8.1. ROUTE CONFIGURATION	103
8.1.1. Creating an HTTP-based route	103
8.1.2. Configuring route timeouts	104
8.1.3. HTTP Strict Transport Security	105
8.1.3.1. Enabling HTTP Strict Transport Security per-route	105
8.1.3.2. Disabling HTTP Strict Transport Security per-route	106
8.1.4. Using cookies to keep route statefulness	107
8.1.4.1. Annotating a route with a cookie	107
8.1.5. Path-based routes	108
8.1.6. HTTP header configuration	109
8.1.6.1. Order of precedence	110
8.1.6.2. Special case headers	111
8.1.7. Setting or deleting HTTP request and response headers in a route	112
8.1.8. Route-specific annotations	114
8.1.9. Creating a route using the default certificate through an Ingress object	121
8.1.10. Creating a route using the destination CA certificate in the Ingress annotation	123
8.2. SECURED ROUTES	124
8.2.1. Creating a re-encrypt route with a custom certificate	124
8.2.2. Creating an edge route with a custom certificate	125
8.2.3. Creating a passthrough route	127
8.2.4. Creating a route with externally managed certificate	127

CHAPTER 1. DNS OPERATOR IN OPENSIFT DEDICATED

In OpenShift Dedicated, the DNS Operator deploys and manages a CoreDNS instance to provide a name resolution service to pods inside the cluster, enables DNS-based Kubernetes Service discovery, and resolves internal **cluster.local** names.

1.1. CHECKING THE STATUS OF THE DNS OPERATOR

The DNS Operator implements the **dns** API from the **operator.openshift.io** API group. The Operator deploys CoreDNS using a daemon set, creates a service for the daemon set, and configures the kubelet to instruct pods to use the CoreDNS service IP address for name resolution.

Procedure

The DNS Operator is deployed during installation with a **Deployment** object.

1. Use the **oc get** command to view the deployment status:

```
$ oc get -n openshift-dns-operator deployment/dns-operator
```

Example output

```
NAME          READY   UP-TO-DATE   AVAILABLE   AGE
dns-operator  1/1     1             1           23h
```

2. Use the **oc get** command to view the state of the DNS Operator:

```
$ oc get clusteroperator/dns
```

Example output

```
NAME      VERSION   AVAILABLE   PROGRESSING   DEGRADED   SINCE   MESSAGE
dns      4.1.15-0.11 True       False         False       92m
```

AVAILABLE, **PROGRESSING**, and **DEGRADED** provide information about the status of the Operator. **AVAILABLE** is **True** when at least 1 pod from the CoreDNS daemon set reports an **Available** status condition, and the DNS service has a cluster IP address.

1.2. VIEW THE DEFAULT DNS

Every new OpenShift Dedicated installation has a **dns.operator** named **default**.

Procedure

1. Use the **oc describe** command to view the default **dns**:

```
$ oc describe dns.operator/default
```

Example output

```
Name:      default
Namespace:
```

```

Labels:    <none>
Annotations: <none>
API Version: operator.openshift.io/v1
Kind:      DNS
...
Status:
  Cluster Domain: cluster.local 1
  Cluster IP:    172.30.0.10 2
  ...

```

- 1 The Cluster Domain field is the base DNS domain used to construct fully qualified pod and service domain names.
- 2 The Cluster IP is the address pods query for name resolution. The IP is defined as the 10th address in the service CIDR range.

1.3. USING DNS FORWARDING

You can use DNS forwarding to override the default forwarding configuration in the `/etc/resolv.conf` file in the following ways:

- Specify name servers (**spec.servers**) for every zone. If the forwarded zone is the ingress domain managed by OpenShift Dedicated, then the upstream name server must be authorized for the domain.

IMPORTANT

You must specify at least one zone. Otherwise, your cluster can lose functionality.

- Provide a list of upstream DNS servers (**spec.upstreamResolvers**).
- Change the default forwarding policy.

NOTE

A DNS forwarding configuration for the default domain can have both the default servers specified in the `/etc/resolv.conf` file and the upstream DNS servers.

Procedure

1. Modify the DNS Operator object named **default**:

```
$ oc edit dns.operator/default
```

After you issue the previous command, the Operator creates and updates the config map named **dns-default** with additional server configuration blocks based on **spec.servers**.

IMPORTANT

When specifying values for the **zones** parameter, ensure that you only forward to specific zones, such as your intranet. You must specify at least one zone. Otherwise, your cluster can lose functionality.

If none of the servers have a zone that matches the query, then name resolution falls back to the upstream DNS servers.

Configuring DNS forwarding

```

apiVersion: operator.openshift.io/v1
kind: DNS
metadata:
  name: default
spec:
  cache:
    negativeTTL: 0s
    positiveTTL: 0s
  logLevel: Normal
  nodePlacement: {}
  operatorLogLevel: Normal
  servers:
  - name: example-server 1
    zones:
    - example.com 2
    forwardPlugin:
      policy: Random 3
      upstreams: 4
      - 1.1.1.1
      - 2.2.2.2:5353
    upstreamResolvers: 5
      policy: Random 6
      protocolStrategy: "" 7
      transportConfig: {} 8
      upstreams:
      - type: SystemResolvConf 9
      - type: Network
        address: 1.2.3.4 10
        port: 53 11
    status:
      clusterDomain: cluster.local
      clusterIP: x.y.z.10
      conditions:
  ...

```

- 1** Must comply with the **rfc6335** service name syntax.
- 2** Must conform to the definition of a subdomain in the **rfc1123** service name syntax. The cluster domain, **cluster.local**, is an invalid subdomain for the **zones** field.
- 3** Defines the policy to select upstream resolvers listed in the **forwardPlugin**. Default value is **Random**. You can also use the values **RoundRobin**, and **Sequential**.
- 4** A maximum of 15 **upstreams** is allowed per **forwardPlugin**.
- 5** You can use **upstreamResolvers** to override the default forwarding policy and forward DNS resolution to the specified DNS resolvers (upstream resolvers) for the default domain. If you do not provide any upstream resolvers, the DNS name queries go to the servers declared in **/etc/resolv.conf**.

- 6 Determines the order in which upstream servers listed in **upstreams** are selected for querying. You can specify one of these values: **Random**, **RoundRobin**, or **Sequential**. The
- 7 When omitted, the platform chooses a default, normally the protocol of the original client request. Set to **TCP** to specify that the platform should use TCP for all upstream DNS requests, even if the client request uses UDP.
- 8 Used to configure the transport type, server name, and optional custom CA or CA bundle to use when forwarding DNS requests to an upstream resolver.
- 9 You can specify two types of **upstreams**: **SystemResolvConf** or **Network**. **SystemResolvConf** configures the upstream to use `/etc/resolv.conf` and **Network** defines a **Networkresolver**. You can specify one or both.
- 10 If the specified type is **Network**, you must provide an IP address. The **address** field must be a valid IPv4 or IPv6 address.
- 11 If the specified type is **Network**, you can optionally provide a port. The **port** field must have a value between **1** and **65535**. If you do not specify a port for the upstream, the default port is 853.

Additional resources

- For more information on DNS forwarding, see the [CoreDNS forward documentation](#).

1.4. CHECKING DNS OPERATOR STATUS

You can inspect the status and view the details of the DNS Operator using the **oc describe** command.

Procedure

- View the status of the DNS Operator:

```
$ oc describe clusteroperators/dns
```

Though the messages and spelling might vary in a specific release, the expected status output looks like:

```
Status:
Conditions:
  Last Transition Time: <date>
  Message:           DNS "default" is available.
  Reason:            AsExpected
  Status:            True
  Type:              Available
  Last Transition Time: <date>
  Message:           Desired and current number of DNSes are equal
  Reason:            AsExpected
  Status:            False
  Type:              Progressing
  Last Transition Time: <date>
  Reason:            DNSNotDegraded
  Status:            False
  Type:              Degraded
```

```

Last Transition Time: <date>
Message:             DNS default is upgradeable: DNS Operator can be upgraded
Reason:              DNSUpgradeable
Status:              True
Type:                Upgradeable

```

1.5. VIEWING DNS OPERATOR LOGS

You can view DNS Operator logs by using the **oc logs** command.

Procedure

- View the logs of the DNS Operator:

```
$ oc logs -n openshift-dns-operator deployment/dns-operator -c dns-operator
```

1.6. SETTING THE COREDNS LOG LEVEL

Log levels for CoreDNS and the CoreDNS Operator are set by using different methods. You can configure the CoreDNS log level to determine the amount of detail in logged error messages. The valid values for CoreDNS log level are **Normal**, **Debug**, and **Trace**. The default **logLevel** is **Normal**.

NOTE

The CoreDNS error log level is always enabled. The following log level settings report different error responses:

- **logLevel: Normal** enables the "errors" class: **log . { class error }**.
- **logLevel: Debug** enables the "denial" class: **log . { class denial error }**.
- **logLevel: Trace** enables the "all" class: **log . { class all }**.

Procedure

- To set **logLevel** to **Debug**, enter the following command:

```
$ oc patch dnses.operator.openshift.io/default -p '{"spec":{"logLevel":"Debug"}}' --type=merge
```

- To set **logLevel** to **Trace**, enter the following command:

```
$ oc patch dnses.operator.openshift.io/default -p '{"spec":{"logLevel":"Trace"}}' --type=merge
```

Verification

- To ensure the desired log level was set, check the config map:

```
$ oc get configmap/dns-default -n openshift-dns -o yaml
```

For example, after setting the **logLevel** to **Trace**, you should see this stanza in each server block:

```

errors
log . {
  class all
}

```

1.7. SETTING THE COREDNS OPERATOR LOG LEVEL

Log levels for CoreDNS and CoreDNS Operator are set by using different methods. Cluster administrators can configure the Operator log level to more quickly track down OpenShift DNS issues. The valid values for **operatorLogLevel** are **Normal**, **Debug**, and **Trace**. **Trace** has the most detailed information. The default **operatorLogLevel** is **Normal**. There are seven logging levels for Operator issues: Trace, Debug, Info, Warning, Error, Fatal, and Panic. After the logging level is set, log entries with that severity or anything above it will be logged.

- **operatorLogLevel: "Normal"** sets `logrus.SetLogLevel("Info")`.
- **operatorLogLevel: "Debug"** sets `logrus.SetLogLevel("Debug")`.
- **operatorLogLevel: "Trace"** sets `logrus.SetLogLevel("Trace")`.

Procedure

- To set **operatorLogLevel** to **Debug**, enter the following command:

```
$ oc patch dnses.operator.openshift.io/default -p '{"spec":{"operatorLogLevel":"Debug"}}' --type=merge
```

- To set **operatorLogLevel** to **Trace**, enter the following command:

```
$ oc patch dnses.operator.openshift.io/default -p '{"spec":{"operatorLogLevel":"Trace"}}' --type=merge
```

Verification

1. To review the resulting change, enter the following command:

```
$ oc get dnses.operator -A -oyaml
```

You should see two log level entries. The **operatorLogLevel** applies to OpenShift DNS Operator issues, and the **logLevel** applies to the daemonset of CoreDNS pods:

```

logLevel: Trace
operatorLogLevel: Debug

```

2. To review the logs for the daemonset, enter the following command:

```
$ oc logs -n openshift-dns ds/dns-default
```

1.8. TUNING THE COREDNS CACHE

For CoreDNS, you can configure the maximum duration of both successful or unsuccessful caching, also known respectively as positive or negative caching. Tuning the cache duration of DNS query responses can reduce the load for any upstream DNS resolvers.

WARNING

Setting TTL fields to low values could lead to an increased load on the cluster, any upstream resolvers, or both.

Procedure

1. Edit the DNS Operator object named **default** by running the following command:

```
$ oc edit dns.operator.openshift.io/default
```

2. Modify the time-to-live (TTL) caching values:

Configuring DNS caching

```
apiVersion: operator.openshift.io/v1
kind: DNS
metadata:
  name: default
spec:
  cache:
    positiveTTL: 1h 1
    negativeTTL: 0.5h10m 2
```

- 1** The string value **1h** is converted to its respective number of seconds by CoreDNS. If this field is omitted, the value is assumed to be **0s** and the cluster uses the internal default value of **900s** as a fallback.
- 2** The string value can be a combination of units such as **0.5h10m** and is converted to its respective number of seconds by CoreDNS. If this field is omitted, the value is assumed to be **0s** and the cluster uses the internal default value of **30s** as a fallback.

Verification

1. To review the change, look at the config map again by running the following command:

```
oc get configmap/dns-default -n openshift-dns -o yaml
```

2. Verify that you see entries that look like the following example:

```
cache 3600 {
  denial 9984 2400
}
```

Additional resources

For more information on caching, see [CoreDNS cache](#).

1.9. ADVANCED TASKS

1.9.1. Changing the DNS Operator managementState

The DNS Operator manages the CoreDNS component to provide a name resolution service for pods and services in the cluster. The **managementState** of the DNS Operator is set to **Managed** by default, which means that the DNS Operator is actively managing its resources. You can change it to **Unmanaged**, which means the DNS Operator is not managing its resources.

The following are use cases for changing the DNS Operator **managementState**:

- You are a developer and want to test a configuration change to see if it fixes an issue in CoreDNS. You can stop the DNS Operator from overwriting the configuration change by setting the **managementState** to **Unmanaged**.
- You are a cluster administrator and have reported an issue with CoreDNS, but need to apply a workaround until the issue is fixed. You can set the **managementState** field of the DNS Operator to **Unmanaged** to apply the workaround.

Procedure

1. Change **managementState** to **Unmanaged** in the DNS Operator:

```
oc patch dns.operator.openshift.io default --type merge --patch '{"spec": {"managementState": "Unmanaged"}}'
```

2. Review **managementState** of the DNS Operator using the **jsonpath** command line JSON parser:

```
$ oc get dns.operator.openshift.io default -ojsonpath='{.spec.managementState}'
```

Example output

```
"Unmanaged"
```

NOTE

You cannot upgrade while the **managementState** is set to **Unmanaged**.

1.9.2. Controlling DNS pod placement

The DNS Operator has two daemon sets: one for CoreDNS called **dns-default** and one for managing the **/etc/hosts** file called **node-resolver**.

You might find a need to control which nodes have CoreDNS pods assigned and running, although this is not a common operation. For example, if the cluster administrator has configured security policies that can prohibit communication between pairs of nodes, that would necessitate restricting the set of nodes

on which the daemonset for CoreDNS runs. If DNS pods are running on some nodes in the cluster and the nodes where DNS pods are not running have network connectivity to nodes where DNS pods are running, DNS service will be available to all pods.

The **node-resolver** daemon set must run on every node host because it adds an entry for the cluster image registry to support pulling images. The **node-resolver** pods have only one job: to look up the **image-registry.openshift-image-registry.svc** service's cluster IP address and add it to **/etc/hosts** on the node host so that the container runtime can resolve the service name.

As a cluster administrator, you can use a custom node selector to configure the daemon set for CoreDNS to run or not run on certain nodes.

Prerequisites

- You installed the **oc** CLI.
- You are logged in to the cluster as a user with **cluster-admin** privileges.
- Your DNS Operator **managementState** is set to **Managed**.

Procedure

- To allow the daemon set for CoreDNS to run on certain nodes, configure a taint and toleration:
 1. Modify the DNS Operator object named **default**:

```
$ oc edit dns.operator/default
```

2. Specify a taint key and a toleration for the taint:

```
spec:
  nodePlacement:
    tolerations:
      - effect: NoExecute
        key: "dns-only"
        operators: Equal
        value: abc
        tolerationSeconds: 3600 1
```

- 1 If the taint is **dns-only**, it can be tolerated indefinitely. You can omit **tolerationSeconds**.

1.9.3. Configuring DNS forwarding with TLS

When working in a highly regulated environment, you might need the ability to secure DNS traffic when forwarding requests to upstream resolvers so that you can ensure additional DNS traffic and data privacy.

Be aware that CoreDNS caches forwarded connections for 10 seconds. CoreDNS will hold a TCP connection open for those 10 seconds if no request is issued. With large clusters, ensure that your DNS server is aware that it might get many new connections to hold open because you can initiate a connection per node. Set up your DNS hierarchy accordingly to avoid performance issues.

IMPORTANT

When specifying values for the **zones** parameter, ensure that you only forward to specific zones, such as your intranet. You must specify at least one zone. Otherwise, your cluster can lose functionality.

Procedure

1. Modify the DNS Operator object named **default**:

```
$ oc edit dns.operator/default
```

Cluster administrators can configure transport layer security (TLS) for forwarded DNS queries.

Configuring DNS forwarding with TLS

```
apiVersion: operator.openshift.io/v1
kind: DNS
metadata:
  name: default
spec:
  servers:
  - name: example-server 1
    zones:
    - example.com 2
  forwardPlugin:
    transportConfig:
      transport: TLS 3
      tls:
        caBundle:
          name: mycacert
          serverName: dnstls.example.com 4
    policy: Random 5
  upstreams: 6
  - 1.1.1.1
  - 2.2.2.2:5353
  upstreamResolvers: 7
  transportConfig:
    transport: TLS
    tls:
      caBundle:
        name: mycacert
        serverName: dnstls.example.com
  upstreams:
  - type: Network 8
    address: 1.2.3.4 9
    port: 53 10
```

- 1** Must comply with the **rfc6335** service name syntax.
- 2** Must conform to the definition of a subdomain in the **rfc1123** service name syntax. The cluster domain, **cluster.local**, is an invalid subdomain for the **zones** field. The cluster domain, **cluster.local**, is an invalid **subdomain** for **zones**.

- 3 When configuring TLS for forwarded DNS queries, set the **transport** field to have the value **TLS**.
- 4 When configuring TLS for forwarded DNS queries, this is a mandatory server name used as part of the server name indication (SNI) to validate the upstream TLS server certificate.
- 5 Defines the policy to select upstream resolvers. Default value is **Random**. You can also use the values **RoundRobin**, and **Sequential**.
- 6 Required. Use it to provide upstream resolvers. A maximum of 15 **upstreams** entries are allowed per **forwardPlugin** entry.
- 7 Optional. You can use it to override the default policy and forward DNS resolution to the specified DNS resolvers (upstream resolvers) for the default domain. If you do not provide any upstream resolvers, the DNS name queries go to the servers in **/etc/resolv.conf**.
- 8 Only the **Network** type is allowed when using TLS and you must provide an IP address. **Network** type indicates that this upstream resolver should handle forwarded requests separately from the upstream resolvers listed in **/etc/resolv.conf**.
- 9 The **address** field must be a valid IPv4 or IPv6 address.
- 10 You can optionally provide a port. The **port** must have a value between **1** and **65535**. If you do not specify a port for the upstream, the default port is 853.

NOTE

If **servers** is undefined or invalid, the config map only contains the default server.

Verification

1. View the config map:

```
$ oc get configmap/dns-default -n openshift-dns -o yaml
```

Sample DNS ConfigMap based on TLS forwarding example

```
apiVersion: v1
data:
  Corefile: |
    example.com:5353 {
      forward . 1.1.1.1 2.2.2.2:5353
    }
    bar.com:5353 example.com:5353 {
      forward . 3.3.3.3 4.4.4.4:5454 1
    }
    .:5353 {
      errors
      health
      kubernetes cluster.local in-addr.arpa ip6.arpa {
        pods insecure
        upstream
        fallthrough in-addr.arpa ip6.arpa
      }
    }
  }
```

```
prometheus :9153
forward . /etc/resolv.conf 1.2.3.4:53 {
  policy Random
}
cache 30
reload
}
kind: ConfigMap
metadata:
  labels:
    dns.operator.openshift.io/owning-dns: default
  name: dns-default
  namespace: openshift-dns
```

- 1** Changes to the **forwardPlugin** triggers a rolling update of the CoreDNS daemon set.

Additional resources

- For more information on DNS forwarding, see the [CoreDNS forward documentation](#).

CHAPTER 2. INGRESS OPERATOR IN OPENSIFT DEDICATED

2.1. OPENSIFT DEDICATED INGRESS OPERATOR

When you create your OpenShift Dedicated cluster, pods and services running on the cluster are each allocated their own IP addresses. The IP addresses are accessible to other pods and services running nearby but are not accessible to outside clients. The Ingress Operator implements the **IngressController** API and is the component responsible for enabling external access to OpenShift Dedicated cluster services.

The Ingress Operator makes it possible for external clients to access your service by deploying and managing one or more HAProxy-based [Ingress Controllers](#) to handle routing. Red Hat Site Reliability Engineers (SRE) manage the Ingress Operator for OpenShift Dedicated clusters. While you cannot alter the settings for the Ingress Operator, you may view the default Ingress Controller configurations, status, and logs as well as the Ingress Operator status.

2.2. THE INGRESS CONFIGURATION ASSET

The installation program generates an asset with an **Ingress** resource in the **config.openshift.io** API group, **cluster-ingress-02-config.yml**.

YAML Definition of the **Ingress** resource

```
apiVersion: config.openshift.io/v1
kind: Ingress
metadata:
  name: cluster
spec:
  domain: apps.openshift demos.com
```

The installation program stores this asset in the **cluster-ingress-02-config.yml** file in the **manifests/** directory. This **Ingress** resource defines the cluster-wide configuration for Ingress. This Ingress configuration is used as follows:

- The Ingress Operator uses the domain from the cluster Ingress configuration as the domain for the default Ingress Controller.
- The OpenShift API Server Operator uses the domain from the cluster Ingress configuration. This domain is also used when generating a default host for a **Route** resource that does not specify an explicit host.

2.3. INGRESS CONTROLLER CONFIGURATION PARAMETERS

The **ingresscontrollers.operator.openshift.io** resource offers the following configuration parameters.

Parameter	Description
-----------	-------------

Parameter	Description
domain	<p>domain is a DNS name serviced by the Ingress Controller and is used to configure multiple features:</p> <ul style="list-style-type: none"> • For the LoadBalancerService endpoint publishing strategy, domain is used to configure DNS records. See endpointPublishingStrategy. • When using a generated default certificate, the certificate is valid for domain and its subdomains. See defaultCertificate. • The value is published to individual Route statuses so that users know where to target external DNS records. <p>The domain value must be unique among all Ingress Controllers and cannot be updated.</p> <p>If empty, the default value is ingress.config.openshift.io/cluster.spec.domain.</p>
replicas	<p>replicas is the desired number of Ingress Controller replicas. If not set, the default value is 2.</p>
endpointPublishingStrategy	<p>endpointPublishingStrategy is used to publish the Ingress Controller endpoints to other networks, enable load balancer integrations, and provide access to other systems.</p> <p>You can configure the following endpointPublishingStrategy fields:</p> <ul style="list-style-type: none"> • loadBalancer.scope • loadBalancer.allowedSourceRanges <p>If not set, the default value is based on infrastructure.config.openshift.io/cluster.status.platform:</p> <ul style="list-style-type: none"> • Amazon Web Services (AWS): LoadBalancerService (with External scope) • Google Cloud Platform (GCP): LoadBalancerService (with External scope)

Parameter	Description	NOTE
	<p>HostNetwork has a hostNetwork field with the following default values for the optional binding ports: httpPort: 80, httpsPort: 443, and statsPort: 1936. With the binding ports, you can deploy multiple Ingress Controllers on the same node for the HostNetwork strategy.</p> <p>Example</p> <pre>apiVersion: operator.openshift.io/v1 kind: IngressController metadata: name: internal namespace: openshift-ingress-operator spec: domain: example.com endpointPublishingStrategy: type: HostNetwork hostNetwork: httpPort: 80 httpsPort: 443 statsPort: 1936</pre> <p>NOTE</p> <p>On Red Hat OpenStack Platform (RHOSP), the LoadBalancerService endpoint publishing strategy is only supported if a cloud provider is configured to create health monitors. For RHOSP 16.2, this strategy is only possible if you use the Amphora Octavia provider.</p>	
defaultCertificate	<p>The defaultCertificate value is a reference to a secret that contains the default certificate that is served by the Ingress Controller. When Routes do not specify their own certificate, defaultCertificate is used.</p> <p>For most platforms, the endpointPublishingStrategy value can be updated. On GCP, you can configure the following fields:</p> <ul style="list-style-type: none"> • loadBalancer.scope • loadbalancer.providerParameters.gcp.clientAccess • hostNetwork.protocol • nodePort.protocol <p>If not set, a default certificate is automatically generated and used. The certificate is valid for the Ingress Controller domain and subdomains, and the generated certificates CA is automatically integrated with the cluster's trust store.</p> <p>The in-use certificate, whether generated or user-specified, is automatically integrated with OpenShift Dedicated built-in OAuth server.</p>	<p>For more information, see the "Setting cloud provider options" section of the RHOSP Installation documentation.</p> <p>The secret must contain the following keys and data: tls.crt: certificate file contents, tls.key: private key contents.</p>
namespaceSelector	namespaceSelector is used to filter the set of namespaces serviced by the Ingress Controller. This is useful for implementing shards.	
routeSelector	routeSelector is used to filter the set of Routes serviced by the Ingress Controller. This is useful for implementing shards.	

Parameter	Description
<p>nodePlacement</p>	<p>nodePlacement enables explicit control over the scheduling of the Ingress Controller.</p> <p>If not set, the defaults values are used.</p> <div data-bbox="517 405 625 842" style="float: left; width: 60px; height: 195px; background: repeating-linear-gradient(45deg, transparent, transparent 2px, #ccc 2px, #ccc 4px);"></div> <p>NOTE</p> <p>The nodePlacement parameter includes two parts, nodeSelector and tolerations. For example:</p> <pre style="border-left: 2px solid #ccc; padding-left: 10px;">nodePlacement: nodeSelector: matchLabels: kubernetes.io/os: linux tolerations: - effect: NoSchedule operator: Exists</pre>
<p>tlsSecurityProfile</p>	<p>tlsSecurityProfile specifies settings for TLS connections for Ingress Controllers.</p> <p>If not set, the default value is based on the apiservers.config.openshift.io/cluster resource.</p> <p>When using the Old, Intermediate, and Modern profile types, the effective profile configuration is subject to change between releases. For example, given a specification to use the Intermediate profile deployed on release X.Y.Z, an upgrade to release X.Y.Z+1 may cause a new profile configuration to be applied to the Ingress Controller, resulting in a rollout.</p> <p>The minimum TLS version for Ingress Controllers is 1.1, and the maximum TLS version is 1.3.</p> <div data-bbox="517 1659 625 1792" style="float: left; width: 60px; height: 59px; background: repeating-linear-gradient(45deg, transparent, transparent 2px, #ccc 2px, #ccc 4px);"></div> <p>NOTE</p> <p>Ciphers and the minimum TLS version of the configured security profile are reflected in the TLSPROFILE status.</p> <div data-bbox="517 1841 625 1973" style="float: left; width: 60px; height: 59px; background: repeating-linear-gradient(45deg, transparent, transparent 2px, #ccc 2px, #ccc 4px);"></div> <p>IMPORTANT</p> <p>The Ingress Operator converts the TLS 1.0 of an Old or Custom profile to 1.1.</p>

Parameter	Description
clientTLS	<p>clientTLS authenticates client access to the cluster and services; as a result, mutual TLS authentication is enabled. If not set, then client TLS is not enabled.</p> <p>clientTLS has the required subfields, spec.clientTLS.clientCertificatePolicy and spec.clientTLS.ClientCA.</p> <p>The ClientCertificatePolicy subfield accepts one of the two values: Required or Optional. The ClientCA subfield specifies a config map that is in the openshift-config namespace. The config map should contain a CA certificate bundle.</p> <p>The AllowedSubjectPatterns is an optional value that specifies a list of regular expressions, which are matched against the distinguished name on a valid client certificate to filter requests. The regular expressions must use PCRE syntax. At least one pattern must match a client certificate's distinguished name; otherwise, the Ingress Controller rejects the certificate and denies the connection. If not specified, the Ingress Controller does not reject certificates based on the distinguished name.</p>
routeAdmission	<p>routeAdmission defines a policy for handling new route claims, such as allowing or denying claims across namespaces.</p> <p>namespaceOwnership describes how hostname claims across namespaces should be handled. The default is Strict.</p> <ul style="list-style-type: none"> ● Strict: does not allow routes to claim the same hostname across namespaces. ● InterNamespaceAllowed: allows routes to claim different paths of the same hostname across namespaces. <p>wildcardPolicy describes how routes with wildcard policies are handled by the Ingress Controller.</p> <ul style="list-style-type: none"> ● WildcardsAllowed: Indicates routes with any wildcard policy are admitted by the Ingress Controller. ● WildcardsDisallowed: Indicates only routes with a wildcard policy of None are admitted by the Ingress Controller. Updating wildcardPolicy from WildcardsAllowed to WildcardsDisallowed causes admitted routes with a wildcard policy of Subdomain to stop working. These routes must be recreated to a wildcard policy of None to be readmitted by the Ingress Controller. WildcardsDisallowed is the default setting.

Parameter	Description
IngressControllerLogging	<p>logging defines parameters for what is logged where. If this field is empty, operational logs are enabled but access logs are disabled.</p> <ul style="list-style-type: none"> ● access describes how client requests are logged. If this field is empty, access logging is disabled. <ul style="list-style-type: none"> ○ destination describes a destination for log messages. <ul style="list-style-type: none"> ■ type is the type of destination for logs: <ul style="list-style-type: none"> ● Container specifies that logs should go to a sidecar container. The Ingress Operator configures the container, named logs, on the Ingress Controller pod and configures the Ingress Controller to write logs to the container. The expectation is that the administrator configures a custom logging solution that reads logs from this container. Using container logs means that logs may be dropped if the rate of logs exceeds the container runtime capacity or the custom logging solution capacity. ● Syslog specifies that logs are sent to a Syslog endpoint. The administrator must specify an endpoint that can receive Syslog messages. The expectation is that the administrator has configured a custom Syslog instance. ■ container describes parameters for the Container logging destination type. Currently there are no parameters for container logging, so this field must be empty. ■ syslog describes parameters for the Syslog logging destination type: <ul style="list-style-type: none"> ● address is the IP address of the syslog endpoint that receives log messages. ● port is the UDP port number of the syslog endpoint that receives log messages. ● maxLength is the maximum length of the syslog message. It must be between 480 and 4096 bytes. If this field is empty, the maximum length is set to the default value of 1024 bytes. ● facility specifies the syslog facility of log messages. If this field is empty, the facility is local1. Otherwise, it must specify a valid syslog facility: kern, user, mail, daemon, auth, syslog, lpr, news, uucp, cron, auth2, ftp, ntp, audit, alert, cron2, local0, local1, local2, local3, local4, local5, local6, or local7. ○ httpLogFormat specifies the format of the log message for an HTTP request. If this field is empty, log messages use the implementation's default HTTP log format. For HAProxy's default HTTP log format, see the HAProxy documentation.

Parameter	Description
httpHeaders	<p>httpHeaders defines the policy for HTTP headers.</p> <p>By setting the forwardedHeaderPolicy for the IngressControllerHTTPHeaders, you specify when and how the Ingress Controller sets the Forwarded, X-Forwarded-For, X-Forwarded-Host, X-Forwarded-Port, X-Forwarded-Proto, and X-Forwarded-Proto-Version HTTP headers.</p> <p>By default, the policy is set to Append.</p> <ul style="list-style-type: none"> ● Append specifies that the Ingress Controller appends the headers, preserving any existing headers. ● Replace specifies that the Ingress Controller sets the headers, removing any existing headers. ● IfNone specifies that the Ingress Controller sets the headers if they are not already set. ● Never specifies that the Ingress Controller never sets the headers, preserving any existing headers. <p>By setting headerNameCaseAdjustments, you can specify case adjustments that can be applied to HTTP header names. Each adjustment is specified as an HTTP header name with the desired capitalization. For example, specifying X-Forwarded-For indicates that the x-forwarded-for HTTP header should be adjusted to have the specified capitalization.</p> <p>These adjustments are only applied to cleartext, edge-terminated, and re-encrypt routes, and only when using HTTP/1.</p> <p>For request headers, these adjustments are applied only for routes that have the haproxy.router.openshift.io/h1-adjust-case=true annotation. For response headers, these adjustments are applied to all HTTP responses. If this field is empty, no request headers are adjusted.</p> <p>actions specifies options for performing certain actions on headers. Headers cannot be set or deleted for TLS passthrough connections. The actions field has additional subfields spec.httpHeader.actions.response and spec.httpHeader.actions.request:</p> <ul style="list-style-type: none"> ● The response subfield specifies a list of HTTP response headers to set or delete. ● The request subfield specifies a list of HTTP request headers to set or delete.

Parameter	Description
httpCompression	<p>httpCompression defines the policy for HTTP traffic compression.</p> <ul style="list-style-type: none"> ● mimeTypes defines a list of MIME types to which compression should be applied. For example, text/css; charset=utf-8, text/html, text/*, image/svg+xml, application/octet-stream, X-custom/customsub, using the format pattern, type/subtype; [;attribute=value]. The types are: application, image, message, multipart, text, video, or a custom type prefaced by X-; e.g. To see the full notation for MIME types and subtypes, see RFC1341
httpErrorCodePages	<p>httpErrorCodePages specifies custom HTTP error code response pages. By default, an IngressController uses error pages built into the IngressController image.</p>
httpCaptureCookies	<p>httpCaptureCookies specifies HTTP cookies that you want to capture in access logs. If the httpCaptureCookies field is empty, the access logs do not capture the cookies.</p> <p>For any cookie that you want to capture, the following parameters must be in your IngressController configuration:</p> <ul style="list-style-type: none"> ● name specifies the name of the cookie. ● maxLength specifies the maximum length of the cookie. ● matchType specifies if the field name of the cookie exactly matches the capture cookie setting or is a prefix of the capture cookie setting. The matchType field uses the Exact and Prefix parameters. <p>For example:</p> <pre> httpCaptureCookies: - matchType: Exact maxLength: 128 name: MYCOOKIE </pre>

Parameter	Description
<p>httpCaptureHeaders</p>	<p>httpCaptureHeaders specifies the HTTP headers that you want to capture in the access logs. If the httpCaptureHeaders field is empty, the access logs do not capture the headers.</p> <p>httpCaptureHeaders contains two lists of headers to capture in the access logs. The two lists of header fields are request and response. In both lists, the name field must specify the header name and the maxlength field must specify the maximum length of the header. For example:</p> <pre data-bbox="520 524 893 943"> httpCaptureHeaders: request: - maxLength: 256 name: Connection - maxLength: 128 name: User-Agent response: - maxLength: 256 name: Content-Type - maxLength: 256 name: Content-Length </pre>
<p>tuningOptions</p>	<p>tuningOptions specifies options for tuning the performance of Ingress Controller pods.</p> <ul data-bbox="584 1144 1433 2092" style="list-style-type: none"> ● clientFinTimeout specifies how long a connection is held open while waiting for the client response to the server closing the connection. The default timeout is 1s. ● clientTimeout specifies how long a connection is held open while waiting for a client response. The default timeout is 30s. ● headerBufferBytes specifies how much memory is reserved, in bytes, for Ingress Controller connection sessions. This value must be at least 16384 if HTTP/2 is enabled for the Ingress Controller. If not set, the default value is 32768 bytes. Setting this field not recommended because headerBufferBytes values that are too small can break the Ingress Controller, and headerBufferBytes values that are too large could cause the Ingress Controller to use significantly more memory than necessary. ● headerBufferMaxRewriteBytes specifies how much memory should be reserved, in bytes, from headerBufferBytes for HTTP header rewriting and appending for Ingress Controller connection sessions. The minimum value for headerBufferMaxRewriteBytes is 4096. headerBufferBytes must be greater than headerBufferMaxRewriteBytes for incoming HTTP requests. If not set, the default value is 8192 bytes. Setting this field not recommended because headerBufferMaxRewriteBytes values that are too small can break the Ingress Controller and headerBufferMaxRewriteBytes values that are too large could cause the Ingress Controller to use significantly more memory than necessary. ● healthCheckInterval specifies how long the router waits between health checks. The default is 5s.

Parameter	Description
	<ul style="list-style-type: none"> ● serverFinTimeout specifies how long a connection is held open while waiting for the server response to the client that is closing the connection. The default timeout is 1s. ● serverTimeout specifies how long a connection is held open while waiting for a server response. The default timeout is 30s. ● threadCount specifies the number of threads to create per HAProxy process. Creating more threads allows each Ingress Controller pod to handle more connections, at the cost of more system resources being used. HAProxy supports up to 64 threads. If this field is empty, the Ingress Controller uses the default value of 4 threads. The default value can change in future releases. Setting this field is not recommended because increasing the number of HAProxy threads allows Ingress Controller pods to use more CPU time under load, and prevent other pods from receiving the CPU resources they need to perform. Reducing the number of threads can cause the Ingress Controller to perform poorly. ● tlsInspectDelay specifies how long the router can hold data to find a matching route. Setting this value too short can cause the router to fall back to the default certificate for edge-terminated, reencrypted, or passthrough routes, even when using a better matched certificate. The default inspect delay is 5s. ● tunnelTimeout specifies how long a tunnel connection, including websockets, remains open while the tunnel is idle. The default timeout is 1h. ● maxConnections specifies the maximum number of simultaneous connections that can be established per HAProxy process. Increasing this value allows each ingress controller pod to handle more connections at the cost of additional system resources. Permitted values are 0, -1, any value within the range 2000 and 2000000, or the field can be left empty. <ul style="list-style-type: none"> ○ If this field is left empty or has the value 0, the Ingress Controller will use the default value of 50000. This value is subject to change in future releases. ○ If the field has the value of -1, then HAProxy will dynamically compute a maximum value based on the available ulimits in the running container. This process results in a large computed value that will incur significant memory usage compared to the current default value of 50000. ○ If the field has a value that is greater than the current operating system limit, the HAProxy process will not start. ○ If you choose a discrete value and the router pod is migrated to a new node, it is possible the new node does not have an identical ulimit configured. In such cases, the pod fails to start. ○ If you have nodes with different ulimits configured, and you choose a discrete value, it is recommended to use the value of -1 for this field so that the maximum number of connections is calculated at runtime.

Parameter	Description
logEmptyRequests	<p>logEmptyRequests specifies connections for which no request is received and logged. These empty requests come from load balancer health probes or web browser speculative connections (preconnect) and logging these requests can be undesirable. However, these requests can be caused by network errors, in which case logging empty requests can be useful for diagnosing the errors. These requests can be caused by port scans, and logging empty requests can aid in detecting intrusion attempts. Allowed values for this field are Log and Ignore. The default value is Log.</p> <p>The LoggingPolicy type accepts either one of two values:</p> <ul style="list-style-type: none"> ● Log: Setting this value to Log indicates that an event should be logged. ● Ignore: Setting this value to Ignore sets the dontlognull option in the HAproxy configuration.
HTTPEmptyRequestsPolicy	<p>HTTPEmptyRequestsPolicy describes how HTTP connections are handled if the connection times out before a request is received. Allowed values for this field are Respond and Ignore. The default value is Respond.</p> <p>The HTTPEmptyRequestsPolicy type accepts either one of two values:</p> <ul style="list-style-type: none"> ● Respond: If the field is set to Respond, the Ingress Controller sends an HTTP 400 or 408 response, logs the connection if access logging is enabled, and counts the connection in the appropriate metrics. ● Ignore: Setting this option to Ignore adds the http-ignore-probes parameter in the HAproxy configuration. If the field is set to Ignore, the Ingress Controller closes the connection without sending a response, then logs the connection, or incrementing metrics. <p>These connections come from load balancer health probes or web browser speculative connections (preconnect) and can be safely ignored. However, these requests can be caused by network errors, so setting this field to Ignore can impede detection and diagnosis of problems. These requests can be caused by port scans, in which case logging empty requests can aid in detecting intrusion attempts.</p>

**NOTE**

All parameters are optional.

2.3.1. Ingress Controller TLS security profiles

TLS security profiles provide a way for servers to regulate which ciphers a connecting client can use when connecting to the server.

2.3.1.1. Understanding TLS security profiles

You can use a TLS (Transport Layer Security) security profile to define which TLS ciphers are required by various OpenShift Dedicated components. The OpenShift Dedicated TLS security profiles are based on [Mozilla recommended configurations](#).

You can specify one of the following TLS security profiles for each component:

Table 2.1. TLS security profiles

Profile	Description
Old	<p>This profile is intended for use with legacy clients or libraries. The profile is based on the Old backward compatibility recommended configuration.</p> <p>The Old profile requires a minimum TLS version of 1.0.</p> <div style="display: flex; align-items: center;">  <div> <p>NOTE</p> <p>For the Ingress Controller, the minimum TLS version is converted from 1.0 to 1.1.</p> </div> </div>
Intermediate	<p>This profile is the recommended configuration for the majority of clients. It is the default TLS security profile for the Ingress Controller, kubelet, and control plane. The profile is based on the Intermediate compatibility recommended configuration.</p> <p>The Intermediate profile requires a minimum TLS version of 1.2.</p>
Modern	<p>This profile is intended for use with modern clients that have no need for backwards compatibility. This profile is based on the Modern compatibility recommended configuration.</p> <p>The Modern profile requires a minimum TLS version of 1.3.</p>
Custom	<p>This profile allows you to define the TLS version and ciphers to use.</p> <div style="background-color: #fff9c4; padding: 10px; border: 1px solid #ccc;"> <div style="display: flex; align-items: center;">  <div> <p>WARNING</p> <p>Use caution when using a Custom profile, because invalid configurations can cause problems.</p> </div> </div> </div>

NOTE

When using one of the predefined profile types, the effective profile configuration is subject to change between releases. For example, given a specification to use the Intermediate profile deployed on release X.Y.Z, an upgrade to release X.Y.Z+1 might cause a new profile configuration to be applied, resulting in a rollout.

2.3.1.2. Configuring the TLS security profile for the Ingress Controller

To configure a TLS security profile for an Ingress Controller, edit the **IngressController** custom resource (CR) to specify a predefined or custom TLS security profile. If a TLS security profile is not configured, the default value is based on the TLS security profile set for the API server.

Sample IngressController CR that configures the Old TLS security profile

```
apiVersion: operator.openshift.io/v1
kind: IngressController
...
spec:
  tlsSecurityProfile:
    old: {}
    type: Old
  ...
```

The TLS security profile defines the minimum TLS version and the TLS ciphers for TLS connections for Ingress Controllers.

You can see the ciphers and the minimum TLS version of the configured TLS security profile in the **IngressController** custom resource (CR) under **Status.Tls Profile** and the configured TLS security profile under **Spec.Tls Security Profile**. For the **Custom** TLS security profile, the specific ciphers and minimum TLS version are listed under both parameters.

NOTE

The HAProxy Ingress Controller image supports TLS **1.3** and the **Modern** profile.

The Ingress Operator also converts the TLS **1.0** of an **Old** or **Custom** profile to **1.1**.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.

Procedure

- Edit the **IngressController** CR in the **openshift-ingress-operator** project to configure the TLS security profile:

```
$ oc edit IngressController default -n openshift-ingress-operator
```

- Add the **spec.tlsSecurityProfile** field:

Sample IngressController CR for a Custom profile

```
apiVersion: operator.openshift.io/v1
kind: IngressController
...
spec:
  tlsSecurityProfile:
    type: Custom 1
    custom: 2
    ciphers: 3
```

```

- ECDHE-ECDSA-CHACHA20-POLY1305
- ECDHE-RSA-CHACHA20-POLY1305
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-GCM-SHA256
minTLSVersion: VersionTLS11

```

...

- 1 Specify the TLS security profile type (**Old**, **Intermediate**, or **Custom**). The default is **Intermediate**.
- 2 Specify the appropriate field for the selected type:
 - **old:** {}
 - **intermediate:** {}
 - **custom:**
- 3 For the **custom** type, specify a list of TLS ciphers and minimum accepted TLS version.

3. Save the file to apply the changes.

Verification

- Verify that the profile is set in the **IngressController** CR:

```
$ oc describe IngressController default -n openshift-ingress-operator
```

Example output

```

Name:      default
Namespace: openshift-ingress-operator
Labels:    <none>
Annotations: <none>
API Version: operator.openshift.io/v1
Kind:      IngressController
...
Spec:
...
  Tls Security Profile:
    Custom:
      Ciphers:
        ECDHE-ECDSA-CHACHA20-POLY1305
        ECDHE-RSA-CHACHA20-POLY1305
        ECDHE-RSA-AES128-GCM-SHA256
        ECDHE-ECDSA-AES128-GCM-SHA256
      Min TLS Version: VersionTLS11
    Type:      Custom
...

```

2.3.1.3. Configuring mutual TLS authentication

You can configure the Ingress Controller to enable mutual TLS (mTLS) authentication by setting a **spec.clientTLS** value. The **clientTLS** value configures the Ingress Controller to verify client certificates.

This configuration includes setting a **clientCA** value, which is a reference to a config map. The config map contains the PEM-encoded CA certificate bundle that is used to verify a client's certificate. Optionally, you can also configure a list of certificate subject filters.

If the **clientCA** value specifies an X509v3 certificate revocation list (CRL) distribution point, the Ingress Operator downloads and manages a CRL config map based on the HTTP URI X509v3 **CRL Distribution Point** specified in each provided certificate. The Ingress Controller uses this config map during mTLS/TLS negotiation. Requests that do not provide valid certificates are rejected.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a PEM-encoded CA certificate bundle.
- If your CA bundle references a CRL distribution point, you must have also included the end-entity or leaf certificate to the client CA bundle. This certificate must have included an HTTP URI under **CRL Distribution Points**, as described in RFC 5280. For example:

```
Issuer: C=US, O=Example Inc, CN=Example Global G2 TLS RSA SHA256 2020 CA1
Subject: SOME SIGNED CERT          X509v3 CRL Distribution Points:
Full Name:
URI:http://crl.example.com/example.crl
```

Procedure

1. In the **openshift-config** namespace, create a config map from your CA bundle:

```
$ oc create configmap \
  router-ca-certs-default \
  --from-file=ca-bundle.pem=client-ca.crt \ 1
-n openshift-config
```

- 1 The config map data key must be **ca-bundle.pem**, and the data value must be a CA certificate in PEM format.

2. Edit the **IngressController** resource in the **openshift-ingress-operator** project:

```
$ oc edit IngressController default -n openshift-ingress-operator
```

3. Add the **spec.clientTLS** field and subfields to configure mutual TLS:

Sample IngressController CR for a **clientTLS** profile that specifies filtering patterns

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  clientTLS:
    clientCertificatePolicy: Required
    clientCA:
```

```
name: router-ca-certs-default
allowedSubjectPatterns:
- "^/CN=example.com/ST=NC/C=US/O=Security/OU=OpenShift$"
```

- Optional, get the Distinguished Name (DN) for **allowedSubjectPatterns** by entering the following command.

```
$ openssl x509 -in custom-cert.pem -noout -subject
subject= /CN=example.com/ST=NC/C=US/O=Security/OU=OpenShift
```

2.4. VIEW THE DEFAULT INGRESS CONTROLLER

The Ingress Operator is a core feature of OpenShift Dedicated and is enabled out of the box.

Every new OpenShift Dedicated installation has an **ingresscontroller** named default. It can be supplemented with additional Ingress Controllers. If the default **ingresscontroller** is deleted, the Ingress Operator will automatically recreate it within a minute.

Procedure

- View the default Ingress Controller:

```
$ oc describe --namespace=openshift-ingress-operator ingresscontroller/default
```

2.5. VIEW INGRESS OPERATOR STATUS

You can view and inspect the status of your Ingress Operator.

Procedure

- View your Ingress Operator status:

```
$ oc describe clusteroperators/ingress
```

2.6. VIEW INGRESS CONTROLLER LOGS

You can view your Ingress Controller logs.

Procedure

- View your Ingress Controller logs:

```
$ oc logs --namespace=openshift-ingress-operator deployments/ingress-operator -c
<container_name>
```

2.7. VIEW INGRESS CONTROLLER STATUS

You can view the status of a particular Ingress Controller.

Procedure

- View the status of an Ingress Controller:

```
$ oc describe --namespace=openshift-ingress-operator ingresscontroller/<name>
```

2.8. CREATING A CUSTOM INGRESS CONTROLLER

As a cluster administrator, you can create a new custom Ingress Controller. Because the default Ingress Controller might change during OpenShift Dedicated updates, creating a custom Ingress Controller can be helpful when maintaining a configuration manually that persists across cluster updates.

This example provides a minimal spec for a custom Ingress Controller. To further customize your custom Ingress Controller, see "Configuring the Ingress Controller".

Prerequisites

- Install the OpenShift CLI (**oc**).
- Log in as a user with **cluster-admin** privileges.

Procedure

1. Create a YAML file that defines the custom **IngressController** object:

Example custom-ingress-controller.yaml file

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: <custom_name> 1
  namespace: openshift-ingress-operator
spec:
  defaultCertificate:
    name: <custom-ingress-custom-certs> 2
  replicas: 1 3
  domain: <custom_domain> 4
```

- 1 Specify the a custom **name** for the **IngressController** object.
- 2 Specify the name of the secret with the custom wildcard certificate.
- 3 Minimum replica needs to be ONE
- 4 Specify the domain to your domain name. The domain specified on the IngressController object and the domain used for the certificate must match. For example, if the domain value is "custom_domain.mycompany.com", then the certificate must have SAN *.custom_domain.mycompany.com (with the *. added to the domain).

2. Create the object by running the following command:

```
$ oc create -f custom-ingress-controller.yaml
```

2.9. CONFIGURING THE INGRESS CONTROLLER

2.9.1. Setting a custom default certificate

As an administrator, you can configure an Ingress Controller to use a custom certificate by creating a Secret resource and editing the **IngressController** custom resource (CR).

Prerequisites

- You must have a certificate/key pair in PEM-encoded files, where the certificate is signed by a trusted certificate authority or by a private trusted certificate authority that you configured in a custom PKI.
- Your certificate meets the following requirements:
 - The certificate is valid for the ingress domain.
 - The certificate uses the **subjectAltName** extension to specify a wildcard domain, such as ***.apps.ocp4.example.com**.
- You must have an **IngressController** CR. You may use the default one:

```
$ oc --namespace openshift-ingress-operator get ingresscontrollers
```

Example output

```
NAME    AGE
default 10m
```

NOTE

If you have intermediate certificates, they must be included in the **tls.crt** file of the secret containing a custom default certificate. Order matters when specifying a certificate; list your intermediate certificate(s) after any server certificate(s).

Procedure

The following assumes that the custom certificate and key pair are in the **tls.crt** and **tls.key** files in the current working directory. Substitute the actual path names for **tls.crt** and **tls.key**. You also may substitute another name for **custom-certs-default** when creating the Secret resource and referencing it in the IngressController CR.

NOTE

This action will cause the Ingress Controller to be redeployed, using a rolling deployment strategy.

1. Create a Secret resource containing the custom certificate in the **openshift-ingress** namespace using the **tls.crt** and **tls.key** files.

```
$ oc --namespace openshift-ingress create secret tls custom-certs-default --cert=tls.crt --key=tls.key
```

2. Update the IngressController CR to reference the new certificate secret:

```
$ oc patch --type=merge --namespace openshift-ingress-operator ingresscontrollers/default \
  --patch '{"spec":{"defaultCertificate":{"name":"custom-certs-default"}}}'
```

3. Verify the update was effective:

```
$ echo Q |\
  openssl s_client -connect console-openshift-console.apps.<domain>:443 -showcerts
2>/dev/null |\
  openssl x509 -noout -subject -issuer -enddate
```

where:

<domain>

Specifies the base domain name for your cluster.

Example output

```
subject=C = US, ST = NC, L = Raleigh, O = RH, OU = OCP4, CN = *.apps.example.com
issuer=C = US, ST = NC, L = Raleigh, O = RH, OU = OCP4, CN = example.com
notAfter=May 10 08:32:45 2022 GM
```

TIP

You can alternatively apply the following YAML to set a custom default certificate:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  defaultCertificate:
    name: custom-certs-default
```

The certificate secret name should match the value used to update the CR.

Once the IngressController CR has been modified, the Ingress Operator updates the Ingress Controller's deployment to use the custom certificate.

2.9.2. Removing a custom default certificate

As an administrator, you can remove a custom certificate that you configured an Ingress Controller to use.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have installed the OpenShift CLI (**oc**).
- You previously configured a custom default certificate for the Ingress Controller.

Procedure

- To remove the custom certificate and restore the certificate that ships with OpenShift Dedicated, enter the following command:

```
$ oc patch -n openshift-ingress-operator ingresscontrollers/default \
--type json -p '$- op: remove\n path: /spec/defaultCertificate'
```

There can be a delay while the cluster reconciles the new certificate configuration.

Verification

- To confirm that the original cluster certificate is restored, enter the following command:

```
$ echo Q | \
openssl s_client -connect console-openshift-console.apps.<domain>:443 -showcerts
2>/dev/null | \
openssl x509 -noout -subject -issuer -enddate
```

where:

<domain>

Specifies the base domain name for your cluster.

Example output

```
subject=CN = *.apps.<domain>
issuer=CN = ingress-operator@1620633373
notAfter=May 10 10:44:36 2023 GMT
```

2.9.3. Autoscaling an Ingress Controller

Automatically scale an Ingress Controller to dynamically meet routing performance or availability requirements such as the requirement to increase throughput. The following procedure provides an example for scaling up the default **IngressController**.

Prerequisites

- You have the OpenShift CLI (**oc**) installed.
- You have access to an OpenShift Dedicated cluster as a user with the **cluster-admin** role.
- You have the Custom Metrics Autoscaler Operator installed.
- You are in the **openshift-ingress-operator** project namespace.

Procedure

- Create a service account to authenticate with Thanos by running the following command:

```
$ oc create serviceaccount thanos && oc describe serviceaccount thanos
```

Example output

-

```
Name:          thanos
Namespace:     openshift-ingress-operator
Labels:       <none>
Annotations:   <none>
Image pull secrets: thanos-dockercfg-b4l9s
Mountable secrets: thanos-dockercfg-b4l9s
Tokens:       thanos-token-c422q
Events:       <none>
```

2. Define a **TriggerAuthentication** object within the **openshift-ingress-operator** namespace using the service account's token.

- a. Define the variable **secret** that contains the secret by running the following command:

```
$ secret=$(oc get secret | grep thanos-token | head -n 1 | awk '{ print $1 }')
```

- b. Create the **TriggerAuthentication** object and pass the value of the **secret** variable to the **TOKEN** parameter:

```
$ oc process TOKEN="$secret" -f - <<EOF | oc apply -f -
apiVersion: template.openshift.io/v1
kind: Template
parameters:
- name: TOKEN
objects:
- apiVersion: keda.sh/v1alpha1
  kind: TriggerAuthentication
  metadata:
    name: keda-trigger-auth-prometheus
  spec:
    secretTargetRef:
      - parameter: bearerToken
        name: ${TOKEN}
        key: token
      - parameter: ca
        name: ${TOKEN}
        key: ca.crt
EOF
```

3. Create and apply a role for reading metrics from Thanos:

- a. Create a new role, **thanos-metrics-reader.yaml**, that reads metrics from pods and nodes:

thanos-metrics-reader.yaml

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: thanos-metrics-reader
rules:
- apiGroups:
  - ""
  resources:
  - pods
  - nodes
```

```

verbs:
- get
- apiGroups:
- metrics.k8s.io
resources:
- pods
- nodes
verbs:
- get
- list
- watch
- apiGroups:
- ""
resources:
- namespaces
verbs:
- get

```

- b. Apply the new role by running the following command:

```
$ oc apply -f thanos-metrics-reader.yaml
```

4. Add the new role to the service account by entering the following commands:

```
$ oc adm policy add-role-to-user thanos-metrics-reader -z thanos --role-namespace=openshift-ingress-operator
```

```
$ oc adm policy -n openshift-ingress-operator add-cluster-role-to-user cluster-monitoring-view -z thanos
```

NOTE

The argument **add-cluster-role-to-user** is only required if you use cross-namespace queries. The following step uses a query from the **kube-metrics** namespace which requires this argument.

5. Create a new **ScaledObject** YAML file, **ingress-autoscaler.yaml**, that targets the default Ingress Controller deployment:

Example ScaledObject definition

```

apiVersion: keda.sh/v1alpha1
kind: ScaledObject
metadata:
  name: ingress-scaler
spec:
  scaleTargetRef: 1
    apiVersion: operator.openshift.io/v1
    kind: IngressController
    name: default
    envSourceContainerName: ingress-operator
  minReplicaCount: 1
  maxReplicaCount: 20 2

```

```

cooldownPeriod: 1
pollingInterval: 1
triggers:
- type: prometheus
  metricType: AverageValue
  metadata:
    serverAddress: https://thanos-querier.openshift-monitoring.svc.cluster.local:9091 3
    namespace: openshift-ingress-operator 4
    metricName: 'kube-node-role'
    threshold: '1'
    query: 'sum(kube_node_role{role="worker",service="kube-state-metrics"})' 5
    authModes: "bearer"
  authenticationRef:
    name: keda-trigger-auth-prometheus

```

- 1 The custom resource that you are targeting. In this case, the Ingress Controller.
- 2 Optional: The maximum number of replicas. If you omit this field, the default maximum is set to 100 replicas.
- 3 The Thanos service endpoint in the **openshift-monitoring** namespace.
- 4 The Ingress Operator namespace.
- 5 This expression evaluates to however many worker nodes are present in the deployed cluster.

IMPORTANT

If you are using cross-namespace queries, you must target port 9091 and not port 9092 in the **serverAddress** field. You also must have elevated privileges to read metrics from this port.

6. Apply the custom resource definition by running the following command:

```
$ oc apply -f ingress-autoscaler.yaml
```

Verification

- Verify that the default Ingress Controller is scaled out to match the value returned by the **kube-state-metrics** query by running the following commands:
 - Use the **grep** command to search the Ingress Controller YAML file for replicas:

```
$ oc get ingresscontroller/default -o yaml | grep replicas:
```

Example output

```
replicas: 3
```

- Get the pods in the **openshift-ingress** project:

```
$ oc get pods -n openshift-ingress
```

Example output

```
NAME                                READY STATUS RESTARTS AGE
router-default-7b5df44ff-l9pmm    2/2   Running 0      17h
router-default-7b5df44ff-s5sl5    2/2   Running 0      3d22h
router-default-7b5df44ff-wwsth    2/2   Running 0      66s
```

2.9.4. Scaling an Ingress Controller

Manually scale an Ingress Controller to meeting routing performance or availability requirements such as the requirement to increase throughput. **oc** commands are used to scale the **IngressController** resource. The following procedure provides an example for scaling up the default **IngressController**.

NOTE

Scaling is not an immediate action, as it takes time to create the desired number of replicas.

Procedure

1. View the current number of available replicas for the default **IngressController**:

```
$ oc get -n openshift-ingress-operator ingresscontrollers/default -o
jsonpath='{$.status.availableReplicas}'
```

Example output

```
2
```

2. Scale the default **IngressController** to the desired number of replicas using the **oc patch** command. The following example scales the default **IngressController** to 3 replicas:

```
$ oc patch -n openshift-ingress-operator ingresscontroller/default --patch '{"spec":{"replicas":
3}}' --type=merge
```

Example output

```
ingresscontroller.operator.openshift.io/default patched
```

3. Verify that the default **IngressController** scaled to the number of replicas that you specified:

```
$ oc get -n openshift-ingress-operator ingresscontrollers/default -o
jsonpath='{$.status.availableReplicas}'
```

Example output

```
3
```

TIP

You can alternatively apply the following YAML to scale an Ingress Controller to three replicas:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  replicas: 3
```

- 1 If you need a different amount of replicas, change the **replicas** value.

2.9.5. Configuring Ingress access logging

You can configure the Ingress Controller to enable access logs. If you have clusters that do not receive much traffic, then you can log to a sidecar. If you have high traffic clusters, to avoid exceeding the capacity of the logging stack or to integrate with a logging infrastructure outside of OpenShift Dedicated, you can forward logs to a custom syslog endpoint. You can also specify the format for access logs.

Container logging is useful to enable access logs on low-traffic clusters when there is no existing Syslog logging infrastructure, or for short-term use while diagnosing problems with the Ingress Controller.

Syslog is needed for high-traffic clusters where access logs could exceed the OpenShift Logging stack's capacity, or for environments where any logging solution needs to integrate with an existing Syslog logging infrastructure. The Syslog use-cases can overlap.

Prerequisites

- Log in as a user with **cluster-admin** privileges.

Procedure

Configure Ingress access logging to a sidecar.

- To configure Ingress access logging, you must specify a destination using **spec.logging.access.destination**. To specify logging to a sidecar container, you must specify **Container spec.logging.access.destination.type**. The following example is an Ingress Controller definition that logs to a **Container** destination:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  replicas: 2
  logging:
    access:
      destination:
        type: Container
```

- When you configure the Ingress Controller to log to a sidecar, the operator creates a container named **logs** inside the Ingress Controller Pod:

```
$ oc -n openshift-ingress logs deployment.apps/router-default -c logs
```

Example output

```
2020-05-11T19:11:50.135710+00:00 router-default-57dfc6cd95-bpmk6 router-default-57dfc6cd95-bpmk6 haproxy[108]: 174.19.21.82:39654 [11/May/2020:19:11:50.133] public be_http:hello-openshift:hello-openshift/pod:hello-openshift:hello-openshift:10.128.2.12:8080 0/0/1/0/1 200 142 - - --NI 1/1/0/0/0 0/0 "GET / HTTP/1.1"
```

Configure Ingress access logging to a Syslog endpoint.

- To configure Ingress access logging, you must specify a destination using **spec.logging.access.destination**. To specify logging to a Syslog endpoint destination, you must specify **Syslog** for **spec.logging.access.destination.type**. If the destination type is **Syslog**, you must also specify a destination endpoint using **spec.logging.access.destination.syslog.endpoint** and you can specify a facility using **spec.logging.access.destination.syslog.facility**. The following example is an Ingress Controller definition that logs to a **Syslog** destination:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  replicas: 2
  logging:
    access:
      destination:
        type: Syslog
        syslog:
          address: 1.2.3.4
          port: 10514
```

NOTE

The **syslog** destination port must be UDP.

Configure Ingress access logging with a specific log format.

- You can specify **spec.logging.access.httpLogFormat** to customize the log format. The following example is an Ingress Controller definition that logs to a **syslog** endpoint with IP address 1.2.3.4 and port 10514:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  replicas: 2
```

```

logging:
  access:
    destination:
      type: Syslog
    syslog:
      address: 1.2.3.4
      port: 10514
    httpLogFormat: '%ci:%cp [%t] %ft %b/%s %B %bq %HM %HU %HV'

```

Disable Ingress access logging.

- To disable Ingress access logging, leave **spec.logging** or **spec.logging.access** empty:

```

apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  replicas: 2
  logging:
    access: null

```

Allow the Ingress Controller to modify the HAProxy log length when using a sidecar.

- Use **spec.logging.access.destination.syslog.maxLength** if you are using **spec.logging.access.destination.type: Syslog**.

```

apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  replicas: 2
  logging:
    access:
      destination:
        type: Syslog
      syslog:
        address: 1.2.3.4
        maxLength: 4096
        port: 10514

```

- Use **spec.logging.access.destination.container.maxLength** if you are using **spec.logging.access.destination.type: Container**.

```

apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  replicas: 2
  logging:

```

```

access:
destination:
type: Container
container:
maxLength: 8192

```

2.9.6. Setting Ingress Controller thread count

A cluster administrator can set the thread count to increase the amount of incoming connections a cluster can handle. You can patch an existing Ingress Controller to increase the amount of threads.

Prerequisites

- The following assumes that you already created an Ingress Controller.

Procedure

- Update the Ingress Controller to increase the number of threads:

```
$ oc -n openshift-ingress-operator patch ingresscontroller/default --type=merge -p '{"spec": {"tuningOptions": {"threadCount": 8}}}'
```

NOTE

If you have a node that is capable of running large amounts of resources, you can configure **spec.nodePlacement.nodeSelector** with labels that match the capacity of the intended node, and configure **spec.tuningOptions.threadCount** to an appropriately high value.

2.9.7. Configuring an Ingress Controller to use an internal load balancer

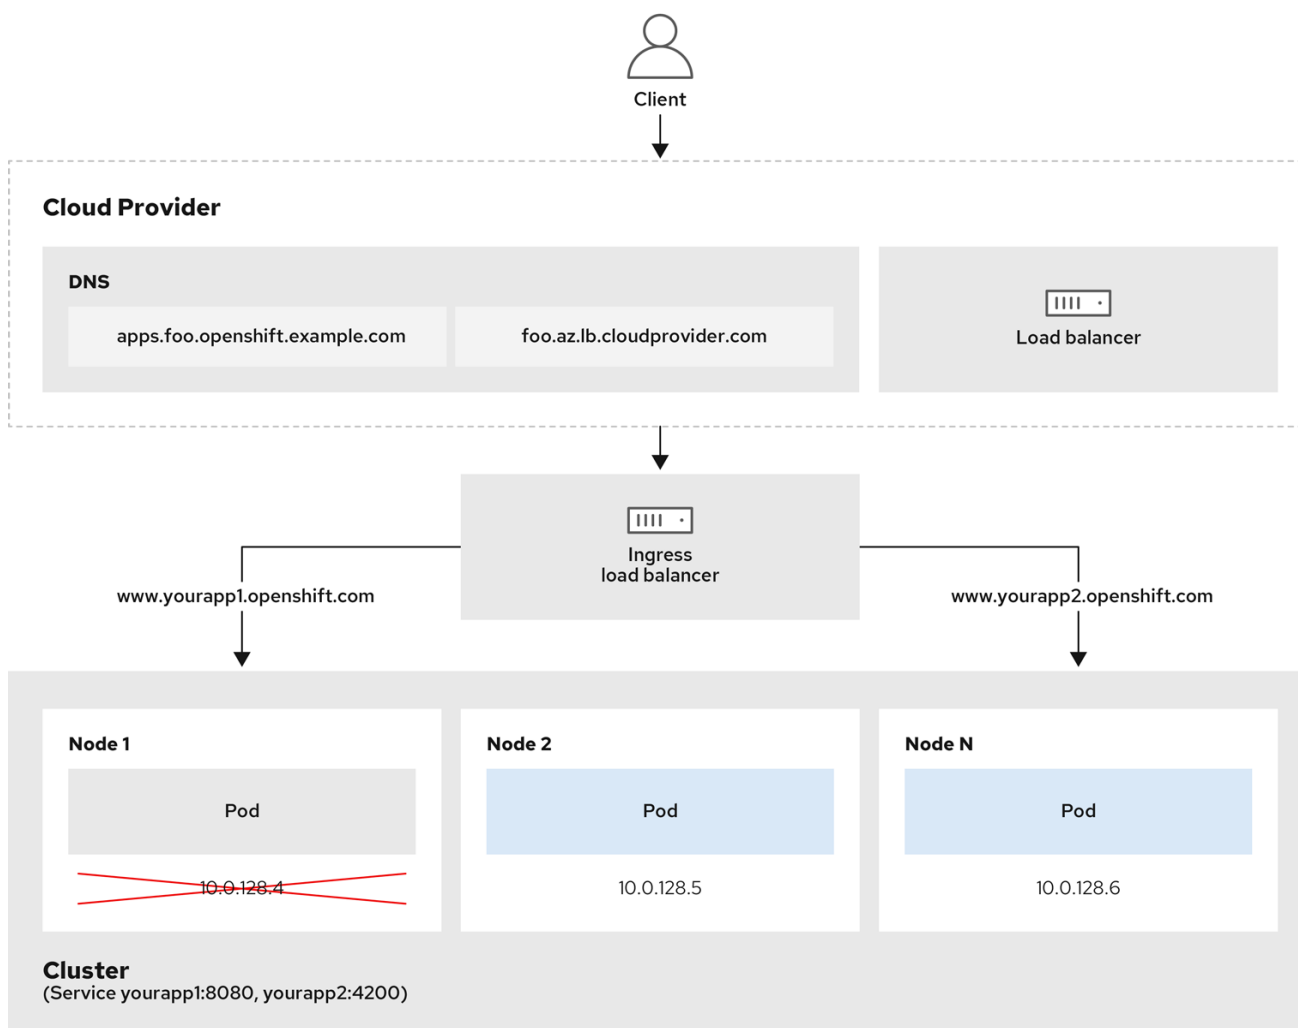

When creating an Ingress Controller on cloud platforms, the Ingress Controller is published by a public cloud load balancer by default. As an administrator, you can create an Ingress Controller that uses an internal cloud load balancer.

IMPORTANT

If you want to change the **scope** for an **IngressController**, you can change the **.spec.endpointPublishingStrategy.loadBalancer.scope** parameter after the custom resource (CR) is created.

Figure 2.1. Diagram of LoadBalancer

202_OpenShift_0222

The preceding graphic shows the following concepts pertaining to OpenShift Dedicated Ingress LoadBalancerService endpoint publishing strategy:

- You can load balance externally, using the cloud provider load balancer, or internally, using the OpenShift Ingress Controller Load Balancer.
- You can use the single IP address of the load balancer and more familiar ports, such as 8080 and 4200 as shown on the cluster depicted in the graphic.
- Traffic from the external load balancer is directed at the pods, and managed by the load balancer, as depicted in the instance of a down node. See the [Kubernetes Services documentation](#) for implementation details.

Prerequisites

- Install the OpenShift CLI (**oc**).
- Log in as a user with **cluster-admin** privileges.

Procedure

1. Create an **IngressController** custom resource (CR) in a file named `<name>-ingress-controller.yaml`, such as in the following example:

```

apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  namespace: openshift-ingress-operator
  name: <name> ❶
spec:
  domain: <domain> ❷
  endpointPublishingStrategy:
    type: LoadBalancerService
  loadBalancer:
    scope: Internal ❸

```

- ❶ Replace **<name>** with a name for the **IngressController** object.
- ❷ Specify the **domain** for the application published by the controller.
- ❸ Specify a value of **Internal** to use an internal load balancer.

2. Create the Ingress Controller defined in the previous step by running the following command:

```
$ oc create -f <name>-ingress-controller.yaml ❶
```

- ❶ Replace **<name>** with the name of the **IngressController** object.

3. Optional: Confirm that the Ingress Controller was created by running the following command:

```
$ oc --all-namespaces=true get ingresscontrollers
```

2.9.8. Setting the Ingress Controller health check interval

A cluster administrator can set the health check interval to define how long the router waits between two consecutive health checks. This value is applied globally as a default for all routes. The default value is 5 seconds.

Prerequisites

- The following assumes that you already created an Ingress Controller.

Procedure

- Update the Ingress Controller to change the interval between back end health checks:

```
$ oc -n openshift-ingress-operator patch ingresscontroller/default --type=merge -p '{"spec": {"tuningOptions": {"healthCheckInterval": "8s"}}}'
```

NOTE

To override the **healthCheckInterval** for a single route, use the route annotation **router.openshift.io/haproxy.health.check.interval**

2.9.9. Configuring the default Ingress Controller for your cluster to be internal

You can configure the **default** Ingress Controller for your cluster to be internal by deleting and recreating it.

IMPORTANT

If you want to change the **scope** for an **IngressController**, you can change the **.spec.endpointPublishingStrategy.loadBalancer.scope** parameter after the custom resource (CR) is created.

Prerequisites

- Install the OpenShift CLI (**oc**).
- Log in as a user with **cluster-admin** privileges.

Procedure

1. Configure the **default** Ingress Controller for your cluster to be internal by deleting and recreating it.

```
$ oc replace --force --wait --filename - <<EOF
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  namespace: openshift-ingress-operator
  name: default
spec:
  endpointPublishingStrategy:
    type: LoadBalancerService
  loadBalancer:
    scope: Internal
EOF
```

2.9.10. Configuring the route admission policy

Administrators and application developers can run applications in multiple namespaces with the same domain name. This is for organizations where multiple teams develop microservices that are exposed on the same hostname.

WARNING

Allowing claims across namespaces should only be enabled for clusters with trust between namespaces, otherwise a malicious user could take over a hostname. For this reason, the default admission policy disallows hostname claims across namespaces.

Prerequisites

- Cluster administrator privileges.

Procedure

- Edit the **.spec.routeAdmission** field of the **ingresscontroller** resource variable using the following command:

```
$ oc -n openshift-ingress-operator patch ingresscontroller/default --patch '{"spec": {"routeAdmission":{"namespaceOwnership":"InterNamespaceAllowed"}}}' --type=merge
```

Sample Ingress Controller configuration

```
spec:
  routeAdmission:
    namespaceOwnership: InterNamespaceAllowed
  ...
```

TIP

You can alternatively apply the following YAML to configure the route admission policy:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  routeAdmission:
    namespaceOwnership: InterNamespaceAllowed
```

2.9.11. Using wildcard routes

The HAProxy Ingress Controller has support for wildcard routes. The Ingress Operator uses **wildcardPolicy** to configure the **ROUTER_ALLOW_WILDCARD_ROUTES** environment variable of the Ingress Controller.

The default behavior of the Ingress Controller is to admit routes with a wildcard policy of **None**, which is backwards compatible with existing **IngressController** resources.

Procedure

1. Configure the wildcard policy.
 - a. Use the following command to edit the **IngressController** resource:

```
$ oc edit IngressController
```

- b. Under **spec**, set the **wildcardPolicy** field to **WildcardsDisallowed** or **WildcardsAllowed**:

```
spec:
  routeAdmission:
    wildcardPolicy: WildcardsDisallowed # or WildcardsAllowed
```

2.9.12. HTTP header configuration

OpenShift Dedicated provides different methods for working with HTTP headers. When setting or deleting headers, you can use specific fields in the Ingress Controller or an individual route to modify request and response headers. You can also set certain headers by using route annotations. The various ways of configuring headers can present challenges when working together.

NOTE

You can only set or delete headers within an **IngressController** or **Route** CR, you cannot append them. If an HTTP header is set with a value, that value must be complete and not require appending in the future. In situations where it makes sense to append a header, such as the X-Forwarded-For header, use the **spec.httpHeaders.forwardedHeaderPolicy** field, instead of **spec.httpHeaders.actions**.

2.9.12.1. Order of precedence

When the same HTTP header is modified both in the Ingress Controller and in a route, HAProxy prioritizes the actions in certain ways depending on whether it is a request or response header.

- For HTTP response headers, actions specified in the Ingress Controller are executed after the actions specified in a route. This means that the actions specified in the Ingress Controller take precedence.
- For HTTP request headers, actions specified in a route are executed after the actions specified in the Ingress Controller. This means that the actions specified in the route take precedence.

For example, a cluster administrator sets the X-Frame-Options response header with the value **DENY** in the Ingress Controller using the following configuration:

Example IngressController spec

```
apiVersion: operator.openshift.io/v1
kind: IngressController
# ...
spec:
  httpHeaders:
    actions:
      response:
        - name: X-Frame-Options
          action:
            type: Set
            set:
              value: DENY
```

A route owner sets the same response header that the cluster administrator set in the Ingress Controller, but with the value **SAMEORIGIN** using the following configuration:

Example Route spec

```
apiVersion: route.openshift.io/v1
kind: Route
# ...
spec:
  httpHeaders:
    actions:
      response:
```

```
- name: X-Frame-Options
  action:
    type: Set
    set:
      value: SAMEORIGIN
```

When both the **IngressController** spec and **Route** spec are configuring the X-Frame-Options response header, then the value set for this header at the global level in the Ingress Controller takes precedence, even if a specific route allows frames. For a request header, the **Route** spec value overrides the **IngressController** spec value.

This prioritization occurs because the **haproxy.config** file uses the following logic, where the Ingress Controller is considered the front end and individual routes are considered the back end. The header value **DENY** applied to the front end configurations overrides the same header with the value **SAMEORIGIN** that is set in the back end:

```
frontend public
  http-response set-header X-Frame-Options 'DENY'

frontend fe_sni
  http-response set-header X-Frame-Options 'DENY'

frontend fe_no_sni
  http-response set-header X-Frame-Options 'DENY'

backend be_secure:openshift-monitoring:alertmanager-main
  http-response set-header X-Frame-Options 'SAMEORIGIN'
```

Additionally, any actions defined in either the Ingress Controller or a route override values set using route annotations.

2.9.12.2. Special case headers

The following headers are either prevented entirely from being set or deleted, or allowed under specific circumstances:

Table 2.2. Special case header configuration options

Header name	Configurable using IngressController spec	Configurable using Route spec	Reason for disallowment	Configurable using another method
-------------	--	--------------------------------------	-------------------------	-----------------------------------

Header name	Configurable using IngressController spec	Configurable using Route spec	Reason for disallowment	Configurable using another method
proxy	No	No	The proxy HTTP request header can be used to exploit vulnerable CGI applications by injecting the header value into the HTTP_PROXY environment variable. The proxy HTTP request header is also non-standard and prone to error during configuration.	No
host	No	Yes	When the host HTTP request header is set using the IngressController CR, HAProxy can fail when looking up the correct route.	No
strict-transport-security	No	No	The strict-transport-security HTTP response header is already handled using route annotations and does not need a separate implementation.	Yes: the haproxy.router.openshift.io/hosts_header route annotation

Header name	Configurable using IngressController spec	Configurable using Route spec	Reason for disallowment	Configurable using another method
cookie and set-cookie	No	No	The cookies that HAProxy sets are used for session tracking to map client connections to particular back-end servers. Allowing these headers to be set could interfere with HAProxy's session affinity and restrict HAProxy's ownership of a cookie.	Yes: <ul style="list-style-type: none"> the haproxy.router.openshift.io/disable_cookie route annotation the haproxy.router.openshift.io/cookie_name route annotation

2.9.13. Setting or deleting HTTP request and response headers in an Ingress Controller

You can set or delete certain HTTP request and response headers for compliance purposes or other reasons. You can set or delete these headers either for all routes served by an Ingress Controller or for specific routes.

For example, you might want to migrate an application running on your cluster to use mutual TLS, which requires that your application checks for an X-Forwarded-Client-Cert request header, but the OpenShift Dedicated default Ingress Controller provides an X-SSL-Client-Der request header.

The following procedure modifies the Ingress Controller to set the X-Forwarded-Client-Cert request header, and delete the X-SSL-Client-Der request header.

Prerequisites

- You have installed the OpenShift CLI (**oc**).
- You have access to an OpenShift Dedicated cluster as a user with the **cluster-admin** role.

Procedure

1. Edit the Ingress Controller resource:

```
$ oc -n openshift-ingress-operator edit ingresscontroller/default
```

2. Replace the X-SSL-Client-Der HTTP request header with the X-Forwarded-Client-Cert HTTP request header:

```

apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  httpHeaders:
    actions: ❶
    request: ❷
    - name: X-Forwarded-Client-Cert ❸
      action:
        type: Set ❹
        set:
          value: "%{+Q}[ssl_c_der,base64]" ❺
    - name: X-SSL-Client-Der
      action:
        type: Delete

```

- ❶ The list of actions you want to perform on the HTTP headers.
- ❷ The type of header you want to change. In this case, a request header.
- ❸ The name of the header you want to change. For a list of available headers you can set or delete, see *HTTP header configuration*.
- ❹ The type of action being taken on the header. This field can have the value **Set** or **Delete**.
- ❺ When setting HTTP headers, you must provide a **value**. The value can be a string from a list of available directives for that header, for example **DENY**, or it can be a dynamic value that will be interpreted using HAProxy's dynamic value syntax. In this case, a dynamic value is added.

NOTE

For setting dynamic header values for HTTP responses, allowed sample fetchers are **res.hdr** and **ssl_c_der**. For setting dynamic header values for HTTP requests, allowed sample fetchers are **req.hdr** and **ssl_c_der**. Both request and response dynamic values can use the **lower** and **base64** converters.

3. Save the file to apply the changes.

2.9.14. Using X-Forwarded headers

You configure the HAProxy Ingress Controller to specify a policy for how to handle HTTP headers including **Forwarded** and **X-Forwarded-For**. The Ingress Operator uses the **HTTPHeaders** field to configure the **ROUTER_SET_FORWARDED_HEADERS** environment variable of the Ingress Controller.

Procedure

1. Configure the **HTTPHeader**s field for the Ingress Controller.
 - a. Use the following command to edit the **IngressController** resource:

```
$ oc edit IngressController
```

- b. Under **spec**, set the **HTTPHeader**s policy field to **Append**, **Replace, IfNone**, or **Never**:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  httpHeaders:
    forwardedHeaderPolicy: Append
```

Example use cases

As a cluster administrator, you can:

- Configure an external proxy that injects the **X-Forwarded-For** header into each request before forwarding it to an Ingress Controller.
To configure the Ingress Controller to pass the header through unmodified, you specify the **never** policy. The Ingress Controller then never sets the headers, and applications receive only the headers that the external proxy provides.
- Configure the Ingress Controller to pass the **X-Forwarded-For** header that your external proxy sets on external cluster requests through unmodified.
To configure the Ingress Controller to set the **X-Forwarded-For** header on internal cluster requests, which do not go through the external proxy, specify the **if-none** policy. If an HTTP request already has the header set through the external proxy, then the Ingress Controller preserves it. If the header is absent because the request did not come through the proxy, then the Ingress Controller adds the header.

As an application developer, you can:

- Configure an application-specific external proxy that injects the **X-Forwarded-For** header.
To configure an Ingress Controller to pass the header through unmodified for an application's Route, without affecting the policy for other Routes, add an annotation **haproxy.router.openshift.io/set-forwarded-headers: if-none** or **haproxy.router.openshift.io/set-forwarded-headers: never** on the Route for the application.

NOTE

You can set the **haproxy.router.openshift.io/set-forwarded-headers** annotation on a per route basis, independent from the globally set value for the Ingress Controller.

2.9.15. Enabling HTTP/2 Ingress connectivity

You can enable transparent end-to-end HTTP/2 connectivity in HAProxy. It allows application owners to make use of HTTP/2 protocol capabilities, including single connection, header compression, binary streams, and more.

You can enable HTTP/2 connectivity for an individual Ingress Controller or for the entire cluster.

To enable the use of HTTP/2 for the connection from the client to HAProxy, a route must specify a custom certificate. A route that uses the default certificate cannot use HTTP/2. This restriction is necessary to avoid problems from connection coalescing, where the client re-uses a connection for different routes that use the same certificate.

The connection from HAProxy to the application pod can use HTTP/2 only for re-encrypt routes and not for edge-terminated or insecure routes. This restriction is because HAProxy uses Application-Level Protocol Negotiation (ALPN), which is a TLS extension, to negotiate the use of HTTP/2 with the back-end. The implication is that end-to-end HTTP/2 is possible with passthrough and re-encrypt and not with insecure or edge-terminated routes.

IMPORTANT

For non-passthrough routes, the Ingress Controller negotiates its connection to the application independently of the connection from the client. This means a client may connect to the Ingress Controller and negotiate HTTP/1.1, and the Ingress Controller may then connect to the application, negotiate HTTP/2, and forward the request from the client HTTP/1.1 connection using the HTTP/2 connection to the application. This poses a problem if the client subsequently tries to upgrade its connection from HTTP/1.1 to the WebSocket protocol, because the Ingress Controller cannot forward WebSocket to HTTP/2 and cannot upgrade its HTTP/2 connection to WebSocket. Consequently, if you have an application that is intended to accept WebSocket connections, it must not allow negotiating the HTTP/2 protocol or else clients will fail to upgrade to the WebSocket protocol.

Procedure

Enable HTTP/2 on a single Ingress Controller.

- To enable HTTP/2 on an Ingress Controller, enter the **oc annotate** command:

```
$ oc -n openshift-ingress-operator annotate ingresscontrollers/<ingresscontroller_name>
ingress.operator.openshift.io/default-enable-http2=true
```

Replace **<ingresscontroller_name>** with the name of the Ingress Controller to annotate.

Enable HTTP/2 on the entire cluster.

- To enable HTTP/2 for the entire cluster, enter the **oc annotate** command:

```
$ oc annotate ingresses.config/cluster ingress.operator.openshift.io/default-enable-http2=true
```

TIP

You can alternatively apply the following YAML to add the annotation:

```
apiVersion: config.openshift.io/v1
kind: Ingress
metadata:
  name: cluster
  annotations:
    ingress.operator.openshift.io/default-enable-http2: "true"
```

2.9.16. Configuring the PROXY protocol for an Ingress Controller

A cluster administrator can configure [the PROXY protocol](#) when an Ingress Controller uses either the **HostNetwork** or **NodePortService** endpoint publishing strategy types. The PROXY protocol enables the load balancer to preserve the original client addresses for connections that the Ingress Controller receives. The original client addresses are useful for logging, filtering, and injecting HTTP headers. In the default configuration, the connections that the Ingress Controller receives only contain the source address that is associated with the load balancer.

This feature is not supported in cloud deployments. This restriction is because when OpenShift Dedicated runs in a cloud platform, and an IngressController specifies that a service load balancer should be used, the Ingress Operator configures the load balancer service and enables the PROXY protocol based on the platform requirement for preserving source addresses.

IMPORTANT

You must configure both OpenShift Dedicated and the external load balancer to either use the PROXY protocol or to use TCP.

WARNING

The PROXY protocol is unsupported for the default Ingress Controller with installer-provisioned clusters on non-cloud platforms that use a Keepalived Ingress VIP.

Prerequisites

- You created an Ingress Controller.

Procedure

- Edit the Ingress Controller resource:

```
$ oc -n openshift-ingress-operator edit ingresscontroller/default
```

- Set the PROXY configuration:

- If your Ingress Controller uses the `hostNetwork` endpoint publishing strategy type, set the `spec.endpointPublishingStrategy.hostNetwork.protocol` subfield to **PROXY**:

Sample `hostNetwork` configuration to PROXY

```
spec:
  endpointPublishingStrategy:
    hostNetwork:
      protocol: PROXY
      type: HostNetwork
```

- If your Ingress Controller uses the `NodePortService` endpoint publishing strategy type, set the `spec.endpointPublishingStrategy.nodePort.protocol` subfield to **PROXY**:

Sample `nodePort` configuration to PROXY

```
spec:
  endpointPublishingStrategy:
    nodePort:
      protocol: PROXY
      type: NodePortService
```

2.9.17. Specifying an alternative cluster domain using the `appsDomain` option

As a cluster administrator, you can specify an alternative to the default cluster domain for user-created routes by configuring the `appsDomain` field. The `appsDomain` field is an optional domain for OpenShift Dedicated to use instead of the default, which is specified in the `domain` field. If you specify an alternative domain, it overrides the default cluster domain for the purpose of determining the default host for a new route.

For example, you can use the DNS domain for your company as the default domain for routes and ingresses for applications running on your cluster.

Prerequisites

- You deployed an OpenShift Dedicated cluster.
- You installed the `oc` command line interface.

Procedure

1. Configure the `appsDomain` field by specifying an alternative default domain for user-created routes.
 - a. Edit the ingress `cluster` resource:

```
$ oc edit ingresses.config/cluster -o yaml
```

- b. Edit the YAML file:

Sample `appsDomain` configuration to `test.example.com`

```
apiVersion: config.openshift.io/v1
kind: Ingress
metadata:
  name: cluster
spec:
  domain: apps.example.com
  appsDomain: <test.example.com>
```

- 1 Specifies the default domain. You cannot modify the default domain after installation.
- 2 Optional: Domain for OpenShift Dedicated infrastructure to use for application routes. Instead of the default prefix, `apps`, you can use an alternative prefix like `test`.

2. Verify that an existing route contains the domain name specified in the `appsDomain` field by exposing the route and verifying the route domain change:

**NOTE**

Wait for the **openshift-apiserver** finish rolling updates before exposing the route.

- a. Expose the route:

```
$ oc expose service hello-openshift
route.route.openshift.io/hello-openshift exposed
```

Example output:

```
$ oc get routes
NAME          HOST/PORT          PATH  SERVICES  PORT
TERMINATION  WILDCARD
hello-openshift  hello_openshift-<my_project>.test.example.com
hello-openshift  8080-tcp          None
```

2.9.18. Converting HTTP header case

HAProxy lowercases HTTP header names by default, for example, changing **Host: xyz.com** to **host: xyz.com**. If legacy applications are sensitive to the capitalization of HTTP header names, use the Ingress Controller **spec.httpHeaders.headerNameCaseAdjustments** API field for a solution to accommodate legacy applications until they can be fixed.

**IMPORTANT**

Because OpenShift Dedicated includes HAProxy 2.8, be sure to add the necessary configuration by using **spec.httpHeaders.headerNameCaseAdjustments** before upgrading.

Prerequisites

- You have installed the OpenShift CLI (**oc**).
- You have access to the cluster as a user with the **cluster-admin** role.

Procedure

As a cluster administrator, you can convert the HTTP header case by entering the **oc patch** command or by setting the **HeaderNameCaseAdjustments** field in the Ingress Controller YAML file.

- Specify an HTTP header to be capitalized by entering the **oc patch** command.
 1. Enter the **oc patch** command to change the HTTP **host** header to **Host**:

```
$ oc -n openshift-ingress-operator patch ingresscontrollers/default --type=merge --
patch='{"spec":{"httpHeaders":{"headerNameCaseAdjustments":["Host"]}}}'
```

2. Annotate the route of the application:

```
$ oc annotate routes/my-application haproxy.router.openshift.io/h1-adjust-case=true
```

The Ingress Controller then adjusts the **host** request header as specified.

- Specify adjustments using the **HeaderNameCaseAdjustments** field by configuring the Ingress Controller YAML file.
 - The following example Ingress Controller YAML adjusts the **host** header to **Host** for HTTP/1 requests to appropriately annotated routes:

Example Ingress Controller YAML

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  httpHeaders:
    headerNameCaseAdjustments:
      - Host
```

- The following example route enables HTTP response header name case adjustments using the **haproxy.router.openshift.io/h1-adjust-case** annotation:

Example route YAML

```
apiVersion: route.openshift.io/v1
kind: Route
metadata:
  annotations:
    haproxy.router.openshift.io/h1-adjust-case: true 1
  name: my-application
  namespace: my-application
spec:
  to:
    kind: Service
    name: my-application
```

- Set **haproxy.router.openshift.io/h1-adjust-case** to true.

2.9.19. Using router compression

You configure the HAProxy Ingress Controller to specify router compression globally for specific MIME types. You can use the **mimeTypes** variable to define the formats of MIME types to which compression is applied. The types are: application, image, message, multipart, text, video, or a custom type prefaced by "X-". To see the full notation for MIME types and subtypes, see [RFC1341](#).

NOTE

Memory allocated for compression can affect the max connections. Additionally, compression of large buffers can cause latency, like heavy regex or long lists of regex.

Not all MIME types benefit from compression, but HAProxy still uses resources to try to compress if instructed to. Generally, text formats, such as html, css, and js, formats benefit from compression, but formats that are already compressed, such as image, audio, and video, benefit little in exchange for the time and resources spent on compression.

Procedure

1. Configure the **httpCompression** field for the Ingress Controller.

- a. Use the following command to edit the **IngressController** resource:

```
$ oc edit -n openshift-ingress-operator ingresscontrollers/default
```

- b. Under **spec**, set the **httpCompression** policy field to **mimeTypes** and specify a list of MIME types that should have compression applied:

```
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
  namespace: openshift-ingress-operator
spec:
  httpCompression:
    mimeTypes:
      - "text/html"
      - "text/css; charset=utf-8"
      - "application/json"
  ...
```

2.9.20. Exposing router metrics

You can expose the HAProxy router metrics by default in Prometheus format on the default stats port, 1936. The external metrics collection and aggregation systems such as Prometheus can access the HAProxy router metrics. You can view the HAProxy router metrics in a browser in the HTML and comma separated values (CSV) format.

Prerequisites

- You configured your firewall to access the default stats port, 1936.

Procedure

1. Get the router pod name by running the following command:

```
$ oc get pods -n openshift-ingress
```

Example output

```
NAME                                READY STATUS RESTARTS AGE
router-default-76bffb66c-46qwp    1/1   Running 0      11h
```

2. Get the router's username and password, which the router pod stores in the **/var/lib/haproxy/conf/metrics-auth/statsUsername** and **/var/lib/haproxy/conf/metrics-auth/statsPassword** files:

- a. Get the username by running the following command:

```
$ oc rsh <router_pod_name> cat metrics-auth/statsUsername
```

- b. Get the password by running the following command:

```
$ oc rsh <router_pod_name> cat metrics-auth/statsPassword
```

3. Get the router IP and metrics certificates by running the following command:

```
$ oc describe pod <router_pod>
```

4. Get the raw statistics in Prometheus format by running the following command:

```
$ curl -u <user>:<password> http://<router_IP>:<stats_port>/metrics
```

5. Access the metrics securely by running the following command:

```
$ curl -u user:password https://<router_IP>:<stats_port>/metrics -k
```

6. Access the default stats port, 1936, by running the following command:

```
$ curl -u <user>:<password> http://<router_IP>:<stats_port>/metrics
```

Example 2.1. Example output

```
...
# HELP haproxy_backend_connections_total Total number of connections.
# TYPE haproxy_backend_connections_total gauge
haproxy_backend_connections_total{backend="http",namespace="default",route="hello-route"} 0
haproxy_backend_connections_total{backend="http",namespace="default",route="hello-route-alt"} 0
haproxy_backend_connections_total{backend="http",namespace="default",route="hello-route01"} 0
...
# HELP haproxy_exporter_server_threshold Number of servers tracked and the current threshold value.
# TYPE haproxy_exporter_server_threshold gauge
haproxy_exporter_server_threshold{type="current"} 11
haproxy_exporter_server_threshold{type="limit"} 500
...
# HELP haproxy_frontend_bytes_in_total Current total of incoming bytes.
# TYPE haproxy_frontend_bytes_in_total gauge
haproxy_frontend_bytes_in_total{frontend="fe_no_sni"} 0
haproxy_frontend_bytes_in_total{frontend="fe_sni"} 0
haproxy_frontend_bytes_in_total{frontend="public"} 119070
...
# HELP haproxy_server_bytes_in_total Current total of incoming bytes.
# TYPE haproxy_server_bytes_in_total gauge
haproxy_server_bytes_in_total{namespace="",pod="",route="",server="fe_no_sni",service=""} 0
haproxy_server_bytes_in_total{namespace="",pod="",route="",server="fe_sni",service=""} 0
haproxy_server_bytes_in_total{namespace="default",pod="docker-registry-5-nk5fz",route="docker-registry",server="10.130.0.89:5000",service="docker-registry"} 0
```

```
haproxy_server_bytes_in_total{namespace="default",pod="hello-rc-vkjqx",route="hello-
route",server="10.130.0.90:8080",service="hello-svc-1"} 0
...
```

7. Launch the stats window by entering the following URL in a browser:

```
http://<user>:<password>@<router_IP>:<stats_port>
```

8. Optional: Get the stats in CSV format by entering the following URL in a browser:

```
http://<user>:<password>@<router_ip>:1936/metrics;csv
```

2.9.21. Customizing HAProxy error code response pages

As a cluster administrator, you can specify a custom error code response page for either 503, 404, or both error pages. The HAProxy router serves a 503 error page when the application pod is not running or a 404 error page when the requested URL does not exist. For example, if you customize the 503 error code response page, then the page is served when the application pod is not running, and the default 404 error code HTTP response page is served by the HAProxy router for an incorrect route or a non-existing route.

Custom error code response pages are specified in a config map then patched to the Ingress Controller. The config map keys have two available file names as follows: **error-page-503.http** and **error-page-404.http**.

Custom HTTP error code response pages must follow the [HAProxy HTTP error page configuration guidelines](#). Here is an example of the default OpenShift Dedicated HAProxy router [http 503 error code response page](#). You can use the default content as a template for creating your own custom page.

By default, the HAProxy router serves only a 503 error page when the application is not running or when the route is incorrect or non-existent. This default behavior is the same as the behavior on OpenShift Dedicated 4.8 and earlier. If a config map for the customization of an HTTP error code response is not provided, and you are using a custom HTTP error code response page, the router serves a default 404 or 503 error code response page.

NOTE

If you use the OpenShift Dedicated default 503 error code page as a template for your customizations, the headers in the file require an editor that can use CRLF line endings.

Procedure

1. Create a config map named **my-custom-error-code-pages** in the **openshift-config** namespace:

```
$ oc -n openshift-config create configmap my-custom-error-code-pages \
--from-file=error-page-503.http \
--from-file=error-page-404.http
```

IMPORTANT

If you do not specify the correct format for the custom error code response page, a router pod outage occurs. To resolve this outage, you must delete or correct the config map and delete the affected router pods so they can be recreated with the correct information.

2. Patch the Ingress Controller to reference the **my-custom-error-code-pages** config map by name:

```
$ oc patch -n openshift-ingress-operator ingresscontroller/default --patch '{"spec": {"httpErrorCodePages":{"name":"my-custom-error-code-pages"}}}' --type=merge
```

The Ingress Operator copies the **my-custom-error-code-pages** config map from the **openshift-config** namespace to the **openshift-ingress** namespace. The Operator names the config map according to the pattern, **<your_ingresscontroller_name>-errorpages**, in the **openshift-ingress** namespace.

3. Display the copy:

```
$ oc get cm default-errorpages -n openshift-ingress
```

Example output

```
NAME          DATA  AGE
default-errorpages  2     25s 1
```

- 1** The example config map name is **default-errorpages** because the **default** Ingress Controller custom resource (CR) was patched.

4. Confirm that the config map containing the custom error response page mounts on the router volume where the config map key is the filename that has the custom HTTP error code response:

- For 503 custom HTTP custom error code response:

```
$ oc -n openshift-ingress rsh <router_pod> cat
/var/lib/haproxy/conf/error_code_pages/error-page-503.http
```

- For 404 custom HTTP custom error code response:

```
$ oc -n openshift-ingress rsh <router_pod> cat
/var/lib/haproxy/conf/error_code_pages/error-page-404.http
```

Verification

Verify your custom error code HTTP response:

1. Create a test project and application:

```
$ oc new-project test-ingress
```

```
$ oc new-app django-psql-example
```

-
- 2. For 503 custom http error code response:

- a. Stop all the pods for the application.
- b. Run the following curl command or visit the route hostname in the browser:

```
$ curl -vk <route_hostname>
```

- 3. For 404 custom http error code response:

- a. Visit a non-existent route or an incorrect route.
- b. Run the following curl command or visit the route hostname in the browser:

```
$ curl -vk <route_hostname>
```

- 4. Check if the **errorfile** attribute is properly in the **haproxy.config** file:

```
$ oc -n openshift-ingress rsh <router> cat /var/lib/haproxy/conf/haproxy.config | grep errorfile
```

2.9.22. Setting the Ingress Controller maximum connections

A cluster administrator can set the maximum number of simultaneous connections for OpenShift router deployments. You can patch an existing Ingress Controller to increase the maximum number of connections.

Prerequisites

- The following assumes that you already created an Ingress Controller

Procedure

- Update the Ingress Controller to change the maximum number of connections for HAProxy:

```
$ oc -n openshift-ingress-operator patch ingresscontroller/default --type=merge -p '{"spec": {"tuningOptions": {"maxConnections": 7500}}}'
```

WARNING

If you set the **spec.tuningOptions.maxConnections** value greater than the current operating system limit, the HAProxy process will not start. See the table in the "Ingress Controller configuration parameters" section for more information about this parameter.

2.10. OPENSIFT DEDICATED INGRESS OPERATOR CONFIGURATIONS

The following table details the components of the Ingress Operator and if Red Hat Site Reliability Engineers (SRE) maintains this component on OpenShift Dedicated clusters.

Table 2.3. Ingress Operator Responsibility Chart

Ingress component	Managed by	Default configuration?
Scaling Ingress Controller	SRE	Yes
Ingress Operator thread count	SRE	Yes
Ingress Controller access logging	SRE	Yes
Ingress Controller sharding	SRE	Yes
Ingress Controller route admission policy	SRE	Yes
Ingress Controller wildcard routes	SRE	Yes
Ingress Controller X-Forwarded headers	SRE	Yes
Ingress Controller route compression	SRE	Yes

CHAPTER 3. OPENSIFT SDN DEFAULT CNI NETWORK PROVIDER

3.1. ENABLING MULTICAST FOR A PROJECT

NOTE

OpenShift SDN CNI is deprecated as of OpenShift Dedicated 4.14. As of OpenShift Dedicated 4.15, the network plugin is not an option for new installations. In a subsequent future release, the OpenShift SDN network plugin is planned to be removed and no longer supported. Red Hat will provide bug fixes and support for this feature until it is removed, but this feature will no longer receive enhancements. As an alternative to OpenShift SDN CNI, you can use OVN Kubernetes CNI instead.

3.1.1. About multicast

With IP multicast, data is broadcast to many IP addresses simultaneously.

IMPORTANT

- At this time, multicast is best used for low-bandwidth coordination or service discovery and not a high-bandwidth solution.
- By default, network policies affect all connections in a namespace. However, multicast is unaffected by network policies. If multicast is enabled in the same namespace as your network policies, it is always allowed, even if there is a **deny-all** network policy. Cluster administrators should consider the implications to the exemption of multicast from network policies before enabling it.

Multicast traffic between OpenShift Dedicated pods is disabled by default. If you are using the OpenShift SDN network plugin, you can enable multicast on a per-project basis.

When using the OpenShift SDN network plugin in **networkpolicy** isolation mode:

- Multicast packets sent by a pod will be delivered to all other pods in the project, regardless of **NetworkPolicy** objects. Pods might be able to communicate over multicast even when they cannot communicate over unicast.
- Multicast packets sent by a pod in one project will never be delivered to pods in any other project, even if there are **NetworkPolicy** objects that allow communication between the projects.

When using the OpenShift SDN network plugin in **multitenant** isolation mode:

- Multicast packets sent by a pod will be delivered to all other pods in the project.
- Multicast packets sent by a pod in one project will be delivered to pods in other projects only if each project is joined together and multicast is enabled in each joined project.

3.1.2. Enabling multicast between pods

You can enable multicast between pods for your project.

Prerequisites

- Install the OpenShift CLI (**oc**).
- You must log in to the cluster with a user that has the **cluster-admin** or the **dedicated-admin** role.

Procedure

- Run the following command to enable multicast for a project. Replace **<namespace>** with the namespace for the project you want to enable multicast for.

```
$ oc annotate netnamespace <namespace> \
  netnamespace.network.openshift.io/multicast-enabled=true
```

Verification

To verify that multicast is enabled for a project, complete the following procedure:

1. Change your current project to the project that you enabled multicast for. Replace **<project>** with the project name.

```
$ oc project <project>
```

2. Create a pod to act as a multicast receiver:

```
$ cat <<EOF | oc create -f -
apiVersion: v1
kind: Pod
metadata:
  name: mlistener
  labels:
    app: multicast-verify
spec:
  containers:
  - name: mlistener
    image: registry.access.redhat.com/ubi9
    command: ["/bin/sh", "-c"]
    args:
      ["dnf -y install socat hostname && sleep inf"]
    ports:
    - containerPort: 30102
      name: mlistener
      protocol: UDP
EOF
```

3. Create a pod to act as a multicast sender:

```
$ cat <<EOF | oc create -f -
apiVersion: v1
kind: Pod
metadata:
  name: msender
  labels:
    app: multicast-verify
```

```
spec:
  containers:
  - name: msender
    image: registry.access.redhat.com/ubi9
    command: ["/bin/sh", "-c"]
    args:
    ["dnf -y install socat && sleep inf"]
EOF
```

4. In a new terminal window or tab, start the multicast listener.

a. Get the IP address for the Pod:

```
$ POD_IP=$(oc get pods mlistener -o jsonpath='{.status.podIP}')
```

b. Start the multicast listener by entering the following command:

```
$ oc exec mlistener -i -t -- \
  socat UDP4-RECVFROM:30102,ip-add-membership=224.1.0.1:$POD_IP,fork
  EXEC:hostname
```

5. Start the multicast transmitter.

a. Get the pod network IP address range:

```
$ CIDR=$(oc get Network.config.openshift.io cluster \
  -o jsonpath='{.status.clusterNetwork[0].cidr}')
```

b. To send a multicast message, enter the following command:

```
$ oc exec msender -i -t -- \
  /bin/bash -c "echo | socat STDIO UDP4-
  DATAGRAM:224.1.0.1:30102,range=$CIDR,ip-multicast-ttl=64"
```

If multicast is working, the previous command returns the following output:

```
mlistener
```

CHAPTER 4. NETWORK VERIFICATION FOR OPENSIFT DEDICATED CLUSTERS

Network verification checks run automatically when you deploy an OpenShift Dedicated cluster into an existing Virtual Private Cloud (VPC) or create an additional machine pool with a subnet that is new to your cluster. The checks validate your network configuration and highlight errors, enabling you to resolve configuration issues prior to deployment.

You can also run the network verification checks manually to validate the configuration for an existing cluster.

4.1. UNDERSTANDING NETWORK VERIFICATION FOR OPENSIFT DEDICATED CLUSTERS

When you deploy an OpenShift Dedicated cluster into an existing Virtual Private Cloud (VPC) or create an additional machine pool with a subnet that is new to your cluster, network verification runs automatically. This helps you identify and resolve configuration issues prior to deployment.

When you prepare to install your cluster by using Red Hat OpenShift Cluster Manager, the automatic checks run after you input a subnet into a subnet ID field on the **Virtual Private Cloud (VPC) subnet settings** page.

When you add a machine pool with a subnet that is new to your cluster, the automatic network verification checks the subnet to ensure that network connectivity is available before the machine pool is provisioned.

After automatic network verification completes, a record is sent to the service log. The record provides the results of the verification check, including any network configuration errors. You can resolve the identified issues before a deployment and the deployment has a greater chance of success.

You can also run the network verification manually for an existing cluster. This enables you to verify the network configuration for your cluster after making configuration changes. For steps to run the network verification checks manually, see *Running the network verification manually*.

4.2. SCOPE OF THE NETWORK VERIFICATION CHECKS

The network verification includes checks for each of the following requirements:

- The parent Virtual Private Cloud (VPC) exists.
- All specified subnets belong to the VPC.
- The VPC has **enableDnsSupport** enabled.
- The VPC has **enableDnsHostnames** enabled.
- Egress is available to the required domain and port combinations that are specified in the [AWS firewall prerequisites](#) section.

4.3. AUTOMATIC NETWORK VERIFICATION BYPASSING

You can bypass the automatic network verification if you want to deploy an OpenShift Dedicated cluster with known network configuration issues into an existing Virtual Private Cloud (VPC).

If you bypass the network verification when you create a cluster, the cluster has a limited support status. After installation, you can resolve the issues and then manually run the network verification. The limited support status is removed after the verification succeeds.

When you install a cluster into an existing VPC by using Red Hat OpenShift Cluster Manager, you can bypass the automatic verification by selecting **Bypass network verification** on the **Virtual Private Cloud (VPC) subnet settings** page.

4.4. RUNNING THE NETWORK VERIFICATION MANUALLY

You can manually run the network verification checks for an existing OpenShift Dedicated cluster by using Red Hat OpenShift Cluster Manager.

Prerequisites

- You have an existing OpenShift Dedicated cluster.
- You are the cluster owner or you have the cluster editor role.

Procedure

1. Navigate to [OpenShift Cluster Manager](#) and select your cluster.
2. Select **Verify networking** from the **Actions** drop-down menu.

CHAPTER 5. CONFIGURING A CLUSTER-WIDE PROXY

If you are using an existing Virtual Private Cloud (VPC), you can configure a cluster-wide proxy during an OpenShift Dedicated cluster installation or after the cluster is installed. When you enable a proxy, the core cluster components are denied direct access to the internet, but the proxy does not affect user workloads.

NOTE

Only cluster system egress traffic is proxied, including calls to the cloud provider API.

You can enable a proxy only for OpenShift Dedicated clusters that use the Customer Cloud Subscription (CCS) model.

If you use a cluster-wide proxy, you are responsible for maintaining the availability of the proxy to the cluster. If the proxy becomes unavailable, then it might impact the health and supportability of the cluster.

5.1. PREREQUISITES FOR CONFIGURING A CLUSTER-WIDE PROXY

To configure a cluster-wide proxy, you must meet the following requirements. These requirements are valid when you configure a proxy during installation or postinstallation.

General requirements

- You are the cluster owner.
- Your account has sufficient privileges.
- You have an existing Virtual Private Cloud (VPC) for your cluster.
- You are using the Customer Cloud Subscription (CCS) model for your cluster.
- The proxy can access the VPC for the cluster and the private subnets of the VPC. The proxy is also accessible from the VPC for the cluster and from the private subnets of the VPC.
- You have added the following endpoints to your VPC endpoint:
 - **ec2.<aws_region>.amazonaws.com**
 - **elasticloadbalancing.<aws_region>.amazonaws.com**
 - **s3.<aws_region>.amazonaws.com**

These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works at the container level and not at the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not enough.

IMPORTANT

When using a cluster-wide proxy, you must configure the **s3.<aws_region>.amazonaws.com** endpoint as type **Gateway**.

Network requirements

- If your proxy re-encrypts egress traffic, you must create exclusions to the domain and port combinations. The following table offers guidance into these exceptions.
 - Your proxy must exclude re-encrypting the following OpenShift URLs:

Address	Pro toc ol/ Por t	Function
observatorium- mst.api.openshift.com	htt ps/ 443	Required. Used for Managed OpenShift-specific telemetry.
sso.redhat.com	htt ps/ 443	The https://cloud.redhat.com/openshift site uses authentication from sso.redhat.com to download the cluster pull secret and use Red Hat SaaS solutions to facilitate monitoring of your subscriptions, cluster inventory, and chargeback reporting.

- Your proxy must exclude re-encrypting the following site reliability engineering (SRE) and management URLs:

Address	Pro toc ol/ Por t	Function
*.osdsecuritylogs.splunkcloud.com OR inputs1.osdsecuritylogs.splunkcloud.com inputs2.osdsecuritylogs.splunkcloud.com inputs4.osdsecuritylogs.splunkcloud.com inputs5.osdsecuritylogs.splunkcloud.com inputs6.osdsecuritylogs.splunkcloud.com inputs7.osdsecuritylogs.splunkcloud.com inputs8.osdsecuritylogs.splunkcloud.com inputs9.osdsecuritylogs.splunkcloud.com inputs10.osdsecuritylogs.splunkcloud.com inputs11.osdsecuritylogs.splunkcloud.com inputs12.osdsecuritylogs.splunkcloud.com inputs13.osdsecuritylogs.splunkcloud.com inputs14.osdsecuritylogs.splunkcloud.com inputs15.osdsecuritylogs.splunkcloud.com	tcp /99 97	Used by the splunk-forwarder-operator as a log forwarding endpoint to be used by Red Hat SRE for log-based alerting.

Address	Protocol/Port	Function
http-inputs- osdsecuritylogs.splunkcloud.com	https/443	Used by the splunk-forwarder-operator as a log forwarding endpoint to be used by Red Hat SRE for log-based alerting.

Additional Resources

- For the installation prerequisites for OpenShift Dedicated clusters that use the Customer Cloud Subscription (CCS) model, see [Customer Cloud Subscriptions on AWS](#) or [Customer Cloud Subscriptions on GCP](#).

5.2. RESPONSIBILITIES FOR ADDITIONAL TRUST BUNDLES

If you supply an additional trust bundle, you are responsible for the following requirements:

- Ensuring that the contents of the additional trust bundle are valid
- Ensuring that the certificates, including intermediary certificates, contained in the additional trust bundle have not expired
- Tracking the expiry and performing any necessary renewals for certificates contained in the additional trust bundle
- Updating the cluster configuration with the updated additional trust bundle

5.3. CONFIGURING A PROXY DURING INSTALLATION

You can configure an HTTP or HTTPS proxy when you install an OpenShift Dedicated with Customer Cloud Subscription (CCS) cluster into an existing Virtual Private Cloud (VPC). You can configure the proxy during installation by using Red Hat OpenShift Cluster Manager.

5.4. CONFIGURING A PROXY DURING INSTALLATION USING OPENSIFT CLUSTER MANAGER

If you are installing an OpenShift Dedicated cluster into an existing Virtual Private Cloud (VPC), you can use Red Hat OpenShift Cluster Manager to enable a cluster-wide HTTP or HTTPS proxy during installation. You can enable a proxy only for clusters that use the Customer Cloud Subscription (CCS) model.

Prior to the installation, you must verify that the proxy is accessible from the VPC that the cluster is being installed into. The proxy must also be accessible from the private subnets of the VPC.

For detailed steps to configure a cluster-wide proxy during installation by using OpenShift Cluster Manager, see *Creating a cluster on AWS with CCS* or *Creating a cluster on GCP with CCS*.

Additional Resources

- [Creating a cluster on AWS with CCS](#)
- [Creating a cluster on GCP with CCS](#)

5.5. CONFIGURING A PROXY AFTER INSTALLATION

You can configure an HTTP or HTTPS proxy after you install an OpenShift Dedicated with Customer Cloud Subscription (CCS) cluster into an existing Virtual Private Cloud (VPC). You can configure the proxy after installation by using Red Hat OpenShift Cluster Manager.

5.6. CONFIGURING A PROXY AFTER INSTALLATION USING OPENSIFT CLUSTER MANAGER

You can use Red Hat OpenShift Cluster Manager to add a cluster-wide proxy configuration to an existing OpenShift Dedicated cluster in a Virtual Private Cloud (VPC). You can enable a proxy only for clusters that use the Customer Cloud Subscription (CCS) model.

You can also use OpenShift Cluster Manager to update an existing cluster-wide proxy configuration. For example, you might need to update the network address for the proxy or replace the additional trust bundle if any of the certificate authorities for the proxy expire.

IMPORTANT

The cluster applies the proxy configuration to the control plane and compute nodes. While applying the configuration, each cluster node is temporarily placed in an unschedulable state and drained of its workloads. Each node is restarted as part of the process.

Prerequisites

- You have an OpenShift Dedicated cluster that uses the Customer Cloud Subscription (CCS) model.
- Your cluster is deployed in a VPC.

Procedure

1. Navigate to [OpenShift Cluster Manager](#) and select your cluster.
2. Under the **Virtual Private Cloud (VPC)** section on the **Networking** page, click **Edit cluster-wide proxy**.
3. On the **Edit cluster-wide proxy** page, provide your proxy configuration details:
 - a. Enter a value in at least one of the following fields:
 - Specify a valid **HTTP proxy URL**
 - Specify a valid **HTTPS proxy URL**
 - In the **Additional trust bundle** field, provide a PEM encoded X.509 certificate bundle. If you are replacing an existing trust bundle file, select **Replace file** to view the field. The bundle is added to the trusted certificate store for the cluster nodes. An additional trust bundle file is required if you use a TLS-inspecting proxy unless the identity certificate for the proxy is signed by an authority from the Red Hat Enterprise Linux CoreOS

(RHCOS) trust bundle. This requirement applies regardless of whether the proxy is transparent or requires explicit configuration using the **http-proxy** and **https-proxy** arguments.

- b. Click **Confirm**.

Verification

- Under the **Virtual Private Cloud (VPC)** section on the **Networking** page, verify that the proxy configuration for your cluster is as expected.

CHAPTER 6. CIDR RANGE DEFINITIONS

You must specify non-overlapping ranges for the following CIDR ranges.

NOTE

Machine CIDR ranges cannot be changed after creating your cluster.

When specifying subnet CIDR ranges, ensure that the subnet CIDR range is within the defined Machine CIDR. You must verify that the subnet CIDR ranges allow for enough IP addresses for all intended workloads depending on which platform the cluster is hosted.

IMPORTANT

OVN-Kubernetes, the default network provider in OpenShift Dedicated 4.14 and later versions, uses the following IP address ranges internally: **100.64.0.0/16**, **169.254.169.0/29**, **100.88.0.0/16**, **fd98::/64**, **fd69::/125**, and **fd97::/64**. If your cluster uses OVN-Kubernetes, do not include any of these IP address ranges in any other CIDR definitions in your cluster or infrastructure.

6.1. MACHINE CIDR

In the Machine classless inter-domain routing (CIDR) field, you must specify the IP address range for machines or cluster nodes. This range must encompass all CIDR address ranges for your virtual private cloud (VPC) subnets. Subnets must be contiguous. A minimum IP address range of 128 addresses, using the subnet prefix **/25**, is supported for single availability zone deployments. A minimum address range of 256 addresses, using the subnet prefix **/24**, is supported for deployments that use multiple availability zones.

The default is **10.0.0.0/16**. This range must not conflict with any connected networks.

6.2. SERVICE CIDR

In the Service CIDR field, you must specify the IP address range for services. It is recommended, but not required, that the address block is the same between clusters. This will not create IP address conflicts. The range must be large enough to accommodate your workload. The address block must not overlap with any external service accessed from within the cluster. The default is **172.30.0.0/16**.

6.3. POD CIDR

In the pod CIDR field, you must specify the IP address range for pods.

It is recommended, but not required, that the address block is the same between clusters. This will not create IP address conflicts. The range must be large enough to accommodate your workload. The address block must not overlap with any external service accessed from within the cluster. The default is **10.128.0.0/14**.

6.4. HOST PREFIX

In the Host Prefix field, you must specify the subnet prefix length assigned to pods scheduled to individual machines. The host prefix determines the pod IP address pool for each machine.

For example, if the host prefix is set to **/23**, each machine is assigned a **/23** subnet from the pod CIDR address range. The default is **/23**, allowing 512 cluster nodes, and 512 pods per node (both of which are beyond our maximum supported).

CHAPTER 7. NETWORK SECURITY

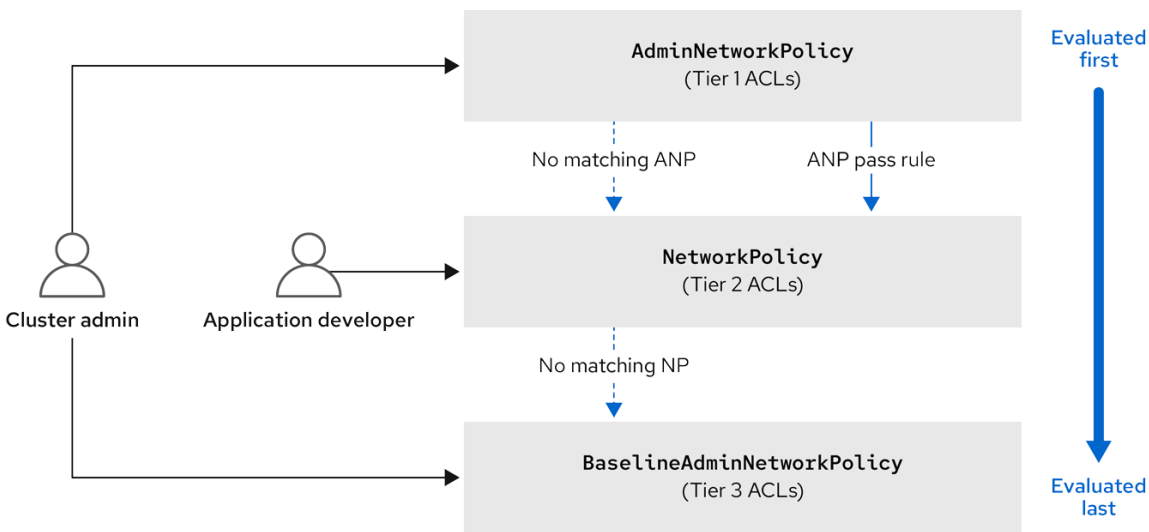

7.1. UNDERSTANDING NETWORK POLICY APIS

Kubernetes offers two features that users can use to enforce network security. One feature that allows users to enforce network policy is the **NetworkPolicy** API that is designed mainly for application developers and namespace tenants to protect their namespaces by creating namespace-scoped policies.

The second feature is **AdminNetworkPolicy** which consists of two APIs: the **AdminNetworkPolicy** (ANP) API and the **BaselineAdminNetworkPolicy** (BANP) API. ANP and BANP are designed for cluster and network administrators to protect their entire cluster by creating cluster-scoped policies. Cluster administrators can use ANPs to enforce non-overrideable policies that take precedence over **NetworkPolicy** objects. Administrators can use BANP to set up and enforce optional cluster-scoped network policy rules that are overrideable by users using **NetworkPolicy** objects when necessary. When used together, ANP, BANP, and network policy can achieve full multi-tenant isolation that administrators can use to secure their cluster.

OVN-Kubernetes CNI in OpenShift Dedicated implements these network policies using Access Control List (ACL) Tiers to evaluate and apply them. ACLs are evaluated in descending order from Tier 1 to Tier 3.

Tier 1 evaluates **AdminNetworkPolicy** (ANP) objects. Tier 2 evaluates **NetworkPolicy** objects. Tier 3 evaluates **BaselineAdminNetworkPolicy** (BANP) objects.

615_OpenShift_0324

ANPs are evaluated first. When the match is an ANP **allow** or **deny** rule, any existing **NetworkPolicy** and **BaselineAdminNetworkPolicy** (BANP) objects in the cluster are skipped from evaluation. When the match is an ANP **pass** rule, then evaluation moves from tier 1 of the ACL to tier 2 where the **NetworkPolicy** policy is evaluated. If no **NetworkPolicy** matches the traffic then evaluation moves from tier 2 ACLs to tier 3 ACLs where BANP is evaluated.

7.1.1. Key differences between AdminNetworkPolicy and NetworkPolicy custom resources

The following table explains key differences between the cluster scoped **AdminNetworkPolicy** API and the namespace scoped **NetworkPolicy** API.

Policy elements	AdminNetworkPolicy	NetworkPolicy
Applicable user	Cluster administrator or equivalent	Namespace owners
Scope	Cluster	Namespaced
Drop traffic	Supported with an explicit Deny action set as a rule.	Supported via implicit Deny isolation at policy creation time.
Delegate traffic	Supported with an Pass action set as a rule.	Not applicable
Allow traffic	Supported with an explicit Allow action set as a rule.	The default action for all rules is to allow.
Rule precedence within the policy	Depends on the order in which they appear within an ANP. The higher the rule's position the higher the precedence.	Rules are additive
Policy precedence	Among ANPs the priority field sets the order for evaluation. The lower the priority number higher the policy precedence.	There is no policy ordering between policies.
Feature precedence	Evaluated first via tier 1 ACL and BANP is evaluated last via tier 3 ACL.	Enforced after ANP and before BANP, they are evaluated in tier 2 of the ACL.
Matching pod selection	Can apply different rules across namespaces.	Can apply different rules across pods in single namespace.
Cluster egress traffic	Supported via nodes and networks peers	Supported through ipBlock field along with accepted CIDR syntax.
Cluster ingress traffic	Not supported	Not supported
Fully qualified domain names (FQDN) peer support	Not supported	Not supported
Namespace selectors	Supports advanced selection of Namespaces with the use of namespaces.matchLabels field	Supports label based namespace selection with the use of namespaceSelector field

7.2. NETWORK POLICY

7.2.1. About network policy

As a cluster administrator, you can define network policies that restrict traffic to pods in your cluster.

7.2.1.1. About network policy

In a cluster using a network plugin that supports Kubernetes network policy, network isolation is controlled entirely by **NetworkPolicy** objects. In OpenShift Dedicated 4, OpenShift SDN supports using network policy in its default network isolation mode.

WARNING

Network policy does not apply to the host network namespace. Pods with host networking enabled are unaffected by network policy rules. However, pods connecting to the host-networked pods might be affected by the network policy rules.

Network policies cannot block traffic from localhost or from their resident nodes.

By default, all pods in a project are accessible from other pods and network endpoints. To isolate one or more pods in a project, you can create **NetworkPolicy** objects in that project to indicate the allowed incoming connections. Project administrators can create and delete **NetworkPolicy** objects within their own project.

If a pod is matched by selectors in one or more **NetworkPolicy** objects, then the pod will accept only connections that are allowed by at least one of those **NetworkPolicy** objects. A pod that is not selected by any **NetworkPolicy** objects is fully accessible.

A network policy applies to only the TCP, UDP, ICMP, and SCTP protocols. Other protocols are not affected.

The following example **NetworkPolicy** objects demonstrate supporting different scenarios:

- Deny all traffic:
To make a project deny by default, add a **NetworkPolicy** object that matches all pods but accepts no traffic:

```
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: deny-by-default
spec:
  podSelector: {}
  ingress: []
```

- Only allow connections from the OpenShift Dedicated Ingress Controller:
To make a project allow only connections from the OpenShift Dedicated Ingress Controller, add the following **NetworkPolicy** object.

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
```

```

name: allow-from-openshift-ingress
spec:
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          network.openshift.io/policy-group: ingress
  podSelector: {}
  policyTypes:
  - Ingress

```

- Only accept connections from pods within a project:
To make pods accept connections from other pods in the same project, but reject all other connections from pods in other projects, add the following **NetworkPolicy** object:

```

kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: allow-same-namespace
spec:
  podSelector: {}
  ingress:
  - from:
    - podSelector: {}

```

- Only allow HTTP and HTTPS traffic based on pod labels:
To enable only HTTP and HTTPS access to the pods with a specific label (**role=frontend** in following example), add a **NetworkPolicy** object similar to the following:

```

kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: allow-http-and-https
spec:
  podSelector:
    matchLabels:
      role: frontend
  ingress:
  - ports:
    - protocol: TCP
      port: 80
    - protocol: TCP
      port: 443

```

- Accept connections by using both namespace and pod selectors:
To match network traffic by combining namespace and pod selectors, you can use a **NetworkPolicy** object similar to the following:

```

kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: allow-pod-and-namespace-both
spec:
  podSelector:

```

```

matchLabels:
  name: test-pods
ingress:
- from:
  - namespaceSelector:
      matchLabels:
        project: project_name
    podSelector:
      matchLabels:
        name: test-pods

```

NetworkPolicy objects are additive, which means you can combine multiple **NetworkPolicy** objects together to satisfy complex network requirements.

For example, for the **NetworkPolicy** objects defined in previous samples, you can define both **allow-same-namespace** and **allow-http-and-https** policies within the same project. Thus allowing the pods with the label **role=frontend**, to accept any connection allowed by each policy. That is, connections on any port from pods in the same namespace, and connections on ports **80** and **443** from pods in any namespace.

7.2.1.1.1. Using the allow-from-router network policy

Use the following **NetworkPolicy** to allow external traffic regardless of the router configuration:

```

apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: allow-from-router
spec:
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          policy-group.network.openshift.io/ingress: "" 1
  podSelector: {}
  policyTypes:
  - Ingress

```

1 **policy-group.network.openshift.io/ingress: ""** label supports both OpenShift-SDN and OVN-Kubernetes.

7.2.1.1.2. Using the allow-from-hostnetwork network policy

Add the following **allow-from-hostnetwork NetworkPolicy** object to direct traffic from the host network pods:

```

apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: allow-from-hostnetwork
spec:
  ingress:
  - from:
    - namespaceSelector:

```

```

matchLabels:
  policy-group.network.openshift.io/host-network: ""
podSelector: {}
policyTypes:
- Ingress

```

7.2.1.2. Optimizations for network policy with OpenShift SDN

Use a network policy to isolate pods that are differentiated from one another by labels within a namespace.

It is inefficient to apply **NetworkPolicy** objects to large numbers of individual pods in a single namespace. Pod labels do not exist at the IP address level, so a network policy generates a separate Open vSwitch (OVS) flow rule for every possible link between every pod selected with a **podSelector**.

For example, if the spec **podSelector** and the ingress **podSelector** within a **NetworkPolicy** object each match 200 pods, then 40,000 (200*200) OVS flow rules are generated. This might slow down a node.

When designing your network policy, refer to the following guidelines:

- Reduce the number of OVS flow rules by using namespaces to contain groups of pods that need to be isolated.
NetworkPolicy objects that select a whole namespace, by using the **namespaceSelector** or an empty **podSelector**, generate only a single OVS flow rule that matches the VXLAN virtual network ID (VNID) of the namespace.
- Keep the pods that do not need to be isolated in their original namespace, and move the pods that require isolation into one or more different namespaces.
- Create additional targeted cross-namespace network policies to allow the specific traffic that you do want to allow from the isolated pods.

7.2.1.3. Optimizations for network policy with OVN-Kubernetes network plugin

When designing your network policy, refer to the following guidelines:

- For network policies with the same **spec.podSelector** spec, it is more efficient to use one network policy with multiple **ingress** or **egress** rules, than multiple network policies with subsets of **ingress** or **egress** rules.
- Every **ingress** or **egress** rule based on the **podSelector** or **namespaceSelector** spec generates the number of OVS flows proportional to **number of pods selected by network policy + number of pods selected by ingress or egress rule**. Therefore, it is preferable to use the **podSelector** or **namespaceSelector** spec that can select as many pods as you need in one rule, instead of creating individual rules for every pod.

For example, the following policy contains two rules:

```

apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: test-network-policy
spec:
  podSelector: {}
  ingress:
  - from:

```

- podSelector:
 - matchLabels:
 - role: frontend
- from:
 - podSelector:
 - matchLabels:
 - role: backend

The following policy expresses those same two rules as one:

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: test-network-policy
spec:
  podSelector: {}
  ingress:
  - from:
    - podSelector:
      matchExpressions:
      - {key: role, operator: In, values: [frontend, backend]}
```

The same guideline applies to the **spec.podSelector** spec. If you have the same **ingress** or **egress** rules for different network policies, it might be more efficient to create one network policy with a common **spec.podSelector** spec. For example, the following two policies have different rules:

```
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: policy1
spec:
  podSelector:
    matchLabels:
      role: db
  ingress:
  - from:
    - podSelector:
      matchLabels:
        role: frontend
---
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: policy2
spec:
  podSelector:
    matchLabels:
      role: client
  ingress:
  - from:
    - podSelector:
      matchLabels:
        role: frontend
```

The following network policy expresses those same two rules as one:

```

apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: policy3
spec:
  podSelector:
    matchExpressions:
      - {key: role, operator: In, values: [db, client]}
  ingress:
    - from:
      - podSelector:
          matchLabels:
            role: frontend

```

You can apply this optimization when only multiple selectors are expressed as one. In cases where selectors are based on different labels, it may not be possible to apply this optimization. In those cases, consider applying some new labels for network policy optimization specifically.

7.2.1.4. Next steps

- [Creating a network policy](#)

7.2.2. Creating a network policy

As a user with the **admin** role, you can create a network policy for a namespace.

7.2.2.1. Example NetworkPolicy object

The following annotates an example NetworkPolicy object:

```

kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: allow-27107 1
spec:
  podSelector: 2
    matchLabels:
      app: mongodb
  ingress:
    - from:
      - podSelector: 3
          matchLabels:
            app: app
  ports: 4
    - protocol: TCP
      port: 27017

```

- 1** The name of the NetworkPolicy object.
- 2** A selector that describes the pods to which the policy applies. The policy object can only select pods in the project that defines the NetworkPolicy object.

- 3 A selector that matches the pods from which the policy object allows ingress traffic. The selector matches pods in the same namespace as the NetworkPolicy.
- 4 A list of one or more destination ports on which to accept traffic.

7.2.2.2. Creating a network policy using the CLI

To define granular rules describing ingress or egress network traffic allowed for namespaces in your cluster, you can create a network policy.

NOTE

If you log in with a user with the **cluster-admin** role, then you can create a network policy in any namespace in the cluster.

Prerequisites

- Your cluster uses a network plugin that supports **NetworkPolicy** objects, such as the OVN-Kubernetes network plugin or the OpenShift SDN network plugin with **mode: NetworkPolicy** set. This mode is the default for OpenShift SDN.
- You installed the OpenShift CLI (**oc**).
- You are logged in to the cluster with a user with **admin** privileges.
- You are working in the namespace that the network policy applies to.

Procedure

1. Create a policy rule:
 - a. Create a **<policy_name>.yaml** file:

```
$ touch <policy_name>.yaml
```

where:

<policy_name>

Specifies the network policy file name.

- b. Define a network policy in the file that you just created, such as in the following examples:

Deny ingress from all pods in all namespaces

This is a fundamental policy, blocking all cross-pod networking other than cross-pod traffic allowed by the configuration of other Network Policies.

```
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: deny-by-default
spec:
  podSelector: {}
```

```

policyTypes:
- Ingress
ingress: []

```

Allow ingress from all pods in the same namespace

```

kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: allow-same-namespace
spec:
  podSelector:
  ingress:
  - from:
    - podSelector: {}

```

Allow ingress traffic to one pod from a particular namespace

This policy allows traffic to pods labelled **pod-a** from pods running in **namespace-y**.

```

kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: allow-traffic-pod
spec:
  podSelector:
    matchLabels:
      pod: pod-a
  policyTypes:
  - Ingress
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          kubernetes.io/metadata.name: namespace-y

```

- To create the network policy object, enter the following command:

```
$ oc apply -f <policy_name>.yaml -n <namespace>
```

where:

<policy_name>

Specifies the network policy file name.

<namespace>

Optional: Specifies the namespace if the object is defined in a different namespace than the current namespace.

Example output

```
networkpolicy.networking.k8s.io/deny-by-default created
```

**NOTE**

If you log in to the web console with **cluster-admin** privileges, you have a choice of creating a network policy in any namespace in the cluster directly in YAML or from a form in the web console.

7.2.2.3. Creating a default deny all network policy

This is a fundamental policy, blocking all cross-pod networking other than network traffic allowed by the configuration of other deployed network policies. This procedure enforces a default **deny-by-default** policy.

**NOTE**

If you log in with a user with the **cluster-admin** role, then you can create a network policy in any namespace in the cluster.

Prerequisites

- Your cluster uses a network plugin that supports **NetworkPolicy** objects, such as the OVN-Kubernetes network plugin or the OpenShift SDN network plugin with **mode: NetworkPolicy** set. This mode is the default for OpenShift SDN.
- You installed the OpenShift CLI (**oc**).
- You are logged in to the cluster with a user with **admin** privileges.
- You are working in the namespace that the network policy applies to.

Procedure

1. Create the following YAML that defines a **deny-by-default** policy to deny ingress from all pods in all namespaces. Save the YAML in the **deny-by-default.yaml** file:

```
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: deny-by-default
  namespace: default 1
spec:
  podSelector: {} 2
  ingress: [] 3
```

- 1 namespace: default** deploys this policy to the **default** namespace.
- 2 podSelector:** is empty, this means it matches all the pods. Therefore, the policy applies to all pods in the default namespace.
- 3** There are no **ingress** rules specified. This causes incoming traffic to be dropped to all pods.

2. Apply the policy by entering the following command:

```
$ oc apply -f deny-by-default.yaml
```

-

Example output

```
networkpolicy.networking.k8s.io/deny-by-default created
```

7.2.2.4. Creating a network policy to allow traffic from external clients

With the **deny-by-default** policy in place you can proceed to configure a policy that allows traffic from external clients to a pod with the label **app=web**.

NOTE

If you log in with a user with the **cluster-admin** role, then you can create a network policy in any namespace in the cluster.

Follow this procedure to configure a policy that allows external service from the public Internet directly or by using a Load Balancer to access the pod. Traffic is only allowed to a pod with the label **app=web**.

Prerequisites

- Your cluster uses a network plugin that supports **NetworkPolicy** objects, such as the OVN-Kubernetes network plugin or the OpenShift SDN network plugin with **mode: NetworkPolicy** set. This mode is the default for OpenShift SDN.
- You installed the OpenShift CLI (**oc**).
- You are logged in to the cluster with a user with **admin** privileges.
- You are working in the namespace that the network policy applies to.

Procedure

1. Create a policy that allows traffic from the public Internet directly or by using a load balancer to access the pod. Save the YAML in the **web-allow-external.yaml** file:

```
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: web-allow-external
  namespace: default
spec:
  policyTypes:
  - Ingress
  podSelector:
    matchLabels:
      app: web
  ingress:
  - {}
```

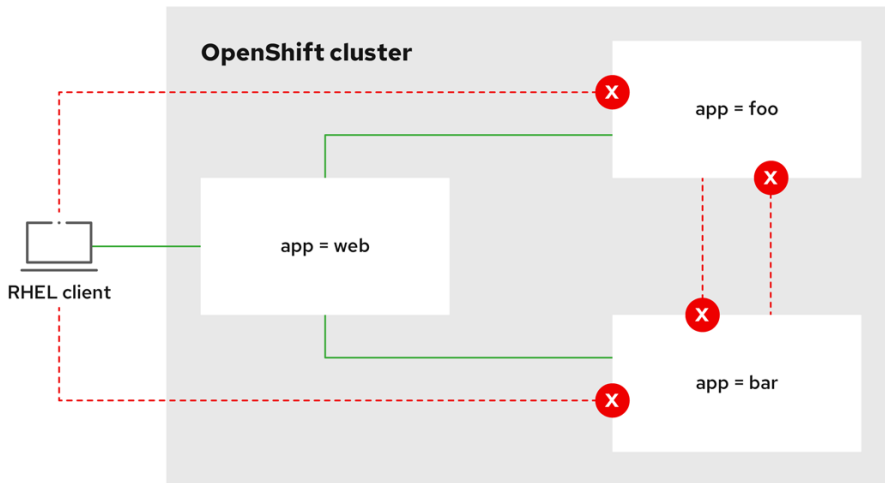

2. Apply the policy by entering the following command:

```
$ oc apply -f web-allow-external.yaml
```

Example output

```
networkpolicy.networking.k8s.io/web-allow-external created
```

This policy allows traffic from all resources, including external traffic as illustrated in the following diagram:

292_OpenShift_1122

7.2.2.5. Creating a network policy allowing traffic to an application from all namespaces

NOTE

If you log in with a user with the **cluster-admin** role, then you can create a network policy in any namespace in the cluster.

Follow this procedure to configure a policy that allows traffic from all pods in all namespaces to a particular application.

Prerequisites

- Your cluster uses a network plugin that supports **NetworkPolicy** objects, such as the OVN-Kubernetes network plugin or the OpenShift SDN network plugin with **mode: NetworkPolicy** set. This mode is the default for OpenShift SDN.
- You installed the OpenShift CLI (**oc**).
- You are logged in to the cluster with a user with **admin** privileges.
- You are working in the namespace that the network policy applies to.

Procedure

1. Create a policy that allows traffic from all pods in all namespaces to a particular application. Save the YAML in the **web-allow-all-namespaces.yaml** file:

```
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: web-allow-all-namespaces
```

```

namespace: default
spec:
  podSelector:
    matchLabels:
      app: web ❶
  policyTypes:
  - Ingress
  ingress:
  - from:
    - namespaceSelector: {} ❷

```

- ❶ Applies the policy only to **app:web** pods in default namespace.
- ❷ Selects all pods in all namespaces.

NOTE

By default, if you omit specifying a **namespaceSelector** it does not select any namespaces, which means the policy allows traffic only from the namespace the network policy is deployed to.

2. Apply the policy by entering the following command:

```
$ oc apply -f web-allow-all-namespaces.yaml
```

Example output

```
networkpolicy.networking.k8s.io/web-allow-all-namespaces created
```

Verification

1. Start a web service in the **default** namespace by entering the following command:

```
$ oc run web --namespace=default --image=nginx --labels="app=web" --expose --port=80
```

2. Run the following command to deploy an **alpine** image in the **secondary** namespace and to start a shell:

```
$ oc run test-$RANDOM --namespace=secondary --rm -i -t --image=alpine -- sh
```

3. Run the following command in the shell and observe that the request is allowed:

```
# wget -qO- --timeout=2 http://web.default
```

Expected output

```

<!DOCTYPE html>
<html>
<head>
<title>Welcome to nginx!</title>

```

```

<style>
html { color-scheme: light dark; }
body { width: 35em; margin: 0 auto;
font-family: Tahoma, Verdana, Arial, sans-serif; }
</style>
</head>
<body>
<h1>Welcome to nginx!</h1>
<p>If you see this page, the nginx web server is successfully installed and
working. Further configuration is required.</p>

<p>For online documentation and support please refer to
<a href="http://nginx.org/">nginx.org</a>.<br/>

<a href="http://nginx.com/">nginx.com</a>.</p>

<p><em>Thank you for using nginx.</em></p>
</body>
</html>

```

7.2.2.6. Creating a network policy allowing traffic to an application from a namespace

NOTE

If you log in with a user with the **cluster-admin** role, then you can create a network policy in any namespace in the cluster.

Follow this procedure to configure a policy that allows traffic to a pod with the label **app=web** from a particular namespace. You might want to do this to:

- Restrict traffic to a production database only to namespaces where production workloads are deployed.
- Enable monitoring tools deployed to a particular namespace to scrape metrics from the current namespace.

Prerequisites

- Your cluster uses a network plugin that supports **NetworkPolicy** objects, such as the OVN-Kubernetes network plugin or the OpenShift SDN network plugin with **mode: NetworkPolicy** set. This mode is the default for OpenShift SDN.
- You installed the OpenShift CLI (**oc**).
- You are logged in to the cluster with a user with **admin** privileges.
- You are working in the namespace that the network policy applies to.

Procedure

1. Create a policy that allows traffic from all pods in a particular namespaces with a label **purpose=production**. Save the YAML in the **web-allow-prod.yaml** file:

```
kind: NetworkPolicy
```

```

apiVersion: networking.k8s.io/v1
metadata:
  name: web-allow-prod
  namespace: default
spec:
  podSelector:
    matchLabels:
      app: web ❶
  policyTypes:
  - Ingress
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          purpose: production ❷

```

- ❶ Applies the policy only to **app:web** pods in the default namespace.
- ❷ Restricts traffic to only pods in namespaces that have the label **purpose=production**.

2. Apply the policy by entering the following command:

```
$ oc apply -f web-allow-prod.yaml
```

Example output

```
networkpolicy.networking.k8s.io/web-allow-prod created
```

Verification

1. Start a web service in the **default** namespace by entering the following command:

```
$ oc run web --namespace=default --image=nginx --labels="app=web" --expose --port=80
```

2. Run the following command to create the **prod** namespace:

```
$ oc create namespace prod
```

3. Run the following command to label the **prod** namespace:

```
$ oc label namespace/prod purpose=production
```

4. Run the following command to create the **dev** namespace:

```
$ oc create namespace dev
```

5. Run the following command to label the **dev** namespace:

```
$ oc label namespace/dev purpose=testing
```

6. Run the following command to deploy an **alpine** image in the **dev** namespace and to start a shell:

```
$ oc run test-$RANDOM --namespace=dev --rm -i -t --image=alpine -- sh
```

7. Run the following command in the shell and observe that the request is blocked:

```
# wget -qO- --timeout=2 http://web.default
```

Expected output

```
wget: download timed out
```

8. Run the following command to deploy an **alpine** image in the **prod** namespace and start a shell:

```
$ oc run test-$RANDOM --namespace=prod --rm -i -t --image=alpine -- sh
```

9. Run the following command in the shell and observe that the request is allowed:

```
# wget -qO- --timeout=2 http://web.default
```

Expected output

```
<!DOCTYPE html>
<html>
<head>
<title>Welcome to nginx!</title>
<style>
html { color-scheme: light dark; }
body { width: 35em; margin: 0 auto;
font-family: Tahoma, Verdana, Arial, sans-serif; }
</style>
</head>
<body>
<h1>Welcome to nginx!</h1>
<p>If you see this page, the nginx web server is successfully installed and
working. Further configuration is required.</p>

<p>For online documentation and support please refer to
<a href="http://nginx.org/">nginx.org</a>.<br/>
Commercial support is available at
<a href="http://nginx.com/">nginx.com</a>.</p>

<p><em>Thank you for using nginx.</em></p>
</body>
</html>
```

7.2.2.7. Creating a network policy using OpenShift Cluster Manager

To define granular rules describing the ingress or egress network traffic allowed for namespaces in your cluster, you can create a network policy.

Prerequisites

- You logged in to [OpenShift Cluster Manager](#).
- You created an OpenShift Dedicated cluster.
- You configured an identity provider for your cluster.
- You added your user account to the configured identity provider.
- You created a project within your OpenShift Dedicated cluster.

Procedure

1. From [OpenShift Cluster Manager](#), click on the cluster you want to access.
2. Click **Open console** to navigate to the OpenShift web console.
3. Click on your identity provider and provide your credentials to log in to the cluster.
4. From the administrator perspective, under **Networking**, click **NetworkPolicies**.
5. Click **Create NetworkPolicy**.
6. Provide a name for the policy in the **Policy name** field.
7. Optional: You can provide the label and selector for a specific pod if this policy applies only to one or more specific pods. If you do not select a specific pod, then this policy will be applicable to all pods on the cluster.
8. Optional: You can block all ingress and egress traffic by using the **Deny all ingress traffic** or **Deny all egress traffic** checkboxes.
9. You can also add any combination of ingress and egress rules, allowing you to specify the port, namespace, or IP blocks you want to approve.
10. Add ingress rules to your policy:
 - a. Select **Add ingress rule** to configure a new rule. This action creates a new **Ingress rule** row with an **Add allowed source** drop-down menu that enables you to specify how you want to limit inbound traffic. The drop-down menu offers three options to limit your ingress traffic:
 - **Allow pods from the same namespace** limits traffic to pods within the same namespace. You can specify the pods in a namespace, but leaving this option blank allows all of the traffic from pods in the namespace.
 - **Allow pods from inside the cluster** limits traffic to pods within the same cluster as the policy. You can specify namespaces and pods from which you want to allow inbound traffic. Leaving this option blank allows inbound traffic from all namespaces and pods within this cluster.
 - **Allow peers by IP block** limits traffic from a specified Classless Inter-Domain Routing (CIDR) IP block. You can block certain IPs with the exceptions option. Leaving the CIDR field blank allows all inbound traffic from all external sources.
 - b. You can restrict all of your inbound traffic to a port. If you do not add any ports then all ports are accessible to traffic.

11. Add egress rules to your network policy:

- a. Select **Add egress rule** to configure a new rule. This action creates a new **Egress rule** row with an **Add allowed destination*** drop-down menu that enables you to specify how you want to limit outbound traffic. The drop-down menu offers three options to limit your egress traffic:
 - **Allow pods from the same namespace** limits outbound traffic to pods within the same namespace. You can specify the pods in a namespace, but leaving this option blank allows all of the traffic from pods in the namespace.
 - **Allow pods from inside the cluster** limits traffic to pods within the same cluster as the policy. You can specify namespaces and pods from which you want to allow outbound traffic. Leaving this option blank allows outbound traffic from all namespaces and pods within this cluster.
 - **Allow peers by IP block** limits traffic from a specified CIDR IP block. You can block certain IPs with the exceptions option. Leaving the CIDR field blank allows all outbound traffic from all external sources.
- b. You can restrict all of your outbound traffic to a port. If you do not add any ports then all ports are accessible to traffic.

7.2.3. Viewing a network policy

As a user with the **admin** role, you can view a network policy for a namespace.

7.2.3.1. Example NetworkPolicy object

The following annotates an example NetworkPolicy object:

```
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: allow-27107 1
spec:
  podSelector: 2
    matchLabels:
      app: mongodb
  ingress:
  - from:
    - podSelector: 3
      matchLabels:
        app: app
  ports: 4
  - protocol: TCP
    port: 27017
```

1 The name of the NetworkPolicy object.

2 A selector that describes the pods to which the policy applies. The policy object can only select pods in the project that defines the NetworkPolicy object.

3 A selector that matches the pods from which the policy object allows ingress traffic. The selector matches pods in the same namespace as the NetworkPolicy.

- 4 A list of one or more destination ports on which to accept traffic.

7.2.3.2. Viewing network policies using the CLI

You can examine the network policies in a namespace.

NOTE

If you log in with a user with the **cluster-admin** role, then you can view any network policy in the cluster.

Prerequisites

- You installed the OpenShift CLI (**oc**).
- You are logged in to the cluster with a user with **admin** privileges.
- You are working in the namespace where the network policy exists.

Procedure

- List network policies in a namespace:
 - To view network policy objects defined in a namespace, enter the following command:

```
$ oc get networkpolicy
```

- Optional: To examine a specific network policy, enter the following command:

```
$ oc describe networkpolicy <policy_name> -n <namespace>
```

where:

<policy_name>

Specifies the name of the network policy to inspect.

<namespace>

Optional: Specifies the namespace if the object is defined in a different namespace than the current namespace.

For example:

```
$ oc describe networkpolicy allow-same-namespace
```

Output for **oc describe** command

```
Name:      allow-same-namespace
Namespace: ns1
Created on: 2021-05-24 22:28:56 -0400 EDT
Labels:    <none>
Annotations: <none>
Spec:
```

```
PodSelector: <none> (Allowing the specific traffic to all pods in this namespace)
Allowing ingress traffic:
  To Port: <any> (traffic allowed to all ports)
  From:
    PodSelector: <none>
Not affecting egress traffic
Policy Types: Ingress
```

**NOTE**

If you log in to the web console with **cluster-admin** privileges, you have a choice of viewing a network policy in any namespace in the cluster directly in YAML or from a form in the web console.

7.2.3.3. Viewing network policies using OpenShift Cluster Manager

You can view the configuration details of your network policy in Red Hat OpenShift Cluster Manager.

Prerequisites

- You logged in to [OpenShift Cluster Manager](#).
- You created an OpenShift Dedicated cluster.
- You configured an identity provider for your cluster.
- You added your user account to the configured identity provider.
- You created a network policy.

Procedure

1. From the **Administrator** perspective in the OpenShift Cluster Manager web console, under **Networking**, click **NetworkPolicies**.
2. Select the desired network policy to view.
3. In the **Network Policy** details page, you can view all of the associated ingress and egress rules.
4. Select **YAML** on the network policy details to view the policy configuration in YAML format.

**NOTE**

You can only view the details of these policies. You cannot edit these policies.

7.2.4. Deleting a network policy

As a user with the **admin** role, you can delete a network policy from a namespace.

7.2.4.1. Deleting a network policy using the CLI

You can delete a network policy in a namespace.

**NOTE**

If you log in with a user with the **cluster-admin** role, then you can delete any network policy in the cluster.

Prerequisites

- Your cluster uses a network plugin that supports **NetworkPolicy** objects, such as the OVN-Kubernetes network plugin or the OpenShift SDN network plugin with **mode: NetworkPolicy** set. This mode is the default for OpenShift SDN.
- You installed the OpenShift CLI (**oc**).
- You are logged in to the cluster with a user with **admin** privileges.
- You are working in the namespace where the network policy exists.

Procedure

- To delete a network policy object, enter the following command:

```
$ oc delete networkpolicy <policy_name> -n <namespace>
```

where:

<policy_name>

Specifies the name of the network policy.

<namespace>

Optional: Specifies the namespace if the object is defined in a different namespace than the current namespace.

Example output

```
networkpolicy.networking.k8s.io/default-deny deleted
```

**NOTE**

If you log in to the web console with **cluster-admin** privileges, you have a choice of deleting a network policy in any namespace in the cluster directly in YAML or from the policy in the web console through the **Actions** menu.

7.2.4.2. Deleting a network policy using OpenShift Cluster Manager

You can delete a network policy in a namespace.

Prerequisites

- You logged in to [OpenShift Cluster Manager](#).
- You created an OpenShift Dedicated cluster.
- You configured an identity provider for your cluster.

- You added your user account to the configured identity provider.

Procedure

1. From the **Administrator** perspective in the OpenShift Cluster Manager web console, under **Networking**, click **NetworkPolicies**.
2. Use one of the following methods for deleting your network policy:
 - Delete the policy from the **Network Policies** table:
 - a. From the **Network Policies** table, select the stack menu on the row of the network policy you want to delete and then, click **Delete NetworkPolicy**.
 - Delete the policy using the **Actions** drop-down menu from the individual network policy details:
 - a. Click on **Actions** drop-down menu for your network policy.
 - b. Select **Delete NetworkPolicy** from the menu.

7.2.5. Configuring multitenant isolation with network policy

As a cluster administrator, you can configure your network policies to provide multitenant network isolation.

NOTE

If you are using the OpenShift SDN network plugin, configuring network policies as described in this section provides network isolation similar to multitenant mode but with network policy mode set.

7.2.5.1. Configuring multitenant isolation by using network policy

You can configure your project to isolate it from pods and services in other project namespaces.

Prerequisites

- Your cluster uses a network plugin that supports **NetworkPolicy** objects, such as the OVN-Kubernetes network plugin or the OpenShift SDN network plugin with **mode: NetworkPolicy** set. This mode is the default for OpenShift SDN.
- You installed the OpenShift CLI (**oc**).
- You are logged in to the cluster with a user with **admin** privileges.

Procedure

1. Create the following **NetworkPolicy** objects:
 - a. A policy named **allow-from-openshift-ingress**.

```
$ cat << EOF | oc create -f -
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
```

```

name: allow-from-openshift-ingress
spec:
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          policy-group.network.openshift.io/ingress: ""
    podSelector: {}
  policyTypes:
  - Ingress
EOF

```

**NOTE**

policy-group.network.openshift.io/ingress: "" is the preferred namespace selector label for OpenShift SDN. You can use the **network.openshift.io/policy-group: ingress** namespace selector label, but this is a legacy label.

- b. A policy named **allow-from-openshift-monitoring**:

```

$ cat << EOF | oc create -f -
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: allow-from-openshift-monitoring
spec:
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          network.openshift.io/policy-group: monitoring
    podSelector: {}
  policyTypes:
  - Ingress
EOF

```

- c. A policy named **allow-same-namespace**:

```

$ cat << EOF | oc create -f -
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
  name: allow-same-namespace
spec:
  podSelector:
  ingress:
  - from:
    - podSelector: {}
EOF

```

- d. A policy named **allow-from-kube-apiserver-operator**:

```

$ cat << EOF | oc create -f -

```

```

apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: allow-from-kube-apiserver-operator
spec:
  ingress:
  - from:
    - namespaceSelector:
        matchLabels:
          kubernetes.io/metadata.name: openshift-kube-apiserver-operator
      podSelector:
        matchLabels:
          app: kube-apiserver-operator
  policyTypes:
  - Ingress
EOF

```

For more details, see [New kube-apiserver-operator webhook controller validating health of webhook](#).

- Optional: To confirm that the network policies exist in your current project, enter the following command:

```
$ oc describe networkpolicy
```

Example output

```

Name:      allow-from-openshift-ingress

CHAPTER 8. CONFIGURING ROUTES

8.1. ROUTE CONFIGURATION

8.1.1. Creating an HTTP-based route

A route allows you to host your application at a public URL. It can either be secure or unsecured, depending on the network security configuration of your application. An HTTP-based route is an unsecured route that uses the basic HTTP routing protocol and exposes a service on an unsecured application port.

The following procedure describes how to create a simple HTTP-based route to a web application, using the **hello-openshift** application as an example.

Prerequisites

- You installed the OpenShift CLI (**oc**).
- You are logged in as an administrator.
- You have a web application that exposes a port and a TCP endpoint listening for traffic on the port.

Procedure

1. Create a project called **hello-openshift** by running the following command:

```
$ oc new-project hello-openshift
```

2. Create a pod in the project by running the following command:

```
$ oc create -f https://raw.githubusercontent.com/openshift/origin/master/examples/hello-openshift/hello-pod.json
```

3. Create a service called **hello-openshift** by running the following command:

```
$ oc expose pod/hello-openshift
```

4. Create an unsecured route to the **hello-openshift** application by running the following command:

```
$ oc expose svc hello-openshift
```

Verification

- To verify that the **route** resource that you created, run the following command:

```
$ oc get routes -o yaml <name of resource> 1
```

- 1** In this example, the route is named **hello-openshift**.

Sample YAML definition of the created unsecured route:

```
apiVersion: route.openshift.io/v1
kind: Route
metadata:
  name: hello-openshift
spec:
  host: hello-openshift-hello-openshift.<Ingress_Domain> 1
  port:
    targetPort: 8080 2
  to:
    kind: Service
    name: hello-openshift
```

- 1 **<Ingress_Domain>** is the default ingress domain name. The **ingresses.config/cluster** object is created during the installation and cannot be changed. If you want to specify a different domain, you can specify an alternative cluster domain using the **appsDomain** option.
- 2 **targetPort** is the target port on pods that is selected by the service that this route points to.

NOTE

To display your default ingress domain, run the following command:

```
$ oc get ingresses.config/cluster -o jsonpath={.spec.domain}
```

8.1.2. Configuring route timeouts

You can configure the default timeouts for an existing route when you have services in need of a low timeout, which is required for Service Level Availability (SLA) purposes, or a high timeout, for cases with a slow back end.

Prerequisites

- You need a deployed Ingress Controller on a running cluster.

Procedure

1. Using the **oc annotate** command, add the timeout to the route:

```
$ oc annotate route <route_name> \
  --overwrite haproxy.router.openshift.io/timeout=<timeout><time_unit> 1
```

- 1 Supported time units are microseconds (us), milliseconds (ms), seconds (s), minutes (m), hours (h), or days (d).

The following example sets a timeout of two seconds on a route named **myroute**:

```
$ oc annotate route myroute --overwrite haproxy.router.openshift.io/timeout=2s
```

8.1.3. HTTP Strict Transport Security

HTTP Strict Transport Security (HSTS) policy is a security enhancement, which signals to the browser client that only HTTPS traffic is allowed on the route host. HSTS also optimizes web traffic by signaling HTTPS transport is required, without using HTTP redirects. HSTS is useful for speeding up interactions with websites.

When HSTS policy is enforced, HSTS adds a Strict Transport Security header to HTTP and HTTPS responses from the site. You can use the **insecureEdgeTerminationPolicy** value in a route to redirect HTTP to HTTPS. When HSTS is enforced, the client changes all requests from the HTTP URL to HTTPS before the request is sent, eliminating the need for a redirect.

Cluster administrators can configure HSTS to do the following:

- Enable HSTS per-route
- Disable HSTS per-route
- Enforce HSTS per-domain, for a set of domains, or use namespace labels in combination with domains

IMPORTANT

HSTS works only with secure routes, either edge-terminated or re-encrypt. The configuration is ineffective on HTTP or passthrough routes.

8.1.3.1. Enabling HTTP Strict Transport Security per-route

HTTP strict transport security (HSTS) is implemented in the HAProxy template and applied to edge and re-encrypt routes that have the **haproxy.router.openshift.io/hsts_header** annotation.

Prerequisites

- You are logged in to the cluster with a user with administrator privileges for the project.
- You installed the OpenShift CLI (**oc**).

Procedure

- To enable HSTS on a route, add the **haproxy.router.openshift.io/hsts_header** value to the edge-terminated or re-encrypt route. You can use the **oc annotate** tool to do this by running the following command:

```
$ oc annotate route <route_name> -n <namespace> --overwrite=true
"haproxy.router.openshift.io/hsts_header"="max-age=31536000;\
includeSubDomains;preload" 1
```

- 1** In this example, the maximum age is set to **31536000** ms, which is approximately 8.5 hours.

NOTE

In this example, the equal sign (=) is in quotes. This is required to properly execute the annotate command.

Example route configured with an annotation

```

apiVersion: route.openshift.io/v1
kind: Route
metadata:
  annotations:
    haproxy.router.openshift.io/hsts_header: max-age=31536000;includeSubDomains;preload
    1 2 3
  ...
spec:
  host: def.abc.com
  tls:
    termination: "reencrypt"
    ...
  wildcardPolicy: "Subdomain"

```

- 1 Required. **max-age** measures the length of time, in seconds, that the HSTS policy is in effect. If set to **0**, it negates the policy.
- 2 Optional. When included, **includeSubDomains** tells the client that all subdomains of the host must have the same HSTS policy as the host.
- 3 Optional. When **max-age** is greater than 0, you can add **preload** in **haproxy.router.openshift.io/hsts_header** to allow external services to include this site in their HSTS preload lists. For example, sites such as Google can construct a list of sites that have **preload** set. Browsers can then use these lists to determine which sites they can communicate with over HTTPS, even before they have interacted with the site. Without **preload** set, browsers must have interacted with the site over HTTPS, at least once, to get the header.

8.1.3.2. Disabling HTTP Strict Transport Security per-route

To disable HTTP strict transport security (HSTS) per-route, you can set the **max-age** value in the route annotation to **0**.

Prerequisites

- You are logged in to the cluster with a user with administrator privileges for the project.
- You installed the OpenShift CLI (**oc**).

Procedure

- To disable HSTS, set the **max-age** value in the route annotation to **0**, by entering the following command:

```

$ oc annotate route <route_name> -n <namespace> --overwrite=true
"haproxy.router.openshift.io/hsts_header"="max-age=0"

```

TIP

You can alternatively apply the following YAML to create the config map:

Example of disabling HSTS per-route

```
metadata:
  annotations:
    haproxy.router.openshift.io/hsts_header: max-age=0
```

- To disable HSTS for every route in a namespace, enter the following command:

```
$ oc annotate route --all -n <namespace> --overwrite=true
"haproxy.router.openshift.io/hsts_header"="max-age=0"
```

Verification

1. To query the annotation for all routes, enter the following command:

```
$ oc get route --all-namespaces -o go-template='{{range .items}}{{if .metadata.annotations}}
{{ $a := index .metadata.annotations "haproxy.router.openshift.io/hsts_header" }}{{ $n :=
.metadata.name }}{{with $a}}Name: {{ $n }} HSTS: {{ $a }}{{ "\n" }}{{ else }}{{ "" }}{{ end }}{{ end }}
{{ end }}'
```

Example output

```
Name: routename HSTS: max-age=0
```

8.1.4. Using cookies to keep route statefulness

OpenShift Dedicated provides sticky sessions, which enables stateful application traffic by ensuring all traffic hits the same endpoint. However, if the endpoint pod terminates, whether through restart, scaling, or a change in configuration, this statefulness can disappear.

OpenShift Dedicated can use cookies to configure session persistence. The ingress controller selects an endpoint to handle any user requests, and creates a cookie for the session. The cookie is passed back in the response to the request and the user sends the cookie back with the next request in the session. The cookie tells the ingress controller which endpoint is handling the session, ensuring that client requests use the cookie so that they are routed to the same pod.

**NOTE**

Cookies cannot be set on passthrough routes, because the HTTP traffic cannot be seen. Instead, a number is calculated based on the source IP address, which determines the backend.

If backends change, the traffic can be directed to the wrong server, making it less sticky. If you are using a load balancer, which hides source IP, the same number is set for all connections and traffic is sent to the same pod.

8.1.4.1. Annotating a route with a cookie

You can set a cookie name to overwrite the default, auto-generated one for the route. This allows the application receiving route traffic to know the cookie name. Deleting the cookie can force the next request to re-choose an endpoint. The result is that if a server is overloaded, that server tries to remove the requests from the client and redistribute them.

Procedure

1. Annotate the route with the specified cookie name:

```
$ oc annotate route <route_name> router.openshift.io/cookie_name="<cookie_name>"
```

where:

<route_name>

Specifies the name of the route.

<cookie_name>

Specifies the name for the cookie.

For example, to annotate the route **my_route** with the cookie name **my_cookie**:

```
$ oc annotate route my_route router.openshift.io/cookie_name="my_cookie"
```

2. Capture the route hostname in a variable:

```
$ ROUTE_NAME=$(oc get route <route_name> -o jsonpath='{.spec.host}')
```

where:

<route_name>

Specifies the name of the route.

3. Save the cookie, and then access the route:

```
$ curl $ROUTE_NAME -k -c /tmp/cookie_jar
```

Use the cookie saved by the previous command when connecting to the route:

```
$ curl $ROUTE_NAME -k -b /tmp/cookie_jar
```

8.1.5. Path-based routes

Path-based routes specify a path component that can be compared against a URL, which requires that the traffic for the route be HTTP based. Thus, multiple routes can be served using the same hostname, each with a different path. Routers should match routes based on the most specific path to the least.

The following table shows example routes and their accessibility:

Table 8.1. Route availability

Route	When Compared to	Accessible
<i>www.example.com/test</i>	<i>www.example.com/test</i>	Yes
	<i>www.example.com</i>	No
<i>www.example.com/test</i> and <i>www.example.com</i>	<i>www.example.com/test</i>	Yes
	<i>www.example.com</i>	Yes
<i>www.example.com</i>	<i>www.example.com/text</i>	Yes (Matched by the host, not the route)
	<i>www.example.com</i>	Yes

An unsecured route with a path

```

apiVersion: route.openshift.io/v1
kind: Route
metadata:
  name: route-unsecured
spec:
  host: www.example.com
  path: "/test" ❶
  to:
    kind: Service
    name: service-name

```

- ❶ The path is the only added attribute for a path-based route.

NOTE

Path-based routing is not available when using passthrough TLS, as the router does not terminate TLS in that case and cannot read the contents of the request.

8.1.6. HTTP header configuration

OpenShift Dedicated provides different methods for working with HTTP headers. When setting or deleting headers, you can use specific fields in the Ingress Controller or an individual route to modify request and response headers. You can also set certain headers by using route annotations. The various ways of configuring headers can present challenges when working together.

NOTE

You can only set or delete headers within an **IngressController** or **Route** CR, you cannot append them. If an HTTP header is set with a value, that value must be complete and not require appending in the future. In situations where it makes sense to append a header, such as the X-Forwarded-For header, use the **spec.httpHeaders.forwardedHeaderPolicy** field, instead of **spec.httpHeaders.actions**.

8.1.6.1. Order of precedence

When the same HTTP header is modified both in the Ingress Controller and in a route, HAProxy prioritizes the actions in certain ways depending on whether it is a request or response header.

- For HTTP response headers, actions specified in the Ingress Controller are executed after the actions specified in a route. This means that the actions specified in the Ingress Controller take precedence.
- For HTTP request headers, actions specified in a route are executed after the actions specified in the Ingress Controller. This means that the actions specified in the route take precedence.

For example, a cluster administrator sets the X-Frame-Options response header with the value **DENY** in the Ingress Controller using the following configuration:

Example IngressController spec

```
apiVersion: operator.openshift.io/v1
kind: IngressController
# ...
spec:
  httpHeaders:
    actions:
      response:
        - name: X-Frame-Options
          action:
            type: Set
            set:
              value: DENY
```

A route owner sets the same response header that the cluster administrator set in the Ingress Controller, but with the value **SAMEORIGIN** using the following configuration:

Example Route spec

```
apiVersion: route.openshift.io/v1
kind: Route
# ...
spec:
  httpHeaders:
    actions:
      response:
        - name: X-Frame-Options
          action:
            type: Set
            set:
              value: SAMEORIGIN
```

When both the **IngressController** spec and **Route** spec are configuring the X-Frame-Options response header, then the value set for this header at the global level in the Ingress Controller takes precedence, even if a specific route allows frames. For a request header, the **Route** spec value overrides the **IngressController** spec value.

This prioritization occurs because the **haproxy.config** file uses the following logic, where the Ingress Controller is considered the front end and individual routes are considered the back end. The header

value **DENY** applied to the front end configurations overrides the same header with the value **SAMEORIGIN** that is set in the back end:

```
frontend public
  http-response set-header X-Frame-Options 'DENY'

frontend fe_sni
  http-response set-header X-Frame-Options 'DENY'

frontend fe_no_sni
  http-response set-header X-Frame-Options 'DENY'

backend be_secure:openshift-monitoring:alertmanager-main
  http-response set-header X-Frame-Options 'SAMEORIGIN'
```

Additionally, any actions defined in either the Ingress Controller or a route override values set using route annotations.

8.1.6.2. Special case headers

The following headers are either prevented entirely from being set or deleted, or allowed under specific circumstances:

Table 8.2. Special case header configuration options

Header name	Configurable using IngressController spec	Configurable using Route spec	Reason for disallowment	Configurable using another method
proxy	No	No	The proxy HTTP request header can be used to exploit vulnerable CGI applications by injecting the header value into the HTTP_PROXY environment variable. The proxy HTTP request header is also non-standard and prone to error during configuration.	No

Header name	Configurable using IngressController spec	Configurable using Route spec	Reason for disallowment	Configurable using another method
host	No	Yes	When the host HTTP request header is set using the IngressController CR, HAProxy can fail when looking up the correct route.	No
strict-transport-security	No	No	The strict-transport-security HTTP response header is already handled using route annotations and does not need a separate implementation.	Yes: the haproxy.router.openshift.io/hosts_header route annotation
cookie and set-cookie	No	No	The cookies that HAProxy sets are used for session tracking to map client connections to particular back-end servers. Allowing these headers to be set could interfere with HAProxy's session affinity and restrict HAProxy's ownership of a cookie.	Yes: <ul style="list-style-type: none"> the haproxy.router.openshift.io/disable_cookie route annotation the haproxy.router.openshift.io/cookie_name route annotation

8.1.7. Setting or deleting HTTP request and response headers in a route

You can set or delete certain HTTP request and response headers for compliance purposes or other reasons. You can set or delete these headers either for all routes served by an Ingress Controller or for specific routes.

For example, you might want to enable a web application to serve content in alternate locations for specific routes if that content is written in multiple languages, even if there is a default global location specified by the Ingress Controller serving the routes.

The following procedure creates a route that sets the Content-Location HTTP request header so that the URL associated with the application, **https://app.example.com**, directs to the location **https://app.example.com/lang/en-us**. Directing application traffic to this location means that anyone using that specific route is accessing web content written in American English.

Prerequisites

- You have installed the OpenShift CLI (**oc**).
- You are logged into an OpenShift Dedicated cluster as a project administrator.
- You have a web application that exposes a port and an HTTP or TLS endpoint listening for traffic on the port.

Procedure

1. Create a route definition and save it in a file called **app-example-route.yaml**:

YAML definition of the created route with HTTP header directives

```

apiVersion: route.openshift.io/v1
kind: Route
# ...
spec:
  host: app.example.com
  tls:
    termination: edge
  to:
    kind: Service
    name: app-example
  httpHeaders:
    actions: 1
    response: 2
    - name: Content-Location 3
      action:
        type: Set 4
        set:
          value: /lang/en-us 5

```

- 1 The list of actions you want to perform on the HTTP headers.
- 2 The type of header you want to change. In this case, a response header.
- 3 The name of the header you want to change. For a list of available headers you can set or delete, see *HTTP header configuration*.
- 4 The type of action being taken on the header. This field can have the value **Set** or **Delete**.
- 5 When setting HTTP headers, you must provide a **value**. The value can be a string from a list of available directives for that header, for example **DENY**, or it can be a dynamic value that will be interpreted using HAProxy's dynamic value syntax. In this case, the value is set to the

relative location of the content.

2. Create a route to your existing web application using the newly created route definition:

```
$ oc -n app-example create -f app-example-route.yaml
```

For HTTP request headers, the actions specified in the route definitions are executed after any actions performed on HTTP request headers in the Ingress Controller. This means that any values set for those request headers in a route will take precedence over the ones set in the Ingress Controller. For more information on the processing order of HTTP headers, see *HTTP header configuration*.

8.1.8. Route-specific annotations

The Ingress Controller can set the default options for all the routes it exposes. An individual route can override some of these defaults by providing specific configurations in its annotations. Red Hat does not support adding a route annotation to an operator-managed route.

IMPORTANT

To create a whitelist with multiple source IPs or subnets, use a space-delimited list. Any other delimiter type causes the list to be ignored without a warning or error message.

Table 8.3. Route annotations

Variable	Description	Environment variable used as default
haproxy.router.openshift.io/balance	Sets the load-balancing algorithm. Available options are random , source , roundrobin , and leastconn . The default value is source for TLS passthrough routes. For all other routes, the default is random .	ROUTER_TCP_BALANCE_SCHEME for passthrough routes. Otherwise, use ROUTER_LOAD_BALANCE_ALGORITHM .
haproxy.router.openshift.io/disable_cookies	Disables the use of cookies to track related connections. If set to 'true' or 'TRUE' , the balance algorithm is used to choose which back-end serves connections for each incoming HTTP request.	
router.openshift.io/cookie_name	Specifies an optional cookie to use for this route. The name must consist of any combination of upper and lower case letters, digits, "_", and "-". The default is the hashed internal key name for the route.	

Variable	Description	Environment variable used as default
haproxy.router.openshift.io/pod-concurrent-connections	Sets the maximum number of connections that are allowed to a backing pod from a router. Note: If there are multiple pods, each can have this many connections. If you have multiple routers, there is no coordination among them, each may connect this many times. If not set, or set to 0, there is no limit.	
haproxy.router.openshift.io/rate-limit-connections	Setting 'true' or 'TRUE' enables rate limiting functionality which is implemented through stick-tables on the specific backend per route. Note: Using this annotation provides basic protection against denial-of-service attacks.	
haproxy.router.openshift.io/rate-limit-connections.concurrent-tcp	Limits the number of concurrent TCP connections made through the same source IP address. It accepts a numeric value. Note: Using this annotation provides basic protection against denial-of-service attacks.	
haproxy.router.openshift.io/rate-limit-connections.rate-http	Limits the rate at which a client with the same source IP address can make HTTP requests. It accepts a numeric value. Note: Using this annotation provides basic protection against denial-of-service attacks.	
haproxy.router.openshift.io/rate-limit-connections.rate-tcp	Limits the rate at which a client with the same source IP address can make TCP connections. It accepts a numeric value. Note: Using this annotation provides basic protection against denial-of-service attacks.	
haproxy.router.openshift.io/timeout	Sets a server-side timeout for the route. (TimeUnits)	ROUTER_DEFAULT_SERVER_TIMEOUT

Variable	Description	Environment variable used as default
haproxy.router.openshift.io/timeout-tunnel	This timeout applies to a tunnel connection, for example, WebSocket over cleartext, edge, reencrypt, or passthrough routes. With cleartext, edge, or reencrypt route types, this annotation is applied as a timeout tunnel with the existing timeout value. For the passthrough route types, the annotation takes precedence over any existing timeout value set.	ROUTER_DEFAULT_TUNNEL_TIMEOUT
ingresses.config/cluster ingress.operator.openshift.io/hard-stop-after	You can set either an IngressController or the ingress config . This annotation redeploys the router and configures the HA proxy to emit the haproxy hard-stop-after global option, which defines the maximum time allowed to perform a clean soft-stop.	ROUTER_HARD_STOP_AFTER
router.openshift.io/haproxy.health.check.interval	Sets the interval for the back-end health checks. (TimeUnits)	ROUTER_BACKEND_CHECK_INTERVAL
haproxy.router.openshift.io/ipp_whitelist	<p>Sets an allowlist for the route. The allowlist is a space-separated list of IP addresses and CIDR ranges for the approved source addresses. Requests from IP addresses that are not in the allowlist are dropped.</p> <p>The maximum number of IP addresses and CIDR ranges directly visible in the haproxy.config file is 61. [1]</p>	
haproxy.router.openshift.io/https_header	Sets a Strict-Transport-Security header for the edge terminated or re-encrypt route.	
haproxy.router.openshift.io/rewrite-target	Sets the rewrite path of the request on the backend.	

Variable	Description	Environment variable used as default
router.openshift.io/cookie-same-site	<p>Sets a value to restrict cookies. The values are:</p> <p>Lax: the browser does not send cookies on cross-site requests, but does send cookies when users navigate to the origin site from an external site. This is the default browser behavior when the SameSite value is not specified.</p> <p>Strict: the browser sends cookies only for same-site requests.</p> <p>None: the browser sends cookies for both cross-site and same-site requests.</p> <p>This value is applicable to re-encrypt and edge routes only. For more information, see the SameSite cookies documentation.</p>	
haproxy.router.openshift.io/set-forwarded-headers	<p>Sets the policy for handling the Forwarded and X-Forwarded-For HTTP headers per route. The values are:</p> <p>append: appends the header, preserving any existing header. This is the default value.</p> <p>replace: sets the header, removing any existing header.</p> <p>never: never sets the header, but preserves any existing header.</p> <p>if-none: sets the header if it is not already set.</p>	ROUTER_SET_FORWARDED_HEADERS

1. If the number of IP addresses and CIDR ranges in an allowlist exceeds 61, they are written into a separate file that is then referenced from **haproxy.config**. This file is stored in the **var/lib/haproxy/router/whitelists** folder.

**NOTE**

To ensure that the addresses are written to the allowlist, check that the full list of CIDR ranges are listed in the Ingress Controller configuration file. The etcd object size limit restricts how large a route annotation can be. Because of this, it creates a threshold for the maximum number of IP addresses and CIDR ranges that you can include in an allowlist.

**NOTE**

Environment variables cannot be edited.

Router timeout variables

TimeUnits are represented by a number followed by the unit: **us** *(microseconds), **ms** (milliseconds, default), **s** (seconds), **m** (minutes), **h** *(hours), **d** (days).

The regular expression is: `[1-9][0-9]*(us|ms|s|m|h|d)`.

Variable	Default	Description
ROUTER_BACKEND_CHECK_INTERVAL	5000ms	Length of time between subsequent liveness checks on back ends.
ROUTER_CLIENT_FIN_TIMEOUT	1s	Controls the TCP FIN timeout period for the client connecting to the route. If the FIN sent to close the connection does not answer within the given time, HAProxy closes the connection. This is harmless if set to a low value and uses fewer resources on the router.
ROUTER_DEFAULT_CLIENT_TIMEOUT	30s	Length of time that a client has to acknowledge or send data.
ROUTER_DEFAULT_CONNECT_TIMEOUT	5s	The maximum connection time.
ROUTER_DEFAULT_SERVER_FIN_TIMEOUT	1s	Controls the TCP FIN timeout from the router to the pod backing the route.
ROUTER_DEFAULT_SERVER_TIMEOUT	30s	Length of time that a server has to acknowledge or send data.
ROUTER_DEFAULT_TUNNEL_TIMEOUT	1h	Length of time for TCP or WebSocket connections to remain open. This timeout period resets whenever HAProxy reloads.

Variable	Default	Description
ROUTER_SLOWLORIS_HTTP_KEE PALIVE	300s	Set the maximum time to wait for a new HTTP request to appear. If this is set too low, it can cause problems with browsers and applications not expecting a small keepalive value. Some effective timeout values can be the sum of certain variables, rather than the specific expected timeout. For example, ROUTER_SLOWLORIS_HTTP_KEE PALIVE adjusts timeout http-keep-alive . It is set to 300s by default, but HAProxy also waits on tcp-request inspect-delay , which is set to 5s . In this case, the overall timeout would be 300s plus 5s .
ROUTER_SLOWLORIS_TIMEOUT	10s	Length of time the transmission of an HTTP request can take.
RELOAD_INTERVAL	5s	Allows the minimum frequency for the router to reload and accept new changes.
ROUTER_METRICS_HAPROXY_TIMEOUT	5s	Timeout for the gathering of HAProxy metrics.

A route setting custom timeout

```
apiVersion: route.openshift.io/v1
kind: Route
metadata:
  annotations:
    haproxy.router.openshift.io/timeout: 5500ms 1
...
```

- 1** Specifies the new timeout with HAProxy supported units (**us**, **ms**, **s**, **m**, **h**, **d**). If the unit is not provided, **ms** is the default.

NOTE

Setting a server-side timeout value for passthrough routes too low can cause WebSocket connections to timeout frequently on that route.

A route that allows only one specific IP address

```

metadata:
  annotations:
    haproxy.router.openshift.io/ip_whitelist: 192.168.1.10

```

A route that allows several IP addresses

```

metadata:
  annotations:
    haproxy.router.openshift.io/ip_whitelist: 192.168.1.10 192.168.1.11 192.168.1.12

```

A route that allows an IP address CIDR network

```

metadata:
  annotations:
    haproxy.router.openshift.io/ip_whitelist: 192.168.1.0/24

```

A route that allows both IP an address and IP address CIDR networks

```

metadata:
  annotations:
    haproxy.router.openshift.io/ip_whitelist: 180.5.61.153 192.168.1.0/24 10.0.0.0/8

```

A route specifying a rewrite target

```

apiVersion: route.openshift.io/v1
kind: Route
metadata:
  annotations:
    haproxy.router.openshift.io/rewrite-target: / 1
...

```

1 Sets / as rewrite path of the request on the backend.

Setting the **haproxy.router.openshift.io/rewrite-target** annotation on a route specifies that the Ingress Controller should rewrite paths in HTTP requests using this route before forwarding the requests to the backend application. The part of the request path that matches the path specified in **spec.path** is replaced with the rewrite target specified in the annotation.

The following table provides examples of the path rewriting behavior for various combinations of **spec.path**, request path, and rewrite target.

Table 8.4. rewrite-target examples:

Route.spec.path	Request path	Rewrite target	Forwarded request path
/foo	/foo	/	/
/foo	/foo/	/	/

Route.spec.path	Request path	Rewrite target	Forwarded request path
/foo	/foo/bar	/	/bar
/foo	/foo/bar/	/	/bar/
/foo	/foo	/bar	/bar
/foo	/foo/	/bar	/bar/
/foo	/foo/bar	/baz	/baz/bar
/foo	/foo/bar/	/baz	/baz/bar/
/foo/	/foo	/	N/A (request path does not match route path)
/foo/	/foo/	/	/
/foo/	/foo/bar	/	/bar

Certain special characters in **haproxy.router.openshift.io/rewrite-target** require special handling because they must be escaped properly. Refer to the following table to understand how these characters are handled.

Table 8.5. Special character handling:

For character	Use characters	Notes
#	\#	Avoid # because it terminates the rewrite expression
%	% or %%	Avoid odd sequences such as %%%
'	\'	Avoid ' because it is ignored

All other valid URL characters can be used without escaping.

8.1.9. Creating a route using the default certificate through an Ingress object

If you create an Ingress object without specifying any TLS configuration, OpenShift Dedicated generates an insecure route. To create an Ingress object that generates a secure, edge-terminated route using the default ingress certificate, you can specify an empty TLS configuration as follows.

Prerequisites

- You have a service that you want to expose.

- You have access to the OpenShift CLI (**oc**).

Procedure

1. Create a YAML file for the Ingress object. In this example, the file is called **example-ingress.yaml**:

YAML definition of an Ingress object

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: frontend
  ...
spec:
  rules:
    ...
  tls:
  - {} 1
```

- 1 Use this exact syntax to specify TLS without specifying a custom certificate.

2. Create the Ingress object by running the following command:

```
$ oc create -f example-ingress.yaml
```

Verification

- Verify that OpenShift Dedicated has created the expected route for the Ingress object by running the following command:

```
$ oc get routes -o yaml
```

Example output

```
apiVersion: v1
items:
- apiVersion: route.openshift.io/v1
  kind: Route
  metadata:
    name: frontend-j9sdd 1
    ...
  spec:
    ...
    tls: 2
      insecureEdgeTerminationPolicy: Redirect
      termination: edge 3
    ...
```

- 1 The name of the route includes the name of the Ingress object followed by a random suffix.
- 2 In order to use the default certificate, the route should not specify **spec.certificate**.

- 3 The route should specify the **edge** termination policy.

8.1.10. Creating a route using the destination CA certificate in the Ingress annotation

The **route.openshift.io/destination-ca-certificate-secret** annotation can be used on an Ingress object to define a route with a custom destination CA certificate.

Prerequisites

- You may have a certificate/key pair in PEM-encoded files, where the certificate is valid for the route host.
- You may have a separate CA certificate in a PEM-encoded file that completes the certificate chain.
- You must have a separate destination CA certificate in a PEM-encoded file.
- You must have a service that you want to expose.

Procedure

1. Add the **route.openshift.io/destination-ca-certificate-secret** to the Ingress annotations:

```
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: frontend
  annotations:
    route.openshift.io/termination: "reencrypt"
    route.openshift.io/destination-ca-certificate-secret: secret-ca-cert 1
  ...
```

- 1 The annotation references a kubernetes secret.

2. The secret referenced in this annotation will be inserted into the generated route.

Example output

```
apiVersion: route.openshift.io/v1
kind: Route
metadata:
  name: frontend
  annotations:
    route.openshift.io/termination: reencrypt
    route.openshift.io/destination-ca-certificate-secret: secret-ca-cert
spec:
  ...
  tls:
    insecureEdgeTerminationPolicy: Redirect
    termination: reencrypt
    destinationCACertificate: |
      -----BEGIN CERTIFICATE-----
```

```
[...]
-----END CERTIFICATE-----
...
```

Additional resources

- [Specifying an alternative cluster domain using the appsDomain option](#)

8.2. SECURED ROUTES

Secure routes provide the ability to use several types of TLS termination to serve certificates to the client. The following sections describe how to create re-encrypt, edge, and passthrough routes with custom certificates.

IMPORTANT

If you create routes in Microsoft Azure through public endpoints, the resource names are subject to restriction. You cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

8.2.1. Creating a re-encrypt route with a custom certificate

You can configure a secure route using reencrypt TLS termination with a custom certificate by using the **oc create route** command.

Prerequisites

- You must have a certificate/key pair in PEM-encoded files, where the certificate is valid for the route host.
- You may have a separate CA certificate in a PEM-encoded file that completes the certificate chain.
- You must have a separate destination CA certificate in a PEM-encoded file.
- You must have a service that you want to expose.

NOTE

Password protected key files are not supported. To remove a passphrase from a key file, use the following command:

```
$ openssl rsa -in password_protected_tls.key -out tls.key
```

Procedure

This procedure creates a **Route** resource with a custom certificate and reencrypt TLS termination. The following assumes that the certificate/key pair are in the **tls.crt** and **tls.key** files in the current working directory. You must also specify a destination CA certificate to enable the Ingress Controller to trust the service's certificate. You may also specify a CA certificate if needed to complete the certificate chain.

Substitute the actual path names for **tls.crt**, **tls.key**, **ca.crt**, and (optionally) **ca.crt**. Substitute the name of the **Service** resource that you want to expose for **frontend**. Substitute the appropriate hostname for **www.example.com**.

- Create a secure **Route** resource using reencrypt TLS termination and a custom certificate:

```
$ oc create route reencrypt --service=frontend --cert=tls.crt --key=tls.key --dest-ca-cert=destca.crt --ca-cert=ca.crt --hostname=www.example.com
```

If you examine the resulting **Route** resource, it should look similar to the following:

YAML Definition of the Secure Route

```
apiVersion: route.openshift.io/v1
kind: Route
metadata:
  name: frontend
spec:
  host: www.example.com
  to:
    kind: Service
    name: frontend
  tls:
    termination: reencrypt
    key: |-
      -----BEGIN PRIVATE KEY-----
      [...]
      -----END PRIVATE KEY-----
    certificate: |-
      -----BEGIN CERTIFICATE-----
      [...]
      -----END CERTIFICATE-----
    caCertificate: |-
      -----BEGIN CERTIFICATE-----
      [...]
      -----END CERTIFICATE-----
    destinationCACertificate: |-
      -----BEGIN CERTIFICATE-----
      [...]
      -----END CERTIFICATE-----
```

See **oc create route reencrypt --help** for more options.

8.2.2. Creating an edge route with a custom certificate

You can configure a secure route using edge TLS termination with a custom certificate by using the **oc create route** command. With an edge route, the Ingress Controller terminates TLS encryption before forwarding traffic to the destination pod. The route specifies the TLS certificate and key that the Ingress Controller uses for the route.

Prerequisites

- You must have a certificate/key pair in PEM-encoded files, where the certificate is valid for the route host.

- You may have a separate CA certificate in a PEM-encoded file that completes the certificate chain.
- You must have a service that you want to expose.

NOTE

Password protected key files are not supported. To remove a passphrase from a key file, use the following command:

```
$ openssl rsa -in password_protected_tls.key -out tls.key
```

Procedure

This procedure creates a **Route** resource with a custom certificate and edge TLS termination. The following assumes that the certificate/key pair are in the **tls.crt** and **tls.key** files in the current working directory. You may also specify a CA certificate if needed to complete the certificate chain. Substitute the actual path names for **tls.crt**, **tls.key**, and (optionally) **ca.crt**. Substitute the name of the service that you want to expose for **frontend**. Substitute the appropriate hostname for **www.example.com**.

- Create a secure **Route** resource using edge TLS termination and a custom certificate.

```
$ oc create route edge --service=frontend --cert=tls.crt --key=tls.key --ca-cert=ca.crt --hostname=www.example.com
```

If you examine the resulting **Route** resource, it should look similar to the following:

YAML Definition of the Secure Route

```
apiVersion: route.openshift.io/v1
kind: Route
metadata:
  name: frontend
spec:
  host: www.example.com
  to:
    kind: Service
    name: frontend
  tls:
    termination: edge
    key: |-
      -----BEGIN PRIVATE KEY-----
      [...]
      -----END PRIVATE KEY-----
    certificate: |-
      -----BEGIN CERTIFICATE-----
      [...]
      -----END CERTIFICATE-----
    caCertificate: |-
      -----BEGIN CERTIFICATE-----
      [...]
      -----END CERTIFICATE-----
```

See **oc create route edge --help** for more options.

8.2.3. Creating a passthrough route

You can configure a secure route using passthrough termination by using the **oc create route** command. With passthrough termination, encrypted traffic is sent straight to the destination without the router providing TLS termination. Therefore no key or certificate is required on the route.

Prerequisites

- You must have a service that you want to expose.

Procedure

- Create a **Route** resource:

```
$ oc create route passthrough route-passthrough-secured --service=frontend --port=8080
```

If you examine the resulting **Route** resource, it should look similar to the following:

A Secured Route Using Passthrough Termination

```
apiVersion: route.openshift.io/v1
kind: Route
metadata:
  name: route-passthrough-secured 1
spec:
  host: www.example.com
  port:
    targetPort: 8080
  tls:
    termination: passthrough 2
    insecureEdgeTerminationPolicy: None 3
  to:
    kind: Service
    name: frontend
```

- 1 The name of the object, which is limited to 63 characters.
- 2 The **termination** field is set to **passthrough**. This is the only required **tls** field.
- 3 Optional **insecureEdgeTerminationPolicy**. The only valid values are **None**, **Redirect**, or empty for disabled.

The destination pod is responsible for serving certificates for the traffic at the endpoint. This is currently the only method that can support requiring client certificates, also known as two-way authentication.

8.2.4. Creating a route with externally managed certificate

IMPORTANT

Securing route with external certificates in TLS secrets is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

You can configure OpenShift Dedicated routes with third-party certificate management solutions by using the **.spec.tls.externalCertificate** field of the route API. You can reference externally managed TLS certificates via secrets, eliminating the need for manual certificate management. Using the externally managed certificate reduces errors ensuring a smoother rollout of certificate updates, enabling the OpenShift router to serve renewed certificates promptly.

NOTE

This feature applies to both edge routes and re-encrypt routes.

Prerequisites

- You must enable the **RouteExternalCertificate** feature gate.
- You must have the **create** and **update** permissions on the **routes/custom-host**.
- You must have a secret containing a valid certificate/key pair in PEM-encoded format of type **kubernetes.io/tls**, which includes both **tls.key** and **tls.crt** keys.
- You must place the referenced secret in the same namespace as the route you want to secure.

Procedure

1. Create a **role** in the same namespace as the secret to allow the router service account read access by running the following command:

```
$ oc create role secret-reader --verb=get,list,watch --resource=secrets --resource-name=  
<secret-name> \ 1  
--namespace=<current-namespace> 2
```

- 1** Specify the actual name of your secret.
- 2** Specify the namespace where both your secret and route reside.

2. Create a **rolebinding** in the same namespace as the secret and bind the router service account to the newly created role by running the following command:

```
$ oc create rolebinding secret-reader-binding --role=secret-reader --  
serviceaccount=openshift-ingress:router --namespace=<current-namespace> 1
```

- 1** Specify the namespace where both your secret and route reside.

3. Create a YAML file that defines the **route** and specifies the secret containing your certificate using the following example.

YAML definition of the secure route

```

apiVersion: route.openshift.io/v1
kind: Route
metadata:
  name: myedge
  namespace: test
spec:
  host: myedge-test.apps.example.com
  tls:
    externalCertificate:
      name: <secret-name> 1
    termination: edge
  [...]
  [...]

```

- 1 Specify the actual name of your secret.

4. Create a **route** resource by running the following command:

```
$ oc apply -f <route.yaml> 1
```

- 1 Specify the generated YAML filename.

If the secret exists and has a certificate/key pair, the router will serve the generated certificate if all prerequisites are met.

NOTE

If **.spec.tls.externalCertificate** is not provided, the router will use default generated certificates.

You cannot provide the **.spec.tls.certificate** field or the **.spec.tls.key** field when using the **.spec.tls.externalCertificate** field.

Additional resources

- For troubleshooting routes with externally managed certificates, check the OpenShift Dedicated router pod logs for errors, see [Investigating pod issues](#).
