator status and version
  - The cluster's resource usage
5. Optional: You can view information about your cluster that Red Hat Insights collects by navigating to the **Overview** menu. From this menu you can view the following information:
  - Potential issues that your cluster might be exposed to, categorized by risk level
  - Health-check status by category

**Additional resources**

- See [Using Insights to identify issues with your cluster](#) for more information about reviewing potential issues with your cluster.

/validating-an-installation.adoc

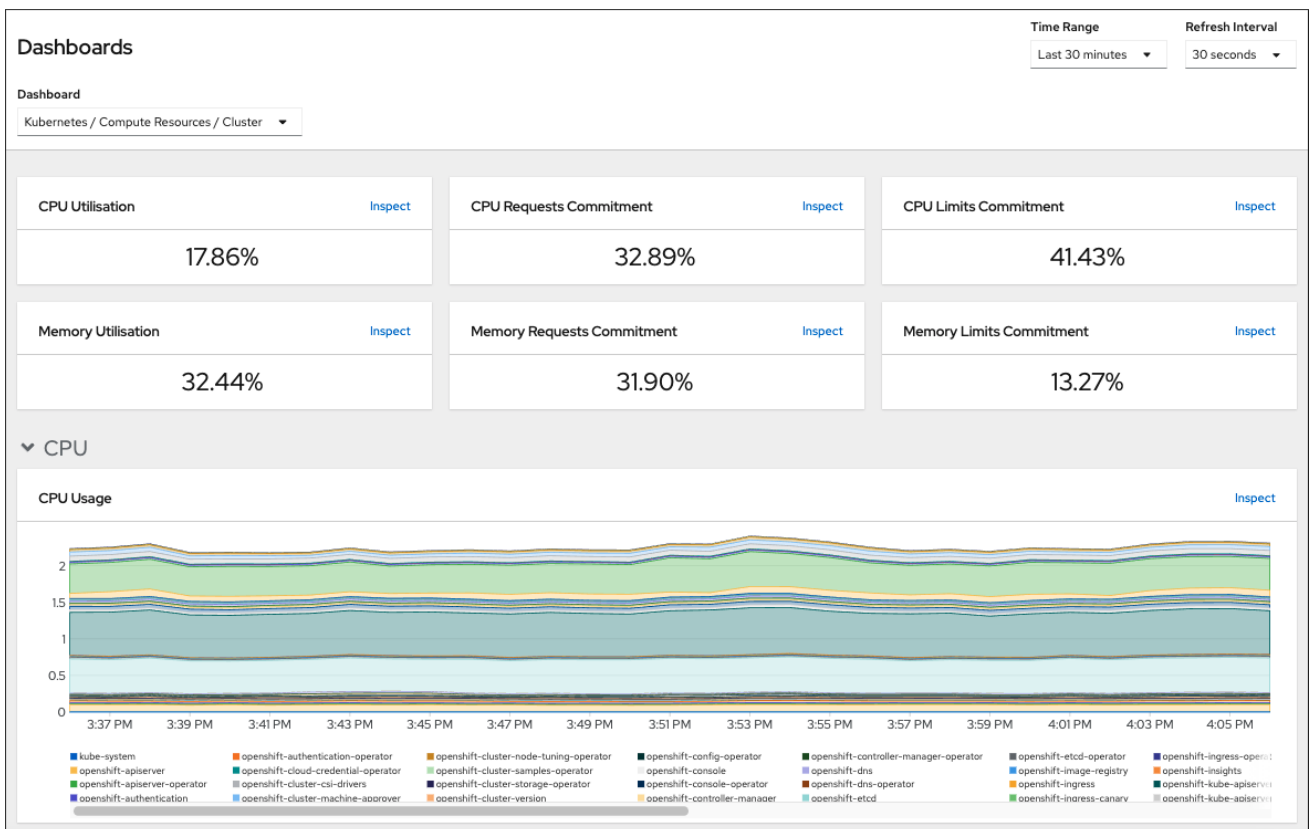

### 24.1.8. Checking cluster resource availability and utilization

OpenShift Container Platform provides a comprehensive set of monitoring dashboards that help you understand the state of cluster components.

In the **Administrator** perspective, you can access dashboards for core OpenShift Container Platform components, including:

- etcd
- Kubernetes compute resources
- Kubernetes network resources
- Prometheus
- Dashboards relating to cluster and node performance

Figure 24.1. Example compute resources dashboard

## Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.

## Procedure

1. In the **Administrator** perspective in the OpenShift Container Platform web console, navigate to **Observe → Dashboards**.
2. Choose a dashboard in the **Dashboard** list. Some dashboards, such as the **etcd** dashboard, produce additional sub-menus when selected.
3. Optional: Select a time range for the graphs in the **Time Range** list.
  - Select a pre-defined time period.
  - Set a custom time range by selecting **Custom time range** in the **Time Range** list.
    - a. Input or select the **From** and **To** dates and times.
    - b. Click **Save** to save the custom time range.
4. Optional: Select a **Refresh Interval**
5. Hover over each of the graphs within a dashboard to display detailed information about specific items.

## Additional resources

- See [Monitoring overview](#) for more information about the OpenShift Container Platform monitoring stack.

/validating-an-installation.adoc

### 24.1.9. Listing alerts that are firing

Alerts provide notifications when a set of defined conditions are true in an OpenShift Container Platform cluster. You can review the alerts that are firing in your cluster by using the Alerting UI in the OpenShift Container Platform web console.

#### Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.

#### Procedure

1. In the **Administrator** perspective, navigate to the **Observe → Alerting → Alerts** page.
2. Review the alerts that are firing, including their **Severity**, **State**, and **Source**.
3. Select an alert to view more detailed information in the **Alert Details** page.

#### Additional resources

- See [Managing alerts](#) for further details about alerting in OpenShift Container Platform.

### 24.1.10. Next steps

- See [Troubleshooting installations](#) if you experience issues when installing your cluster.
- After installing OpenShift Container Platform, you can [further expand and customize your cluster](#).

## 24.2. TROUBLESHOOTING INSTALLATION ISSUES

To assist in troubleshooting a failed OpenShift Container Platform installation, you can gather logs from the bootstrap and control plane machines. You can also get debug information from the installation program. If you are unable to resolve the issue using the logs and debug information, see [Determining where installation issues occur](#) for component-specific troubleshooting.

#### NOTE

If your OpenShift Container Platform installation fails and the debug output or logs contain network timeouts or other connectivity errors, review the guidelines for [configuring your firewall](#). Gathering logs from your firewall and load balancer can help you diagnose network-related errors.

### 24.2.1. Prerequisites

- You attempted to install an OpenShift Container Platform cluster and the installation failed.

### 24.2.2. Gathering logs from a failed installation

If you gave an SSH key to your installation program, you can gather data about your failed installation.

## NOTE

You use a different command to gather logs about an unsuccessful installation than to gather logs from a running cluster. If you must gather logs from a running cluster, use the **oc adm must-gather** command.

## Prerequisites

- Your OpenShift Container Platform installation failed before the bootstrap process finished. The bootstrap node is running and accessible through SSH.
- The **ssh-agent** process is active on your computer, and you provided the same SSH key to both the **ssh-agent** process and the installation program.
- If you tried to install a cluster on infrastructure that you provisioned, you must have the fully qualified domain names of the bootstrap and control plane nodes.

## Procedure

1. Generate the commands that are required to obtain the installation logs from the bootstrap and control plane machines:

- If you used installer-provisioned infrastructure, change to the directory that contains the installation program and run the following command:

```
$./openshift-install gather bootstrap --dir <installation_directory> ❶
```

- ❶ **installation\_directory** is the directory you specified when you ran **./openshift-install create cluster**. This directory contains the OpenShift Container Platform definition files that the installation program creates.

For installer-provisioned infrastructure, the installation program stores information about the cluster, so you do not specify the hostnames or IP addresses.

- If you used infrastructure that you provisioned yourself, change to the directory that contains the installation program and run the following command:

```
$./openshift-install gather bootstrap --dir <installation_directory> \ ❶
--bootstrap <bootstrap_address> \ ❷
--master <master_1_address> \ ❸
--master <master_2_address> \ ❹
--master <master_3_address>" ❺
```

- ❶ For **installation\_directory**, specify the same directory you specified when you ran **./openshift-install create cluster**. This directory contains the OpenShift Container Platform definition files that the installation program creates.

- ❷ **<bootstrap\_address>** is the fully qualified domain name or IP address of the cluster's bootstrap machine.

- ❸ ❹ ❺ For each control plane, or master, machine in your cluster, replace **<master\_\*\_address>** with its fully qualified domain name or IP address.

**NOTE**

A default cluster contains three control plane machines. List all of your control plane machines as shown, no matter how many your cluster uses.

**Example output**

```
INFO Pulling debug logs from the bootstrap machine
INFO Bootstrap gather logs captured here "<installation_directory>/log-bundle-
<timestamp>.tar.gz"
```

If you open a Red Hat support case about your installation failure, include the compressed logs in the case.

**24.2.3. Manually gathering logs with SSH access to your host(s)**

Manually gather logs in situations where **must-gather** or automated collection methods do not work.

**IMPORTANT**

By default, SSH access to the OpenShift Container Platform nodes is disabled on the Red Hat OpenStack Platform (RHOSP) based installations.

**Prerequisites**

- You must have SSH access to your host(s).

**Procedure**

1. Collect the **bootkube.service** service logs from the bootstrap host using the **journalctl** command by running:

```
$ journalctl -b -f -u bootkube.service
```

2. Collect the bootstrap host's container logs using the podman logs. This is shown as a loop to get all of the container logs from the host:

```
$ for pod in $(sudo podman ps -a -q); do sudo podman logs $pod; done
```

3. Alternatively, collect the host's container logs using the **tail** command by running:

```
tail -f /var/lib/containers/storage/overlay-containers/*/userdata/ctr.log
```

4. Collect the **kubelet.service** and **crio.service** service logs from the master and worker hosts using the **journalctl** command by running:

```
$ journalctl -b -f -u kubelet.service -u crio.service
```

5. Collect the master and worker host container logs using the **tail** command by running:

```
$ sudo tail -f /var/log/containers/*
```

### 24.2.4. Manually gathering logs without SSH access to your host(s)

Manually gather logs in situations where **must-gather** or automated collection methods do not work.

If you do not have SSH access to your node, you can access the systems journal to investigate what is happening on your host.

#### Prerequisites

- Your OpenShift Container Platform installation must be complete.
- Your API service is still functional.
- You have system administrator privileges.

#### Procedure

1. Access **journal** unit logs under **/var/log** by running:

```
$ oc adm node-logs --role=master -u kubelet
```

2. Access host file paths under **/var/log** by running:

```
$ oc adm node-logs --role=master --path=openshift-apiserver
```

### 24.2.5. Getting debug information from the installation program

You can use any of the following actions to get debug information from the installation program.

- Look at debug messages from a past installation in the hidden **.openshift\_install.log** file. For example, enter:

```
$ cat ~/<installation_directory>/openshift_install.log 1
```

- 1 For **installation\_directory**, specify the same directory you specified when you ran **./openshift-install create cluster**.

- Change to the directory that contains the installation program and re-run it with **--log-level=debug**:

```
$./openshift-install create cluster --dir <installation_directory> --log-level debug 1
```

- 1 For **installation\_directory**, specify the same directory you specified when you ran **./openshift-install create cluster**.

### 24.2.6. Reinstalling the OpenShift Container Platform cluster

If you are unable to debug and resolve issues in the failed OpenShift Container Platform installation, consider installing a new OpenShift Container Platform cluster. Before starting the installation process again, you must complete thorough cleanup. For a user-provisioned infrastructure (UPI) installation, you must manually destroy the cluster and delete all associated resources. The following procedure is for an installer-provisioned infrastructure (IPI) installation.

## Procedure

1. Destroy the cluster and remove all the resources associated with the cluster, including the hidden installer state files in the installation directory:

```
$./openshift-install destroy cluster --dir <installation_directory> 1
```

- 1 **installation\_directory** is the directory you specified when you ran **./openshift-install create cluster**. This directory contains the OpenShift Container Platform definition files that the installation program creates.

2. Before reinstalling the cluster, delete the installation directory:

```
$ rm -rf <installation_directory>
```

3. Follow the procedure for installing a new OpenShift Container Platform cluster.
