Abstract

This guide describes how to configure AMQ Broker.

Table of Contents

CHAPTER 1. OVERVIEW	7
1.1. AMQ BROKER CONFIGURATION FILES AND LOCATIONS	7
1.2. UNDERSTANDING THE DEFAULT BROKER CONFIGURATION	7
Default message persistence settings	7
Default acceptor settings	9
Default security settings	10
Default message address settings	10
1.3. RELOADING CONFIGURATION UPDATES	11
1.4. MODULARIZING THE BROKER CONFIGURATION FILE	12
1.5. DOCUMENT CONVENTIONS	13
The sudo command	13
About the use of file paths in this document	13
CHAPTER 2. NETWORK CONNECTIONS: ACCEPTORS AND CONNECTORS	14
2.1. ABOUT ACCEPTORS	14
Configuring an Acceptor	14
2.2. ABOUT CONNECTORS	15
Configuring a Connector	15
2.3. CONFIGURING A TCP CONNECTION	15
2.4. CONFIGURING AN HTTP CONNECTION	16
2.5. CONFIGURING AN SSL/TLS CONNECTION	17
2.6. CONFIGURING AN IN-VM CONNECTION	17
2.7. CONFIGURING A CONNECTION FROM THE CLIENT SIDE	17
CHAPTER 3. NETWORK CONNECTIONS: PROTOCOLS	19
3.1. CONFIGURING A NETWORK CONNECTION TO USE A PROTOCOL	19
3.2. USING AMQP WITH A NETWORK CONNECTION	20
3.2.1. Using an AMQP Link as a Topic	21
3.2.2. Configuring AMQP Security	21
3.3. USING MQTT WITH A NETWORK CONNECTION	21
3.4. USING OPENWIRE WITH A NETWORK CONNECTION	22
3.5. USING STOMP WITH A NETWORK CONNECTION	23
3.5.1. Knowing the Limitations When Using STOMP	23
3.5.2. Providing IDs for STOMP Messages	23
3.5.3. Setting a Connection's Time to Live (TTL)	24
Overriding the Broker's Default Time to Live (TTL)	24
3.5.4. Sending and Consuming STOMP Messages from JMS	25
3.5.5. Mapping STOMP Destinations to AMQ Broker Addresses and Queues	25
Mapping STOMP Destinations to JMS Destinations	26
CHAPTER 4. ADDRESSES, QUEUES, AND TOPICS	27
4.1. ADDRESS AND QUEUE NAMING REQUIREMENTS	27
4.2. CONFIGURING POINT-TO-POINT MESSAGING	28
4.3. CONFIGURING PUBLISH-SUBSCRIBE MESSAGING	28
4.4. CONFIGURING A POINT-TO-POINT USING TWO QUEUES	29
4.5. USING POINT-TO-POINT AND PUBLISH-SUBSCRIBE TOGETHER	30
4.6. CONFIGURING SUBSCRIPTION QUEUES	31
Configuring a Durable Subscription Queue	32
Configuring a Non-Shared Durable Subscription	32
4.7. USING A FULLY QUALIFIED QUEUE NAME	33
4.8. CONFIGURING SHARDED QUEUES	34
4.9. LIMITING THE NUMBER OF CONSUMERS CONNECTED TO A QUEUE	34

4.10. EXCLUSIVE QUEUES	35
4.10.1. Configuring Exclusive Queues	35
4.10.2. Setting the Exclusive Queue Default	36
4.11. CONFIGURING A PREFIX TO CONNECT TO A SPECIFIC ROUTING TYPE	36
4.12. PROTOCOL MANAGERS AND ADDRESSES	37
4.13. DISABLING ADVISORY MESSAGES	38
4.14. CONFIGURING ADDRESS SETTINGS	38
AMQ Broker Wildcard Syntax	38
Configuring Wildcard Syntax	39
4.15. CREATING AND DELETING QUEUES AND ADDRESSES AUTOMATICALLY	40
CHAPTER 5. USERS AND ROLES	43
5.1. ENABLING GUEST ACCESS	43
5.2. ADDING USERS	44
5.3. SETTING PERMISSIONS	45
5.3.1. Configuring Message Production for a Single Address	46
5.3.2. Configuring Message Consumption for a Single Address	46
5.3.3. Configuring Complete Access on All Addresses	47
5.3.4. Configuring a Queue with a User	47
5.4. SETTING ROLE BASED ACCESS CONTROL	48
5.4.1. Configuring Whitelist Element for Bypassing the Authentication	48
5.4.2. Configuring Authentication Based on Roles	48
CHAPTER 6. SECURITY	51
6.1. ACCESSING THE AMQ CONSOLE	51
6.2. SECURING NETWORK CONNECTIONS	51
6.2.1. Configuring Server-Side Certificates	51
6.2.2. Configuring Client-Side Certificates	51
TLS Configuration Details	52
6.2.3. Adding Certificate-based Authentication	54
6.2.4. Adding Certificate-based Authentication for AMQP Clients	57
Prerequisites	57
Procedure	57
Additional Resources	58
6.2.5. Using Multiple Login Modules	58
6.2.6. Configure Multiple Security Settings for Address Groups and Sub-groups	59
6.2.7. Setting Resource Limits	60
6.2.7.1. Configuring Connection and Queue Limits	61
6.3. INTEGRATING WITH LDAP	61
6.3.1. Using LDAP for Authentication	61
6.3.2. Configure LDAP Authorization	64
6.3.3. Encrypting the Password in the login.config File	67
6.4. INTEGRATING WITH KERBEROS	67
6.4.1. Enabling Network Connections to Use Kerberos	68
Prerequisites	68
Procedure	68
Related Information	69
6.4.2. Authenticating Clients with Kerberos Credentials	69
Prerequisites	69
Procedure	69
Related Information	70
6.4.2.1. Using an Alternative Configuration Scope	70
6.4.3. Authorizing Clients with Kerberos Credentials	71

Prerequisites	71
Procedure	71
Related Information	72
6.5. ENCRYPTING PASSWORDS IN CONFIGURATION FILES	72
6.6. DISABLING SECURITY	74
CHAPTER 7. PERSISTING MESSAGES	75
7.1. ABOUT JOURNAL-BASED PERSISTENCE	75
7.1.1. Using AIO	76
7.2. CONFIGURING JOURNAL-BASED PERSISTENCE	76
7.2.1. The Message Journal	77
7.2.2. The Bindings Journal	77
7.2.3. The JMS Journal	77
7.2.4. Compacting Journal Files	78
Compacting Journals Using the CLI	78
7.2.5. Disabling Disk Write Cache	79
7.3. CONFIGURING JDBC PERSISTENCE	79
7.4. CONFIGURING ZERO PERSISTENCE	80
CHAPTER 8. PAGING MESSAGES	81
8.1. ABOUT PAGE FILES	81
8.2. CONFIGURING THE PAGING DIRECTORY LOCATION	81
8.3. CONFIGURING AN ADDRESS FOR PAGING	82
8.4. CONFIGURING A GLOBAL PAGING SIZE	82
Configuring the global-max-size	83
8.5. LIMITING DISK USAGE WHEN PAGING	84
Configuring the max-disk-usage	84
8.6. HOW TO DROP MESSAGES	84
8.6.1. Dropping Messages and Throwing an Exception to Producers	85
8.7. HOW TO BLOCK PRODUCERS	85
8.8. CAUTION WITH ADDRESSES WITH MULTICAST QUEUES	85
CHAPTER 9. WORKING WITH LARGE MESSAGES	86
9.1. PREPARING BROKERS TO STORE LARGE MESSAGES	86
Procedure	86
Additional Resources	87
9.2. PREPARING AMQ CORE PROTOCOL JMS CLIENTS TO SEND LARGE MESSAGES	87
Procedure	87
9.3. PREPARING OPENWIRE CLIENTS TO SEND LARGE MESSAGES	88
Procedure	88
9.4. SENDING LARGE MESSAGES	88
Procedure	88
9.5. RECEIVING LARGE MESSAGES	89
Procedure	89
Receiving a Large Message Asynchronously	89
Procedure	89
9.6. LARGE MESSAGES AND JAVA CLIENTS	89
9.7. COMPRESSING LARGE MESSAGES	89
9.8. HANDLING LARGE MESSAGES WITH STOMP	90
CHAPTER 10. DETECTING DEAD CONNECTIONS	92
Detecting Dead Connections from the Client Side	92
10.1. CONNECTION TIME-TO-LIVE	93
Configuring Time-To-Live on the Broker	93

Configuring Time-To-Live on the Client	93
10.2. DISABLING ASYNCHRONOUS CONNECTION EXECUTION	94
10.3. CLOSING CONNECTIONS FROM THE CLIENT SIDE	94
CHAPTER 11. FLOW CONTROL	96
11.1. CONSUMER FLOW CONTROL	96
11.1.1. Setting the Consumer Window Size	96
Setting the Window Size	96
11.1.2. Handling Fast Consumers	96
Setting the Window Size for Fast Consumers	97
11.1.3. Handling Slow Consumers	97
Setting the Window Size for Slow Consumers	97
11.1.4. Setting the Rate of Consuming Messages	98
Setting the Rate of Consuming Messages	98
11.2. PRODUCER FLOW CONTROL	98
11.2.1. Setting the Producer Window Size	99
Setting the Window Size	99
11.2.2. Blocking Messages	99
Configuring the Maximum Size for an Address	100
11.2.3. Blocking AMQP Messages	100
Configuring the Broker to Block AMQP Messages	100
11.2.4. Setting the Rate of Sending Messages	101
Setting the Rate of Sending Messages	101
CHAPTER 12. MESSAGE GROUPING	103
12.1. CLIENT-SIDE MESSAGE GROUPING	103
12.2. AUTOMATIC MESSAGE GROUPING	104
CHAPTER 13. DUPLICATE MESSAGE DETECTION	105
13.1. USING THE DUPLICATE ID MESSAGE PROPERTY	105
13.2. CONFIGURING THE DUPLICATE ID CACHE	105
13.3. DUPLICATE DETECTION AND TRANSACTIONS	106
13.4. DUPLICATE DETECTION AND CLUSTER CONNECTIONS	106
CHAPTER 14. INTERCEPTING MESSAGES	108
14.1. CREATING INTERCEPTORS	108
14.2. CONFIGURING THE BROKER TO USE INTERCEPTORS	110
14.3. INTERCEPTORS ON THE CLIENT SIDE	111
CHAPTER 15. FILTERING MESSAGES	112
15.1. CONFIGURING A QUEUE TO USE A FILTER	112
15.2. FILTERING JMS MESSAGE PROPERTIES	113
Configuring a Filter to Convert a String to a Number	113
Enabling a Filter to Use Hyphens	113
CHAPTER 16. SETTING UP A BROKER CLUSTER	115
16.1. UNDERSTANDING BROKER CLUSTERS	115
16.1.1. How broker clusters balance message load	115
16.1.2. How broker clusters improve reliability	116
16.1.3. Common broker cluster topologies	117
Symmetric clusters	117
Chain clusters	117
16.1.4. Broker discovery methods	118
Dynamic discovery	118
Static discovery	118

16.1.5. Cluster sizing considerations	118
Messaging throughput	119
Topology	119
High availability	119
16.2. CREATING A BROKER CLUSTER	119
16.2.1. Creating a broker cluster with static discovery	119
16.2.2. Creating a broker cluster with UDP-based dynamic discovery	121
16.2.3. Creating a broker cluster with JGroups-based dynamic discovery	124
16.3. IMPLEMENTING HIGH AVAILABILITY	127
16.3.1. How live-backup groups provide high availability	128
16.3.2. High availability policy considerations	129
Shared store considerations	129
Replication considerations	130
Live-only considerations	130
16.3.3. Configuring high availability	130
16.3.3.1. Configuring shared store high availability	131
16.3.3.2. Configuring replication high availability	132
16.3.3.3. Configuring limited high availability with live-only	135
16.3.3.4. Configuring high availability with colocated backups	136
16.3.4. Configuring clients to fail over	138
16.4. ENABLING MESSAGE REDISTRIBUTION	139
16.5. CONFIGURING CLUSTERED MESSAGE GROUPING	140
16.6. CONNECTING CLIENTS TO A BROKER CLUSTER	142
CHAPTER 17. LOGGING	143
17.1. CHANGING THE LOGGING LEVEL	143
17.2. CONFIGURING CONSOLE LOGGING	145
17.3. CONFIGURING FILE LOGGING	146
17.4. CONFIGURING THE LOGGING FORMAT	146
17.5. CLIENT OR EMBEDDED SERVER LOGGING	147
17.6. AMQ BROKER PLUG-INS SUPPORT	148
17.6.1. Adding Plug-ins to the Classpath	148
17.6.2. Registering a Plug-in	148
17.6.3. Registering a Plug-in Programmatically	148
17.6.4. Logging Specific Events	149
APPENDIX A. ACCEPTOR AND CONNECTOR CONFIGURATION PARAMETERS	151
APPENDIX B. ADDRESS SETTING CONFIGURATION ELEMENTS	156
APPENDIX C. CLUSTER CONNECTION CONFIGURATION ELEMENTS	160
APPENDIX D. COMMAND-LINE TOOLS	163
APPENDIX E. MESSAGING JOURNAL CONFIGURATION ELEMENTS	165
APPENDIX F. REPLICATION HIGH AVAILABILITY CONFIGURATION ELEMENTS	167

CHAPTER 1. OVERVIEW

AMQ Broker configuration files define important settings for a broker instance. By editing a broker's configuration files, you can control how the broker operates in your environment.

1.1. AMQ BROKER CONFIGURATION FILES AND LOCATIONS

All of a broker's configuration files are stored in **<broker-instance-dir>/etc**. You can configure a broker by editing the settings in these configuration files.

Each broker instance uses the following configuration files:

broker.xml

The main configuration file. You use this file to configure most aspects of the broker, such as network connections, security settings, message addresses, and so on.

bootstrap.xml

The file that AMQ Broker uses to start a broker instance. You use it to change the location of **broker.xml**, configure the web server, and set some security settings.

logging.properties

You use this file to set logging properties for the broker instance.

artemis.profile

You use this file to set environment variables used while the broker instance is running.

login.config, artemis-users.properties, artemis-roles.properties

Security-related files. You use these files to set up authentication for user access to the broker instance.

1.2. UNDERSTANDING THE DEFAULT BROKER CONFIGURATION

You configure most of a broker's functionality by editing the **broker.xml** configuration file. This file contains default settings, which are sufficient to start and operate a broker. However, you will likely need to change some of the default settings and add new settings to configure the broker for your environment.

By default, **broker.xml** contains default settings for the following functionality:

- Message persistence
- Acceptors
- Security
- Message addresses

Default message persistence settings

By default, AMQ Broker persistence uses an append-only file journal that consists of a set of files on disk. The journal saves messages, transactions, and other information.

```
<configuration ...>
```

```
<core ...>
```

```
...
```

```

<persistence-enabled>>true</persistence-enabled>

<!-- this could be ASYNCIO, MAPPED, NIO
  ASYNCIO: Linux Libaio
  MAPPED: mmap files
  NIO: Plain Java Files
-->
<journal-type>ASYNCIO</journal-type>

<paging-directory>data/paging</paging-directory>

<bindings-directory>data/bindings</bindings-directory>

<journal-directory>data/journal</journal-directory>

<large-messages-directory>data/large-messages</large-messages-directory>

<journal-datasync>true</journal-datasync>

<journal-min-files>2</journal-min-files>

<journal-pool-files>10</journal-pool-files>

<journal-file-size>10M</journal-file-size>

<!--
  This value was determined through a calculation.
  Your system could perform 8.62 writes per millisecond
  on the current journal configuration.
  That translates as a sync write every 115999 nanoseconds.

  Note: If you specify 0 the system will perform writes directly to the disk.
  We recommend this to be 0 if you are using journalType=MAPPED and journal-
datasync=false.
-->
<journal-buffer-timeout>115999</journal-buffer-timeout>

<!--
  When using ASYNCIO, this will determine the writing queue depth for libaio.
-->
<journal-max-io>4096</journal-max-io>

<!-- how often we are looking for how many bytes are being used on the disk in ms -->
<disk-scan-period>5000</disk-scan-period>

<!-- once the disk hits this limit the system will block, or close the connection in certain protocols
  that won't support flow control. -->
<max-disk-usage>90</max-disk-usage>

<!-- should the broker detect dead locks and other issues -->
<critical-analyzer>true</critical-analyzer>

<critical-analyzer-timeout>120000</critical-analyzer-timeout>

<critical-analyzer-check-period>60000</critical-analyzer-check-period>

```

```

<critical-analyzer-policy>HALT</critical-analyzer-policy>

...

</core>

</configuration>

```

Default acceptor settings

Brokers listen for incoming client connections by using an **acceptor** configuration element to define the port and protocols a client can use to make connections. By default, AMQ Broker includes configuration for an acceptor for each supported messaging protocol.

```

<configuration ...>

  <core ...>

    ...

    <acceptors>

      <!-- Acceptor for every supported protocol -->
      <acceptor name="artemis">tcp://0.0.0.0:61616?
tcpSendBufferSize=1048576;tcpReceiveBufferSize=1048576;protocols=CORE,AMQP,STOMP,HORNETQ,
MQTT,OPENWIRE;useEpoll=true;amqpCredits=1000;amqpLowCredits=300</acceptor>

      <!-- AMQP Acceptor. Listens on default AMQP port for AMQP traffic.-->
      <acceptor name="amqp">tcp://0.0.0.0:5672?
tcpSendBufferSize=1048576;tcpReceiveBufferSize=1048576;protocols=AMQP;useEpoll=true;amqpCredits=
1000;amqpLowCredits=300</acceptor>

      <!-- STOMP Acceptor. -->
      <acceptor name="stomp">tcp://0.0.0.0:61613?
tcpSendBufferSize=1048576;tcpReceiveBufferSize=1048576;protocols=STOMP;useEpoll=true</acceptor>

      <!-- HornetQ Compatibility Acceptor. Enables HornetQ Core and STOMP for legacy HornetQ
clients. -->
      <acceptor name="hornetq">tcp://0.0.0.0:5445?
anycastPrefix=jms.queue.;multicastPrefix=jms.topic.;protocols=HORNETQ,STOMP;useEpoll=true</acceptor>

      <!-- MQTT Acceptor -->
      <acceptor name="mqtt">tcp://0.0.0.0:1883?
tcpSendBufferSize=1048576;tcpReceiveBufferSize=1048576;protocols=MQTT;useEpoll=true</acceptor>

    </acceptors>

    ...

  </core>

</configuration>

```

Default security settings

AMQ Broker contains a flexible role-based security model for applying security to queues, based on their addresses. The default configuration uses wildcards to apply the **amq** role to all addresses (represented by the number sign, #).

```
<configuration ...>

  <core ...>

    ...

    <security-settings>
      <security-setting match="#">
        <permission type="createNonDurableQueue" roles="amq"/>
        <permission type="deleteNonDurableQueue" roles="amq"/>
        <permission type="createDurableQueue" roles="amq"/>
        <permission type="deleteDurableQueue" roles="amq"/>
        <permission type="createAddress" roles="amq"/>
        <permission type="deleteAddress" roles="amq"/>
        <permission type="consume" roles="amq"/>
        <permission type="browse" roles="amq"/>
        <permission type="send" roles="amq"/>
        <!-- we need this otherwise ./artemis data imp wouldn't work -->
        <permission type="manage" roles="amq"/>
      </security-setting>
    </security-settings>

    ...

  </core>

</configuration>
```

Default message address settings

AMQ Broker includes a default address that establishes a default set of configuration settings to be applied to any created queue or topic.

Additionally, the default configuration defines two queues: **DLQ** (Dead Letter Queue) handles messages that arrive with no known destination, and **Expiry Queue** holds messages that have lived past their expiration and therefore should not be routed to their original destination.

```
<configuration ...>

  <core ...>

    ...

    <address-settings>
      ...
      <!--default for catch all-->
      <address-setting match="#">
        <dead-letter-address>DLQ</dead-letter-address>
        <expiry-address>ExpiryQueue</expiry-address>
        <redelivery-delay>0</redelivery-delay>
        <!-- with -1 only the global-max-size is in use for limiting -->
```

```

    <max-size-bytes>1</max-size-bytes>
    <message-counter-history-day-limit>10</message-counter-history-day-limit>
    <address-full-policy>PAGE</address-full-policy>
    <auto-create-queues>true</auto-create-queues>
    <auto-create-addresses>true</auto-create-addresses>
    <auto-create-jms-queues>true</auto-create-jms-queues>
    <auto-create-jms-topics>true</auto-create-jms-topics>
  </address-setting>
</address-settings>

<addresses>
  <address name="DLQ">
    <anycast>
      <queue name="DLQ" />
    </anycast>
  </address>
  <address name="ExpiryQueue">
    <anycast>
      <queue name="ExpiryQueue" />
    </anycast>
  </address>
</addresses>

</core>

</configuration>

```

1.3. RELOADING CONFIGURATION UPDATES

By default, a broker checks for changes in the configuration files every 5000 milliseconds. If any are found, the configuration is reloaded to activate the changes. You can change the interval at which the broker checks for configuration changes.

If the configuration is changed, the broker reloads the following modules:

- Address settings and queues
When the configuration file is reloaded, the address settings determine how to handle addresses and queues that have been deleted from the configuration file. You can set this with the **config-delete-addresses** and **config-delete-queues** properties. For more information, see [Appendix B, Address Setting Configuration Elements](#).
- Security settings
SSL/TLS keystores and truststores on an existing acceptor can be reloaded to establish new certificates without any impact to existing clients. Connected clients, even those with older or differing certificates, can continue to send and receive messages.

Procedure

1. Open the **<broker-instance-dir>/etc/broker.xml** configuration file.
2. Within the **<core>** element, add the **<configuration-file-refresh-period>** element and set the refresh period (in milliseconds).
This example sets the configuration refresh period to be 60000 milliseconds:

```

<configuration>

```

```

<core>
  ...
  <configuration-file-refresh-period>60000</configuration-file-refresh-period>
  ...
</core>
</configuration>

```

1.4. MODULARIZING THE BROKER CONFIGURATION FILE

If you have multiple brokers that share common configuration settings, you can define the common configuration in separate files, and then include these files in each broker's **broker.xml** configuration file.

The most common configuration settings that you might share between brokers include:

- Addresses
- Address settings
- Security settings

Procedure

1. Create a separate XML file for each **broker.xml** section that you want to share. Each XML file can only include a single section from **broker.xml** (for example, either addresses or address settings, but not both). The top-level element must also define the element namespace (**xmlns="urn:activemq:core"**).

This example shows a security settings configuration defined in **my-security-settings.xml**:

my-security-settings.xml

```

<security-settings xmlns="urn:activemq:core">
  <security-setting match="a1">
    <permission type="createNonDurableQueue" roles="a1.1"/>
  </security-setting>
  <security-setting match="a2">
    <permission type="deleteNonDurableQueue" roles="a2.1"/>
  </security-setting>
</security-settings>

```

2. Open the **<broker-instance-dir>/etc/broker.xml** configuration file for each broker that should use the common configuration settings.
3. For each **broker.xml** file that you opened, do the following:
 - a. In the **<configuration>** element at the beginning of **broker.xml**, verify that the following line appears:

```
xmlns:xi="http://www.w3.org/2001/XInclude"
```

- b. Add an XML inclusion for each XML file that contains shared configuration settings. This example includes the **my-security-settings.xml** file.

broker.xml

```

<configuration ...>
  <core ...>
    ...
    <xi:include href="/opt/my-broker-config/my-security-settings.xml"/>
    ...
  </core>
</configuration>

```

- c. If desired, validate **broker.xml** to verify that the XML is valid against the schema. You can use any XML validator program. This example uses **xmllint** to validate **broker.xml** against the **artemis-server.xsl** schema.

```

$ xmllint --noout --xinclude --schema /opt/redhat/amq-broker/amq-broker-
7.2.0/schema/artemis-server.xsd /var/opt/amq-broker/mybroker/etc/broker.xml
/var/opt/amq-broker/mybroker/etc/broker.xml validates

```

Additional resources

- For more information about XML Inclusions (XIncludes), see <https://www.w3.org/TR/xinclude/>.

1.5. DOCUMENT CONVENTIONS

This document uses the following conventions for the **sudo** command and file paths.

The **sudo** command

In this document, **sudo** is used for any command that requires root privileges. You should always exercise caution when using **sudo**, as any changes can affect the entire system.

For more information about using **sudo**, see [The **sudo** Command](#).

About the use of file paths in this document

In this document, all file paths are valid for Linux, UNIX, and similar operating systems (for example, **/home/...**). If you are using Microsoft Windows, you should use the equivalent Microsoft Windows paths (for example, **C:\Users\...**).

CHAPTER 2. NETWORK CONNECTIONS: ACCEPTORS AND CONNECTORS

There are two types of connections used in AMQ Broker: network and In-VM. Network connections are used when the two parties are located in different virtual machines, whether on the same server or physically remote. An In-VM connection is used when the client, whether an application or a server, resides within the same virtual machine as the broker.

Network connections rely on Netty. [Netty](#) is a high-performance, low-level network library that allows network connections to be configured in several different ways: using Java IO or NIO, TCP sockets, SSL/TLS, even tunneling over HTTP or HTTPS. Netty also allows for a single port to be used for all messaging protocols. A broker will automatically detect which protocol is being used and direct the incoming message to the appropriate handler for further processing.

The URI within a network connection's configuration determines its type. For example, using **vm** in the URI will create an In-VM connection. In the example below, note that the URI of the **acceptor** starts with **vm**.

```
<acceptor name="in-vm-example">vm://0</acceptor>
```

Using **tcp** in the URI, alternatively, will create a network connection.

```
<acceptor name="network-example">tcp://localhost:61617</acceptor>
```

This chapter will first discuss the two configuration elements specific to network connections, Acceptors and Connectors. Next, configuration steps for TCP, HTTP, and SSL/TLS network connections, as well as In-VM connections, are explained.

2.1. ABOUT ACCEPTORS

One of the most important concepts when discussing network connections in AMQ Broker is the **acceptor**. Acceptors define the way connections are made to the broker. Below is a typical configuration for an **acceptor** that might be found inside the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***.

```
<acceptors>
  <acceptor name="example-acceptor">tcp://localhost:61617</acceptor>
</acceptors>
```

Note that each **acceptor** is grouped inside an **acceptors** element. There is no upper limit to the number of acceptors you can list per server.

Configuring an Acceptor

You configure an **acceptor** by appending key-value pairs to the query string of the URI defined for the **acceptor**. Use a semicolon (;) to separate multiple key-value pairs, as shown in the following example. It configures an acceptor for SSL/TLS by adding multiple key-value pairs at the end of the URI, starting with **sslEnabled=true**.

```
<acceptor name="example-acceptor">tcp://localhost:61617?sslEnabled=true;key-store-
path=/path</acceptor>
```

For details on **connector** configuration parameters, see [Acceptor and Connector Configuration Parameters](#).

2.2. ABOUT CONNECTORS

Whereas acceptors define how a server accepts connections, a **connector** is used by clients to define how they can connect to a server.

Below is a typical **connector** as defined in the ***BROKER_INSTANCE_DIR/etc/broker.xml*** configuration file:

```
<connectors>
  <connector name="example-connector">tcp://localhost:61617</connector>
</connectors>
```

Note that connectors are defined inside a **connectors** element. There is no upper limit to the number of connectors per server.

Although connectors are used by clients, they are configured on the server just like acceptors. There are a couple of important reasons why:

- A server itself can act as a client and therefore needs to know how to connect to other servers. For example, when one server is bridged to another or when a server takes part in a cluster.
- A server is often used by JMS clients to look up connection factory instances. In these cases, JNDI needs to know details of the connection factories used to create client connections. The information is provided to the client when a JNDI lookup is performed. See [Configuring a Connection on the Client Side](#) for more information.

Configuring a Connector

Like acceptors, connectors have their configuration attached to the query string of their URI. Below is an example of a **connector** that has the **tcpNoDelay** parameter set to **false**, which turns off Nagle's algorithm for this connection.

```
<connector name="example-connector">tcp://localhost:61616?tcpNoDelay=false</connector>
```

For details on **connector** configuration parameters, see [Acceptor and Connector Configuration Parameters](#).

2.3. CONFIGURING A TCP CONNECTION

AMQ Broker uses Netty to provide basic, unencrypted, TCP-based connectivity that can be configured to use blocking Java IO or the newer, non-blocking Java NIO. Java NIO is preferred for better scalability with many concurrent connections. However, using the old IO can sometimes give you better latency than NIO when you are less worried about supporting many thousands of concurrent connections.

If you are running connections across an untrusted network, remember that a TCP network connection is unencrypted. You may want to consider using an SSL or HTTPS configuration to encrypt messages sent over this connection if encryption is a priority. Refer to [Configuring Transport Layer Security](#) for details.

When using a TCP connection, all connections are initiated from the client side. In other words, the server does not initiate any connections to the client, which works well with firewall policies that force connections to be initiated from one direction.

For TCP connections, the host and the port of the connector's URI defines the address used for the connection.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add or modify the connection and include a URI that uses **tcp** as the protocol. Be sure to include both an IP or hostname as well as a port.

In the example below, an **acceptor** is configured as a TCP connection. A broker configured with this **acceptor** will accept clients making TCP connections to the IP **10.10.10.1** and port **61617**.

```
<acceptors>
  <acceptor name="tcp-acceptor">tcp://10.10.10.1:61617</acceptor>
  ...
</acceptors>
```

You configure a connector to use TCP in much the same way.

```
<connectors>
  <connector name="tcp-connector">tcp://10.10.10.2:61617</connector>
  ...
</connectors>
```

The **connector** above would be referenced by a client, or even the broker itself, when making a TCP connection to the specified IP and port, **10.10.10.2:61617**.

For details on available configuration parameters for TCP connections, see [Acceptor and Connector Configuration Parameters](#). Most parameters can be used either with acceptors or connectors, but some only work with acceptors.

2.4. CONFIGURING AN HTTP CONNECTION

HTTP connections tunnel packets over the HTTP protocol and are useful in scenarios where firewalls allow only HTTP traffic. With single port support, AMQ Broker will automatically detect if HTTP is being used, so configuring a network connection for HTTP is the same as configuring a connection for TCP. For a full working example showing how to use HTTP, see the **http-transport** example, located under ***INSTALL_DIR/examples/features/standard/***.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add or modify the connection and include a URI that uses **tcp** as the protocol. Be sure to include both an IP or hostname as well as a port

In the example below, the broker will accept HTTP communications from clients connecting to port **80** at the IP address **10.10.10.1**. Furthermore, the broker will automatically detect that the HTTP protocol is in use and will communicate with the client accordingly.

```
<acceptors>
  <acceptor name="http-acceptor">tcp://10.10.10.1:80</acceptor>
  ...
</acceptors>
```

Configuring a connector for HTTP is again the same as for TCP.

```
<connectors>
```

```
<connector name="http-connector">tcp://10.10.10.2:80</connector>
...
</connectors>
```

Using the configuration in the example above, a broker will create an outbound HTTP connection to port **80** at the IP address **10.10.10.2**.

An HTTP connection uses the same configuration parameters as TCP, but it also has some of its own. For details on HTTP-related and other configuration parameters, see [Acceptor and Connector Configuration Parameters](#).

2.5. CONFIGURING AN SSL/TLS CONNECTION

You can also configure connections to use SSL/TLS. Refer to [Configuring Transport Layer Security](#) for details.

2.6. CONFIGURING AN IN-VM CONNECTION

An In-VM connection can be used when multiple brokers are co-located in the same virtual machine, as part of a high availability solution for example. In-VM connections can also be used by local clients running in the same JVM as the server. For an in-VM connection, the authority part of the URI defines a unique server ID. In fact, no other part of the URI is needed.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add or modify the connection and include a URI that uses **vm** as the protocol.

```
<acceptors>
  <acceptor name="in-vm-acceptor">vm://0</acceptor>
  ...
</acceptors>
```

The example **acceptor** above tells the broker to accept connections from the server with an ID of **0**. The other server must be running in the same virtual machine as the broker.

Configuring a connector as an in-vm connection follows the same syntax.

```
<connectors>
  <connector name="in-vm-connector">vm://0</connector>
  ...
</connectors>
```

The **connector** in the example above defines how clients establish an in-VM connection to the server with an ID of **0** that resides in the same virtual machine. The client can be an application or broker.

2.7. CONFIGURING A CONNECTION FROM THE CLIENT SIDE

Connectors are also used indirectly in client applications. You can configure the JMS connection factory directly on the client side without having to define a **connector** on the server side:

```
Map<String, Object> connectionParams = new HashMap<String, Object>();
```

```
connectionParams.put(org.apache.activemq.artemis.core.remoting.impl.netty.TransportConstants.PORT_PROP_NAME, 61617);
```

```
TransportConfiguration transportConfiguration =  
    new TransportConfiguration(  
        "org.apache.activemq.artemis.core.remoting.impl.netty.NettyConnectorFactory",  
        connectionParams);
```

```
ConnectionFactory connectionFactory =  
    ActiveMQJMSClient.createConnectionFactoryWithoutHA(JMSFactoryType.CF,  
        transportConfiguration);
```

```
Connection.jmsConnection = connectionFactory.createConnection();
```

CHAPTER 3. NETWORK CONNECTIONS: PROTOCOLS

AMQ Broker has a pluggable protocol architecture, so that you can easily enable one or more protocols for a network connection.

The broker supports the following protocols:

- [AMQP](#)
- [MQTT](#)
- [OpenWire](#)
- [STOMP](#)

NOTE

In addition to the protocols above, the broker also supports its own native protocol known as "Core". Past versions of this protocol were known as "HornetQ" and used by Red Hat JBoss Enterprise Application Platform.

3.1. CONFIGURING A NETWORK CONNECTION TO USE A PROTOCOL

You must associate a protocol with a network connection before you can use it. (See [Network Connections: Acceptors and Connectors](#) for more information about how to create and configure network connections.) The default configuration, located in the file **`BROKER_INSTANCE_DIR/etc/broker.xml`**, includes several connections already defined. For convenience, AMQ Broker includes an acceptor for each supported protocol, plus a default acceptor that supports all protocols.

Default acceptors in `broker.xml`

```
<configuration>
  <core>
    ...
  <acceptors>
    <!-- Default ActiveMQ Artemis Acceptor. Multi-protocol adapter. Currently supports ActiveMQ
    Artemis Core, OpenWire, STOMP, AMQP, MQTT, and HornetQ Core. -->
    <acceptor name="artemis">tcp://0.0.0.0:61616?
tcpSendBufferSize=1048576;tcpReceiveBufferSize=1048576</acceptor>

    <!-- AMQP Acceptor. Listens on default AMQP port for AMQP traffic.-->
    <acceptor name="amqp">tcp://0.0.0.0:5672?protocols=AMQP</acceptor>

    <!-- STOMP Acceptor. -->
    <acceptor name="stomp">tcp://0.0.0.0:61613?protocols=STOMP</acceptor>

    <!-- HornetQ Compatibility Acceptor. Enables HornetQ Core and STOMP for legacy HornetQ
    clients. -->
    <acceptor name="hornetq">tcp://0.0.0.0:5445?protocols=HORNETQ,STOMP</acceptor>

    <!-- MQTT Acceptor -->
    <acceptor name="mqtt">tcp://0.0.0.0:1883?protocols=MQTT</acceptor>
  </acceptors>
```

```
...
</core>
</configuration>
```

NOTE

The only requirement to enable a protocol is to add the **protocols** parameter to the URI query string. The value of the parameter must be a comma separated list of protocol names. If the protocol parameter is omitted from the URI all protocols are enabled.

For example, to create an acceptor for receiving messages on port 3232 using the AMQP protocol, follow these steps:

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add the following line to the **<acceptors>** stanza:

```
<acceptor name="amqp">tcp://0.0.0.0:3232?protocols=AMQP</acceptor>
```

3.2. USING AMQP WITH A NETWORK CONNECTION

The broker supports the [AMQP 1.0](#) specification. An AMQP link is a uni-directional protocol for messages between a source and a target, that is, a client and the broker.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add or configure an **acceptor** to receive AMQP clients by including the **protocols** parameter with a value of **AMQP** as part of the URI, as shown in the following example:

```
<acceptors>
  <acceptor name="amqp-acceptor">tcp://localhost:5672?protocols=AMQP</acceptor>
  ...
</acceptors>
```

In the preceding example, the broker accepts AMQP 1.0 clients on port 5672, which is the default AMQP port.

An AMQP link has two endpoints, a sender and a receiver. When senders transmit a message, the broker converts it into an internal format, so it can be forwarded to its destination on the broker. Receivers connect to the destination at the broker and convert the messages back into AMQP before they are delivered.

If an AMQP link is dynamic, a temporary queue is created and either the remote source or the remote target address is set to the name of the temporary queue. If the link is not dynamic, the address of the remote target or source is used for the queue. If the remote target or source does not exist, an exception is sent.

A link target can also be a Coordinator, which is used to handle the underlying session as a transaction, either rolling it back or committing it.

**NOTE**

AMQP allows the use of multiple transactions per session, **amqp:multi-txns-per-ssn**, however the current version of AMQ Broker will support only single transactions per session.

**NOTE**

The details of distributed transactions (XA) within AMQP are not provided in the 1.0 version of the specification. If your environment requires support for distributed transactions, it is recommended that you use the AMQ Core Protocol JMS.

See the [AMQP 1.0](#) specification for more information about the protocol and its features.

3.2.1. Using an AMQP Link as a Topic

Unlike JMS, the AMQP protocol does not include topics. However, it is still possible to treat AMQP consumers or receivers as subscriptions rather than just consumers on a queue. By default, any receiving link that attaches to an address with the prefix **jms.topic.** is treated as a subscription, and a subscription queue is created. The subscription queue is made durable or volatile, depending on how the Terminus Durability is configured, as captured in the following table:

To create this kind of subscription for a multicast-only queue...	Set Terminus Durability to this...
Durable	UNSETTLED_STATE or CONFIGURATION
Non-durable	NONE

**NOTE**

The name of a durable queue is composed of the container ID and the link name, for example **my-container-id:my-link-name**.

AMQ Broker also supports the `qpjd-jms` client and will respect its use of topics regardless of the prefix used for the address.

3.2.2. Configuring AMQP Security

The broker supports AMQP SASL Authentication. See [Security](#) for more information about how to configure SASL-based authentication on the broker.

3.3. USING MQTT WITH A NETWORK CONNECTION

The broker supports MQTT v3.1.1 (and also the older v3.1 code message format). MQTT is a lightweight, client to server, publish/subscribe messaging protocol. MQTT reduces messaging overhead and network traffic, as well as a client's code footprint. For these reasons, MQTT is ideally suited to constrained devices such as sensors and actuators and is quickly becoming the de facto standard communication protocol for Internet of Things(IoT).

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add an acceptor with the MQTT protocol enabled. For example:

```
<acceptors>
  <acceptor name="mqtt">tcp://localhost:1883?protocols=MQTT</acceptor>
  ...
</acceptors>
```

MQTT comes with a number of useful features including:

Quality of Service

Each message can define a quality of service that is associated with it. The broker will attempt to deliver messages to subscribers at the highest quality of service level defined.

Retained Messages

Messages can be retained for a particular address. New subscribers to that address receive the last-sent retained message before any other messages, even if the retained message was sent before the client connected.

Wild card subscriptions

MQTT addresses are hierarchical, similar to the hierarchy of a file system. Clients are able to subscribe to specific topics or to whole branches of a hierarchy.

Will Messages

Clients are able to set a "will message" as part of their connect packet. If the client abnormally disconnects, the broker will publish the will message to the specified address. Other subscribers receive the will message and can react accordingly.

The best source of information about the MQTT protocol is in the specification. The MQTT v3.1.1 specification can be downloaded from the [OASIS website](#).

3.4. USING OPENWIRE WITH A NETWORK CONNECTION

The broker supports the [OpenWire protocol](#), which allows a JMS client to talk directly to a broker. Use this protocol to communicate with older versions of AMQ Broker.

Currently AMQ Broker supports OpenWire clients that use standard JMS APIs only.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add or modify an **acceptor** so that it includes **OPENWIRE** as part of the **protocol** parameter, as shown in the following example:

```
<acceptors>
  <acceptor name="openwire-acceptor">tcp://localhost:61616?
  protocols=OPENWIRE</acceptor>
  ...
</acceptors>
```

In the preceding example, the broker will listen on port 61616 for incoming OpenWire commands.

For more details, see the examples located under ***INSTALL_DIR/examples/protocols/openwire***.

3.5. USING STOMP WITH A NETWORK CONNECTION

STOMP is a text-orientated wire protocol that allows STOMP clients to communicate with STOMP Brokers. The broker supports STOMP 1.0, 1.1 and 1.2. STOMP clients are available for several languages and platforms making it a good choice for interoperability.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Configure an existing **acceptor** or create a new one and include a **protocols** parameter with a value of **STOMP**, as below.

```
<acceptors>
  <acceptor name="stomp-acceptor">tcp://localhost:61613?protocols=STOMP</acceptor>
  ...
</acceptors>
```

In the preceding example, the broker accepts STOMP connections on the port **61613**, which is the default.

See the **stomp** example located under ***INSTALL_DIR/examples/protocols*** for an example of how to configure a broker with STOMP.

3.5.1. Knowing the Limitations When Using STOMP

When using STOMP, the following limitations apply:

1. The broker currently does not support virtual hosting, which means the **host** header in **CONNECT** frames are ignored.
2. Message acknowledgements are not transactional. The **ACK** frame cannot be part of a transaction, and it is ignored if its **transaction** header is set).

3.5.2. Providing IDs for STOMP Messages

When receiving STOMP messages through a JMS consumer or a QueueBrowser, the messages do not contain any JMS properties, for example **JMSMessageID**, by default. However, you can set a message ID on each incoming STOMP message by using a broker paramater.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Set the **stompEnableMessageId** parameter to **true** for the **acceptor** used for STOMP connections, as shown in the following example:

```
<acceptors>
  <acceptor name="stomp-acceptor">tcp://localhost:61613?
  protocols=STOMP;stompEnableMessageId=true</acceptor>
  ...
</acceptors>
```

By using the **stompEnableMessageId** parameter, each stomp message sent using this acceptor has an extra property added. The property key is **amq-message-id** and the value is a String representation of an internal message id prefixed with "STOMP", as shown in the following example:

```
amq-message-id : STOMP12345
```

If **stompEnableMessageId** is not specified in the configuration, the default value is **false**.

3.5.3. Setting a Connection's Time to Live (TTL)

STOMP clients must send a **DISCONNECT** frame before closing their connections. This allows the broker to close any server-side resources, such as sessions and consumers. However, if STOMP clients exit without sending a DISCONNECT frame, or if they fail, the broker will have no way of knowing immediately whether the client is still alive. STOMP connections therefore are configured to have a "Time to Live" (TTL) of 1 minute. This means that the broker stops the connection to the STOMP client if it has been idle for more than one minute.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add the **connectionTtl** parameter to URI of the **acceptor** used for STOMP connections, as shown in the following example:

```
<acceptors>
  <acceptor name="stomp-acceptor">tcp://localhost:61613?
  protocols=STOMP;connectionTtl=20000</acceptor>
  ...
</acceptors>
```

In the preceding example, any stomp connection that using the **stomp-acceptor** will have its TTL set to 20 seconds.

NOTE

Version 1.0 of the STOMP protocol does not contain any heartbeat frame. It is therefore the user's responsibility to make sure data is sent within connection-ttl or the broker will assume the client is dead and clean up server-side resources. With version 1.1, you can use heart-beats to maintain the life cycle of stomp connections.

Overriding the Broker's Default Time to Live (TTL)

As noted, the default TTL for a STOMP connection is one minute. You can override this value by adding the **connection-ttl-override** attribute to the broker configuration.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add the **connection-ttl-override** attribute and provide a value in milliseconds for the new default. It belongs inside the **<core>** stanza, as below.

```
<configuration ...>
  ...
  <core ...>
```

```

...
<connection-ttl-override>30000</connection-ttl-override>
...
</core>
<configuration>

```

In the preceding example, the default Time to Live (TTL) for a STOMP connection is set to 30 seconds, **30000** milliseconds.

3.5.4. Sending and Consuming STOMP Messages from JMS

STOMP is mainly a text-orientated protocol. To make it simpler to interoperate with JMS, the STOMP implementation checks for presence of the **content-length** header to decide how to map a STOMP message to JMS.

If you want a STOMP message to map to a ...	The message should....
JMS TextMessage	Not include a content-length header.
JMS BytesMessage	Include a content-length header.

The same logic applies when mapping a JMS message to STOMP. A STOMP client can confirm the presence of the **content-length** header to determine the type of the message body (string or bytes).

See the [STOMP](#) specification for more information about message headers.

3.5.5. Mapping STOMP Destinations to AMQ Broker Addresses and Queues

When sending messages and subscribing, STOMP clients typically include a **destination** header. Destination names are string values, which are mapped to a destination on the broker. In AMQ Broker, these destinations are mapped to **addresses** and **queues**. See the [STOMP](#) specification for more information about the destination frame.

Take for example a STOMP client that sends the following message (headers and body included):

```

SEND
destination:/my/stomp/queue

hello queue a
^@

```

In this case, the broker will forward the message to any queues associated with the address **/my/stomp/queue**.

For example, when a STOMP client sends a message (by using a **SEND** frame), the specified destination is mapped to an address.

It works the same way when the client sends a **SUBSCRIBE** or **UNSUBSCRIBE** frame, but in this case AMQ Broker maps the **destination** to a queue.

```

SUBSCRIBE
destination: /other/stomp/queue

```

```
ack: client
```

```
^@
```

In the preceding example, the broker will map the **destination** to the queue **/other/stomp/queue**.

Mapping STOMP Destinations to JMS Destinations

JMS destinations are also mapped to broker addresses and queues. If you want to use STOMP to send messages to JMS destinations, the STOMP destinations must follow the same convention:

- Send or subscribe to a JMS **Queue** by prepending the queue name by **jms.queue..**. For example, to send a message to the **orders** JMS Queue, the STOMP client must send the frame:

```
SEND
destination:jms.queue.orders
hello queue orders
^@
```

- Send or subscribe to a JMS **Topic** by prepending the topic name by **jms.topic..**. For example, to subscribe to the **stocks** JMS Topic, the STOMP client must send a frame similar to the following:

```
SUBSCRIBE
destination:jms.topic.stocks
^@
```

CHAPTER 4. ADDRESSES, QUEUES, AND TOPICS

AMQ Broker has a unique addressing model that is both powerful and flexible and that offers great performance. The addressing model comprises three main concepts: addresses, queues and routing types.

An **address** represents a messaging endpoint. Within the configuration, a typical address is given a unique name, 0 or more queues, and a routing type.

A **queue** is associated with an address. There can be multiple queues per address. Once an incoming message is matched to an address, the message is sent on to one or more of its queues, depending on the routing type configured. Queues can be configured to be automatically created and deleted.

A **routing type** determines how messages are sent to the queues associated with an address. A AMQ Broker address can be configured with two different routing types.

Table 4.1. Routing Types

If you want your messages routed to...	Use this routing type ...
A single queue within the matching address, in a point-to-point manner.	anycast
Every queue within the matching address, in a publish-subscribe manner.	multicast

NOTE

An address must have at least one routing type.

It is possible to define more than one routing type per address, but this typically results in an anti-pattern and is therefore not recommended.

If an address does use both routing types, however, and the client does not show a preference for either one, the broker typically defaults to the **anycast** routing type. The one exception is when the client uses the MQTT protocol. In that case, the default routing type is **multicast**.

4.1. ADDRESS AND QUEUE NAMING REQUIREMENTS

You should be aware of the following requirements when you configure addresses and queues:

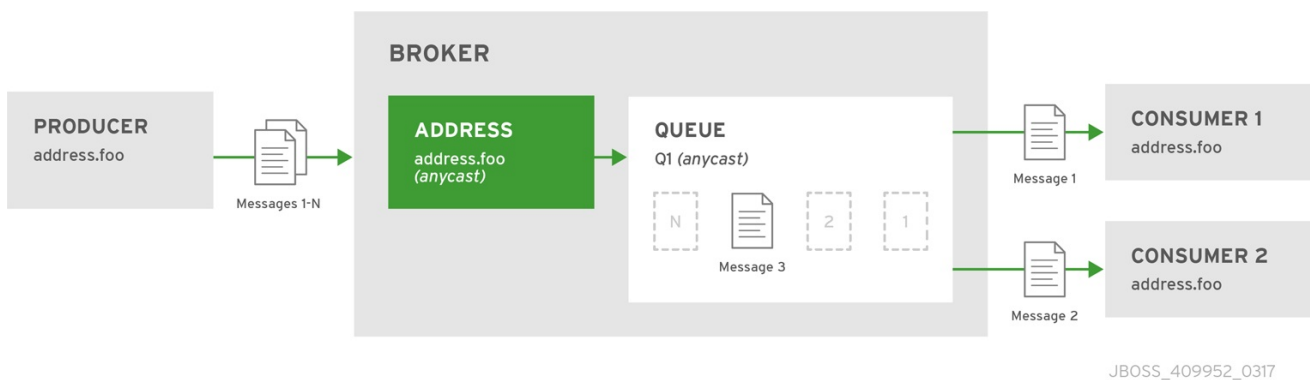

- To ensure that a client can connect to a queue regardless of which wire protocol it uses, your address and queue names should not include any of the following characters:
& ::, ? >
- The **#** and ***** characters are reserved for wildcard expressions. For more information, see [the section called "AMQ Broker Wildcard Syntax"](#).
- Address and queue names should not include any spaces.
- To separate words in an address or queue name, use the configured delimiter character (the default is the **.** character). For more information, see [the section called "AMQ Broker Wildcard Syntax"](#).

4.2. CONFIGURING POINT-TO-POINT MESSAGING

Point-to-point messaging is a common scenario in which a message sent by a producer has only one consumer. AMQP and JMS message producers and consumers can make use of point-to-point messaging queues, for example. Define an **anycast** routing type for an **address** so that its queues receive messages in a point-to-point manner.

When a message is received on an address using **anycast**, AMQ Broker locates the queue associated with the address and routes the message to it. When consumers request to consume from the address, the broker locates the relevant queue and associates this queue with the appropriate consumers. If multiple consumers are connected to the same queue, messages are distributed amongst each consumer equally, providing the consumers are equally able to handle them.

Figure 4.1. Point-to-Point

Procedure

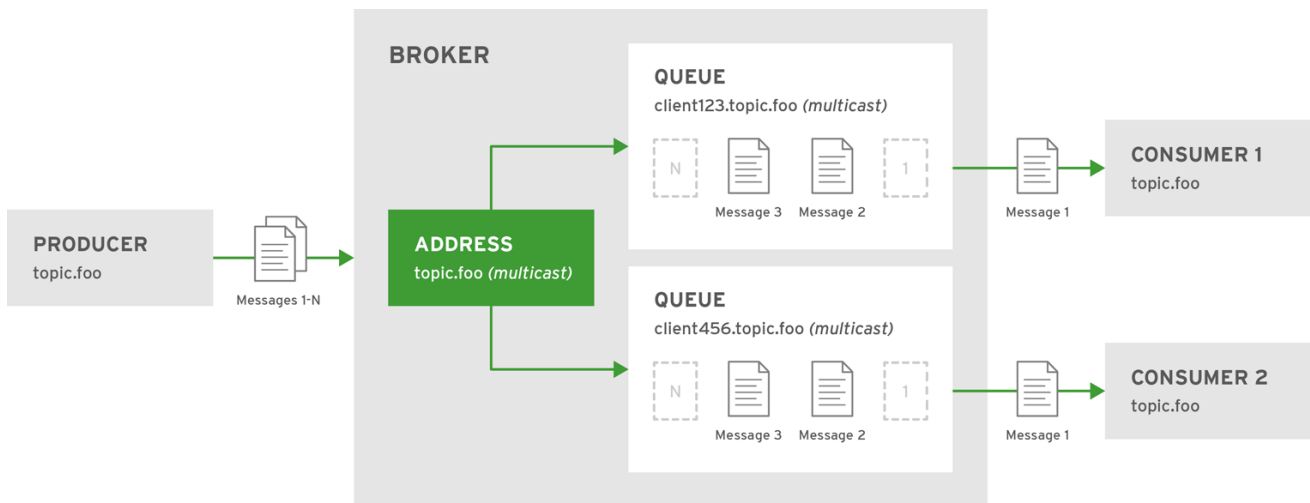

1. Open the file ***BROKER_INSTANCE_DIR/etc/broker.xml*** for editing.
2. Wrap an **anycast** configuration element around the chosen **queue** element of an **address**. Ensure the value of **address name** and **queue name** elements are same.

```
<configuration ...>
  <core ...>
    ...
    <address name="durable">
      <anycast>
        <queue name="durable"/>
      </anycast>
    </address>
  </core>
</configuration>
```

4.3. CONFIGURING PUBLISH-SUBSCRIBE MESSAGING

In a publish-subscribe scenario, messages are sent to every consumer subscribed to an address. JMS topics and MQTT subscriptions are two examples of publish-subscribe messaging. When a message is received on an address with a **multicast** routing type, AMQ Broker routes a copy of the message to each queue. To reduce the overhead of copying, each queue is sent only a reference to the message and not a full copy.

Figure 4.2. Publish-Subscribe

JBoss_409952_0317

Procedure

1. Open the file ***BROKER_INSTANCE_DIR/etc/broker.xml*** for editing.
2. Add an empty **multicast** configuration element to the chosen address.

```
<configuration ...>
  <core ...>
    ...
    <address name="topic.foo">
      <multicast/>
    </address>
  </core>
</configuration>
```

3. (Optional) Add one more **queue** elements to the address and wrap the **multicast** element around them. This step is typically not needed since the broker automatically creates a queue for each subscription requested by a client.

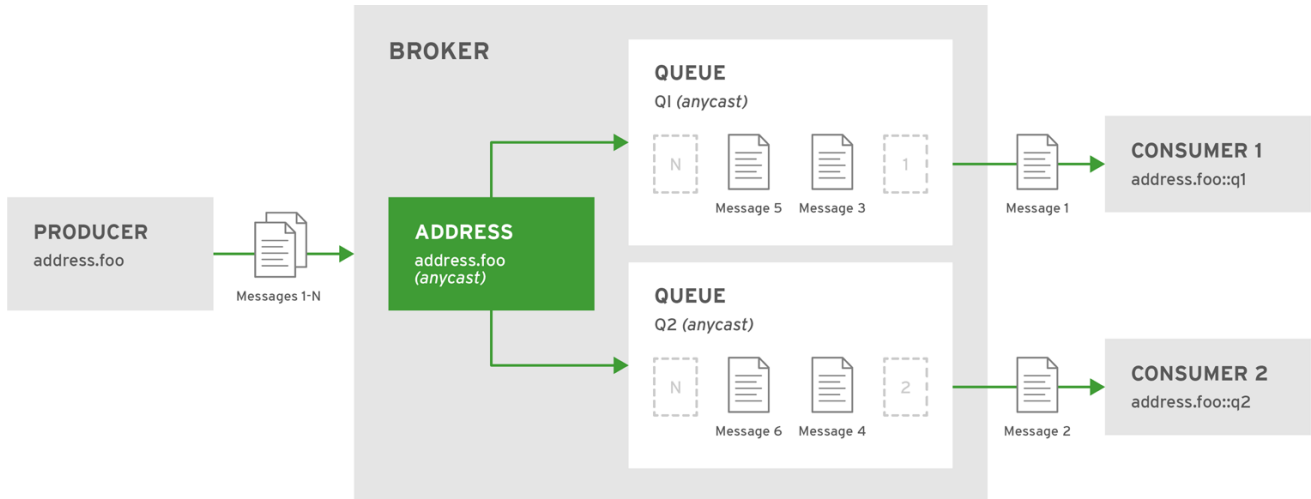

```
<configuration ...>
  <core ...>
    ...
    <address name="topic.foo">
      <multicast>
        <queue name="client123.topic.foo"/>
        <queue name="client456.topic.foo"/>
      </multicast>
    </address>
  </core>
</configuration>
```

4.4. CONFIGURING A POINT-TO-POINT USING TWO QUEUES

You can define more than one queue on an address by using an **anycast** routing type. Messages sent to an **anycast** address are distributed evenly across all associated queues. By using Fully Qualified Queue Names, which are described later, you can have clients connect to a specific queue. If more than one

consumer connects to the same queue, AMQ Broker distributes messages between them.

Figure 4.3. Point-to-Point with Two Queues

JBOSS_409952_0317

NOTE

This is how AMQ Broker handles load balancing of queues across multiple nodes in a cluster.

Procedure

1. Open the file ***BROKER_INSTANCE_DIR/etc/broker.xml*** for editing.
2. Wrap an **anycast** configuration element around the **queue** elements in the **address**.

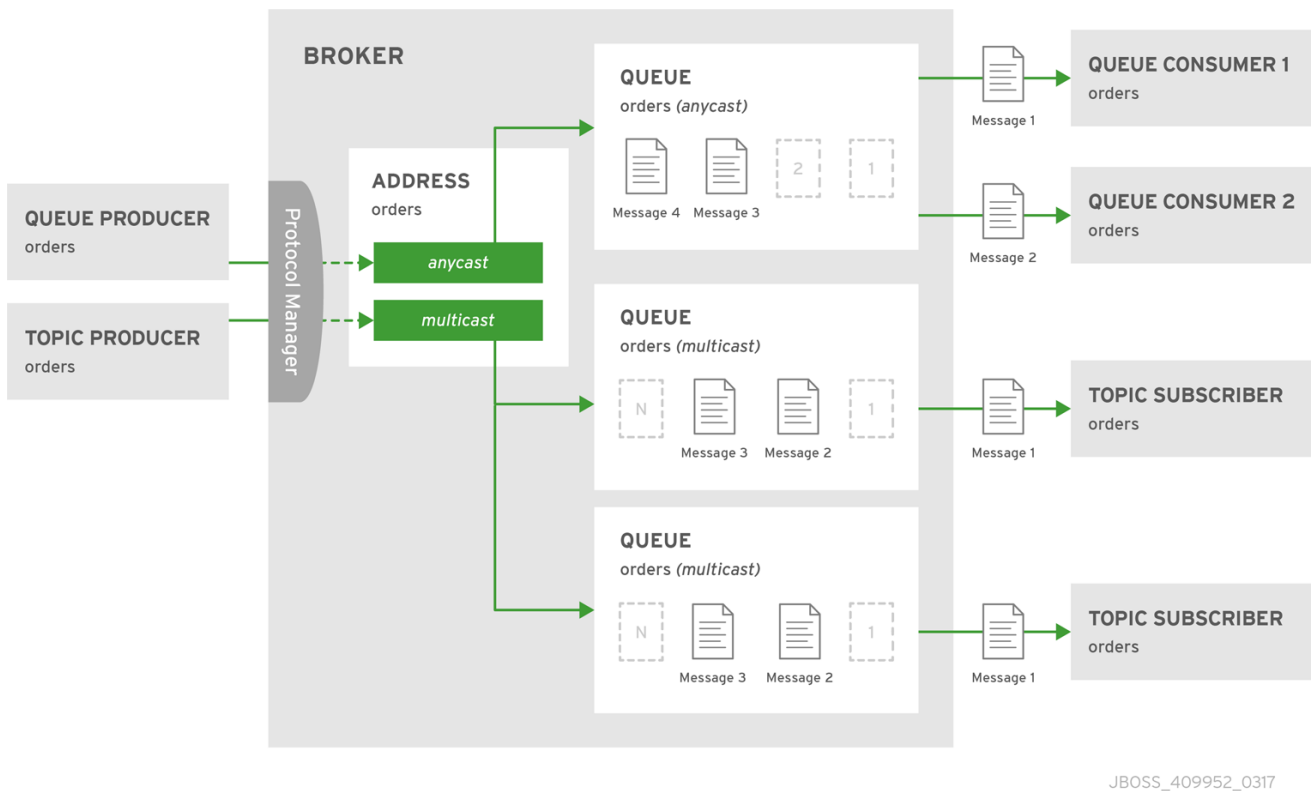

```
<configuration ...>
  <core ...>
    ...
    <address name="address.foo">
      <anycast>
        <queue name="q1"/>
        <queue name="q2"/>
      </anycast>
    </address>
  </core>
</configuration>
```

4.5. USING POINT-TO-POINT AND PUBLISH-SUBSCRIBE TOGETHER

It is possible to define an address with both point-to-point and publish-subscribe semantics enabled. While not typically recommended, this can be useful when you want, for example, a JMS Queue named **orders** and a JMS topic named **orders**. The different routing types make the addresses appear to be distinct.

Using an example of JMS clients, the messages sent by a JMS queue producer are routed using the **anycast** routing type. Messages sent by a JMS topic producer uses the **multicast** routing type. In addition, when a JMS topic consumer attaches, it is attached to its own subscription queue. The JMS queue consumer, however, is attached to the **anycast** queue.

Figure 4.4. Point-to-Point and Publish-Subscribe

**NOTE**

The behavior in this scenario is dependent on the protocol being used. For JMS there is a clear distinction between topic and queue producers and consumers, which makes the logic straightforward. Other protocols like AMQP do not make this distinction. A message being sent via AMQP is routed by both **anycast** and **multicast** and consumers default to **anycast**. For more information, check the behavior of each protocol in the sections on protocols.

The XML excerpt below is an example of what the configuration for an address using both **anycast** and **multicast** routing types would look like in ***BROKER_INSTANCE_DIR/etc/broker.xml***. Note that subscription queues are typically created on demand, so there is no need to list specific **queue** elements inside the **multicast** routing type.

```
<configuration ...>
  <core ...>
    ...
    <address name="foo.orders">
      <anycast>
        <queue name="orders"/>
      </anycast>
      <multicast/>
    </address>
  </core>
</configuration>
```

4.6. CONFIGURING SUBSCRIPTION QUEUES

In most cases it is not necessary to pre-create subscription queues because protocol managers create

subscription queues automatically when clients first request to subscribe to an address. See [Protocol Managers and Addresses](#) for more information. For durable subscriptions, the generated queue name is usually a concatenation of the client id and the address.

Configuring a Durable Subscription Queue

When an queue is configured as a durable subscription, the broker saves messages for any inactive subscribers and delivers them to the subscribers when they reconnect. Clients are therefore guaranteed to receive each message delivered to the queue after subscribing to it.

Procedure

1. Open the file ***BROKER_INSTANCE_DIR/etc/broker.xml*** for editing.
2. Add the **durable** configuration element to the chosen **queue** and assign it a value of **true**.

```
<configuration ...>
  <core ...>
    ...
    <address name="durable.foo">
      <multicast>
        <queue name="q1">
          <durable>true</durable>
        </queue>
      </multicast>
    </address>
  </core>
</configuration>
```

Configuring a Non-Shared Durable Subscription

The broker can be configured to prevent more than one consumer from connecting to a queue at any one time. The subscriptions to queues configured this way are therefore "non-shared".

Procedure

1. Open the file ***BROKER_INSTANCE_DIR/etc/broker.xml*** for editing.
2. Add the **durable** configuration element to each chosen queue.

```
<configuration ...>
  <core ...>
    ...
    <address name="non.shared.durable.foo">
      <multicast>
        <queue name="orders1">
          <durable>true</durable>
        </queue>
        <queue name="orders2">
          <durable>true</durable>
        </queue>
      </multicast>
    </address>
  </core>
</configuration>
```

3. Add the **max-consumers** attribute to each chosen **queue** element and assign it a value of **1**.

```

<configuration ...>
  <core ...>
    ...
    <address name="non.shared.durable.foo">
      <multicast>
        <queue name="orders1" max-consumers="1">
          <durable>true</durable>
        </queue>
        <queue name="orders2" max-consumers="1">
          <durable>true</durable>
        </queue>
      </multicast>
    </address>
  </core>
</configuration>

```

4.7. USING A FULLY QUALIFIED QUEUE NAME

Internally the broker maps a client's request for an address to specific queues. The broker decides on behalf of the client which queues to send messages, or from which queue to receive messages. However, more advanced use cases might require that the client specify a queue directly. In these situations the client can use a Fully Qualified Queue Name (FQQN), by specifying both the address name and the queue name, separated by a ::.

Prerequisites

- An address is configured with two or more queues. In the example below the address **foo** has two queues, **q1** and **q2**.

```

<configuration ...>
  <core ...>
    ...
    <addresses>
      <address name="foo">
        <anycast>
          <queue name="q1" />
          <queue name="q2" />
        </anycast>
      </address>
    </addresses>
  </core>
</configuration>

```

Procedure

- In the client code, use both the address name and the queue name when requesting a connection from the broker. Remember to use two colons, ::, to separate the names, as in the example Java code below.

```

String FQQN = "foo::q1";
Queue q1 session.createQueue(FQQN);
MessageConsumer consumer = session.createConsumer(q1);

```

4.8. CONFIGURING SHARDED QUEUES

A common pattern for processing of messages across a queue where only partial ordering is required is to use queue sharding. In AMQ Broker this can be achieved by creating an **anycast** address that acts as a single logical queue, but which is backed by many underlying physical queues.

Procedure

1. Open **`BROKER_INSTANCE_DIR/etc/broker.xml`** and add an **address** with the desired name. In the example below the **address** named **sharded** is added to the configuration.

```
<configuration ...>
  <core ...>
    ...
    <addresses>
      <address name="sharded"></address>
    </addresses>
  </core>
</configuration>
```

2. Add the **anycast** routing type and include the desired number of sharded queues. In the example below, the queues **q1**, **q2**, and **q3** are added as **anycast** destinations.

```
<configuration ...>
  <core ...>
    ...
    <addresses>
      <address name="sharded">
        <anycast>
          <queue name="q1" />
          <queue name="q2" />
          <queue name="q3" />
        </anycast>
      </address>
    </addresses>
  </core>
</configuration>
```

Using the configuration above, messages sent to **sharded** are distributed equally across **q1**, **q2** and **q3**. Clients are able to connect directly to a specific physical queue when [using a fully qualified queue name](#) and receive messages sent to that specific queue only.

To tie particular messages to a particular queue, clients can specify a message group for each message. The broker routes grouped messages to the same queue, and one consumer processes them all. See the chapter on [Message Grouping](#) for more information.

4.9. LIMITING THE NUMBER OF CONSUMERS CONNECTED TO A QUEUE

You can limit the number of consumers connected to for a particular queue by using the **max-consumers** attribute. Create an exclusive consumer by setting **max-consumers** flag can be set to **1**. The default value is **-1**, which is sets an unlimited number of consumers.

Procedure

1. Open ***BROKER_INSTANCE_DIR/etc/broker.xml*** and add the **max-consumers** attribute to the desired **queue**. In the example below, only **20** consumers can connect to the queue **q3** at the same time.

```
<configuration ...>
  <core ...>
    ...
    <addresses>
      <address name="foo">
        <anycast>
          <queue name="q3" max-consumers="20"/>
        </anycast>
      </address>
    </addresses>
  </core>
</configuration>
```

2. (Optional) Create an exclusive consumer by setting **max-consumers** to **1**, as in the example below.

```
<configuration ...>
  <core ...>
    ...
    <address name="foo">
      <anycast>
        <queue name="q3" max-consumers="1"/>
      </anycast>
    </address>
  </core>
</configuration>
```

3. (Optional) Have an unlimited number of consumers by setting **max-consumers** to **-1**, as in the example below.

```
<configuration ...>
  <core ...>
    ...
    <address name="foo">
      <anycast>
        <queue name="q3" max-consumers="-1"/>
      </anycast>
    </address>
  </core>
</configuration>
```

4.10. EXCLUSIVE QUEUES

Exclusive queues are special queues that route all messages to only one consumer at a time. This is useful when you want all messages to be processed serially by the same consumer. If there are multiple consumers on a queue only one consumer will receive messages. If this consumer disconnects then another consumer is chosen.

4.10.1. Configuring Exclusive Queues

You configure exclusive queues in the **broker.xml** configuration file something like this.

```
<configuration ...>
  <core ...>
    ...
    <address name="foo.bar">
      <multicast>
        <queue name="orders1" exclusive="true"/>
      </multicast>
    </address>
  </core>
</configuration>
```

Or on auto-create when using the JMS Client by using address parameters when creating the destination used by the consumer.

```
Queue queue = session.createQueue("my.destination.name?exclusive=true");
Topic topic = session.createTopic("my.destination.name?exclusive=true");
```

4.10.2. Setting the Exclusive Queue Default

```
<address-setting match="myQueue">
  <default-exclusive-queue>true</default-exclusive-queue>
</address-setting>
```

The default value for **default-exclusive-queue** is **false**.

4.11. CONFIGURING A PREFIX TO CONNECT TO A SPECIFIC ROUTING TYPE

Normally, if a message is received by an address that uses both **anycast** and **multicast**, one of the **anycast** queues receive the message and all of the **multicast** queues. However, clients can specify a special prefix when connecting to an address to specify whether to connect using **anycast** or **multicast**. The prefixes are custom values that are designated using the **anycastPrefix** and **multicastPrefix** parameters within the URL of an **acceptor**.

Configuring an Anycast Prefix

- In **BROKER_INSTANCE_DIR/etc/broker.xml**, add the **anycastPrefix** to the URL of the desired **acceptor**. In the example below, the **acceptor** is configured to use **anycast://** for the **anycastPrefix**. Client code can specify **anycast://foo/** if the client needs to send a message to only one of the anycast queues.

```
<configuration ...>
  <core ...>
    ...
    <acceptors>
      <!-- Acceptor for every supported protocol -->
      <acceptor name="artemis">tcp://0.0.0.0:61616?
protocols=AMQP;anycastPrefix=anycast://</acceptor>
    </acceptors>
```

```

...
</core>
</configuration>

```

Configuring a Multicast Prefix

- In `BROKER_INSTANCE_DIR/etc/broker.xml`, add the `anycastPrefix` to the URL of the desired `acceptor`. In the example below, the `acceptor` is configured to use `multicast://` for the `multicastPrefix`. Client code can specify `multicast://foo/` if the client needs the message sent to only the multicast queues of the address.

```

<configuration ...>
  <core ...>
    ...
    <acceptors>
      <!-- Acceptor for every supported protocol -->
      <acceptor name="artemis">tcp://0.0.0.0:61616?
protocols=AMQP;multicastPrefix=multicast://</acceptor>
    </acceptors>
    ...
  </core>
</configuration>

```

4.12. PROTOCOL MANAGERS AND ADDRESSES

A protocol manager maps protocol-specific concepts down to the AMQ Broker address model concepts: queues and routing types. For example, when a client sends a MQTT subscription packet with the addresses `/house/room1/lights` and `/house/room2/lights`, the MQTT protocol manager understands that the two addresses require `multicast` semantics. The protocol manager therefore first looks to ensure that `multicast` is enabled for both addresses. If not, it attempts to dynamically create them. If successful, the protocol manager then creates special subscription queues for each subscription requested by the client.

Each protocol behaves slightly differently. The table below describes what typically happens when subscribe frames to various types of `queue` are requested.

Table 4.2. Protocol Manager Actions

If the queue is of this type...	The typical action for a protocol manager is to...
Durable Subscription Queue	<p>Look for the appropriate address and ensures that <code>multicast</code> semantics is enabled. It then creates a special subscription queue with the client ID and the address as its name and <code>multicast</code> as its routing type.</p> <p>The special name allows the protocol manager to quickly identify the required client subscription queues should the client disconnect and reconnect at a later date.</p> <p>When the client unsubscribes the queue is deleted.</p>

If the queue is of this type...	The typical action for a protocol manager is to...
Temporary Subscription Queue	<p>Look for the appropriate address and ensures that multicast semantics is enabled. It then creates a queue with a random (read UUID) name under this address with multicast routing type.</p> <p>When the client disconnects the queue is deleted.</p>
Point-to-Point Queue	<p>Look for the appropriate address and ensures that anycast routing type is enabled. If it is, it aims to locate a queue with the same name as the address. If it does not exist, it looks for the first queue available. If this does not exist then it automatically creates the queue (providing auto create is enabled). The queue consumer is bound to this queue.</p> <p>If the queue is auto created, it is automatically deleted once there are no consumers and no messages in it.</p>

4.13. DISABLING ADVISORY MESSAGES

By default, AMQ creates advisory messages about addresses and queues when an OpenWire client is connected to the broker. Advisory messages are sent to internally managed addresses created by the broker. These addresses appear on the AMQ Console within the same display as user-deployed addresses and queues. Although they provide useful information, advisory messages can cause unwanted consequences when the broker manages a large number of destinations. For example, the messages might increase memory usage or strain connection resources. Also, the AMQ Console might become cluttered when attempting to display all of the addresses created to send advisory messages. To avoid these situations, use the **supportAdvisory** and **suppressInternalManagementObjects** parameters to manage the advisory messages behavior on the broker side.

- **supportAdvisory**: Set this option to **true** to enable creation of advisory messages or **false** to disable them. The default value is **true**.
- **suppressInternalManagementObjects**: Set this option to **true** to expose the advisory messages to the management service such as JMX registry and AMQ Console, or **false** to not expose them. The default value is **true**.

Use these parameters by editing the **`BROKER_INSTANCE_DIR/etc/broker.xml`** configuration file and configure the parameters on openwire acceptors by using URLs. For example:

```
<acceptor name="artemis">tcp://127.0.0.1:61616?
protocols=CORE,AMQP,OPENWIRE;supportAdvisory=false;suppressInternalManagementObjects=false
</acceptor>
```

4.14. CONFIGURING ADDRESS SETTINGS

AMQ Broker has several configurable options that control aspects of how and when a message is delivered, how many attempts should be made, and when the message expires. These configuration options all exist within the **<address-setting>** configuration element. You can have AMQ Broker apply a single **<address-setting>** to multiple destinations by using a wildcard syntax.

AMQ Broker Wildcard Syntax

AMQ Broker uses a specific syntax for representing wildcards in security settings, address settings, and when creating consumers.

- A wildcard expression contains words delimited by the character '.'.
- The special characters '#' and '*' also have special meaning and can take the place of a word.
- The character '#' means 'match any sequence of zero or more words'. Use this at the end of your expression.
- The character '*' means 'match a single word'. Use this anywhere within your expression.

Matching is not done character by character, but at each delimiter boundary. For example, an **address-setting** looking to match queues using **my** in their name would not match with a queue named **myqueue**.

When more than one **address-setting** matches a queue, the broker will overlay configurations, using the configuration of the least specific match as the baseline. Literal expressions are more specific than wildcards, and * is more specific than #. For example, both **my.queue** and **my.*** match the queue **my.queue**. In this case, the broker first applies the configuration found under **my.***, since a wildcard expression is less specific than a literal. Next, the broker overlays the configuration of the **my.queue address-setting**, which will overwrite any configuration shared with **my.***. Given the configuration below, the queue **my.queue** would have **max-delivery-attempts** set to **3** and **last-value-queue** set to **false**.

```
<address-setting match="my.*">
  <max-delivery-attempts>3</max-delivery-attempts>
  <last-value-queue>true</last-value-queue>
</address-setting>
<address-setting match="my.queue">
  <last-value-queue>false</last-value-queue>
</address-setting>
```

The examples in the table below illustrate how wildcards are used to match a set of addresses.

Table 4.3. Wildcard Examples

Example	Description
#	The default address-setting used in broker.xml . Matches every address. You can continue to apply this catch-all, or you can add a new address-setting for each address or group of addresses as the need arises.
news.europe.#	Matches news.europe , news.europe.sport , news.europe.politics.fr , but not news.usa or europe .
news.*	Matches news.europe and news.usa , but not news.europe.sport .
news.*.sport	Matches news.europe.sport and news.usa.sport , but not news.europe.fr.sport .

Configuring Wildcard Syntax

You can customize the syntax used for wildcard addresses by adding configuration to **broker.xml**.

Procedure

- Edit **broker.xml** by adding a **<wildcard-addresses>** section to the configuration, as in the example below.

```

<configuration>
  <core>
    ...
    <wildcard-addresses> 1
      <enabled>true</enabled> 2
      <delimiter>,</delimiter> 3
      <any-words>@</any-words> 4
      <single-word>$</single-word> 5
    </wildcard-addresses>
    ...
  </core>
</configuration>

```

- 1 Add **wildcard-addresses** beneath the **core** configuration element.
- 2 Set **enabled** to **true** to tell the broker to use your custom settings.
- 3 Provide a custom character to use as the **delimiter** instead of the default, which is **..**.
- 4 The character provided as the value for **any-words** is used to mean 'match any sequence of zero or more words' and will replace the default **#**. Use this character at the end of your expression.
- 5 The character provided as the value for **single-word** is used to mean 'match a single word' and will replace the default *****. Use this character anywhere within your expression.

4.15. CREATING AND DELETING QUEUES AND ADDRESSES AUTOMATICALLY

You can configure AMQ Broker to automatically create addresses and queues, and to delete them after they are no longer in use. This saves you from having to pre-configure each address before a client can connect to it.

Automatic creation and deletion of queues and addresses is configured on a per **address-setting** basis. The configuration is applied to any address or queue that is a match for the **address-setting**. For more information about how to use wildcard syntax to match addresses and queues to an **address-setting** see [Configuring Address Settings](#).

IMPORTANT

Disabling the automatic creation of queues and addresses can cause problems and is not recommended. AMQ Broker must be able to auto-create addresses and queues by using the **activemq.#** pattern. For an example see the [example address setting](#).

The following table lists the configuration elements available when configuring an **address-setting** to automatically create and delete its queues and addresses.

If you want the address-setting to...	Add this configuration...
Create addresses when a client sends a message to or attempts to consume a message from a queue mapped to an address that does not exist.	auto-create-addresses
Create a queue when a client sends a message to or attempts to consume a message from a queue.	auto-create-queues
Delete an automatically created address when it no longer has any queues.	auto-delete-addresses
Delete an automatically created queue when the queue has 0 consumers and 0 messages.	auto-delete-queues
Use a specific routing type if the client does not specify one.	default-address-routing-type

Procedure

Edit the ***BROKER_INSTANCE_DIR/etc/broker.xml*** file and configure an **address-setting** for automatic creation and deletion. The following example uses all of the configuration elements mentioned in the previous table.

```

<configuration ...>
  <core ...>
    ...
    <address-settings>
      <address-setting match="activemq.#"> ❶
        <auto-create-addresses>true</auto-create-addresses> ❷
        <auto-delete-addresses>true</auto-delete-addresses> ❸
        <auto-create-queues>true</auto-create-queues> ❹
        <auto-delete-queues>true</auto-delete-queues> ❺
        <default-address-routing-type>ANYCAST</default-address-routing-type> ❻
      </address-setting>
    </address-settings>
    ...
  </core>
</configuration>

```

- ❶ The configuration included in this **address-setting** is applied to any address or queue that matches the wildcard **activemq.#**. For more information on using wildcard syntax see [AMQ Broker Wildcard Syntax](#).
- ❷ The broker creates an address that does not exist when a client requests it.
- ❸ An automatically created address is deleted when it no longer has any queues associated with it.
- ❹ The broker creates a queue that does not exist when a client requests it.
- ❺ An automatically created queue is deleted when it no longer has any consumers or messages.

- 6 If the client does not specify a routing type when connecting, the broker uses **ANYCAST** when delivering messages to an address. The default value is **MULTICAST**. See [the introduction of this](#)

CHAPTER 5. USERS AND ROLES

The broker supports a flexible role-based security model for applying security to queues based on their respective addresses. It is important to understand that queues are bound to addresses either one-to-one (for point-to-point style messaging) or many-to-one (for publish-subscribe style messaging). When a message is sent to an address the server looks up the set of queues that are bound to that address and routes the message to that set of queues.

In the default configuration (using **PropertiesLoginModule**), users and their assigned roles are defined in three configuration files:

- **login.config**
- **artemis-users.properties**
- **artemis-roles.properties**

Each of these files is discussed in more detail in the following sections.

The command-line interface allows users and roles to be added to these files via an interactive process.

NOTE

The **artemis-users.properties** file can contain hashed passwords for security.

5.1. ENABLING GUEST ACCESS

A user who does not have login credentials, or whose credentials fail validation, can be granted limited access to the broker using a *guest* account.

A broker instance can be created with guest access enabled using the command-line switch; **--allow-anonymous** (the converse of which is **--require-login**).

The guest account is configured in the **login.config** file.

Procedure

1. In the **login.config** file, define a name and role for the guest account as follows:

```
activemq {
  org.apache.activemq.artemis.spi.core.security.jaas.GuestLoginModule required
    org.apache.activemq.jaas.guest.user="guest" 1
    org.apache.activemq.jaas.guest.role="guest"; 2
};
```

1 Define the username assigned to anonymous users.

2 Define the role assigned to anonymous users.

The guest login module allows users without credentials (and, depending on how it is configured, possibly also users with invalid credentials) to access the broker. It is implemented by **org.apache.activemq.artemis.spi.core.security.jaas.GuestLoginModule**.

It is common for the guest login module to be used in conjunction with another login module, such as a properties login module. Read more about that use-case in the [Section 6.2.5, “Using Multiple Login Modules”](#) section.

5.2. ADDING USERS

When basic username and password validation is required, use the *Properties* login module to define it. This login module checks the user’s credentials against a set of local property files.

Users and their corresponding passwords are listed in the ***BROKER_INSTANCE_DIR/etc/artemis-users.properties*** file. The available roles and the users who are assigned those roles are defined in the ***BROKER_INSTANCE_DIR/etc/artemis-roles.properties*** file.

Both of these files are referenced in the ***BROKER_INSTANCE_DIR/etc/login.config*** file.

See the documentation from your Java vendor for more information on JAAS. For example, [Oracle has a tutorial](#) on configuring **login.config**.

Example 5.1. login.config

```
activemq { 1
    org.apache.activemq.artemis.spi.core.security.jaas.PropertiesLoginModule required 2 3
        org.apache.activemq.jaas.properties.user="artemis-users.properties"; 4
        org.apache.activemq.jaas.properties.role="artemis-roles.properties";
};
```

- 1 An alias for a configuration. In this section the alias used is **activemq**. Substitute another in your environment.
- 2 The implementation class (**org.apache.activemq.artemis.spi.core.security.jaas.PropertiesLoginModule**).
- 3 A flag which indicates whether the success of the **LoginModule** is **required**, **requisite**, **sufficient**, or **optional**.
- 4 A list of configuration options specific to the login module implementation.

Below is an explanation for each of the success states listed in the previous example:

Required

The LoginModule is required to succeed and authentication continues to proceed down the LoginModule list regardless of success or failure.

Requisite

The LoginModule is required to succeed. A failure immediately returns control to the application and authentication does not proceed down the LoginModule list.

Sufficient

The LoginModule is not required to succeed. If it is successful, control returns to the application and authentication does not proceed further. If it fails, the authentication attempt proceeds down the **LoginModule** list.

Optional

The LoginModule is not required to succeed. Authentication continues down the **LoginModules** list regardless of success or failure.

More information on these flags and the authentication process is available in the [Oracle documentation](#).

Example 5.2. artemis-users.properties

```
user1=secret 1
user2=swordfish 2
user3=myPassword 3
```

- 1 *User1* has a password of *secret*.
- 2 *User2* has a password of *swordfish*.
- 3 *User3* has a password of *myPassword*.

Example 5.3. artemis-roles.properties

```
admin=user1,user2 1
developer=user3 2
```

- 1 *User1* and *user2* belong to the *admin* role.
- 2 *User3* belongs to the *developer* role.

NOTE

If necessary, add your security domain alias (in this instance, *activemq*) to the **bootstrap.xml** file as shown below:

```
<jaas-security domain="activemq"/>
```

5.3. SETTING PERMISSIONS

Permissions are defined against the queues based on their address via the **<security-setting>** element in **broker.xml**. Multiple instances of **<security-setting>** can be defined in **<security-settings>**. An exact match on the address can be used or a wildcard match can be used using the wildcard characters **#** and *****.

Different permissions can be given to the set of queues which match the address. Those permissions are:

Table 5.1. Permissions

To allow users to...	Use this parameter...
Create addresses	createAddress

To allow users to...	Use this parameter...
Delete addresses	deleteAddress
Create a durable queue under matching addresses	createDurableQueue
Delete a durable queue under matching addresses	deleteDurableQueue
Create a non-durable queue under matching addresses	createNonDurableQueue
Delete a non-durable queue under matching addresses	deleteNonDurableQueue
Send a message to matching addresses	send
Consume a message from a queue bound to matching addresses	consume
Invoke management operations by sending management messages to the management address	manage
Browse a queue bound to the matching address	browse

For each permission, a list of roles who are granted that permission is specified. If the user has any of those roles, they are granted that permission for that set of addresses.

5.3.1. Configuring Message Production for a Single Address

To define sending permissions for a single address, a configuration similar to the example shown below is used:

```
<security-settings>
  <security-setting match="queue1"> 1
    <permission type="send" roles="producer"/> 2
  </security-setting>
</security-settings>
```

1 Messages sent to this queue get the nominated permissions.

2 The permissions applied to messages in the specified queue.

In the above example, members of the *producer* role have *send* permissions on *queue1*.

5.3.2. Configuring Message Consumption for a Single Address

To define consuming permissions for a single address, a configuration similar to the example shown below is used:

■

```

<security-settings>
  <security-setting match="queue1"> 1
    <permission type="consume" roles="consumer"/> 2
  </security-setting>
</security-settings>

```

- 1 Messages sent to this queue get the nominated permissions.
- 2 The permissions applied to messages in the specified queue.

In the above example, members of the *consumer* role have *consume* permissions on *queue1*.

5.3.3. Configuring Complete Access on All Addresses

To allow complete access to addresses and queues, a configuration similar to the example shown below is used.

```

<security-settings>
  <security-setting match="#"> 1
    <permission type="createDurableQueue" roles="guest"/>
    <permission type="deleteDurableQueue" roles="guest"/>
    <permission type="createNonDurableQueue" roles="guest"/>
    <permission type="deleteNonDurableQueue" roles="guest"/>
    <permission type="createAddress" roles="guest"/>
    <permission type="deleteAddress" roles="guest"/>
    <permission type="send" roles="guest"/>
    <permission type="browse" roles="guest"/>
    <permission type="consume" roles="guest"/>
    <permission type="manage" roles="guest"/>
  </security-setting>
</security-settings>

```

- 1 A wildcard setting to apply to all queues.

In the above configuration, all permissions are granted to members of the *guest* role on all queues. This can be useful in a development scenario where anonymous authentication was configured to assign the **guest** role to every user.

For information about more complex use cases see [Configuring Multiple Permissions for Addresses](#).

5.3.4. Configuring a Queue with a User

The queue is assigned the username of the connecting client when it is auto-created. This is exposed as metadata on the queue. It is exposed by JMX and in the console. The queue is assigned the username of the connecting client when it is auto-created. This is exposed as metadata on the queue. It is exposed by JMX and in the console

You can configure a user on a pre-defined queue in **broker.xml**

To define a user for a queue, use a configuration similar to the example shown below:

```

<address name="ExempleQueue">
  <anycast>

```

```
<queue name="ExampleQueue" user="admin" />
</anycast>
</address>
```

NOTE

Configuring a user on a queue does not change any of the security semantics for that queue, it is only used for metadata on that queue.

5.4. SETTING ROLE BASED ACCESS CONTROL

Role-based access control (RBAC) is used to restrict access to the attributes and methods of MBeans. RBAC enables administrators to grant the correct level of access to all users like web console, management interface, core messages, and so on based on their role. RBAC is configured using the **authorization** element in the ***BROKER_INSTANCE_DIR/etc/management.xml*** configuration file. Within the authorization element, you can configure **Whitelist**, **default-access**, and **role-access** sub-elements.

Prerequisites

You must first [set up roles and add users](#) to configure RBAC.

5.4.1. Configuring Whitelist Element for Bypassing the Authentication

A **whitelist** is a set of pre-approved domains or MBeans that do not require user authentication. You can provide a whitelist of domains or list of MBeans or both that must bypass the authentication. For example, you can use **whitelist** element for any MBeans that are needed by the AMQ Console to run.

Procedure

1. Open the broker ***BROKER_INSTANCE_DIR/etc/management.xml*** configuration file.
2. Search for the **whitelist** element and edit the configuration:

```
<whitelist>
  <entry domain="hawtio"/> 1
</whitelist>
```

- 1 MBean of this domain will bypass the authentication.

In this example, any MBean with the domain **hawtio** will be allowed access without authentication. You can also use wildcard entries like **<entry domain="hawtio" key="type=*" />** for the MBean properties to match.

3. Start or restart the broker by entering the following command:
 - On Linux: ***BROKER_INSTANCE_DIR/bin/artemis run***
 - On Windows: ***BROKER_INSTANCE_DIR\bin\artemis-service.exe start***

5.4.2. Configuring Authentication Based on Roles

The **role-access** method defines how roles are mapped to particular MBeans and their attributes and methods.

Procedure

1. Open the ***BROKER_INSTANCE_DIR/etc/management.xml*** configuration file.
2. Search for the **role-access** element and edit the configuration:

```
<role-access>
  <match domain="org.apache.activemq.artemis"> 1
    <access method="list*" roles="view,update,amq"/> 2
    <access method="get*" roles="view,update,amq"/>
    <access method="is*" roles="view,update,amq"/>
    <access method="set*" roles="update,amq"/>
    <access method="*" roles="amq"/>
  </match>
</role-access>
```

- 1 A match will be applied to any MBean attribute that has the domain name `org.apache.activemq.apache`.
- 2 Specified roles can invoke the listed methods.

IMPORTANT

=== You must ensure that the order of the individual lines in the configuration is as per the template. Any change in the line indentation leads to changes in the semantics of the assigned privileges. For example, if you move the line **`<access method="*" roles="amq,guest"/>`** inside the **`<role-access>`** tag from last position to the first, it changes the semantics of applied privileges. If used as the first line, it means *grant access to everything to these roles with the exception of following specific cases*. If used as the last line, it means *grant access to everything to these roles (default)*. ===

Here, the specific tasks like **list***, **get***, **set***, **is** and ***** are specified using the access method. The invoked method is matched against the methods listed in the configuration. The user is assigned the roles given for the best matching method. For example, if you try to invoke a method called **listMessages** on an MBean with the **org.apache.activemq.artemis** domain, then it would match the access with the method of **list**. You can also explicitly configure this by using the full method name like the following:

```
<access method="listMessages" roles="view,update,amq"/>
```

3. Start or restart the broker by entering the following command:
 - On Linux: ***BROKER_INSTANCE_DIR/bin/artemis run***
 - On Windows: ***BROKER_INSTANCE_DIR\bin\artemis-service.exe start***

You can also match specific MBeans within a domain by adding a **key** attribute that matches an MBean property. For example,

```
<match domain="org.apache.activemq.artemis" key="subcomponent=queues">
  <access method="list*" roles="view,update,amq"/>
  <access method="get*" roles="view,update,amq"/>
  <access method="is*" roles="view,update,amq"/>
```

```
<access method="set*" roles="update,amq"/>  
<access method="*" roles="amq"/>  
</match>
```

Access to MBean attributes are converted to method calls, so these are controlled using the **list***, **set***, **get***, and **is*** syntax. The * (wildcard) syntax is used as a catch-all for every other method that is not listed in the configuration.

NOTE

The **default-access** element is mainly the catch-all for every method call that is not handled using the **role-access** configuration. The **default-access** and **role-access** have the same **match** element semantics.

CHAPTER 6. SECURITY

This chapter covers the various security options available to administrators, and how they are configured. Administrators can use the information provided in this chapter to tailor the functions of the AMQ Broker security subsystems to their needs.

6.1. ACCESSING THE AMQ CONSOLE

Starting with AMQ Broker 7.1.0, you can access the AMQ Console only from the local host by default. You must modify the configuration in ***BROKER_INSTANCE_DIR/etc/jolokia-access.xml*** to enable remote access. For more information, see [Securing AMQ Console and AMQ Broker Connections](#).

6.2. SECURING NETWORK CONNECTIONS

There are two basic use cases for transport layer security (TLS):

- Server-side (or *one-way*); where only the server presents a certificate. This is the most common use case.
- Client-side (or *two-way*); where both the server and the client present certificates. This is sometimes called mutual authentication.

6.2.1. Configuring Server-Side Certificates

One-way TLS is configured in the URL of the relevant **acceptor** in **broker.xml**. Here is a very basic **acceptor** configuration which does not use TLS:

```
<acceptor name="artemis">tcp://0.0.0.0:61616</acceptor>
```

Here is that same **acceptor** configured to use one-way TLS:

```
<acceptor name="artemis">tcp://0.0.0.0:61616?
sslEnabled=true;keyStorePath=../etc/broker.keystore;keyStorePassword=1234!</acceptor>
```

This **acceptor** uses three additional parameters - **sslEnabled**, **keyStorePath**, and **keyStorePassword**. These, at least, are required to enable one-way TLS.

6.2.2. Configuring Client-Side Certificates

Two-way TLS uses the same **sslEnabled**, **keyStorePath**, and **keyStorePassword** properties as one-way TLS, but it adds **needClientAuth** to tell the client it should present a certificate of its own. For example:

```
<acceptor name="artemis">tcp://0.0.0.0:61616?
sslEnabled=true;keyStorePath=../etc/broker.keystore;keyStorePassword=1234!;needClientAuth=true
</acceptor>
```

This configuration assumes that the client's certificate is signed by a trusted provider. If the client's certificate is not signed by a trusted provider (it is self-signed, for example) then the server needs to import the client's certificate into a trust-store and configure the acceptor with **trustStorePath** and **trustStorePassword**. For example:

```
<acceptor name="artemis">tcp://0.0.0.0:61616?
sslEnabled=true;keyStorePath=../etc/broker.keystore;keyStorePassword=1234!;needClientAuth=true;tru
stStorePath=../etc/client.truststore;trustStorePassword=5678!</acceptor>
```

NOTE

AMQ Broker supports multiple protocols, and each protocol and platform has different ways to specify TLS parameters. However, in the case of a client using the Core protocol (a bridge) the TLS parameters are configured on the connector URL much like on the broker's acceptor.

TLS Configuration Details

Below are configuration details to be aware of:

Option	Note
sslEnabled	Must be true to enable TLS. Default is false .
keyStorePath	<p>When used on an acceptor: This is the path to the TLS key store on the server which holds the server's certificates (whether self-signed or signed by an authority).</p> <p>When used on a connector: This is the path to the client-side TLS key store which holds the client certificates. This is only relevant for a connector if you are using two-way TLS (that is, mutual authentication). Although this value is configured on the server, it is downloaded and used by the client. If the client needs to use a different path from that set on the server then it can override the server-side setting by either using the customary javax.net.ssl.keyStore system property or the AMQ-specific org.apache.activemq.ssl.keyStore system property. The AMQ-specific system property is useful if another component on client is already making use of the standard, Java system property.</p>

Option	Note
<p>keyStorePassword</p>	<p>When used on an <i>acceptor</i>: This is the password for the server-side KeyStore.</p> <p>When used on a <i>connector</i>: This is the password for the client-side KeyStore. This is only relevant for a connector if you are using two-way TLS (that is, mutual authentication). Although this value can be configured on the server, it is downloaded and used by the client. If the client needs to use a different password from that set on the server then it can override the server-side setting by either using the customary javax.net.ssl.keyStorePassword system property or the AMQ-specific org.apache.activemq.ssl.keyStorePassword system property. The AMQ-specific system property is useful if another component on client is already making use of the standard, Java system property.</p>
<p>trustStorePath</p>	<p>When used on an <i>acceptor</i>: This is the path to the server-side TLS key store that holds the keys of all the clients that the server trusts. This is only relevant for an acceptor if you are using two-way TLS (mutual authentication).</p> <p>When used on a <i>connector</i>: This is the path to the client-side TLS key store which holds the public keys of all the servers that the client trusts. Although this value can be configured on the server, it is downloaded and used by the client. If the client needs to use a different path from that set on the server then it can override the server-side setting by either using the customary javax.net.ssl.trustStore system property or the AMQ-specific org.apache.activemq.ssl.trustStore system property. The AMQ-specific system property is useful if another component on client is already making use of the standard, Java system property.</p>

Option	Note
trustStorePassword	<p>When used on an <i>acceptor</i>: This is the password for the server-side trust store. This is only relevant for an acceptor if you are using two-way TLS (that is, mutual authentication).</p> <p>When used on a <i>connector</i>: This is the password for the client-side TrustStore. Although this value can be configured on the server, it is downloaded and used by the client. If the client needs to use a different password from that set on the server then it can override the server-side setting by either using the customary javax.net.ssl.trustStorePassword system property or the AMQ-specific org.apache.activemq.ssl.trustStorePassword system property. The AMQ-specific system property is useful if another component on client is already making use of the standard, Java system property.</p>
enabledCipherSuites	Whether used on an acceptor or connector this is a comma-separated list of cipher suites used for TLS communication. The default value is null which means the JVM's default is used.
enabledProtocols	Whether used on an acceptor or connector this is a comma-separated list of protocols used for TLS communication. The default value is null which means the JVM's default is used.
needClientAuth	This property is only for an acceptor . It indicates to a client connecting to this acceptor that two-way TLS is required. Valid values are true or false . Default is false .

6.2.3. Adding Certificate-based Authentication

The JAAS certificate authentication login module requires TLS to be in use and clients must be configured with their own certificates. In this scenario, authentication is actually performed during the TLS handshake, not directly by the JAAS certificate authentication plug-in.

The role of the plug-in is as follows:

- To further constrain the set of acceptable users, because only the user Distinguished Names (DNs) explicitly listed in the relevant properties file are eligible to be authenticated.
- To associate a list of groups with the received user identity, facilitating integration with authorization.

- To require the presence of an incoming certificate (by default, the TLS layer is configured to treat the presence of a client certificate as optional).

The JAAS certificate login module stores a collection of certificate DNs in a pair of flat files. The files associate a username and a list of group IDs with each Distinguished Name.

The certificate login module is implemented by the **org.apache.activemq.artemis.spi.core.security.jaas.TextFileCertificateLoginModule** class.

Prerequisites

- Certificate login configured in **login.config** file.
- A valid **artemis-users.properties** file.
- A valid **artemis-roles.properties** file.
- The Subject DNs from the user certificate(s)

Procedure

1. Obtain the Subject DNs from user certificates
 - a. Export the certificate from the KeyStore file into a temporary file. Substitute your required values into the following command:

```
keytool -export -file __FILENAME__ -alias broker-localhost -keystore broker.ks -storepass __PASSWORD__
```

- b. Print the contents of the exported certificate:

```
keytool -printcert -file __FILENAME__
```

The output is similar to that shown below:

```
Owner: CN=localhost, OU=broker, O=Unknown, L=Unknown, ST=Unknown, C=Unknown
1 Issuer: CN=localhost, OU=broker, O=Unknown, L=Unknown, ST=Unknown, C=Unknown
Serial number: 4537c82e
Valid from: Thu Oct 19 19:47:10 BST 2006 until: Wed Jan 17 18:47:10 GMT 2007
Certificate fingerprints:
    MD5: 3F:6C:0C:89:A8:80:29:CC:F5:2D:DA:5C:D7:3F:AB:37
    SHA1: F0:79:0D:04:38:5A:46:CE:86:E1:8A:20:1F:7B:AB:3A:46:E4:34:5C
```

- 1 The subject DN. The format used to enter the subject DN depends on your platform. The string above could also be represented as;

```
Owner: `CN=localhost,\ OU=broker,\ O=Unknown,\ L=Unknown,\ ST=Unknown,\ C=Unknown`
```

2. Configuring certificate-based authentication
 - a. Open the **login.config** file and reference the user and roles properties files.

- b. Open the files declared in the previous step and supply the required information: Users and their corresponding DN's should be listed in the **artemis-users.properties** file. The available roles and the users who hold those roles are defined in the **artemis-roles.properties** file.

Examples of the syntax of these files is shown below.

- c. Ensure your security domain alias (in this instance, *activemq*) is referenced in **bootstrap.xml** as shown below:

```
<jaas-security domain="activemq"/>
```

Example Configuration

The following example shows how to configure certificate login module in the **login.config** file:

Example 6.1. login.config

```
activemq {
  org.apache.activemq.artemis.spi.core.security.jaas.TextFileCertificateLoginModule 1
  debug=true 2
  org.apache.activemq.jaas.textfiledn.user="artemis-users.properties" 3
  org.apache.activemq.jaas.textfiledn.role="artemis-roles.properties"; 4
};
```

- 1 Configure the JAAS realm. This example uses a single **org.apache.activemq.artemis.spi.core.security.jaas.TextFileCertificateLoginModule**
- 2 Toggle debugging on (**true**) or off (**false**). Default is **false**.
- 3 Define the file used to store user data (relative to the directory containing the **login.config** file).
- 4 Define the file used to store role data (relative to the directory containing the **login.config** file).

The **artemis-users.properties** file consists of a list of properties with the **user=StringifiedSubjectDN** (where the string encoding is specified by RFC 2253):

Example 6.2. artemis-users.properties

```
system=CN=system,O=Progress,C=US 1
user=CN=humble user,O=Progress,C=US
guest=CN=anon,O=Progress,C=DE
```

- 1 The user named **system** is mapped to the **CN=system,O=Progress,C=US** subject DN.

The **artemis-roles.properties** file follows the pattern of **role=user** where **user** can be either a single user or a comma-separated list of users:

Example 6.3. artemis-roles.properties

```
admins=system
users=system,user 1
guests=guest
```

- 1 Multiple users can be included as a comma-separated entry.

6.2.4. Adding Certificate-based Authentication for AMQP Clients

Use the SASL EXTERNAL mechanism configuration parameter to configure your AMQP client for certificate-based authentication when connecting to a broker.

The broker authenticates the TLS/SSL certificate of your AMQP client in the same way that it authenticates any certificate:

- The broker reads the TLS/SSL certificate of the client to obtain an identity from the certificate's subject.
- The certificate subject is mapped to a broker identity by the certificate login module. The broker then authorizes the mapped user based on their roles.

Prerequisites

Before you can configure your AMQP clients to use certificate-based authentication, you must complete the following tasks:

- [Configure a server-side SSL/TLS certificate.](#)
- [Configure a client-side SSL/TLS certificate.](#)
- [Configure the broker to use certificate-based authentication.](#)

Procedure

To enable your AMQP client to use certificate-based authentication, add configuration parameters to the URI that the client uses to connect to a broker.

1. Open the resource containing the URI for editing:

```
amqps://localhost:5500
```

2. Add the parameter **sslEnabled=true** to enable TLS/SSL for the connection:

```
amqps://localhost:5500?sslEnabled=true
```

3. Add parameters related to the TrustStore and KeyStore of the client to enable the exchange of TLS/SSL certificates with the broker:

```
amqps://localhost:5500?
sslEnabled=true&trustStorePath=TRUST_STORE_PATH&trustStorePassword=TRUST_STORE_PASSWORD&keyStorePath=KEY_STORE_PATH&keyStorePassword=KEY_STORE_PASSWORD
```

4. Add the parameter **saslMechanisms=EXTERNAL** to request that the broker authenticate the client by using the identity found in its TLS/SSL certificate:

-

```
amqps://localhost:5500?
sslEnabled=true&trustStorePath=TRUST_STORE_PATH&trustStorePassword=TRUST_STORE_PASSWORD&keyStorePath=KEY_STORE_PATH&keyStorePassword=KEY_STORE_PASSWORD&saslmMechanisms=EXTERNAL
```

Additional Resources

- For more information about certificate-based authentication in AMQ Broker, see [Section 6.2.3, “Adding Certificate-based Authentication”](#).
- For more information about configuring your AMQP client, go to the [Red Hat Customer Portal](#) for product documentation specific to your client.

6.2.5. Using Multiple Login Modules

It is possible to combine login modules to accommodate more complex use cases. The most common reason to combine login modules is to support authentication for both anonymous users and users who submit credentials.

Prerequisites

The prerequisites for different authentication combinations differ based on the methods being implemented. Prerequisites for the most common multiple login scenario are:

- A valid **artemis-users.properties** file
- A valid **artemis-roles.properties** file
- A **login.config** file configured for anonymous access

Procedure

1. Edit the **login.config** file to add entries for the desired authentication modules.
2. Set the parameters in each module entry as required for your environment.
3. Ensure your security domain alias (in this instance, *activemq*) is referenced in **bootstrap.xml** as shown below:

Example 6.4. bootstrap.xml

```
<jaas-security domain="activemq"/>
```

Example Configuration

The following examples illustrate the cascading nature of multiple login configurations:

Example 6.5. login.config

```
activemq {
  org.apache.activemq.artemis.spi.core.security.jaas.PropertiesLoginModule sufficient 1
  debug=true
  org.apache.activemq.jaas.properties.user="artemis-users.properties"
  org.apache.activemq.jaas.properties.role="artemis-roles.properties";
```

```
org.apache.activemq.artemis.spi.core.security.jaas.GuestLoginModule sufficient ❷
  debug=true
  org.apache.activemq.jaas.guest.user="guest"
  org.apache.activemq.jaas.guest.role="restricted";
};
```

- ❶ Password authentications module is activated if the user supplies credentials
- ❷ Guest authentication module is activated if the user supplies no credentials or the credentials supplied are incorrect.

The following example shows how to configure a JAAS login entry for the use case where only those users with no credentials are logged in as guests. Note that the order of the login modules is reversed and the flag attached to the properties login module is changed to **requisite**.

Example 6.6. login.config

```
activemq {
  org.apache.activemq.artemis.spi.core.security.jaas.GuestLoginModule sufficient ❶
    debug=true
    credentialsInvalidate=true ❷
    org.apache.activemq.jaas.guest.user="guest"
    org.apache.activemq.jaas.guest.role="guests";

  org.apache.activemq.artemis.spi.core.security.jaas.PropertiesLoginModule requisite ❸
    debug=true
    org.apache.activemq.jaas.properties.user="artemis-users.properties"
    org.apache.activemq.jaas.properties.role="artemis-roles.properties";
};
```

- ❶ The guest authentication module is activated if no login credentials are supplied.
- ❷ The **credentialsInvalidate** option must be set to **true** in the configuration of the guest login module.
- ❸ The password login module is activated if credentials are supplied and the credentials must be valid.

6.2.6. Configure Multiple Security Settings for Address Groups and Sub-groups

Below is an example security block from a **broker.xml** file. The various configuration options based on this example are explained in this section.

```
<security-setting match="globalqueues.europe.#"> ❶
  <permission type="createDurableQueue" roles="admin"/> ❷
  <permission type="deleteDurableQueue" roles="admin"/> ❸
  <permission type="createNonDurableQueue" roles="admin, guest, europe-users"/> ❹
  <permission type="deleteNonDurableQueue" roles="admin, guest, europe-users"/> ❺
```

```

<permission type="send" roles="admin, europe-users"/> 6
<permission type="consume" roles="admin, europe-users"/> 7
</security-setting>

```

- 1 The '#' character signifies "any sequence of words". Words are delimited by the '.' character. For a full description of the wildcard syntax, see [AMQ Broker Wildcard Syntax](#). The above security block applies to any address that starts with the string *globalqueues.europe*.
- 2 3 Only users who have the **admin** role can create or delete durable queues bound to an address that starts with the string *globalqueues.europe*.
- 4 5 Any users with the roles **admin**, **guest**, or **europe-users** can create or delete temporary queues bound to an address that starts with the string *globalqueues.europe*.
- 6 7 Any users with the roles **admin** or **europe-users** can send messages to these addresses or consume messages from queues bound to an address that starts with the string *globalqueues.europe*.

The mapping between a user and what roles they have is handled by the security manager. AMQ Broker ships with a user manager that reads user credentials from a file on disk, and can also plug into JAAS or JBoss Application Server security.

There can be multiple **security-setting** elements in each XML file, or none, depending on requirements. When the **broker.xml** file contains multiple security-setting elements that can apply to a set of addresses, the most specific match takes precedence.

Let us look at an example of that, here's another **security-setting** block:

```

<security-setting match="globalqueues.europe.orders.#">
  <permission type="send" roles="europe-users"/>
  <permission type="consume" roles="europe-users"/>
</security-setting>

```

In this **security-setting** block the match **globalqueues.europe.orders.#** is more specific than the previous match *'globalqueues.europe.\#'*. So any addresses which match *'globalqueues.europe.orders.\#'* will take their security settings **only** from the latter security-setting block.

Note that settings are not inherited from the former block. All the settings will be taken from the more specific matching block, so for the address **globalqueues.europe.orders.plastics** the only permissions that exist are **send** and **consume** for the role **europe-users**. The permissions **createDurableQueue**, **deleteDurableQueue**, **createNonDurableQueue**, **deleteNonDurableQueue** are not inherited from the other security-setting block.

By not inheriting permissions, you can effectively deny permissions in more specific security-setting blocks by simply not specifying them. Otherwise it would not be possible to deny permissions in sub-groups of addresses.

6.2.7. Setting Resource Limits

Sometimes it is helpful to set particular limits on what certain users can do beyond the normal security settings related to authorization and authentication. For example, one can limit how many connections a user can create or how many queues a user can create.

6.2.7.1. Configuring Connection and Queue Limits

Here is an example of the XML used to set resource limits:

```
<resource-limit-settings>
  <resource-limit-setting match="myUser">
    <max-connections>5</max-connections>
    <max-queues>3</max-queues>
  </resource-limit-setting>
</resource-limit-settings>
```

Unlike the **match** from **address-setting**, this **match** does not use any wildcard syntax. It is a simple 1:1 mapping of the limits to a user.

- **max-connections.** Defines how many connections the matched user can make to the broker. The default is **-1**, which means there is no limit.
- **max-queues.** Defines how many queues the matched user can create. The default is **-1**, which means there is no limit.

6.3. INTEGRATING WITH LDAP

6.3.1. Using LDAP for Authentication

The LDAP login module enables authentication and authorization by checking the incoming credentials against user data stored in a central X.500 directory server. It is implemented by **org.apache.activemq.artemis.spi.core.security.jaas.LDAPLoginModule**.

Procedure

1. Open the ***BROKER_INSTANCE_DIR*/etc/broker.xml** file and add the following lines:

```
<security-settings>
  <security-setting match="#">
    <permission type="createDurableQueue" roles="user"/>
    <permission type="deleteDurableQueue" roles="user"/>
    <permission type="createNonDurableQueue" roles="user"/>
    <permission type="deleteNonDurableQueue" roles="user"/>
    <permission type="send" roles="user"/>
    <permission type="consume" roles="user"/>
  </security-setting>
</security-settings>
```

2. Open the ***BROKER_INSTANCE_DIR*/etc/login.config** file.
3. Locate and edit the appropriate alias block with the appropriate parameters (see the examples included below).
4. Start or restart the broker (service or process).

**NOTE**

Apache DS uses the **OID** portion of DN path; however, Microsoft AD does not, and instead uses the **CN** portion.

For example; The DN path **oid=testuser,dc=example,dc=com** would be used in Apache DS, while **cn=testuser,dc=example,dc=com** would be used in Microsoft AD.

Example 6.7. Example Apache DSlogin.config configuration

```

activemq {
  org.apache.activemq.artemis.spi.core.security.jaas.LDAPLoginModule required
  debug=true 1
  initialContextFactory=com.sun.jndi.ldap.LdapCtxFactory 2
  connectionURL="ldap://localhost:10389" 3
  connectionUsername="uid=admin,ou=system" 4
  connectionPassword=secret 5
  connectionProtocol=s 6
  authentication=simple 7
  userBase="dc=example,dc=com" 8
  userSearchMatching="(uid={0})" 9
  userSearchSubtree=true 10
  roleName= 11
  roleBase="dc=example,dc=com" 12
  roleName=cn 13
  roleSearchMatching="(member={0})" 14
  roleSearchSubtree=true 15
  ;
};

```

Example 6.8. Example Microsoft Active Directorylogin.config Configuration

```

activemq {
  org.apache.activemq.artemis.spi.core.security.jaas.LDAPLoginModule required
  debug=true
  initialContextFactory=com.sun.jndi.ldap.LdapCtxFactory
  connectionURL="LDAP://localhost:389"
  connectionUsername="CN=Administrator,CN=Users,DC=example,DC=com"
  connectionPassword=redhat.123
  connectionProtocol=s
  authentication=simple
  userBase="dc=example,dc=com"
  userSearchMatching="(CN={0})"
  userSearchSubtree=true
  roleBase="dc=example,dc=com"
  roleName=cn
  roleSearchMatching="(member={0})"
  roleSearchSubtree=true
  ;
};

```

- 1 Toggle debugging on (**true**) or off (**false**). Default is **false**.
- 2 The **initialContextFactory** parameter must always be set to **com.sun.jndi.ldap.LdapCtxFactory**
- 3 Specify the location of the directory server using an ldap URL, ldap://Host:Port. One can optionally qualify this URL, by adding a forward slash, /, followed by the DN of a particular node in the directory tree. The default port of Apache DS is **10389** while for Microsoft AD the default is **389**.
- 4 The DN of the user that opens the connection to the directory server. For example, **uid=admin,ou=system**. Directory servers generally require clients to present username/password credentials in order to open a connection.
- 5 The password that matches the DN from **connectionUsername**. In the directory server, in the DIT, the password is normally stored as a **userPassword** attribute in the corresponding directory entry.
- 6 Any value is supported but is effectively unused. This option must be set explicitly because it has no default value.
- 7 Specify the authentication method used when binding to the LDAP server. This parameter can be set to either **simple** (which requires a username and password) or **none** (which allows anonymous access).
- 8 Select a particular subtree of the DIT to search for user entries. The subtree is specified by a DN, which specifies the base node of the subtree. For example, by setting this option to **ou=User,ou=ActiveMQ,ou=system**, the search for user entries is restricted to the subtree beneath the **ou=User,ou=ActiveMQ,ou=system** node.
- 9 Specify an LDAP search filter, which is applied to the subtree selected by **userBase**. See the [Search Matching](#) section below for more information.
- 10 Specify the search depth for user entries, relative to the node specified by **userBase**. This option is a boolean. A setting of **false** indicates it tries to match one of the child entries of the **userBase** node (maps to **javax.naming.directory.SearchControls.ONELEVEL_SCOPE**), while **true** indicates it tries to match any entry belonging to the subtree of the **userBase** node (maps to **javax.naming.directory.SearchControls.SUBTREE_SCOPE**).
- 11 Specify the name of the multi-valued attribute of the user entry that contains a list of role names for the user (where the role names are interpreted as group names by the broker's authorization plug-in). If this option is omitted, no role names are extracted from the user entry.
- 12 If role data is stored directly in the directory server, one can use a combination of role options (**roleBase**, **roleSearchMatching**, **roleSearchSubtree**, and **roleName**) as an alternative to (or in addition to) specifying the **userRoleName** option. This option selects a particular subtree of the DIT to search for role/group entries. The subtree is specified by a DN, which specifies the base node of the subtree. For example, by setting this option to **ou=Group,ou=ActiveMQ,ou=system**, the search for role/group entries is restricted to the subtree beneath the **ou=Group,ou=ActiveMQ,ou=system** node.
- 13 Specify the attribute type of the role entry that contains the name of the role/group (such as C, O, OU, etc.). If this option is omitted the role search feature is effectively disabled.
- 14 Specify an LDAP search filter, which is applied to the subtree selected by **roleBase**. See the [Search Matching](#) section below for more information.
- 15 Specify the search depth for role entries, relative to the node specified by **roleBase**. If set to **false** (which is the default) the search tries to match one of the child entries of the **roleBase** node (maps to **javax.naming.directory.SearchControls.ONELEVEL_SCOPE**). If **true** it tries to match any

entry belonging to the subtree of the roleBase node (maps to `javax.naming.directory.SearchControls.SUBTREE_SCOPE`).

Search Matching

userSearchMatching

Before passing to the LDAP search operation, the string value provided in this configuration parameter is subjected to string substitution, as implemented by the `java.text.MessageFormat` class.

This means that the special string, `{0}`, is substituted by the username, as extracted from the incoming client credentials. After substitution, the string is interpreted as an LDAP search filter (the syntax is defined by the IETF standard RFC 2254).

For example, if this option is set to `(uid={0})` and the received username is `jdoe`, the search filter becomes `(uid=jdoe)` after string substitution.

If the resulting search filter is applied to the subtree selected by the user base, `ou=User,ou=ActiveMQ,ou=system`, it would match the entry, `uid=jdoe,ou=User,ou=ActiveMQ,ou=system`.

A short introduction to the search filter syntax is available from [Oracle's JNDI tutorial](#)

roleSearchMatching

This works in a similar manner to the `userSearchMatching` option, except that it supports two substitution strings.

The substitution string `{0}` substitutes the full DN of the matched user entry (that is, the result of the user search). For example, for the user, `jdoe`, the substituted string could be `uid=jdoe,ou=User,ou=ActiveMQ,ou=system`.

The substitution string `{1}` substitutes the received username. For example, `jdoe`.

If this option is set to `(member=uid={1})` and the received username is `jdoe`, the search filter becomes `(member=uid=jdoe)` after string substitution (assuming ApacheDS search filter syntax).

If the resulting search filter is applied to the subtree selected by the role base, `ou=Group,ou=ActiveMQ,ou=system`, it matches all role entries that have a `member` attribute equal to `uid=jdoe` (the value of a `member` attribute is a DN).

This option must always be set, even if role searching is disabled, because it has no default value. If OpenLDAP is used, the syntax of the search filter is `(member:=uid=jdoe)`.

6.3.2. Configure LDAP Authorization

The `LegacyLDAPSecuritySettingPlugin` security-setting-plugin will read the security information that was previously handled by `LDAPAuthorizationMap` and the `cachedLDAPAuthorizationMap` in Apache A-MQ 6 and turn it into corresponding `security settings` where possible.

The security implementations of the two brokers do not match perfectly so some translation must occur to achieve near equivalent functionality.

Here is an example of the plugin's configuration:

```
<security-setting-plugin class-
```

```

name="org.apache.activemq.artemis.core.server.impl.LegacyLDAPSecuritySettingPlugin"> 1
  <setting name="initialContextFactory" value="com.sun.jndi.Ldap.LdapCtxFactory"/> 2
  <setting name="connectionURL" value="ldap://localhost:1024"/> 3
  <setting name="connectionUsername" value="uid=admin,ou=system"/> 4
  <setting name="connectionPassword" value="secret"/> 5
  <setting name="connectionProtocol" value="s"/> 6
  <setting name="authentication" value="simple"/> 7
</security-setting-plugin>

```

- 1 **class-name.** The implementation is **org.apache.activemq.artemis.core.server.impl.LegacyLDAPSecuritySettingPlugin**.
- 2 **initialContextFactory.** The initial context factory used to connect to LDAP. It must always be set to **com.sun.jndi.Ldap.LdapCtxFactory** (that is, the default value).
- 3 **connectionURL.** Specifies the location of the directory server using an LDAP URL, **ldap://Host:Port**. You can optionally qualify this URL, by adding a forward slash, `/`, followed by the DN of a particular node in the directory tree. For example, **ldap://ldapservers:10389/ou=system**. The default is **ldap://localhost:1024**.
- 4 **connectionUsername.** The DN of the user that opens the connection to the directory server. For example, **uid=admin,ou=system**. Directory servers generally require clients to present username/password credentials in order to open a connection.
- 5 **connectionPassword.** The password that matches the DN from **connectionUsername**. In the directory server, in the DIT, the password is normally stored as a **userPassword** attribute in the corresponding directory entry.
- 6 **connectionProtocol** - any value is supported but is effectively unused. In the future, this option may allow one to select the Secure Socket Layer (SSL) for the connection to the directory server. This option must be set explicitly because it has no default value.
- 7 **authentication.** Specifies the authentication method used when binding to the LDAP server. Can take either of the values, **simple** (username and password, the default value) or **none** (anonymous). Note: Simple Authentication and Security Layer (SASL) authentication is currently not supported.

Other possible settings not shown in the example above are:

destinationBase

Specifies the DN of the node whose children provide the permissions for all destinations. In this case the DN is a literal value (that is, no string substitution is performed on the property value). For example, a typical value of this property is **ou=destinations,o=ActiveMQ,ou=system** (that is, the default value).

filter

Specifies an LDAP search filter, which is used when looking up the permissions for any kind of destination. The search filter attempts to match one of the children or descendants of the queue or topic node. The default value is **(cn=*)**.

roleAttribute

Specifies an attribute of the node matched by **filter** whose value is the DN of a role. Default value is **uniqueMember**.

adminPermissionValue

Specifies a value that matches the **admin** permission. The default value is **admin**.

readPermissionValue

Specifies a value that matches the **read** permission. The default value is **read**.

writePermissionValue

Specifies a value that matches the **write** permission. The default value is **write**.

enableListener

Whether or not to enable a listener that will automatically receive updates made in the LDAP server and update the broker's authorization configuration in real-time. The default value is **true**.

The name of the queue or topic defined in LDAP will serve as the "match" for the security-setting, the permission value will be mapped from the A-MQ 6 type to the AMQ 7 type, and the role will be mapped as-is. Since the name of the queue or topic coming from LDAP will server as the "match" for the security-setting the security-setting may not be applied as expected to JMS destinations since AMQ 7 always prefixes JMS destinations with "jms.queue." or "jms.topic." as necessary.

A-MQ 6 only has three permission types - **read**, **write**, and **admin**. These permission types are described on the ActiveMQ website; <http://activemq.apache.org/security.html>.

However, as described previously, AMQ 7 has 10 permission types:

- **createAddress**
- **deleteAddress**
- **createDurableQueue**
- **deleteDurableQueue**
- **createNonDurableQueue**
- **deleteNonDurableQueue**
- **send**
- **consume**
- **manage**
- **browse**

The list below shows how the old types are mapped to the new types:

- **read** - **consume**, **browse**
- **write** - **send**
- **admin** - **createDurableQueue**, **deleteDurableQueue**, **createNonDurableQueue**, **deleteNonDurableQueue**, **createAddress**, **deleteAddress**

As mentioned, there are a few places where a translation was performed to achieve some equivalence:

- This mapping does not include the AMQ 7 **manage** permission type since there is no type analogous for that in A-MQ 6.
- The **admin** permission in A-MQ 6 relates to whether or not the broker will auto-create a

destination if it does not exist and the user sends a message to it. AMQ 7 automatically allows the automatic creation of a destination if the user has permission to send message to it. Therefore, the plugin will map the **admin** permission to the four aforementioned permissions in AMQ 7.

6.3.3. Encrypting the Password in the login.config File

Because organizations frequently securely store data with LDAP, the **login.config** file can contain the configuration required for the broker to communicate with the organization's LDAP server. This configuration file usually includes a password to log in to the LDAP server, so this password needs to be masked.

Prerequisites

- Ensure that you have modified the **login.config** file to add the required properties as described in [Section 6.3.2, "Configure LDAP Authorization"](#).

Procedure

The following procedure explains how to mask the value of the **connectionPassword** found in the ***BROKER_INSTANCE_DIR/etc/login.config*** file.

1. From a command prompt, use the **mask** utility to encrypt the password:

```
$ BROKER_INSTANCE_DIR/bin/artemis mask PASSWORD
```

The encrypted password is displayed on the screen:

```
result: 3a34fd21b82bf2a822fa49a8d8fa115d
```

2. Open the ***BROKER_INSTANCE_DIR/etc/login.config*** file and locate the **connectionPassword**:

```
connectionPassword = PASSWORD
```

3. Replace the plain text password with the encrypted value that you created in Step 1:

```
connectionPassword = 3a34fd21b82bf2a822fa49a8d8fa115d
```

4. Wrap the encrypted value with the identifier **ENC()**:

```
connectionPassword = ENC(3a34fd21b82bf2a822fa49a8d8fa115d)
```

The login.config file now contains a masked password. Because the password is wrapped with the **ENC()** identifier, AMQ Broker decrypts it before it is used.

Additional Resources

For more information about the configuration files included with AMQ Broker, see [AMQ Broker configuration files and locations](#).

6.4. INTEGRATING WITH KERBEROS

When sending and receiving messages with the AMQP protocol, clients can send Kerberos security

credentials that AMQ Broker authenticates by using the GSSAPI mechanism from the Simple Authentication and Security Layer (SASL) framework. Kerberos credentials can also be used for authorization by mapping an authenticated user to an assigned role configured in an LDAP directory or text-based properties file.

You can use SASL in tandem with Transport Layer Sockets (TLS) to secure your messaging applications. SASL provides user authentication, and TLS provides data integrity.

You must deploy and configure a Kerberos infrastructure before AMQ Broker can authenticate and authorize Kerberos credentials. See your operating system documentation for more information about deploying Kerberos. If your operating system is RHEL 7, for example, see the chapter [Using Kerberos](#). A [Kerberos Authentication Overview](#) is available for Windows as well.

NOTE

You must deploy and configure a Kerberos infrastructure before AMQ Broker can authenticate and authorize Kerberos credentials.

NOTE

Users of an Oracle or IBM JDK should install the Java Cryptography Extension (JCE). See the documentation from the [Oracle version of the JCE](#) or the [IBM version of the JCE](#) for more information.

6.4.1. Enabling Network Connections to Use Kerberos

AMQ Broker integrates with Kerberos security credentials by using the GSSAPI mechanism from the Simple Authentication and Security Layer (SASL) framework. To use Kerberos in AMQ Broker, each **acceptor** authenticating or authorizing clients that use a Kerberos credential must be configured to use the GSSAPI mechanism.

Prerequisites

You must deploy and configure a Kerberos infrastructure before AMQ Broker can authenticate and authorize Kerberos credentials.

Procedure

1. Stop the broker.
 - a. If the broker is running on Linux:

```
BROKER_INSTANCE_DIR/bin/artemis stop
```

- b. If the broker is running on Windows as a service:

```
BROKER_INSTANCE_DIR\bin\artemis-service.exe stop
```

2. Open the **broker.xml** configuration file located under ***BROKER_INSTANCE_DIR*/etc**
3. Add the name-value pair **saslMechanisms=GSSAPI** to the query string of the URL for the **acceptor**, as shown in the following example:

```
<acceptor name="amqp">
  tcp://0.0.0.0:5672?protocols=AMQP;saslMechanisms=GSSAPI
</acceptor>
```

The result is an acceptor that uses the GSSAPI mechanism when authenticating Kerberos credentials.

4. (Optional) The **PLAIN** and **ANONYMOUS** SASL mechanisms are also supported. If you want to use these other mechanisms in addition to **GSSAPI**, add them to the list of **saslMechanisms**. Be sure to separate each value with a comma. In the following example, the name-value pair **saslMechanisms=GSSAPI** is modified to add the value **PLAIN**.

```
<acceptor name="amqp">
  tcp://0.0.0.0:5672?protocols=AMQP;saslMechanisms=GSSAPI,PLAIN
</acceptor>
```

The result is an acceptor that uses both the **GSSAPI** and **PLAIN** SASL mechanisms.

5. Start the broker.
 - a. If the broker is running on Linux:

```
BROKER_INSTANCE_DIR/bin/artemis run
```

- b. If the broker is running on Windows as a service:

```
BROKER_INSTANCE_DIR\bin\artemis-service.exe start
```

Related Information

See [About Acceptors](#) for more information about acceptors.

6.4.2. Authenticating Clients with Kerberos Credentials

AMQ Broker supports Kerberos authentication of AMQP connections that use the GSSAPI mechanism from the Simple Authentication and Security Layer (SASL) framework.

A broker acquires its Kerberos acceptor credentials by using the Java Authentication and Authorization Service (JAAS). The JAAS library included with your Java installation is packaged with a login module, **Krb5LoginModule**, that authenticates Kerberos credentials. See the documentation from your Java vendor for more information about their **Krb5LoginModule**. For example, Oracle provides information about their **Krb5LoginModule** login module as part of their [Java 8 documentation](#).

Prerequisites

You must enable the GSSAPI mechanism of an acceptor before it can authenticate AMQP connections using Kerberos security credentials.

Procedure

1. Stop the broker.
 - a. If the broker is running on Linux:

```
BROKER_INSTANCE_DIR/bin/artemis stop
```

- b. If the broker is running on Windows as a service:

```
BROKER_INSTANCE_DIR\bin\artemis-service.exe stop
```

2. Open the **login.config** configuration file located under ***BROKER_INSTANCE_DIR*/etc**.

3. Add a configuration scope named **amqp-sasl-gssapi** to **login.config**. The following example shows configuration for the **Krb5LoginModule** found in Oracle and OpenJDK versions of the JDK.

NOTE

Verify the fully qualified class name of the **Krb5LoginModule** and its available options by referring to the documentation from your Java vendor.

```
amqp-sasl-gssapi { 1
    com.sun.security.auth.module.Krb5LoginModule required 2
    isInitiator=false
    storeKey=true
    useKeyTab=true 3
    principal="amqp/my_broker_host@example.com" 4
    debug=true;
};
```

- 1 By default, the GSSAPI mechanism implementation on the broker uses a JAAS configuration scope named **amqp-sasl-gssapi** to obtain its Kerberos acceptor credentials.
- 2 This version of the **Krb5LoginModule** is provided by the Oracle and OpenJDK versions of the JDK. Verify the fully qualified class name of the **Krb5LoginModule** and its available options by referring to the documentation from your Java vendor.
- 3 The **Krb5LoginModule** is configured to use a Kerberos keytab when authenticating a principal. Keytabs are generated using tooling from your Kerberos environment. See the documentation from your vendor for details about generating Kerberos keytabs.
- 4 The Principal is set to **amqp/my_broker_host@example.com**. This value must correspond to the service principal created in your Kerberos environment. See the documentation from your vendor for details about creating service principals.

4. Start the broker.

- a. If the broker is running on Linux:

```
BROKER_INSTANCE_DIR/bin/artemis run
```

- b. If the broker is running on Windows as a service:

```
BROKER_INSTANCE_DIR\bin\artemis-service.exe start
```

Related Information

See [Network Connections and Kerberos](#), for more information about enabling the GSSAPI mechanism in AMQ Broker.

6.4.2.1. Using an Alternative Configuration Scope

You can specify an alternative configuration scope by adding the parameter **saslLoginConfigScope** to the URL of an AMQP acceptor. In the following configuration example, the parameter **saslLoginConfigScope** is given the value **alternative-sasl-gssapi**. The result is an acceptor that uses

the alternative scope named **alternative-sasl-gssapi**, which was declared in the ***BROKER_INSTANCE_DIR/etc/login.config*** configuration file.

```
<acceptor name="amqp">
tcp://0.0.0.0:5672?
protocols=AMQP;saslMechanisms=GSSAPI,PLAIN;saslLoginConfigScope=alternative-sasl-gssapi`
</acceptor>
```

6.4.3. Authorizing Clients with Kerberos Credentials

AMQ Broker is packaged with an implementation of the JAAS **Krb5LoginModule** for use by other security modules when mapping roles. The module adds a Kerberos-authenticated Peer Principal to the Subject's principal set as an AMQ Broker UserPrincipal. The credentials can then be passed to a **PropertiesLoginModule** or **LDAPLoginModule**, which maps the Kerberos-authenticated Peer Principal to an AMQ Broker role.

NOTE

The Kerberos Peer Principal does not exist as a broker user, only as a role member.

Prerequisites

You must enable the GSSAPI mechanism of an acceptor before it can authorize AMQP connections using Kerberos security credentials.

Procedure

1. Stop the broker.
 - a. If the broker is running on Linux:

```
BROKER_INSTANCE_DIR/bin/artemis stop
```
 - b. If the broker is running on Windows as a service:

```
BROKER_INSTANCE_DIRbin\artemis-service.exe stop
```
2. Open the **login.config** configuration file located under ***BROKER_INSTANCE_DIR/etc***.
3. Add configuration for the AMQ Broker **Krb5LoginModule** and the **LDAPLoginModule**.

NOTE

Verify the configuration options by referring to the documentation from your LDAP provider.

```
org.apache.activemq.artemis.spi.core.security.jaas.Krb5LoginModule required
;
org.apache.activemq.artemis.spi.core.security.jaas.LDAPLoginModule optional
initialContextFactory=com.sun.jndi ldap.LdapCtxFactory
connectionURL="ldap://localhost:1024"
authentication=GSSAPI
saslLoginConfigScope=broker-sasl-gssapi
connectionProtocol=s
```

```

userBase="ou=users,dc=example,dc=com"
userSearchMatching="(krb5PrincipalName={0})"
userSearchSubtree=true
authenticateUser=false
roleBase="ou=system"
roleName=cn
roleSearchMatching="(member={0})"
roleSearchSubtree=false
;

```

- 1 This version of the **Krb5LoginModule** is distributed with AMQ Broker and transforms the Kerberos identity into a broker identity that can be used by other AMQ modules for role mapping.

4. Start the broker.

- a. If the broker is running on Linux:

```
BROKER_INSTANCE_DIR/bin/artemis run
```

- b. If the broker is running on Windows as a service:

```
BROKER_INSTANCE_DIRbin\artemis-service.exe start
```

Related Information

See [Network Connections and Kerberos](#) for more information about enabling the GSSAPI mechanism in AMQ Broker.

See [Users and Roles](#) for more information about the **PropertiesLoginModule**.

See [Integrating with LDAP](#) for more information about the **LDAPLoginModule**.

6.5. ENCRYPTING PASSWORDS IN CONFIGURATION FILES

By default, AMQ Broker stores all passwords in configuration files as plain text. Be sure to secure all configuration files with the correct permissions to prevent unauthorized access. You can also encrypt, or mask, the plain text passwords to prevent unwanted viewers from reading them.

A masked password is the encrypted version of a plain text password. The encrypted version is generated by the **mask** command-line utility provided by AMQ Broker. For more information about the **mask** utility, see the command-line help documentation:

```
$ BROKER_INSTANCE_DIR/bin/artemis help mask
```

To mask a password, replace its plain text value with the encrypted one. The masked password must be wrapped by the identifier **ENC()** so that it is decrypted when the actual value is needed.

In the following example, the configuration file ***BROKER_INSTANCE_DIR/etc/bootstrap.xml*** contains masked passwords for the attributes **keyStorePassword** and **trustStorePassword**.

Example with bootstrap.xml

```
<web bind="https://localhost:8443" path="web"
```

```
keyStorePassword="ENC(-342e71445830a32f95220e791dd51e82)"
trustStorePassword="ENC(32f94e9a68c45d89d962ee7dc68cb9d1)">
<app url="activemq-branding" war="activemq-branding.war"/>
</web>
```

You can use masked passwords only with the following configuration files.

Supported Configuration Files

- broker.xml
- bootstrap.xml
- management.xml
- artemis-users.properties
- login.config (for use with the **LDAPLoginModule**)

Configuration files are found at ***BROKER_INSTANCE_DIR/etc***.

NOTE

When a user is created upon broker creation, the **artemis-users.properties** file contains hashed passwords by default. The default **PropertiesLoginModule** will not decode the passwords in **artemis-users.properties** file but will instead hash the input and compare the two hashed values for password verification. Changing the hashed password to masked password does not allow access to the AMQ Console. You can use both *masked* and *hashed* password in other configuration files except the **artemis-users.properties** file.

Procedure

As an example, the following procedure explains how to mask the value of the **cluster-password** configuration element found in the file ***BROKER_INSTANCE_DIR/etc/broker.xml***.

1. From a command prompt, use the **mask** utility to encrypt a password:

```
$ BROKER_INSTANCE_DIR/bin/artemis mask PASSWORD
```

The encrypted password is displayed on the screen:

```
result: 3a34fd21b82bf2a822fa49a8d8fa115d
```

2. Open the configuration file containing the plain text password you want to mask:

```
<cluster-password>
  PASSWORD
</cluster-password>
```

3. Replace the plain text password with the encrypted value that you created in Step 1:

```
<cluster-password>  
3a34fd21b82bf2a822fa49a8d8fa115d  
</cluster-password>
```

4. Wrap the encrypted value with the identifier **ENC()**:

```
<cluster-password>  
ENC(3a34fd21b82bf2a822fa49a8d8fa115d)  
</cluster-password>
```

The configuration file now contains a masked password. Because the password is wrapped with the **ENC()** identifier, AMQ Broker decrypts it before it is used.

Additional Resources

For more information about the configuration files included with AMQ Broker, see [AMQ Broker configuration files and locations](#).

6.6. DISABLING SECURITY

Security is **enabled** by default. Broker security can be enabled or disabled by setting the **<security-enabled>** parameter in the **<core>** element of the **broker.xml** configuration file.

Procedure

1. Open the **broker.xml** file.
2. Locate the **<security-enabled>** parameter.
3. Edit the entry as needed:
 - Set the parameter to **false** to disable security:

```
<security-enabled>>false</security-enabled>
```

4. If necessary, change the **security-invalidation-interval** entry (which periodically invalidates secure logins) to a different value (in **ms**). The default is **10000**.

CHAPTER 7. PERSISTING MESSAGES

This chapter describes how persistence works with AMQ Broker and how to configure it.

The broker ships with two persistence options:

1. [Journal-based](#)
The default. A highly performant option that writes messages to journals on the file system.
2. [JDBC-based](#)
Uses the broker's JDBC Store to persist messages to a database of your choice.

Alternatively, you can also configure the broker for [zero persistence](#).

The broker uses a different solution for persisting large messages outside the message journal. See [Working with Large Messages](#) for more information. The broker can also be configured to page messages to disk in low memory situations. See [Paging Messages](#) for more information.

NOTE

For current information regarding which databases and network file systems are supported see [Red Hat AMQ 7 Supported Configurations](#) on the Red Hat Customer Portal.

7.1. ABOUT JOURNAL-BASED PERSISTENCE

A broker's journal is a set of **append only** files on disk. Each file is pre-created to a fixed size and initially filled with padding. As messaging operations are performed on the broker, records are appended to end of the journal. Appending records allows the broker to minimize disk head movement and random access operations, which are typically the slowest operation on a disk. When one journal file is full, the broker uses a new one.

The journal file size is configurable, minimizing the number of disk cylinders used by each file. Modern disk topologies are complex, however, and the broker cannot control which cylinder(s) the file is mapped to. Journal file sizing therefore is not an exact science.

Other persistence-related features include:

- A sophisticated file garbage collection algorithm that determines whether a particular journal file is still in use. If not, the file can be reclaimed and re-used.
- A compaction algorithm that removes dead space from the journal and that compresses the data. This results in the journal using fewer files on disk.
- Support for local transactions.
- Support for XA transactions when using AMQ JMS clients.

The majority of the journal is written in Java. However, the interaction with the actual file system is abstracted, so you can use different, pluggable implementations. AMQ Broker ships with two implementations:

- [Java NIO](#).
Uses the standard Java NIO to interface with the file system. This provides extremely good performance and runs on any platform with a Java 6 or later runtime.

- Linux Asynchronous IO

Uses a thin native wrapper to talk to the Linux asynchronous IO library (AIO). With AIO, the broker is called back after the data has made it to disk, avoiding explicit syncs altogether. By default the broker tries to use an AIO journal, and falls back to using NIO if AIO is not available.

Using AIO typically provides even better performance than using Java NIO. For instructions on how to install libaio see [Using an AIO journal](#).

NOTE

For current information regarding which network file systems are supported see [Red Hat AMQ 7 Supported Configurations](#) on the Red Hat Customer Portal.

7.1.1. Using AIO

The Java NIO journal is highly performant, but if you are running the broker using Linux Kernel 2.6 or later, Red Hat recommends using the AIO journal for better persistence performance. It is not possible to use the AIO journal with other operating systems or earlier versions of the Linux kernel.

To use the AIO journal you must install the **libaio** if it is not already installed.

Procedure

- Use the **yum** command to install **libaio**, as in the example below:

```
yum install libaio
```

7.2. CONFIGURING JOURNAL-BASED PERSISTENCE

Persistence configuration is maintained in the file ***BROKER_INSTANCE_DIR/etc/broker.xml***. The broker's default configuration uses journal based persistence and includes the elements shown below.

```
<configuration>
  <core>
    ...
    <persistence-enabled>true</persistence-enabled> 1
    <journal-type>ASYNCIO</journal-type> 2
    <bindings-directory>./data/bindings</bindings-directory> 3
    <journal-directory>./data/journal</journal-directory> 4
    <journal-datasync>true</journal-datasync> 5
    <journal-min-files>2</journal-min-files> 6
    <journal-pool-files>1</journal-pool-files> 7
    ...
  </core>
</configuration>
```

- 1 Set to **true** to use the file based journal for persistence.
- 2 The type of journal to use. If set to ASYNCIO, the broker first attempts to use AIO and falls back to NIO if ASYNCIO is not found.
- 3 The file system location of the bindings journal. The default setting is relative to ***BROKER_INSTANCE_DIR***.

- 4 The file system location of the messaging journal. The default setting is relative to ***BROKER_INSTANCE_DIR***.
- 5 Set to **true** to use **fdatasync** to confirm writes to the disk.
- 6 The number of journal files to pre-create when the broker starts.
- 7 The number of files to keep after reclaiming un-used files. The default value, **-1**, means that no files are deleted during clean up.

7.2.1. The Message Journal

The message journal stores all message-related data, including the messages themselves and duplicate ID caches. The files on this journal are prefixed as **activemq-data**. Each file has a **amq** extension and a default size of **10485760** bytes. The location of the message journal is set using the **journal-directory** configuration element. The default value is ***BROKER_INSTANCE_DIR/data/journal***. The default configuration includes other elements related to the messaging journal:

- **journal-min-files**
The number of journal files to pre-create when the broker starts. The default is **2**.
- **journal-pool-files**
The number of files to keep after reclaiming un-used files. The default value, **-1**, means that no files are deleted once created by the broker. However, the system cannot grow infinitely, so you are required to use paging for destinations that are unbounded in this way. See the chapter on [Paging Messages](#) for more information.

There are several other configuration elements available for the messaging journal. See the [appendix for a full list](#).

7.2.2. The Bindings Journal

The bindings journal is used to store bindings-related data, such as the set of queues deployed on the server and their attributes. It also stores data such as ID sequence counters.

The bindings journal always uses NIO because it is typically low throughput when compared to the message journal. Files on this journal are prefixed with **activemq-bindings**. Each file has a **bindings** extension and a default size of **1048576** bytes.

Use the following configuration elements in ***BROKER_INSTANCE_DIR/etc/broker.xml*** to configure the bindings journal.

- **bindings-directory**
This is the directory in which the bindings journal lives. The default value is ***BROKER_INSTANCE_DIR/data/bindings***.
- **create-bindings-dir**
If this is set to **true** then the bindings directory is automatically created at the location specified in **bindings-directory** if it does not already exist. The default value is **true**

7.2.3. The JMS Journal

The JMS journal stores all JMS-related data, including JMS Queues, Topics, and Connection Factories, as well as any JNDI bindings for these resources. Also, any JMS Resources created via the management API is persisted to this journal, but any resources configured via configuration files are not. The JMS

Journal is only created if JMS is being used.

The files on this journal are prefixed as **activemq-jms**. Each file has a **jms** extension and a default size of **1048576** bytes.

The JMS journal shares its configuration with the bindings journal.

7.2.4. Compacting Journal Files

AMQ Broker includes a compaction algorithm that removes dead space from the journal and compresses its data so that it takes up less space on disk. There are two criteria used to determine when to start compaction. After both criteria are met, the compaction process parses the journal and removes all dead records. Consequently, the journal comprises fewer files. The criteria are:

- The number of files created for the journal.
- The percentage of live data in the journal's files.

You configure both criteria in ***BROKER_INSTANCE_DIR/etc/broker.xml***.

Procedure

- To configure the criteria for the compaction process, add the following two elements, as in the example below.

```
<configuration>
  <core>
    ...
    <journal-compact-min-files>15</journal-compact-min-files> 1
    <journal-compact-percentage>25</journal-compact-percentage> 2
    ...
  </core>
</configuration>
```

- 1** The minimum number of files created before compaction begins. That is, the compacting algorithm does not start until you have at least **journal-compact-min-files**. The default value is **10**. Setting this to **0** disables compaction, which is dangerous because the journal could grow indefinitely.
- 2** The percentage of live data in the journal's files. When less than this percentage is considered live data, compacting begins. Remember that compacting does not begin until you also have at least **journal-compact-min-files** data files on the journal. The default value is **30**.

Compacting Journals Using the CLI

You can also use the command-line interface (CLI) to compact journals.

Procedure

1. As the owner of the ***BROKER_INSTANCE_DIR***, stop the broker. In the example below, the user **amq-broker** was created during the installation of AMQ Broker.

```

su - amq-broker
cd __BROKER_INSTANCE_DIR__/bin
$ ./artemis stop

```

- (Optional) Run the following CLI command to get a full list of parameters for the data tool. Note that by default, the tool uses settings found in ***BROKER_INSTANCE_DIR/etc/broker.xml***.

```
$ ./artemis help data compact.
```

- Run the following CLI command to compact the data.

```
$ ./artemis data compact.
```

- After the tool has successfully compacted the data, restart the broker.

```
$ ./artemis run
```

Related Information

AMQ Broker includes a number of CLI commands for managing your journal files. See [command-line Tools](#) in the Appendix for more information.

7.2.5. Disabling Disk Write Cache

Most disks contain hardware write caches. A write cache can increase the apparent performance of the disk because writes are lazily written to the disk later. By default many systems ship with disk write cache enabled. This means that even after syncing from the operating system there is no guarantee the data has actually made it to disk, so if a failure occurs, critical data can be lost.

Some more expensive disks have non-volatile or battery-backed write caches that do not necessarily lose data in event of failure, but you should test them. If your disk does not have such features, you should ensure that write cache is disabled. Be aware that disabling disk write cache can negatively affect performance.

Procedure

- On Linux, manage your disk's write cache settings using the tools **hdparm** (for IDE disks) or **sdparm** or **sginfo** (for SDSI/SATA disks).
- On Windows, manage the cache setting by right-clicking the disk and clicking **Properties**.

7.3. CONFIGURING JDBC PERSISTENCE

The JDBC persistence store uses a JDBC connection to store messages and bindings data in database tables. The data in the tables is encoded using AMQ Broker journal encoding.

NOTE

For current information regarding which databases are supported see [Red Hat AMQ 7 Supported Configurations](#) on the Red Hat Customer Portal.

Procedure

1. Add the appropriate JDBC client libraries to the broker runtime. You can do this by adding the relevant jars to the ***BROKER_INSTANCE_DIR/lib*** directory.
2. Create a **store** element in your ***BROKER_INSTANCE_DIR/etc/broker.xml*** configuration file under the **core** element, as in the example below.

```

<configuration>
  <core>
    <store>
      <database-store>
        <jdbc-connection-url>jdbc:derby:data/derby/database-store;create=true</jdbc-
connection-url> ①
        <bindings-table-name>BINDINGS_TABLE</bindings-table-name> ②
        <message-table-name>MESSAGE_TABLE</message-table-name> ③
        <large-message-table-name>LARGE_MESSAGES_TABLE</large-message-table-
name> ④
        <jdbc-driver-class-name>org.apache.derby.jdbc.EmbeddedDriver</jdbc-driver-class-
name> ⑤
      </database-store>
    </store>
  </core>
</configuration>

```

- ① **jdbc-connection-url** is the full JDBC connection URL for your database server. The connection url should include all configuration parameters and database name.
- ② **bindings-table-name** is the name of the table in which the bindings data is stored. Specifying table name allows users to share single database amongst multiple servers, without interference.
- ③ **message-table-name** is the name of the table in which the bindings data is stored.
- ④ **large-message-table-name** is the name of the table in which messages and related data is persisted.
- ⑤ **jdbc-driver-class-name** is the fully qualified class name of the desired database Driver.

7.4. CONFIGURING ZERO PERSISTENCE

In some situations, zero persistence is sometimes required for a messaging system. Configuring the broker to perform zero persistence is straightforward. Set the parameter **persistence-enabled** in ***BROKER_INSTANCE_DIR/etc/broker.xml*** to **false**.

Note that if you set this parameter to false, then **zero** persistence occurs. That means no bindings data, message data, large message data, duplicate ID caches or paging data is persisted.

CHAPTER 8. PAGING MESSAGES

AMQ Broker transparently supports huge queues containing millions of messages while the server is running with limited memory.

In such a situation it's not possible to store all of the queues in memory at any one time, so AMQ Broker transparently **pages** messages into and out of memory as they are needed, thus allowing massive queues with a low memory footprint.

Paging is done individually per address. AMQ Broker will start paging messages to disk when the size of all messages in memory for an address exceeds a configured maximum size. For more information about addresses, see [Addresses, Queues, and Topics](#).

By default, AMQ Broker does not page messages. You must explicitly configure paging to enable it.

See the **paging** example located under ***INSTALL_DIR/examples/standard/*** for a working example showing how to use paging with AMQ Broker.

8.1. ABOUT PAGE FILES

Messages are stored per address on the file system. Each address has an individual folder where messages are stored in multiple files (page files). Each file will contain messages up to a max configured size (**page-size-bytes**). The system will navigate on the files as needed, and it will remove the page file as soon as all the messages are acknowledged up to that point.

Browsers will read through the page-cursor system.

Consumers with selectors will also navigate through the page-files and ignore messages that don't match the criteria.

NOTE

When you have a queue, and consumers filtering the queue with a very restrictive selector you may get into a situation where you won't be able to read more data from paging until you consume messages from the queue.

Example: in one consumer you make a selector as 'color="red"' but you only have one color red one million messages after blue, you won't be able to consume red until you consume blue ones. This is different to browsing as we will "browse" the entire queue looking for messages and while we "depage" messages while feeding the queue.

8.2. CONFIGURING THE PAGING DIRECTORY LOCATION

To configure the location of the paging directory, add the **paging-directory** configuration element to the broker's main configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***, as in the example below.

```
<configuration ...>
...
<core ...>
  <paging-directory>/somewhere/paging-directory</paging-directory>
...
</core>
</configuration>
```

AMQ Broker will create one directory for each address being paged under the configured location.

8.3. CONFIGURING AN ADDRESS FOR PAGING

Configuration for paging is done at the address level by adding elements to a specific **address-settings**, as in the example below.

```
<address-settings>
  <address-setting match="jms.paged.queue">
    <max-size-bytes>104857600</max-size-bytes>
    <page-size-bytes>10485760</page-size-bytes>
    <address-full-policy>PAGE</address-full-policy>
  </address-setting>
</address-settings>
```

In the example above, when messages sent to the address **jms.paged.queue** exceed **104857600** bytes in memory, the broker will begin paging.

NOTE

Paging is done individually per address. If you specify **max-size-bytes** for an address, each matching address does not exceed the maximum size that you specified. It **DOES NOT** mean that the total overall size of all matching addresses is limited to **max-size-bytes**.

This is the list of available parameters on the address settings.

Table 8.1. Paging Configuration Elements

Element Name	Description	Default
max-size-bytes	The maximum size in memory allowed for the address before the broker enters page mode.	-1 (disabled)
page-size-bytes	The size of each page file used on the paging system.	10MiB (10 * 1024 * 1024 bytes)
address-full-policy	Valid values are PAGE , DROP , BLOCK , and FAIL . If the value is PAGE then further messages will be paged to disk. If the value is DROP then further messages will be silently dropped. If the value is FAIL then the messages will be dropped and the client message producers will receive an exception. If the value is BLOCK then client message producers will block when they try and send further messages.	PAGE
page-max-cache-size	The system will keep up to this number of page files in memory to optimize IO during paging navigation.	5

8.4. CONFIGURING A GLOBAL PAGING SIZE

Sometimes configuring a memory limit per address is not practical, such as when a broker manages many addresses that have different usage patterns. In these situations, use the **global-max-size** configuration element to set a global limit to the amount of memory the broker can use before it enters into the page mode configured for the address associated with the incoming message. The value for **global-max-size** is in bytes, but you can use byte notation ("K", "Mb", "GB", for example) for convenience. The default value for **global-max-size** is **-1**, which means no limit.

Configuring the **global-max-size**

Procedure

1. Stop the broker.
 - a. If the broker is running on Linux, run the following command:

```
BROKER_INSTANCE_DIR/bin/artemis stop
```

- b. If the broker is running on Windows as a service, run the following command:

```
BROKER_INSTANCE_DIRbin\artemis-service.exe stop
```

2. Open the **broker.xml** configuration file located under **BROKER_INSTANCE_DIR/etc**.
3. Add the **global-max-size** configuration element to **broker.xml** to limit the amount of memory, in bytes, the broker can use. Note that you can also use byte notation (**K**, **Mb**, **GB**) for the value of **global-max-size**, as shown in the following example.

```
<configuration>
  <core>
    ...
    <global-max-size>1GB</global-max-size>
    ...
  </core>
</configuration>
```

In the preceding example, the broker is configured to use a maximum of one gigabyte, **1GB**, of available memory when processing messages. If the configured limit is exceeded, the broker enters the page mode configured for the address associated with the incoming message.

4. Start the broker.
 - a. If the broker is running on Linux, run the following command:

```
__BROKER_INSTANCE_DIR__ /bin/artemis run
```

- b. If the broker is running on Windows as a service, run the following command:

```
BROKER_INSTANCE_DIRbin\artemis-service.exe start
```

Related Information

See [Section 8.3, "Configuring an Address for Paging"](#) for information about setting the paging mode for an address.

8.5. LIMITING DISK USAGE WHEN PAGING

You can limit the amount of physical disk the broker uses before it blocks incoming messages rather than pages them. Add the **max-disk-usage** to the **broker.xml** configuration file and provide a value for the percentage of disk space the broker is allowed to use when paging messages. The default value for **max-disk-usage** is **90**, which means the limit is set at **90** percent of disk space.

Configuring the max-disk-usage

Procedure

1. Stop the broker.
 - a. If the broker is running on Linux, run the following command:

```
BROKER_INSTANCE_DIR/bin/artemis stop
```

- b. If the broker is running on Windows as a service, run the following command:

```
BROKER_INSTANCE_DIR\bin\artemis-service.exe stop
```

2. Open the **broker.xml** configuration file located under **BROKER_INSTANCE_DIR/etc**.
3. Add the **max-disk-usage** configuration element and set a limit to the amount disk space to use when paging messages.

```
<configuration>  
  <core>  
    ...  
    <max-disk-usage>50</max-disk-usage>  
    ...  
  </core>  
</configuration>
```

In the preceding example, the broker is limited to using **50** percent of disk space when paging messages. Messages are blocked and no longer paged after **50** percent of the disk is used.

4. Start the broker.
 - a. If the broker is running on Linux, run the following command:

```
BROKER_INSTANCE_DIR/bin/artemis run
```

- b. If the broker is running on Windows as a service, run the following command:

```
BROKER_INSTANCE_DIR\bin\artemis-service.exe start
```

8.6. HOW TO DROP MESSAGES

Instead of paging messages when the max size is reached, an address can also be configured to just drop messages when the address is full.

To do this just set the **address-full-policy** to **DROP** in the address settings

8.6.1. Dropping Messages and Throwing an Exception to Producers

Instead of paging messages when the max size is reached, an address can also be configured to drop messages and also throw an exception on the client-side when the address is full.

To do this just set the **address-full-policy** to **FAIL** in the address settings

8.7. HOW TO BLOCK PRODUCERS

Instead of paging messages when the max size is reached, an address can also be configured to block producers from sending further messages when the address is full, thus preventing the memory from being exhausted on the server.

NOTE

Blocking works only if the protocol being used supports it. For example, an AMQP producer will understand a Block packet when it is sent by the broker, but a STOMP producer will not.

When memory is freed up on the server, producers will automatically unblock and be able to continue sending.

To do this just set the **address-full-policy** to **BLOCK** in the address settings.

In the default configuration, all addresses are configured to block producers after 10 MiB of data are in the address.

8.8. CAUTION WITH ADDRESSES WITH MULTICAST QUEUES

When a message is routed to an address that has multicast queues bound to it, for example, a JMS subscription in a Topic, there is only one copy of the message in memory. Each queue handles only a reference to it. Because of this the memory is only freed up after all queues referencing the message have delivered it.

If you have a single lazy subscription, the entire address will suffer IO performance hit as all the queues will have messages being sent through an extra storage on the paging system.

For example:

- An address has 10 queues
- One of the queues does not deliver its messages (maybe because of a slow consumer).
- Messages continually arrive at the address and paging is started.
- The other 9 queues are empty even though messages have been sent.

In this example, all the other 9 queues will be consuming messages from the page system. This may cause performance issues if this is an undesirable state.

CHAPTER 9. WORKING WITH LARGE MESSAGES

You can configure AMQ Broker to store large messages on a physical disk or in a database table. Handling large messages in this way avoids the memory overhead that occurs when storing several large messages in memory.

AMQ Broker can persist large messages even if the client and broker are running with limited memory. The maximum size of a large message depends only on the amount of space available for your physical disk or database table.

NOTE

Large message support is available for the AMQP, Core, and OpenWire protocols. Additionally, the STOMP protocol provides its own method for handling large messages. See "[Handling Large Messages with STOMP](#)" for more information.

NOTE

If you persist large messages on a disk, it is recommended that the large messages directory be located on a different volume than the one used to persist the message journal or the paging directory.

9.1. PREPARING BROKERS TO STORE LARGE MESSAGES

Large messages are stored on physical disk or database table. You must configure the broker to specify where large messages are stored.

Procedure

- Add configuration to ***BROKER_INSTANCE_DIR/etc/broker.xml*** that references the storage location for large messages.
 - If you are storing large messages on disk, add the **large-messages-directory** configuration element and provide the file system location, as shown in the following example:

```
<configuration>
  <core>
    ...
    <large-messages-directory>/path/to/large-messages</large-messages-directory> 1
    ...
  </core>
</configuration>
```

- 1 The default value for the **large-messages-directory** configuration element is ***BROKER_INSTANCE_DIR/data/largemessages***

- If you are storing large messages in a database table, add the name of the table to your **database-store**, as shown in the following example:

```
<store>
  <database-store>
    ...
```

```
<large-message-table>MY_TABLE</large-message-table> 1
</database-store>
</store>
```

- 1 The default value for the **large-message-table** configuration element is **LARGE_MESSAGE_TABLE**.

NOTE

Handling large AMQP messages: The broker treats AMQP messages that are larger than the size of either the **journal-buffer-size** or **journal-file-size** as large messages. For more information about the journal, see [Messaging Journal Configuration Elements](#).

Additional Resources

See the **large-message** example found under **BROKER_INSTANCE_DIR/examples/standard/** for a working example showing how to work with large messages.

For more information about configuring a **data-store** see [Configuring JDBC Persistence](#).

9.2. PREPARING AMQ CORE PROTOCOL JMS CLIENTS TO SEND LARGE MESSAGES

You prepare client connections to handle large messages by setting a value for the property **minLargeMessageSize**. The value can be provided as a parameter in the connection URL, or it can be set by using a supported client API. Any message larger than **minLargeMessageSize** is considered a large message.

NOTE

AMQ Broker messages are encoded using two bytes per character. Therefore, if the message data is filled with ASCII characters (which are one byte in size), the size of the resulting message would roughly double. When setting the value of **minLargeMessageSize**, remember that encoding can increase message size. The default value for `minLargeMessageSize`` is 100KiB.

Procedure

- Set the minimum size for large messages.
 - If you are using JNDI to instantiate your connection factory, set the size in a **jndi.properties** file by using the parameter **minLargeMessageSize**.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?
minLargeMessageSize=250000
```

- If you are not using JNDI, set the size using the method **ActiveMQConnectionFactory.setMinLargeMessageSize()**.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setMinLargeMessageSize(250000);
```

9.3. PREPARING OPENWIRE CLIENTS TO SEND LARGE MESSAGES

NOTE

Configuration options added to the connection URI used by an AMQ OpenWire JMS client must include the prefix **wireFormat.** to take effect. Options missing this prefix are ignored.

Procedure

- Set the minimum size for large messages.
 - If you are using JNDI to instantiate your connection factory, set the size in a **jndi.properties** file by using the parameter **minLargeMessageSize**. You must add the prefix **wireFormat.** to the parameter for it to take effect.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?
wireFormat.minLargeMessageSize=250000
```

- If you are not using JNDI, set the size using the method **ActiveMQConnectionFactory.setMinLargeMessageSize()**.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setMinLargeMessageSize(250000);
```

9.4. SENDING LARGE MESSAGES

AMQ Broker supports Java-based **InputStreams** for sending large messages. The most common use case is to send files stored on your disk, but you could also send the data as JDBC Blobs or JSON objects recovered from **HttpRequests**.

NOTE

When using JMS, streaming large messages is supported only when using **StreamMessage** and **BytesMessage**.

Procedure

- To send a large message, set the **JMS_AMQ_InputStream** property to mark the message as streamed:

```
BytesMessage message = session.createBytesMessage();
FileInputStream fileInputStream = new FileInputStream(fileInput);
BufferedInputStream bufferedInput = new BufferedInputStream(fileInputStream);
message.setObjectProperty("JMS_AMQ_InputStream", bufferedInput);
...
```

9.5. RECEIVING LARGE MESSAGES

The AMQ Broker Core JMS API has a method for synchronously receiving a streamed message. The methods block further processing until the input stream is completely received.

Procedure

- To receive a large message, set the **JMS_AMQ_SaveStream** on the message object:

```

BytesMessage messageReceived = (BytesMessage)messageConsumer.receive(120000);
File outputFile = new File("large_message_received.dat");
FileOutputStream fileOutputStream = new FileOutputStream(outputFile);
BufferedOutputStream bufferedOutput = new BufferedOutputStream(fileOutputStream);

// This will block until the entire content is saved on disk
messageReceived.setObjectProperty("JMS_AMQ_SaveStream", bufferedOutput);

```

Receiving a Large Message Asynchronously

The Core JMS API also has a method for asynchronously receiving a streamed message. The method does not block processing by a consumer while it receives the input stream.

Procedure

- To receive a large message asynchronously, set the **JMS_AMQ_OutputStream** parameter on the message object:

```

BytesMessage messageReceived = (BytesMessage)messageConsumer.receive(120000);
File outputFile = new File("large_message_received.dat");
FileOutputStream fileOutputStream = new FileOutputStream(outputFile);
BufferedOutputStream bufferedOutput = new BufferedOutputStream(fileOutputStream);

// This will not block until the entire content is saved on disk
messageReceived.setObjectProperty("JMS_AMQ_OutputStream", bufferedOutput);

```

9.6. LARGE MESSAGES AND JAVA CLIENTS

There are two recommended options available to Java developers who are writing clients that use large messages.

One option is to use an instance of **InputStream** and **OutputStream**. For example, a **FileInputStream** could be used to send a message taken from a large file on a physical disk. A **FileOutputStream** could then be used by the receiver to stream the message to a location on its local file system.

Another option is to stream a JMS **BytesMessage** or **StreamMessage** directly:

```

BytesMessage rm = (BytesMessage)cons.receive(10000);
byte data[] = new byte[1024];
for (int i = 0; i < rm.getBodyLength(); i += 1024)
{
    int numberOfBytes = rm.readBytes(data);
    // Do whatever you want with the data
}

```

9.7. COMPRESSING LARGE MESSAGES

You can enable clients to compress large messages before sending them. The ZIP algorithm is used to compress the message body as the message is sent to the broker.

NOTE

If the compressed size of a large message is less than the value of **minLargeMessageSize**, the message is sent as a regular message. Therefore, it is not written to the broker's large-message data directory.

- If you use a Core JMS client and JNDI, use the JNDI context environment to enable message compression:

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?
compressLargeMessages=true
```

- Add the **minLargeMessageSize** parameter to the connection factory URL to set the minimum size requirement for messages to be compressed. In the following example, messages are compressed only when they exceed 250 kilobytes in size.

```
connectionFactory.myConnectionFactory=tcp://localhost:61616?
compressLargeMessages=true&minLargeMessageSize=250kb
```

9.8. HANDLING LARGE MESSAGES WITH STOMP

STOMP clients might send large bodies of frames, which can exceed the size of the broker's internal buffer, causing unexpected errors.

To prevent this situation from occurring, set the acceptor's **stompMinLargeMessageSize** parameter to the desired size. Proper sizing is affected by system resources such as the amount of disk space available, as well as the size of the messages. It is recommended that you run performance tests using several values for **stompMinLargeMessageSize** to determine an appropriate size.

The broker checks the size of the body of each STOMP frame coming from connections established with this acceptor. If the size of the body is equal to or greater than the value of **stompMinLargeMessageSize**, the message is persisted as a large message.

Procedure

1. Open the configuration file ***BROKER_INSTANCE_DIR/etc/broker.xml***
2. Add the **stompMinLargeMessageSize** parameter and its desired value to an existing or new **acceptor**, as shown in the following example:

```
<acceptors>
  <acceptor name="stomp-acceptor">tcp://localhost:61613?
  protocols=STOMP;stompMinLargeMessageSize=10240</acceptor>
  ...
</acceptors>
```

In the preceding example, the broker is configured to accept STOMP messages on port **61613**. If the acceptor receives a STOMP frame with a body larger than or equal to **10240** bytes the broker will persist it as a large message.

When a large message is delivered to a STOMP consumer, the broker automatically converts it from a large message to a normal message before sending it to the client. If a large message is compressed, the broker decompresses it before sending it to STOMP clients.

The default value of **stompMinLargeMessageSize** is 102400 bytes.

CHAPTER 10. DETECTING DEAD CONNECTIONS

Sometimes clients stop unexpectedly and do not have a chance to clean up their resources. If this occurs, it can leave resources in a faulty state and result in the broker running out of memory or other system resources. The broker detects that a client's connection was not properly shut down at garbage collection time. The connection is then closed and a message similar to the one below is written to the log. The log captures the exact line of code where the client session was instantiated. This enables you to identify the error and correct it.

```
[Finalizer] 20:14:43,244 WARNING [org.apache.activemq.artemis.core.client.impl.DelegatingSession]
I'm closing a JMS Conection you left open. Please make sure you close all connections explicitly
before let
ting them go out of scope!
[Finalizer] 20:14:43,244 WARNING [org.apache.activemq.artemis.core.client.impl.DelegatingSession]
The session you didn't close was created here:
java.lang.Exception
    at org.apache.activemq.artemis.core.client.impl.DelegatingSession.<init>
(DelegatingSession.java:83)
    at org.acme.yourproject.YourClass (YourClass.java:666) 1
```

1 The line in the client code where the connection was instantiated.

Detecting Dead Connections from the Client Side

As long as it is receiving data from the broker, the client considers a connection to be alive. Configure the client to check its connection for failure by providing a value for the **client-failure-check-period** property. The default check period for a network connection is **30000** milliseconds (30 seconds), while the default value for an In-VM connection, is **-1**, which means the client never fails the connection from its side if no data is received.

Typically, you set the check period to be much lower than the value used for the broker's connection time-to-live, which ensures that clients can reconnect in case of a temporary failure.

The examples below show how to set the check period to **10000** milliseconds (10 seconds) using Core JMS clients.

Procedure

- Set the check period for detecting dead connections.
 - If you are using JNDI with your Core JMS client, set the check period within the JNDI context environment, **jndi.properties**, for example, as below.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?
clientFailureCheckPeriod=10000
```

- If you are not using JNDI set the check period directly by passing a value to **ActiveMQConnectionFactory.setClientFailureCheckPeriod()**.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setClientFailureCheckPeriod(10000);
```

10.1. CONNECTION TIME-TO-LIVE

Because the network connection between the client and the server can fail and then come back online, allowing a client to reconnect, AMQ Broker waits to clean up inactive server-side resources. This wait period is called a time-to-live (TTL). The default TTL for a network-based connection is **60000** milliseconds (1 minute). The default TTL on an In-VM connection is **-1**, which means the broker never times out the connection on the broker side.

Configuring Time-To-Live on the Broker

If you do not want clients to specify their own connection TTL, you can set a global value on the broker side. This can be done by specifying the **connection-ttl-override** element in the broker configuration.

The logic to check connections for TTL violations runs periodically on the broker, as determined by the **connection-ttl-check-interval** element.

Procedure

- Edit *BROKER_INSTANCE_DIR/etc/broker.xml* by adding the **connection-ttl-override** configuration element and providing a value for the time-to-live, as in the example below.

```
<configuration>
  <core>
    ...
    <connection-ttl-override>30000</connection-ttl-override> 1
    <connection-ttl-check-interval>1000</connection-ttl-check-interval> 2
    ...
  </core>
</configuration>
```

- 1 The global TTL for all connections is set to **30000** milliseconds (30 seconds). The default value is **-1**, which allows clients to set their own TTL.
- 2 The interval between checks for dead connections is set to **1000** milliseconds (1 second). By default, the checks are done every **2000** milliseconds (2 seconds).

Configuring Time-To-Live on the Client

By default clients can set a TTL for their own connections. The examples below show you how to set the Time-To-Live using Core JMS clients.

Procedure

- Set the Time-To-Live for a Client Connection.
 - If you are using JNDI to instantiate your connection factory, you can specify it in the xml config, using the parameter **connectionTtl**.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?connectionTtl=30000
```

- If you are not using JNDI, the connection TTL is defined by the **ConnectionTTL** attribute on a **ActiveMQConnectionFactory** instance.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setConnectionTTL(30000);
```

10.2. DISABLING ASYNCHRONOUS CONNECTION EXECUTION

Most packets received on the broker side are executed on the **remoting** thread. These packets represent short-running operations and are always executed on the **remoting** thread for performance reasons. However, some packet types are executed using a thread pool instead of the **remoting** thread, which adds a little network latency.

The packet types that use the thread pool are implemented within the Java classes listed below. The classes are all found in the package

org.apache.activemq.artemis.core.protocol.core.impl.wireformat.

- RollbackMessage
- SessionCloseMessage
- SessionCommitMessage
- SessionXACommitMessage
- SessionXAPrepareMessage
- SessionXARollbackMessage

Procedure

- To disable asynchronous connection execution, add the **async-connection-execution-enabled** configuration element to *BROKER_INSTANCE_DIR/etc/broker.xml* and set it to **false**, as in the example below. The default value is **true**.

```
<configuration>
  <core>
    ...
    <async-connection-execution-enabled>false</async-connection-execution-enabled>
    ...
  </core>
</configuration>
```

10.3. CLOSING CONNECTIONS FROM THE CLIENT SIDE

A client application must close its resources in a controlled manner before it exits to prevent dead connections from occurring. In Java, it is recommended to close connections inside a **finally** block:

```
Connection jmsConnection = null;
try {
  ConnectionFactory jmsConnectionFactory =
  ActiveMQJMSClient.createConnectionFactoryWithoutHA(...);
  jmsConnection = jmsConnectionFactory.createConnection();
  ...use the connection...
}
finally {
  if (jmsConnection != null) {
```

```
    jmsConnection.close();  
  }  
}
```

CHAPTER 11. FLOW CONTROL

Flow control prevents producers and consumers from becoming overburdened by limiting the flow of data between them. Using AMQ Broker allows you to configure flow control for both consumers and producers.

11.1. CONSUMER FLOW CONTROL

Consumer flow control regulates the flow of data between the broker and the client as the client consumes messages from the broker. AMQ Broker clients buffer messages by default before delivering them to consumers. Without a buffer, the client would first need to request each message from the broker before consuming it. This type of "round-trip" communication is costly. Regulating the flow of data on the client side is important because out of memory issues can result when a consumer cannot process messages quickly enough and the buffer begins to overflow with incoming messages.

11.1.1. Setting the Consumer Window Size

The maximum size of messages held in the client-side buffer is determined by its *window size*. The default size of the window for AMQ Broker clients is 1 MiB, or 1024 * 1024 bytes. The default is fine for most use cases. For other cases, finding the optimal value for the window size might require benchmarking your system. AMQ Broker allows you to set the buffer window size if you need to change the default.

Setting the Window Size

The following examples demonstrate how to set the consumer window size parameter when using a Core JMS client. Each example sets a consumers window size to **300000** bytes.

Procedure

- Set the consumer window size.
 - If the Core JMS Client uses JNDI to instantiate its connection factory, include the **consumerWindowSize** parameter as part of the connection string URL. Store the URL within a JNDI context environment. The example below uses a **jndi.properties** file to store the URL.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory  
  
connectionFactory.myConnectionFactory=tcp://localhost:61616?  
consumerWindowSize=300000
```

- If the Core JMS client does not use JNDI to instantiate its connection factory, pass a value to **ActiveMQConnectionFactory.setConsumerWindowSize()**.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)  
cf.setConsumerWindowSize(300000);
```

11.1.2. Handling Fast Consumers

Fast consumers can process messages as fast as they consume them. If you are confident that the consumers in your messaging system are that fast, consider setting the window size to **-1**. This setting allows for unbounded message buffering on the client side. Use this setting with caution, however. It can overflow client-side memory if the consumer is not able to process messages as fast as it receives them.

Setting the Window Size for Fast Consumers

Procedure

The examples below show how to set the window size to **-1** when using a Core JMS client that is a fast consumer of messages.

- Set the consumer window size to **-1**.
 - If the Core JMS Client uses JNDI to instantiate its connection factory, include the **consumerWindowSize** parameter as part of the connection string URL. Store the URL within a JNDI context environment. The example below uses a **jndi.properties** file to store the URL.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?consumerWindowSize=-1
```

- If the Core JMS client does not use JNDI to instantiate its connection factory, pass a value to **ActiveMQConnectionFactory.setConsumerWindowSize()**.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setConsumerWindowSize(-1);
```

11.1.3. Handling Slow Consumers

Slow consumers take significant time to process each message. In these cases, it is recommended to not buffer messages on the client side. Messages remain on the broker side ready to be consumed by other consumers instead. One benefit of turning off the buffer is that it provides deterministic distribution between multiple consumers on a queue. To handle slow consumers by disabling the client-side buffer, set the window size to **0**.

Setting the Window Size for Slow Consumers

Procedure

The examples below show you how to set the window size to **0** when using the Core JMS client that is a slow consumer of messages.

- Set the consumer window size to **0**.
 - If the Core JMS Client uses JNDI to instantiate its connection factory, include the **consumerWindowSize** parameter as part of the connection string URL. Store the URL within a JNDI context environment. The example below uses a **jndi.properties** file to store the URL.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?
consumerWindowSize=0
```

- If the Core JMS client does not use JNDI to instantiate its connection factory, pass a value to **ActiveMQConnectionFactory.setConsumerWindowSize()**.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setConsumerWindowSize(0);
```

Related Information

See the example **no-consumer-buffering** in *INSTALL_DIR/examples/standard* for an example that shows how to configure the broker to prevent consumer buffering when dealing with slow consumers.

11.1.4. Setting the Rate of Consuming Messages

You can regulate the rate at which a consumer can consume messages. Also known as "throttling", regulating the rate of consumption ensures that a consumer never consumes messages at a rate faster than configuration allows.

NOTE

Rate-limited flow control can be used in conjunction with window-based flow control. Rate-limited flow control affects only how many messages a client can consume in a second and not how many messages are in its buffer. With a slow rate limit and a high window-based limit, the internal buffer of the client fills up with messages quickly.

The rate must be a positive integer to enable this functionality and is the maximum desired message consumption rate specified in units of messages per second. Setting the rate to **-1** disables rate-limited flow control. The default value is **-1**.

Setting the Rate of Consuming Messages

Procedure

The examples below use a Core JMS client that limits the rate of consuming messages to **10** messages per second.

- Set the consumer rate.
 - If the Core JMS Client uses JNDI to instantiate its connection factory, include the **consumerMaxRate** parameter as part of the connection string URL. Store the URL within a JNDI context environment. The example below uses a **jndi.properties** file to store the URL.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
java.naming.provider.url=tcp://localhost:61616?consumerMaxRate=10
```

- If the Core JMS client does not use JNDI to instantiate its connection factory, pass the value to **ActiveMQConnectionFactory.setConsumerMaxRate()**.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setConsumerMaxRate(10);
```

Related information

See the **consumer-rate-limit** example in *INSTALL_DIR/examples/standard* for a working example of how to limit the consumer rate.

11.2. PRODUCER FLOW CONTROL

In a similar way to consumer window-based flow control, AMQ Broker can limit the amount of data sent from a producer to a broker to prevent the broker from being overburdened with too much data. In the case of a producer, the window size determines the amount of bytes that can be in-flight at any one time.

11.2.1. Setting the Producer Window Size

The window size is negotiated between the broker and producer on the basis of credits, one credit for each byte in the window. As messages are sent and credits are used, the producer must request, and be granted, credits from the broker before it can send more messages. The exchange of credits between producer and broker regulates the flow of data between them.

Setting the Window Size

The following examples demonstrate how to set the producer window size to **1024** bytes when using Core JMS clients.

Procedure

- Set the producer window size.
 - If the Core JMS Client uses JNDI to instantiate its connection factory, include the **producerWindowSize** parameter as part of the connection string URL. Store the URL within a JNDI context environment. The example below uses a **jndi.properties** file to store the URL.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
java.naming.provider.url=tcp://localhost:61616?producerWindowSize=1024
```

- If the Core JMS client does not use JNDI to instantiate its connection factory, pass the value to **ActiveMQConnectionFactory.setProducerWindowSize()**.

```
ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setProducerWindowSize(1024);
```

11.2.2. Blocking Messages

Because more than one producer can be associated with the same address, it is possible for the broker to allocate more credits across all producers than what is actually available. However, you can set a maximum size on any address that prevents the broker from sending more credits than are available.

In the default configuration, a global maximum size of 100Mb is used for each address. When the address is full, the broker writes further messages to the paging journal instead of routing them to the queue. Instead of paging, you can block the sending of more messages on the client side until older messages are consumed. Blocking producer flow control in this way prevents the broker from running out of memory due to producers sending more messages than can be handled at any one time.

In the configuration, blocking producer flow control is managed on a per **address-setting** basis. The configuration applies to all queues registered to an address. In other words, the total memory for all queues bound to that address is capped by the value given for **max-size-bytes**.

**NOTE**

Blocking is protocol dependent. In AMQ Broker the AMQP, OpenWire, and Core protocols feature producer flow control. The AMQP protocol handles flow control differently, however. See [Blocking Flow Control Using AMQP](#) for more information.

Configuring the Maximum Size for an Address

To configure the broker to block messages if they are larger than the set maximum number of bytes, add a new **address-setting** configuration element to ***BROKER_INSTANCE_DIR/etc/broker.xml***.

Procedure

- In the example configuration below, an **address-setting** is set to **BLOCK** producers from sending messages after reaching its maximum size of **300000** bytes.

```
<configuration>
  <core>
    ...
    <address-settings>
      <address-setting match="my.blocking.queue"> 1
        <max-size-bytes>300000</max-size-bytes> 2
        <address-full-policy>BLOCK</address-full-policy> 3
      </address-setting>
    </address-settings>
  </core>
</configuration>
```

- 1 The above configuration applies to any queue referenced by the **my.blocking.queue** address .
- 2 Sets the maximum size to **300000** bytes. The broker will block producers from sending to the address if the message exceeds **max-size-bytes**. Note that this element supports byte notation such as "K", "Mb", and "GB".
- 3 Sets the **address-full-policy** to **BLOCK** to enable blocking producer flow control.

11.2.3. Blocking AMQP Messages

As explained earlier in this chapter the Core protocol uses a producer window-size flow control system. In this system, credits represent bytes and are allocated to producers. If a producer wants to send a message, it must wait until it has sufficient credits to accommodate the size of a message before sending it.

AMQP flow control credits are not representative of bytes, however, but instead represent the number of messages a producer is permitted to send, regardless of the message size. It is therefore possible in some scenarios for an AMQP client to significantly exceed the **max-size-bytes** of an address.

To manage this situation, add the element **max-size-bytes-reject-threshold** to the **address-setting** to specify an upper bound on an address size in bytes. Once this upper bound is reached, the broker rejects AMQP messages. By default, **max-size-bytes-reject-threshold** is set to **-1**, or no limit.

Configuring the Broker to Block AMQP Messages

To configure the broker to block AMQP messages if they are larger than the set maximum number of bytes, add a new **address-setting** configuration element to ***BROKER_INSTANCE_DIR/etc/broker.xml***.

Procedure

- The example configuration below applies a maximum size of **300000** bytes to any AMQP message routed to the **my.amqp.blocking.queue** address.

```

<configuration>
  <core>
    ...
    <address-settings>
      ...
      <address-setting match="my.amqp.blocking.queue"> 1
        <max-size-bytes-reject-threshold>300000</max-size-bytes-reject-threshold> 2
      </address-setting>
    </address-settings>
  </core>
</configuration>

```

- The above configuration applies to any queue referenced by the **my.amqp.blocking.queue** address.
- The broker is configured to reject AMQP messages sent to queues matching this address if they are larger than the **max-size-bytes-reject-threshold** of **300000** bytes. Note that this element *does not* support byte notation such as **K**, **Mb**, and **GB**.

11.2.4. Setting the Rate of Sending Messages

AMQ Broker can also limit the rate a producer can emit messages. The producer rate is specified in units of messages per second. Setting it to **-1**, the default, disables rate-limited flow control.

Setting the Rate of Sending Messages

The examples below demonstrate how to set the rate of sending messages when the producer is using a Core JMS client. Each example sets the maximum rate of sending messages to **10** per second.

Procedure

- Set the rate that a producer can send messages.
 - If the Core JMS Client uses JNDI to instantiate its connection factory, include the **producerMaxRate** parameter as part of the connection string URL. Store the URL within a JNDI context environment. The example below uses a **jndi.properties** file to store the URL.

```

java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
java.naming.provider.url=tcp://localhost:61616?producerMaxRate=10

```

- If the Core JMS client does not use JNDI to instantiate its connection factory, pass the value to **ActiveMQConnectionFactory.setProducerMaxRate()**.

```

ConnectionFactory cf = ActiveMQJMSClient.createConnectionFactory(...)
cf.setProducerMaxRate(10);

```

Related Information

See the **producer-rate-limit** example in *INSTALL_DIR/examples/standard* for a working example of how to limit a the rate of sending messages.

CHAPTER 12. MESSAGE GROUPING

Message groups are sets of messages that have the following characteristics:

- Messages in a message group share the same group ID, that is, they have same group identifier property. For JMS messages, the property is **JMSXGroupID**.
- Messages in a message group are always consumed by the same consumer, even if there are many consumers on a queue. Another consumer is chosen to receive a message group if the original consumer closes.

Message groups are useful when you want all messages for a certain value of the property to be processed serially by the same consumer. For example, you may want orders for any particular stock purchase to be processed serially by the same consumer. To do this you could create a pool of consumers, then set the stock name as the value of the message property. This ensures that all messages for a particular stock are always processed by the same consumer.

NOTE

Grouped messages might impact the concurrent processing of non-grouped messages due to the underlying FIFO semantics of a queue. For example, if there is a chunk of 100 grouped messages at the head of a queue followed by 1,000 non-grouped messages, all the grouped messages are sent to the appropriate client before any of the non-grouped messages are consumed. The functional impact in this scenario is a temporary suspension of concurrent message processing while all the grouped messages are processed. Keep this potential performance bottleneck in mind when determining the size of your message groups. Consider whether to isolate your grouped messages from your non-grouped messages.

12.1. CLIENT-SIDE MESSAGE GROUPING

The examples below show how to use message grouping using Core JMS clients.

Procedure

- Set the group ID.
 - If you are using JNDI to establish a JMS connection factory for your JMS client, add the **groupId** parameter and supply a value. All messages sent using this connection factory have the property **JMSXGroupID** set to the specified value.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?groupId=MyGroup
```

- If you are not using JNDI, set the **JMSXGroupID** property using the **setStringProperty()** method.

```
Message message = new TextMessage();
message.setStringProperty("JMSXGroupID", "MyGroup");
producer.send(message);
```

Related Information

See **mesagge-group** and **message-group2** under *INSTALL_DIR/examples/features/standard* for working examples of how message groups are configured and used.

12.2. AUTOMATIC MESSAGE GROUPING

Instead of supplying a group ID yourself, you can have the ID automatically generated for you. Messages grouped in this way are still processed serially by a single consumer.

Procedure

The examples below show how to enable message grouping using Core JMS clients.

- Enable automatic generation of the group ID.
 - If you are using a JNDI context environment to instantiate your JMS connection factory, add the **autogroup=true** name-value pair to the query string of the connection URL.

```
java.naming.factory.initial=org.apache.activemq.artemis.jndi.ActiveMQInitialContextFactory
connectionFactory.myConnectionFactory=tcp://localhost:61616?autoGroup=true
```

- If you are not using JNDI, set **autogroup** to **true** on the **ActiveMQConnectonFactory**.

```
ActiveMQConnectionFactory cf =
ActiveMQJMSSClient.createConnectionFactoryWithoutHA(...);
cf.setAutoGroup(true);
```

CHAPTER 13. DUPLICATE MESSAGE DETECTION

AMQ Broker includes automatic duplicate message detection, which filters out any duplicate messages it receives so you do not have to code your own duplicate detection logic.

Without duplicate detection, a client cannot determine whether a message it sent was successful whenever the target broker or the connection to it fails. For example, if the broker or connection fails *before* the message was received and processed by the broker, the message never arrives at its address, and the client does not receive a response from the broker due to the failure. On the other hand, if the broker or connection failed *after* a message was received and processed by the broker, the message is routed correctly, but the client still does not receive a response.

Moreover, using a transaction to determine success does not help in these cases. If the broker or connection fails while the transaction commit is being processed, for example, the client is still unable to determine whether it successfully sent the message.

If the client resends the last message in an effort to correct the assumed failure, the result could be a duplicate message being sent to the address, which could negatively impact your system. Sending a duplicate message could mean that a purchase order is fulfilled twice, for example. Fortunately, {AMQ Broker} provides automatic duplicate messages detection as a way to prevent these kind of issues from happening.

13.1. USING THE DUPLICATE ID MESSAGE PROPERTY

To enable duplicate message detection provide a unique value for the message property `_AMQ_DUPL_ID`. When a broker receives a message, it checks if `_AMQ_DUPL_ID` has a value. If it does, the broker then checks in its memory cache to see if it has already received a message with that value. If a message with the same value is found, the incoming message is ignored.

Procedure

The examples below illustrate how to set the duplicate detection property using a Core JMS Client.

Note that for convenience, the clients use the value of the constant

`org.apache.activemq.artemis.api.core.Message.HDR_DUPLICATE_DETECTION_ID` for the name of the duplicate ID property, `_AMQ_DUPL_ID`.

- Set the value for `_AMQ_DUPL_ID` to a unique **String**.

```
Message jmsMessage = session.createMessage();
String myUniqueID = "This is my unique id";
message.setStringProperty(HDR_DUPLICATE_DETECTION_ID.toString(), myUniqueID);
```

13.2. CONFIGURING THE DUPLICATE ID CACHE

The broker maintains caches of received values of the `_AMQ_DUPL_ID` property. Each address has its own distinct cache. The cache is circular and fixed. New entries replace the oldest ones as cache space demands.

NOTE

Be sure to size the cache appropriately. If a previous message arrived more than **id-cache-size** messages before the arrival of a new message with the same `_AMQ_DUPL_ID`, the broker cannot detect the duplicate. This results in both messages being processed by the broker.

Procedure

The example configuration below illustrates how to configure the ID cache by adding elements to ***BROKER_INSTANCE_DIR/etc/broker.xml***.

```
<configuration>
  <core>
    ...
    <id-cache-size>5000</id-cache-size> 1
    <persist-id-cache>>false</persist-id-cache> 2
  </core>
</configuration>
```

- 1 The maximum size of the cache is configured by the parameter **id-cache-size**. The default value is **20000** entries. In the example above, the cache size is set to **5000** entries.
- 2 Set **persist-id-cache** to **true** to have each ID persisted to disk as they are received. The default value is **true**. In the example above, persistence is disabled by setting the value to **false**.

13.3. DUPLICATE DETECTION AND TRANSACTIONS

Using duplicate detection to move messages between brokers can give you the same once and only once delivery guarantees as using an XA transaction to consume messages, but with less overhead and much easier configuration than using XA.

If you are sending messages in a transaction, you do not have to set **_AMQ_DUPL_ID** for every message in the transaction, but only in one of them. If the broker detects a duplicate message for any message in the transaction, it ignores the entire transaction.

13.4. DUPLICATE DETECTION AND CLUSTER CONNECTIONS

You can configure cluster connections to insert a duplicate ID for each message they move across the cluster.

Procedure

- Add the element **use-duplicate-detection** to the configuration of the desired cluster connection found in ***BROKER_INSTANCE_DIR/etc/broker.xml***. Note that the default value for this parameter is **true**. In the example below, the element is added to the configuration for the cluster connection **my-cluster**.

```
<configuration>
  <core>
    ...
    <cluster-connection>
      <cluster-connection name="my-cluster"> 2
      <use-duplicate-detection>>true</use-duplicate-detection>
    </cluster-connection>
    ...
  </cluster-connections>
</core>
</configuration>
```

Related Information

For more information about broker clusters, see [Section 16.2, "Creating a broker cluster"](#).

CHAPTER 14. INTERCEPTING MESSAGES

With AMQ Broker you can intercept packets entering or exiting the broker, allowing you to audit packets or filter messages. Interceptors can change the packets they intercept, which makes them powerful, but also potentially dangerous.

You can develop interceptors to meet your business requirements. Interceptors are protocol specific and must implement the appropriate interface.

Interceptors must implement the **intercept()** method, which returns a boolean value. If the value is **true**, the message packet continues onward. If **false**, the process is aborted, no other interceptors are called, and the message packet is not processed further.

14.1. CREATING INTERCEPTORS

You can create your own incoming and outgoing interceptors. All interceptors are protocol specific and are called for any packet entering or exiting the server respectively. This allows you to create interceptors to meet business requirements such as auditing packets. Interceptors can change the packets they intercept. This makes them powerful as well as potentially dangerous, so be sure to use them with caution.

Interceptors and their dependencies must be placed in the Java classpath of the broker. You can use the ***BROKER_INSTANCE_DIR/lib*** directory since it is part of the classpath by default.

Procedure

The following examples demonstrate how to create an interceptor that checks the size of each packet passed to it. Note that the examples implement a specific interface for each protocol.

- Implement the appropriate interface and override its **intercept()** method.
 - If you are using the AMQP protocol, implement the **org.apache.activemq.artemis.protocol.amqp.broker.AmqpInterceptor** interface.

```
package com.example;

import org.apache.activemq.artemis.protocol.amqp.broker.AMQPMessage;
import org.apache.activemq.artemis.protocol.amqp.broker.AmqpInterceptor;
import org.apache.activemq.artemis.spi.core.protocol.RemotingConnection;

public class MyInterceptor implements AmqpInterceptor
{
    private final int ACCEPTABLE_SIZE = 1024;

    @Override
    public boolean intercept(final AMQPMessage message, RemotingConnection
connection)
    {
        int size = message.getEncodeSize();
        if (size <= ACCEPTABLE_SIZE) {
            System.out.println("This AMQPMessage has an acceptable size.");
            return true;
        }
        return false;
    }
}
```

- If you are using the Core protocol, your interceptor must implement the **org.apache.artemis.activemq.api.core.Interceptor** interface.

```
package com.example;

import org.apache.artemis.activemq.api.core.Interceptor;
import org.apache.activemq.artemis.core.protocol.core.Packet;
import org.apache.activemq.artemis.spi.core.protocol.RemotingConnection;

public class MyInterceptor implements Interceptor
{
    private final int ACCEPTABLE_SIZE = 1024;

    @Override
    boolean intercept(Packet packet, RemotingConnection connection)
    throws ActiveMQException
    {
        int size = packet.getPacketSize();
        if (size <= ACCEPTABLE_SIZE) {
            System.out.println("This Packet has an acceptable size.");
            return true;
        }
        return false;
    }
}
```

- If you are using the MQTT protocol, implement the **org.apache.activemq.artemis.core.protocol.mqtt.MQTTInterceptor** interface.

```
package com.example;

import org.apache.activemq.artemis.core.protocol.mqtt.MQTTInterceptor;
import io.netty.handler.codec.mqtt.MqttMessage;
import org.apache.activemq.artemis.spi.core.protocol.RemotingConnection;

public class MyInterceptor implements Interceptor
{
    private final int ACCEPTABLE_SIZE = 1024;

    @Override
    boolean intercept(MqttMessage mqttMessage, RemotingConnection connection)
    throws ActiveMQException
    {
        byte[] msg = (mqttMessage.toString()).getBytes();
        int size = msg.length;
        if (size <= ACCEPTABLE_SIZE) {
            System.out.println("This MqttMessage has an acceptable size.");
            return true;
        }
        return false;
    }
}
```

- If you are using the Stomp protocol, implement the **org.apache.activemq.artemis.core.protocol.stomp.StompFrameInterceptor** interface.

```

package com.example;

import org.apache.activemq.artemis.core.protocol.stomp.StompFrameInterceptor;
import org.apache.activemq.artemis.core.protocol.stomp.StompFrame;
import org.apache.activemq.artemis.spi.core.protocol.RemotingConnection;

public class MyInterceptor implements Interceptor
{
    private final int ACCEPTABLE_SIZE = 1024;

    @Override
    boolean intercept(StompFrame stompFrame, RemotingConnection connection)
    throws ActiveMQException
    {
        int size = stompFrame.getEncodedSize();
        if (size <= ACCEPTABLE_SIZE) {
            System.out.println("This StompFrame has an acceptable size.");
            return true;
        }
        return false;
    }
}

```

14.2. CONFIGURING THE BROKER TO USE INTERCEPTORS

Once you have created an interceptor, you must configure the broker to use it.

Prerequisites

You must create an interceptor class and add it (and its dependencies) to the Java classpath of the broker before you can configure it for use by the broker. You can use the ***BROKER_INSTANCE_DIR/lib*** directory since it is part of the classpath by default.

Procedure

- Configure the broker to use an interceptor by adding configuration to ***BROKER_INSTANCE_DIR/etc/broker.xml***
 - If your interceptor is intended for incoming messages, add its **class-name** to the list of **remoting-incoming-interceptors**.

```

<configuration>
  <core>
    ...
    <remoting-incoming-interceptors>
      <class-name>org.example.MyIncomingInterceptor</class-name>
    </remoting-incoming-interceptors>
    ...
  </core>
</configuration>

```

- If your interceptor is intended for outgoing messages, add its **class-name** to the list of **remoting-outgoing-interceptors**.

```

<configuration>

```

```
<core>
...
<remoting-outgoing-interceptors>
  <class-name>org.example.MyOutgoingInterceptor</class-name>
</remoting-outgoing-interceptors>
</core>
</configuration>
```

14.3. INTERCEPTORS ON THE CLIENT SIDE

Clients can use interceptors to intercept packets either sent by the client to the server or by the server to the client. As in the case of a broker-side interceptor, if it returns **false**, no other interceptors are called and the client does not process the packet further. This process happens transparently to the client except when an outgoing packet is sent in a **blocking** fashion. In those cases, an **ActiveMQException** is thrown to the caller because blocking sends provides reliability. The **ActiveMQException** thrown contains the name of the interceptor that returned false.

As on the server, the client interceptor classes and their dependencies must be added to the Java classpath of the client to be properly instantiated and invoked.

CHAPTER 15. FILTERING MESSAGES

AMQ Broker provides a powerful filter language based on a subset of the SQL 92 expression syntax. The filter language uses the same syntax as used for JMS selectors, but the predefined identifiers are different. The table below lists the identifiers that apply to a AMQ Broker message.

Identifier	Attribute
AMQPriority	The priority of a message. Message priorities are integers with valid values from 0 through 9 . 0 is the lowest priority and 9 is the highest.
AMQExpiration	The expiration time of a message. The value is a long integer.
AMQDurable	Whether a message is durable or not. The value is a string. Valid values are DURABLE or NON_DURABLE .
AMQTimestamp	The timestamp of when the message was created. The value is a long integer.
AMQSize	The size of a message in bytes. The value is an integer.

Any other identifiers used in core filter expressions are assumed to be properties of the message. For documentation on selector syntax for JMS Messages, see the [Java EE API](#).

15.1. CONFIGURING A QUEUE TO USE A FILTER

You can add a filter to the queues you configure in ***BROKER_INSTANCE_DIR/etc/broker.xml***. Only messages that match the filter expression enter the queue.

Procedure

- Add the **filter** element to the desired **queue** and include the filter you want to apply as the value of the element. In the example below, the filter **NEWS='technology'** is added to the queue **technologyQueue**.

```
<configuration>
  <core>
    ...
    <addresses>
      <address name="myQueue">
        <anycast>
          <queue name="myQueue">
            <filter string="NEWS='technology'"/>
          </queue>
        </anycast>
      </address>
    </addresses>
  </core>
</configuration>
```

15.2. FILTERING JMS MESSAGE PROPERTIES

The JMS specification states that a String property must not be converted to a numeric type when used in a selector. For example, if a message has the **age** property set to the String value **21**, the selector **age > 18** must not match it. This restriction limits STOMP clients because they can send only messages with String properties.

The JMS specification also states that hyphens cannot be used as property identifiers, making them unavailable for use in filters. However, this constraint can be overcome by using the **hyphenated_props:** prefix.

Configuring a Filter to Convert a String to a Number

To convert String properties to a numeric type, add the prefix **convert_string_expressions:** to the value of the **filter**.

Procedure

- Edit **BROKER_INSTANCE_DIR/etc/broker.xml** by applying the prefix **convert_string_expressions:** to the desired **filter**. The example below edits the **filter** value from **age > 18** to **convert_string_expressions:age > 18**.

```
<configuration>
  <core>
    ...
    <addresses>
      <address name="myQueue">
        <anycast>
          <queue name="myQueue">
            <filter string="convert_string_expressions='age > 18'"/>
          </queue>
        </anycast>
      </address>
    </addresses>
  </core>
</configuration>
```

Enabling a Filter to Use Hyphens

To enable the use of hyphens when filtering JMS properties, add the prefix **hyphenated_props:** to the value of the **filter**.

Procedure

- Edit **BROKER_INSTANCE_DIR/etc/broker.xml** by applying the prefix **hyphenated_props:** to the desired **filter**. In the example below, a **filter** is edited so that it can select for the hyphenated property **foo-bar**.

```
<configuration>
  <core>
    ...
    <addresses>
      <address name="myQueue">
        <anycast>
          <queue name="myQueue">
            <filter string="hyphenated_props='foo-bar = 0'"/>
          </queue>
        </anycast>
      </address>
    </addresses>
  </core>
</configuration>
```

```
    </anycast>  
  </address>  
</addresses>  
</core>  
</configuration>
```

CHAPTER 16. SETTING UP A BROKER CLUSTER

A cluster consists of multiple broker instances that have been grouped together. Broker clusters enhance performance by distributing the message processing load across multiple brokers. In addition, broker clusters can minimize downtime through high availability.

You can connect brokers together in many different cluster topologies. Within the cluster, each active broker manages its own messages and handles its own connections.

You can also balance client connections across the cluster and redistribute messages to avoid broker starvation.

16.1. UNDERSTANDING BROKER CLUSTERS

Before creating a broker cluster, you should understand some important clustering concepts.

16.1.1. How broker clusters balance message load

When brokers are connected to form a cluster, AMQ Broker automatically balances the message load between the brokers. This ensures that the cluster can maintain high message throughput.

Consider a symmetric cluster of four brokers. Each broker is configured with a queue named **OrderQueue**. The **OrderProducer** client connects to **Broker1** and sends messages to **OrderQueue**. **Broker1** forwards the messages to the other brokers in round-robin fashion. The **OrderConsumer** clients connected to each broker consume the messages. The exact order depends on the order in which the brokers started.

Figure 16.1. Message load balancing

Without message load balancing, the messages sent to **Broker1** would stay on **Broker1** and only **OrderConsumer1** would be able to consume them.

While AMQ Broker automatically load balances messages by default, you can configure the cluster to only load balance messages to brokers that have a matching consumer. You can also configure message redistribution to automatically redistribute messages from queues that do not have any consumers to queues that do have consumers.

Additional resources

- The message load balancing policy is configured with the **message-load-balancing** property in each broker's cluster connection. For more information, see [Appendix C, Cluster Connection Configuration Elements](#).
- For more information about message redistribution, see [Section 16.4, "Enabling message redistribution"](#).

16.1.2. How broker clusters improve reliability

Broker clusters make high availability and failover possible, which makes them more reliable than standalone brokers. By configuring high availability, you can ensure that client applications can continue to send and receive messages even if a broker encounters a failure event.

With high availability, the brokers in the cluster are grouped into live-backup groups. A live-backup group consists of a live broker that serves client requests, and one or more backup brokers that wait

passively to replace the live broker if it fails. If a failure occurs, the backup brokers replace the live broker in its live-backup group, and the clients reconnect and continue their work.

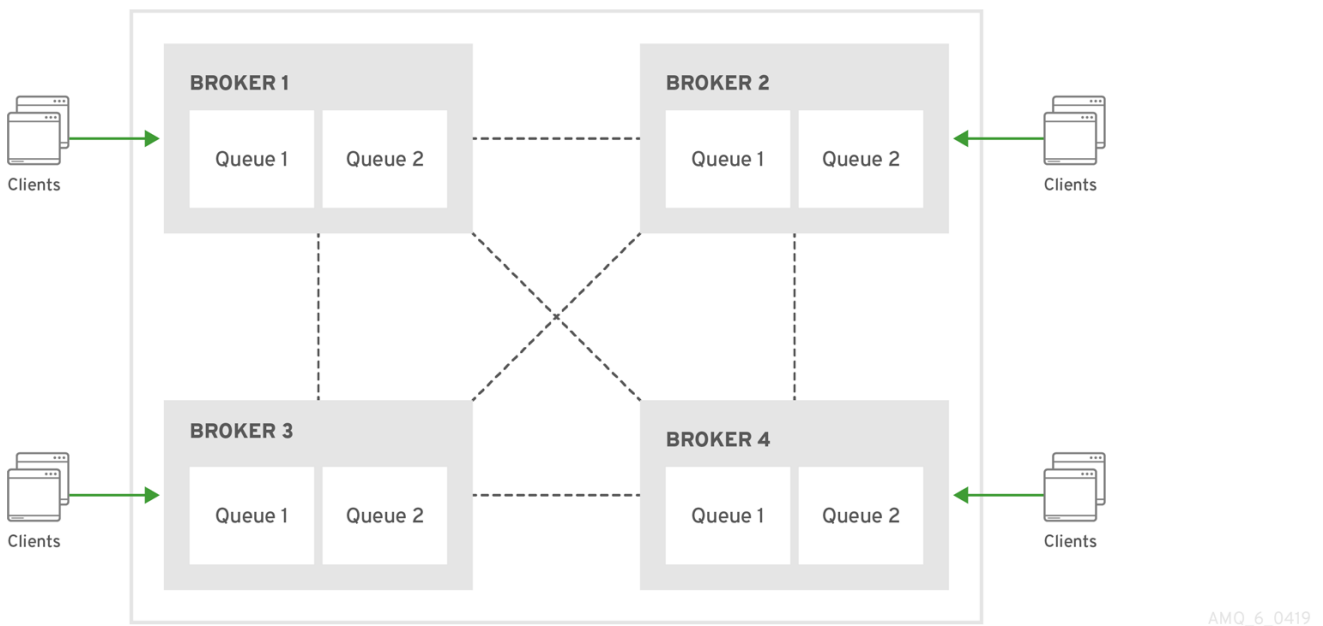

16.1.3. Common broker cluster topologies

You can connect brokers to form either a *symmetric* or *chain* cluster topology. The topology you implement depends on your environment and messaging requirements.

Symmetric clusters

In a symmetric cluster, every broker is connected to every other broker. This means that every broker is no more than one hop away from every other broker.

Figure 16.2. Symmetric cluster

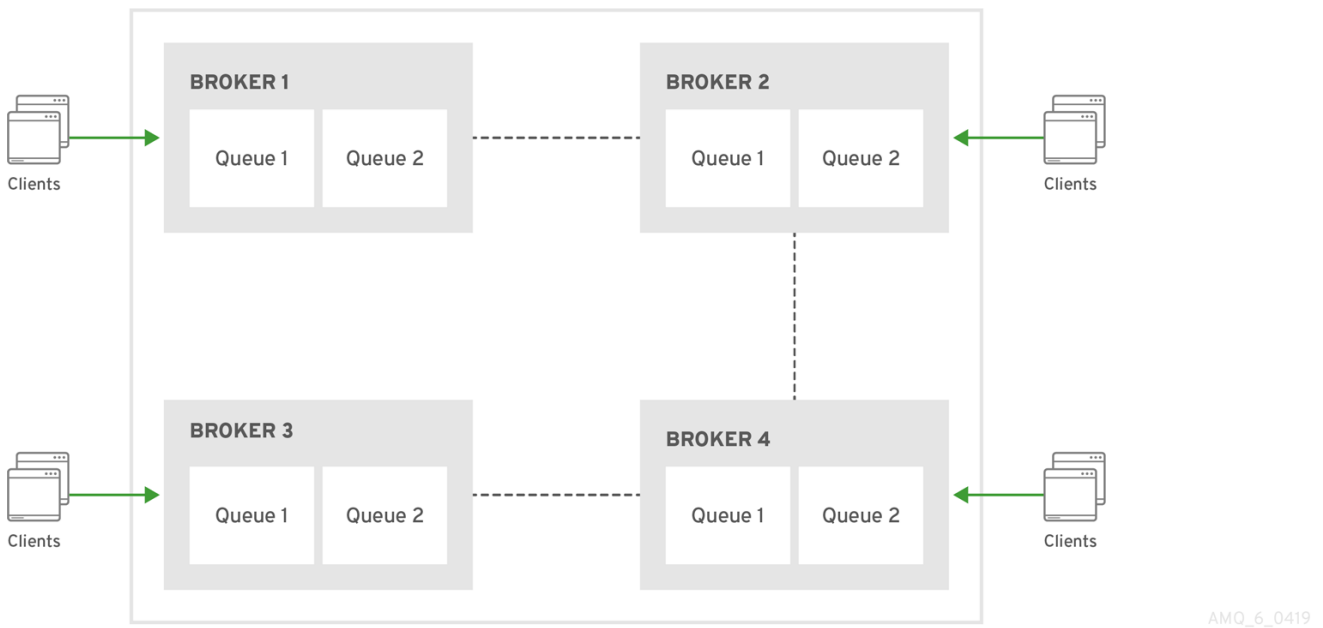

Each broker in a symmetric cluster is aware of all of the queues that exist on every other broker in the cluster and the consumers that are listening on those queues. Therefore, symmetric clusters are able to load balance and redistribute messages more optimally than a chain cluster.

Symmetric clusters are easier to set up than chain clusters, but they can be difficult to use in environments in which network restrictions prevent brokers from being directly connected.

Chain clusters

In a chain cluster, each broker in the cluster is not connected to every broker in the cluster directly. Instead, the brokers form a chain with a broker on each end of the chain and all other brokers just connecting to the previous and next brokers in the chain.

Figure 16.3. Chain cluster

Chain clusters are more difficult to set up than symmetric clusters, but can be useful when brokers are on separate networks and cannot be directly connected. By using a chain cluster, an intermediary broker can indirectly connect two brokers to enable messages to flow between them even though the two brokers are not directly connected.

16.1.4. Broker discovery methods

Discovery is the mechanism by which brokers in a cluster propagate their connection details to each other. AMQ Broker supports both *dynamic discovery* and *static discovery*.

Dynamic discovery

Each broker in the cluster broadcasts its connection settings to the other members through either UDP multicast or JGroups. In this method, each broker uses:

- A *broadcast group* to push information about its cluster connection to other potential members of the cluster.
- A *discovery group* to receive and store cluster connection information about the other brokers in the cluster.

Static discovery

If you are not able to use UDP or JGroups in your network, or if you want to manually specify each member of the cluster, you can use static discovery. In this method, a broker "joins" the cluster by connecting to a second broker and sending its connection details. The second broker then propagates those details to the other brokers in the cluster.

16.1.5. Cluster sizing considerations

Before creating a broker cluster, consider your messaging throughput, topology, and high availability requirements. These factors affect the number of brokers to include in the cluster.

**NOTE**

After creating the cluster, you can adjust the size by adding and removing brokers. You can add and remove brokers without losing any messages.

Messaging throughput

The cluster should contain enough brokers to provide the messaging throughput that you require. The more brokers in the cluster, the greater the throughput. However, large clusters can be complex to manage.

Topology

You can create either symmetric clusters or chain clusters. The type of topology you choose affects the number of brokers you may need.

For more information, see [Section 16.1.3, “Common broker cluster topologies”](#).

High availability

If you require high availability (HA), consider choosing an HA policy before creating the cluster. The HA policy affects the size of the cluster, because each master broker should have at least one slave broker.

For more information, see [Section 16.3, “Implementing high availability”](#).

16.2. CREATING A BROKER CLUSTER

You create a broker cluster by configuring a cluster connection on each broker that should participate in the cluster. The cluster connection defines how the broker should connect to the other brokers.

You can create a broker cluster that uses static discovery or dynamic discovery (either UDP multicast or JGroups).

Prerequisites

- You should have determined the size of the broker cluster.
For more information, see [Section 16.1.5, “Cluster sizing considerations”](#).

16.2.1. Creating a broker cluster with static discovery

You can create a broker cluster by specifying a static list of brokers. Use this static discovery method if you are unable to use UDP multicast or JGroups on your network.

Procedure

1. Open the `<broker-instance-dir>/etc/broker.xml` configuration file.
2. Within the `<core>` element, add the following connectors:
 - A connector that defines how other brokers can connect to this one
 - One or more connectors that define how this broker can connect to other brokers in the cluster

```
<configuration>
  <core>
    ...
    <connectors>
```

```

    <connector name="netty-connector">tcp://localhost:61617</connector> 1
    <connector name="broker2">tcp://localhost:61618</connector> 2
    <connector name="broker3">tcp://localhost:61619</connector>
  </connectors>
  ...
</core>
</configuration>

```

- 1** This connector defines connection information that other brokers can use to connect to this one. This information will be sent to other brokers in the cluster during discovery.
- 2** The **broker2** and **broker3** connectors define how this broker can connect to two other brokers in the cluster, one of which will always be available. If there are other brokers in the cluster, they will be discovered by one of these connectors when the initial connection is made.

For more information about connectors, see [Section 2.2, "About Connectors"](#).

3. Add a cluster connection and configure it to use static discovery.
By default, the cluster connection will load balance messages for all addresses in a symmetric topology.

```

<configuration>
  <core>
    ...
    <cluster-connections>
      <cluster-connection name="my-cluster">
        <connector-ref>netty-connector</connector-ref>
        <static-connectors>
          <connector-ref>broker2-connector</connector-ref>
          <connector-ref>broker3-connector</connector-ref>
        </static-connectors>
      </cluster-connection>
    </cluster-connections>
    ...
  </core>
</configuration>

```

cluster-connection

Use the **name** attribute to specify the name of the cluster connection.

connector-ref

The connector that defines how other brokers can connect to this one.

static-connectors

One or more connectors that this broker can use to make an initial connection to another broker in the cluster. After making this initial connection, the broker will discover the other brokers in the cluster. You only need to configure this property if the cluster uses static discovery.

4. Configure any additional properties for the cluster connection.
These additional cluster connection properties have default values that are suitable for most common use cases. Therefore, you only need to configure these properties if you do not want the default behavior. For more information, see [Appendix C, Cluster Connection Configuration Elements](#).

5. Create the cluster user and password.

AMQ Broker ships with default cluster credentials, but you should change them to prevent unauthorized remote clients from using these default credentials to connect to the broker.

IMPORTANT

The cluster password must be the same on every broker in the cluster.

```
<configuration>
  <core>
    ...
    <cluster-user>cluster_user</cluster-user>
    <cluster-password>cluster_user_password</cluster-password>
    ...
  </core>
</configuration>
```

6. Repeat this procedure on each additional broker.

You can copy the cluster configuration to each additional broker. However, do not copy any of the other AMQ Broker data files (such as the bindings, journal, and large messages directories). These files must be unique among the nodes in the cluster or the cluster will not form properly.

Additional resources

- For an example of a broker cluster that uses static discovery, see the [clustered-static-discovery AMQ Broker example program](#).

16.2.2. Creating a broker cluster with UDP-based dynamic discovery

You can create a broker cluster in which the brokers discover each other dynamically through UDP multicast.

Procedure

1. Open the `<broker-instance-dir>/etc/broker.xml` configuration file.
2. Within the `<core>` element, add a connector.
This connector defines connection information that other brokers can use to connect to this one. This information will be sent to other brokers in the cluster during discovery.

```
<configuration>
  <core>
    ...
    <connectors>
      <connector name="netty-connector">tcp://localhost:61617</connector>
    </connectors>
    ...
  </core>
</configuration>
```

3. Add a UDP broadcast group.

The broadcast group enables the broker to push information about its cluster connection to the other brokers in the cluster. This broadcast group uses UDP to broadcast the connection settings:

```
<configuration>
  <core>
    ...
    <broadcast-groups>
      <broadcast-group name="my-broadcast-group">
        <local-bind-address>172.16.9.3</local-bind-address>
        <local-bind-port>-1</local-bind-port>
        <group-address>231.7.7.7</group-address>
        <group-port>9876</group-port>
        <broadcast-period>2000</broadcast-period>
        <connector-ref>netty-connector</connector-ref>
      </broadcast-group>
    </broadcast-groups>
    ...
  </core>
</configuration>
```

The following parameters are required unless otherwise noted:

broadcast-group

Use the **name** attribute to specify a unique name for the broadcast group.

local-bind-address

The address to which the UDP socket is bound. If you have multiple network interfaces on your broker, you should specify which one you want to use for broadcasts. If this property is not specified, the socket will be bound to an IP address chosen by the operating system. This is a UDP-specific attribute.

local-bind-port

The port to which the datagram socket is bound. In most cases, use the default value of **-1**, which specifies an anonymous port. This parameter is used in connection with **local-bind-address**. This is a UDP-specific attribute.

group-address

The multicast address to which the data will be broadcast. It is a class D IP address in the range **224.0.0.0** – **239.255.255.255** inclusive. The address **224.0.0.0** is reserved and is not available for use. This is a UDP-specific attribute.

group-port

The UDP port number used for broadcasting. This is a UDP-specific attribute.

broadcast-period (optional)

The interval in milliseconds between consecutive broadcasts. The default value is 2000 milliseconds (2 seconds).

connector-ref

The previously configured cluster connector that should be broadcasted.

4. Add a UDP discovery group.

The discovery group defines how this broker receives connector information from other brokers. The broker maintains a list of connectors (one entry for each broker). As it receives broadcasts from a broker, it updates its entry. If it does not receive a broadcast from a broker for a length of time, it removes the entry.

This discovery group uses UDP to discover the brokers in the cluster:

```
<configuration>
  <core>
    ...
    <discovery-groups>
      <discovery-group name="my-discovery-group">
        <local-bind-address>172.16.9.7</local-bind-address>
        <group-address>231.7.7.7</group-address>
        <group-port>9876</group-port>
        <refresh-timeout>10000</refresh-timeout>
      </discovery-group>
    </discovery-groups>
    ...
  </core>
</configuration>
```

The following parameters are required unless otherwise noted:

discovery-group

Use the **name** attribute to specify a unique name for the discovery group.

local-bind-address (optional)

If the machine on which the broker is running uses multiple network interfaces, you can specify the network interface to which the discovery group should listen. This is a UDP-specific attribute.

group-address

The multicast address of the group on which to listen. It should match the **group-address** in the broadcast group that you want to listen from. This is a UDP-specific attribute.

group-port

The UDP port number of the multicast group. It should match the **group-port** in the broadcast group that you want to listen from. This is a UDP-specific attribute.

refresh-timeout (optional)

The amount of time in milliseconds that the discovery group waits after receiving the last broadcast from a particular broker before removing that broker's connector pair entry from its list. The default is 10000 milliseconds (10 seconds).

Set this to a much higher value than the **broadcast-period** on the broadcast group.

Otherwise, brokers might periodically disappear from the list even though they are still broadcasting (due to slight differences in timing).

5. Create a cluster connection and configure it to use dynamic discovery.

By default, the cluster connection will load balance messages for all addresses in a symmetric topology.

```
<configuration>
  <core>
    ...
    <cluster-connections>
      <cluster-connection name="my-cluster">
        <connector-ref>netty-connector</connector-ref>
        <discovery-group-ref discovery-group-name="my-discovery-group"/>
      </cluster-connection>
    </cluster-connections>
  </core>
</configuration>
```

```

    </cluster-connections>
    ...
  </core>
</configuration>

```

cluster-connection

Use the **name** attribute to specify the name of the cluster connection.

connector-ref

The connector that defines how other brokers can connect to this one.

discovery-group-ref

The discovery group that this broker should use to locate other members of the cluster. You only need to configure this property if the cluster uses dynamic discovery.

- Configure any additional properties for the cluster connection. These additional cluster connection properties have default values that are suitable for most common use cases. Therefore, you only need to configure these properties if you do not want the default behavior. For more information, see [Appendix C, Cluster Connection Configuration Elements](#).
- Create the cluster user and password. AMQ Broker ships with default cluster credentials, but you should change them to prevent unauthorized remote clients from using these default credentials to connect to the broker.

**IMPORTANT**

The cluster password must be the same on every broker in the cluster.

```

<configuration>
  <core>
    ...
    <cluster-user>cluster_user</cluster-user>
    <cluster-password>cluster_user_password</cluster-password>
    ...
  </core>
</configuration>

```

- Repeat this procedure on each additional broker. You can copy the cluster configuration to each additional broker. However, do not copy any of the other AMQ Broker data files (such as the bindings, journal, and large messages directories). These files must be unique among the nodes in the cluster or the cluster will not form properly.

Additional resources

- For an example of a broker cluster configuration that uses dynamic discovery with UDP, see the [clustered-queue AMQ Broker example program](#).

16.2.3. Creating a broker cluster with JGroups-based dynamic discovery

If you are already using JGroups in your environment, you can use it to create a broker cluster in which the brokers discover each other dynamically.

Prerequisites

- JGroups must be installed and configured.
For an example of a JGroups configuration file, see the [clustered-jgroups AMQ Broker example program](#).

Procedure

1. Open the `<broker-instance-dir>/etc/broker.xml` configuration file.
2. Within the `<core>` element, add a connector.
This connector defines connection information that other brokers can use to connect to this one. This information will be sent to other brokers in the cluster during discovery.

```
<configuration>
  <core>
    ...
    <connectors>
      <connector name="netty-connector">tcp://localhost:61617</connector>
    </connectors>
    ...
  </core>
</configuration>
```

3. Within the `<core>` element, add a JGroups broadcast group.
The broadcast group enables the broker to push information about its cluster connection to the other brokers in the cluster. This broadcast group uses JGroups to broadcast the connection settings:

```
<configuration>
  <core>
    ...
    <broadcast-groups>
      <broadcast-group name="my-broadcast-group">
        <jgroups-file>test-jgroups-file_ping.xml</jgroups-file>
        <jgroups-channel>activemq_broadcast_channel</jgroups-channel>
        <broadcast-period>2000</broadcast-period>
        <connector-ref>netty-connector</connector-ref>
      </broadcast-group>
    </broadcast-groups>
    ...
  </core>
</configuration>
```

The following parameters are required unless otherwise noted:

broadcast-group

Use the **name** attribute to specify a unique name for the broadcast group.

jgroups-file

The name of JGroups configuration file to initialize JGroups channels. The file must be in the Java resource path so that the broker can load it.

jgroups-channel

The name of the JGroups channel to connect to for broadcasting.

broadcast-period (optional)

The interval in milliseconds between consecutive broadcasts. The default value is 2000 milliseconds (2 seconds).

connector-ref

The previously configured cluster connector that should be broadcasted.

4. Add a JGroups discovery group.

The discovery group defines how connector information is received. The broker maintains a list of connectors (one entry for each broker). As it receives broadcasts from a broker, it updates its entry. If it does not receive a broadcast from a broker for a length of time, it removes the entry.

This discovery group uses JGroups to discover the brokers in the cluster:

```
<configuration>
  <core>
    ...
    <discovery-groups>
      <discovery-group name="my-discovery-group">
        <jgroups-file>test-jgroups-file_ping.xml</jgroups-file>
        <jgroups-channel>activemq_broadcast_channel</jgroups-channel>
        <refresh-timeout>10000</refresh-timeout>
      </discovery-group>
    </discovery-groups>
    ...
  </core>
</configuration>
```

The following parameters are required unless otherwise noted:

discovery-group

Use the **name** attribute to specify a unique name for the discovery group.

jgroups-file

The name of JGroups configuration file to initialize JGroups channels. The file must be in the Java resource path so that the broker can load it.

jgroups-channel

The name of the JGroups channel to connect to for receiving broadcasts.

refresh-timeout (optional)

The amount of time in milliseconds that the discovery group waits after receiving the last broadcast from a particular broker before removing that broker's connector pair entry from its list. The default is 10000 milliseconds (10 seconds).

Set this to a much higher value than the **broadcast-period** on the broadcast group.

Otherwise, brokers might periodically disappear from the list even though they are still broadcasting (due to slight differences in timing).

5. Create a cluster connection and configure it to use dynamic discovery.

By default, the cluster connection will load balance messages for all addresses in a symmetric topology.

```
<configuration>
  <core>
    ...
    <cluster-connections>
```

```

    <cluster-connection name="my-cluster">
      <connector-ref>netty-connector</connector-ref>
      <discovery-group-ref discovery-group-name="my-discovery-group"/>
    </cluster-connection>
  </cluster-connections>
  ...
</core>
</configuration>

```

cluster-connection

Use the **name** attribute to specify the name of the cluster connection.

connector-ref

The connector that defines how other brokers can connect to this one.

discovery-group-ref

The discovery group that this broker should use to locate other members of the cluster. You only need to configure this property if the cluster uses dynamic discovery.

6. Configure any additional properties for the cluster connection.

These additional cluster connection properties have default values that are suitable for most common use cases. Therefore, you only need to configure these properties if you do not want the default behavior. For more information, see [Appendix C, Cluster Connection Configuration Elements](#).

7. Create the cluster user and password.

AMQ Broker ships with default cluster credentials, but you should change them to prevent unauthorized remote clients from using these default credentials to connect to the broker.

IMPORTANT

The cluster password must be the same on every broker in the cluster.

```

<configuration>
  <core>
    ...
    <cluster-user>cluster_user</cluster-user>
    <cluster-password>cluster_user_password</cluster-password>
    ...
  </core>
</configuration>

```

8. Repeat this procedure on each additional broker.

You can copy the cluster configuration to each additional broker. However, do not copy any of the other AMQ Broker data files (such as the bindings, journal, and large messages directories). These files must be unique among the nodes in the cluster or the cluster will not form properly.

Additional resources

- For an example of a broker cluster that uses dynamic discovery with JGroups, see the [clustered-jgroups AMQ Broker example program](#).

16.3. IMPLEMENTING HIGH AVAILABILITY

After creating a broker cluster, you can improve its reliability by implementing high availability (HA). With HA, the broker cluster can continue to function even if one or more brokers go offline.

Implementing HA involves several steps:

1. [Understand how live-backup groups provide HA](#) .
2. [Choose an HA policy](#) .
3. [Configure the HA policy on each broker in the cluster](#) .
4. [Configure your client applications to use failover](#) .

16.3.1. How live-backup groups provide high availability

In AMQ Broker, you implement high availability (HA) by linking together the brokers in your cluster to form *live-backup groups*. Live-backup groups provide *failover*, which means that if one broker fails, another broker can take over its message processing.

A live-backup group consists of one live broker (sometimes called the *master broker*) linked to one or more backup brokers (sometimes called *slave brokers*). The live broker serves client requests, while the backup brokers wait in passive mode. If the live broker fails, a backup broker replaces the live broker, enabling the clients to reconnect and continue their work.

In a live-backup group, failover requires the persistent message data (the journal) to be synchronized between the live and backup brokers. AMQ Broker provides two different strategies for synchronizing this data, called *HA policies*:

Shared store

The live and backup brokers store their messaging data in a single directory on a shared file system (typically a Storage Area Network, or SAN). If the live broker fails, the backup broker loads the messaging data from the shared file system and takes over for the failed live broker.

JBOSS_409952_0317

Replication

The live and backup brokers continuously synchronize their messaging data over the network. If the live broker fails, the backup broker loads the synchronized data and takes over for the failed live broker.

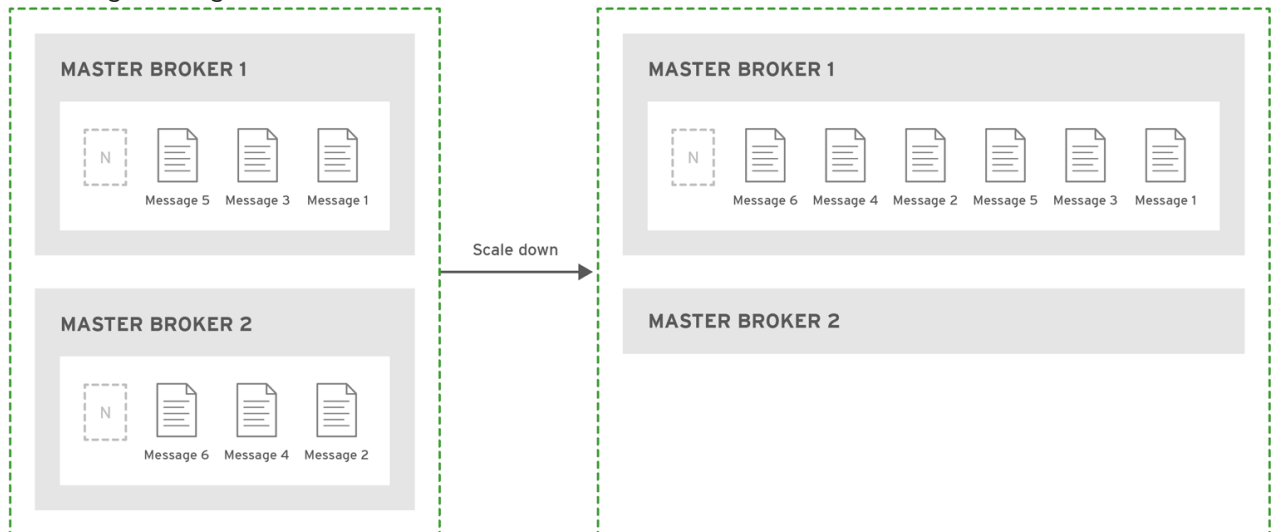

Data synchronization between the live and backup brokers ensures that no messaging data is lost if the live broker fails. Initially, the backup broker synchronizes all of the existing messaging data from the live broker. After this initial phase is complete and the backup broker has all of the current messaging data from the live broker, the live broker synchronizes any new messaging data to the backup broker on an ongoing basis, as it receives it.

JBOSSE_409952_0317

Live-only (limited HA)

When a live broker is stopped gracefully, it copies its messages and transaction state to another live broker and then shuts down. Clients can then reconnect to the other broker to continue sending and receiving messages.

JBOSSE_409952_0317

Additional resources

- For more information about the persistent message data that is shared between brokers in a live-backup group, see [Section 7.1, "About Journal-based Persistence"](#).

16.3.2. High availability policy considerations

A high availability (HA) policy defines how failover should be accomplished in a live-backup group. You should understand the benefits and trade-offs of each policy so that you can implement the one that best meets your requirements.

Shared store considerations

- Use shared store for production environments with a shared file system.
- Because the live and backup brokers do not need to synchronize their messaging data over the network, shared store offers better performance than replication.

- Shared store requires a shared file system on a SAN that the live and backup brokers can both access.
You should not use Network Attached Storage (NAS) for a shared store. If using a SAN is not possible, you should use replication.
- When using shared store, the startup time for the backup broker depends on the size of the message journal.
When the backup broker takes over for a failed live broker, it loads the journal from the shared store. This process can be time consuming if the journal contains a lot of data.

Replication considerations

- Use replication as an alternative to shared store, if you do not have a shared file system.
- Replication requires at least six brokers (three live brokers and three backup brokers).
At least three live-backup groups are required to avoid potential *split-brain* issues.
- Because the live and backup brokers must synchronize their messaging data over the network, replication adds a performance overhead.
- The data synchronization process blocks journal operations, but it does not block clients.
You can configure the maximum amount of time that journal operations can be blocked for data synchronization.

Live-only considerations

- Use live-only for scaling down a broker cluster.
- The live-only HA policy only handles cases when the broker is stopped gracefully.
Live-only does not handle unexpected broker failures.
- While live-only HA prevents message loss, it may not preserve message order.
If a broker configured with live-only HA is stopped, its messages will be appended to the end of the queues of another broker. For example, consider two live brokers with 10 messages distributed evenly between them. If one of the brokers scales down, the messages are appended to the queue on the other broker. Consequently, after the second broker scales down, the order of the messages in the first broker would be: 1, 3, 5, 7, 9, 2, 4, 6, 8, 10.

16.3.3. Configuring high availability

After choosing a high availability (HA) policy, configure the policy on each broker in the cluster.

You can configure HA in any of the following ways:

- Shared store HA
- Replication HA
- Limited HA with live-only
- Colocated backups (using either shared store or replication as the HA policy)

Prerequisites

- You must have chosen the HA policy that best fits your requirements.
For more information, see [Section 16.3.2, “High availability policy considerations”](#).

16.3.3.1. Configuring shared store high availability

You can use the shared store high availability (HA) policy to implement high availability in a broker cluster. With shared store, both live and backup brokers access a single directory on a shared file system. If a live broker encounters a failure, the backup broker loads the message data from the shared store and takes over for the failed live broker.

Prerequisites

- A shared file system must be accessible to the live and backup brokers. Typically, you should use a Storage Area Network (SAN) to provide the shared store.

Procedure

1. Group the brokers in your cluster into live-backup groups. In most cases, a live-backup group should consist of two brokers: a live broker and a backup broker. If you have six brokers in your cluster, you would need three live-backup groups.
2. Create the first live-backup group consisting of one live broker and one backup broker.
 - a. Open the live broker's **<broker-instance-dir>/etc/broker.xml** configuration file.
 - b. Verify that the live broker's paging, bindings, journal, and large messages directories point to a shared location that the backup broker can also access.

```
<configuration>
  <core>
    ...
    <paging-directory>../sharedstore/data/paging</paging-directory>
    <bindings-directory>../sharedstore/data/bindings</bindings-directory>
    <journal-directory>../sharedstore/data/journal</journal-directory>
    <large-messages-directory>../sharedstore/data/large-messages</large-messages-
directory>
    ...
  </core>
</configuration>
```

- c. Configure the live broker to use shared store for its HA policy.

```
<configuration>
  <core>
    ...
    <ha-policy>
      <shared-store>
        <master>
          <failover-on-shutdown>true</failover-on-shutdown>
        </master>
      </shared-store>
    </ha-policy>
    ...
  </core>
</configuration>
```

failover-on-shutdown

```
.....
```

If this broker is stopped normally, this property controls whether the backup broker should become live and take over.

- d. Open the backup broker's **<broker-instance-dir>/etc/broker.xml** configuration file.
- e. Verify that the backup broker's paging, bindings, journal, and large messages directories point to the same shared location as the live broker.

```
<configuration>
  <core>
    ...
    <paging-directory>../sharedstore/data/paging</paging-directory>
    <bindings-directory>../sharedstore/data/bindings</bindings-directory>
    <journal-directory>../sharedstore/data/journal</journal-directory>
    <large-messages-directory>../sharedstore/data/large-messages</large-messages-
directory>
    ...
  </core>
</configuration>
```

- f. Configure the backup broker to use shared store for its HA policy.

```
<configuration>
  <core>
    ...
    <ha-policy>
      <shared-store>
        <slave>
          <failover-on-shutdown>true</failover-on-shutdown>
          <allow-failback>true</allow-failback>
        </slave>
      </shared-store>
    </ha-policy>
    ...
  </core>
</configuration>
```

failover-on-shutdown

If this broker has become live and then is stopped normally, this property controls whether the backup broker (the original live broker) should become live and take over.

allow-failback

If failover has occurred and the backup broker has taken over for the live broker, this property controls whether the backup broker should fail back to the original live broker when it restarts and reconnects to the cluster.

3. Repeat Step 2 for each remaining live-backup group in the cluster.

16.3.3.2. Configuring replication high availability

You can use the replication high availability (HA) policy to implement high availability in a broker cluster. With replication, persistent data is synchronized between the live and backup brokers. If a live broker encounters a failure, message data is synchronized to the backup broker and it takes over for the failed live broker.

Replication requires at least six brokers (three live brokers and three backup brokers). The following

procedure describes how to configure HA for a six-broker cluster. In this topology, the six brokers are grouped into three live-backup pairs: each of the three live brokers is paired with a dedicated backup broker.

Prerequisites

- You must have a broker cluster with at least six brokers.
For more information about adding brokers to a cluster, see [Chapter 16, Setting up a broker cluster](#).

Procedure

- Group the brokers in your cluster into live-backup groups.
In most cases, a live-backup group should consist of two brokers: a live broker and a backup broker. If you have six brokers in your cluster, you would need three live-backup groups.
- Create the first live-backup group consisting of one live broker and one backup broker.
 - Open the live broker's `<broker-instance-dir>/etc/broker.xml` configuration file.
 - Configure the live broker to use replication for its HA policy.

```
<configuration>
  <core>
    ...
    <ha-policy>
      <replication>
        <master>
          <check-for-live-server>true</check-for-live-server>
          <group-name>my-group-1</group-name>
          ...
        </master>
      </replication>
    </ha-policy>
    ...
  </core>
</configuration>
```

check-for-live-server

If the live broker fails, this property controls whether clients should fail back to it when it restarts.

If you set this to **true**, when the broker restarts, it searches for another broker in the cluster with the same cluster node ID. If it finds one, it synchronizes its data with it and then requests that the other broker shut down. The live broker then resumes its active role, and clients reconnect to it.

**WARNING**

If you restart a live broker after failover has occurred, then the value for **check-for-live-server** must be set to **true**. Otherwise, the live broker restarts and processes the same messages that its backup broker has already handled, causing duplicates.

group-name

A name for this live-backup group. To form a live-backup group, the live and backup brokers must be configured with the same group name.

- c. Configure any additional HA properties for the live broker.
These additional HA properties have default values that are suitable for most common use cases. Therefore, you only need to configure these properties if you do not want the default behavior. For more information, see [Appendix F, Replication High Availability Configuration Elements](#).
- d. Open the backup broker's `<broker-instance-dir>/etc/broker.xml` configuration file.
- e. Configure the backup broker to use replication for its HA policy.

```
<configuration>
  <core>
    ...
    <ha-policy>
      <replication>
        <slave>
          <allow-failback>true</allow-failback>
          <group-name>my-group-1</group-name>
        ...
      </slave>
    </replication>
  </ha-policy>
  ...
</core>
</configuration>
```

allow-failback

If failover has occurred and the backup broker has taken over for the live broker, this property controls whether the backup broker should fail back to the original live broker when it restarts and reconnects to the cluster.

group-name

The group name of the live broker to which this backup should connect. A backup broker connects only to a live broker that shares the same group name.

- f. Configure any additional HA properties for the backup broker.
These additional HA properties have default values that are suitable for most common use cases. Therefore, you only need to configure these properties if you do not want the default behavior. For more information, see [Appendix F, Replication High Availability Configuration](#)

Elements.

- Repeat Step 2 for each additional live-backup group in the cluster.

If there are six brokers in the cluster, you would repeat this procedure two more times: once for each remaining live-backup group.

Additional resources

- For examples of broker clusters that use replication for HA, see the [HA example programs](#).

16.3.3.3. Configuring limited high availability with live-only

The live-only HA policy enables you to shut down a broker in a cluster without losing any messages. With live-only, when a live broker is stopped gracefully, it copies its messages and transaction state to another live broker and then shuts down. Clients can then reconnect to the other broker to continue sending and receiving messages.

The live-only HA policy only handles cases when the broker is stopped gracefully. It does not handle unexpected broker failures.

**NOTE**

When a broker is preparing to scale down, it sends a message to its clients before they are disconnected informing them which new broker is ready to process their messages. However, clients should reconnect to the new broker only after their initial broker has finished scaling down. This ensures that any state, such as queues or transactions, is available on the other broker when the client reconnects. The normal reconnect settings apply when the client is reconnecting, so you should set these high enough to deal with the time needed to scale down.

This procedure describes how to configure each broker in the cluster to scale down. After completing this procedure, whenever a broker is stopped gracefully, it will copy its messages and transaction state to another broker in the cluster.

Procedure

- Open the first broker's `<broker-instance-dir>/etc/broker.xml` configuration file.
- Configure the broker to use the live-only HA policy.

```
<configuration>
  <core>
    ...
    <ha-policy>
      <live-only>
    </live-only>
    </ha-policy>
    ...
  </core>
</configuration>
```

- Configure a method for scaling down the broker cluster. Specify the broker or group of brokers to which this broker should scale down.

To scale down to...	Do this...
A specific broker in the cluster	Specify the connector of the broker to which you want to scale down. <pre> <live-only> <scale-down> <connectors> <connector-ref>broker1-connector</connector-ref> </connectors> </scale-down> </live-only> </pre>
Any broker in the cluster	Specify the broker cluster's discovery group. <pre> <live-only> <scale-down> <discovery-group-ref discovery-group-name="my- discovery-group"/> </scale-down> </live-only> </pre>
A broker in a particular broker group	Specify a broker group. <pre> <live-only> <scale-down> <group-name>my-group-name</group-name> </scale-down> </live-only> </pre>

- Repeat this procedure for each remaining broker in the cluster.

Additional resources

- For an example of a broker cluster that uses live-only to scale down the cluster, see the [scale-down example programs](#).

16.3.3.4. Configuring high availability with colocated backups

Rather than configure live-backup groups, you can colocate backup brokers in the same JVM as another live broker. In this configuration, each live broker is configured to request another live broker to create and start a backup broker in its JVM.

Figure 16.4. Colocated live and backup brokers

You can use colocation with either shared store or replication as the high availability (HA) policy. The new backup broker inherits its configuration from the live broker that creates it. The name of the backup is set to **colocated_backup_n** where **n** is the number of backups the live broker has created.

In addition, the backup broker inherits the configuration for its connectors and acceptors from the live broker that creates it. By default, port offset of 100 is applied to each. For example, if the live broker has an acceptor for port 61616, the first backup broker created will use port 61716, the second backup will use 61816, and so on.

Directories for the journal, large messages, and paging are set according to the HA policy you choose. If you choose shared store, the requesting broker notifies the target broker which directories to use. If replication is chosen, directories are inherited from the creating broker and have the new backup's name appended to them.

This procedure configures each broker in the cluster to use shared store HA, and to request a backup to be created and colocated with another broker in the cluster.

Procedure

1. Open the first broker's **<broker-instance-dir>/etc/broker.xml** configuration file.
2. Configure the broker to use an HA policy and colocation.
In this example, the broker is configured with shared store HA and colocation.

```

<configuration>
  <core>
    ...
    <ha-policy>
      <shared-store>
        <colocated>
          <request-backup>true</request-backup>
          <max-backups>1</max-backups>
          <backup-request-retries>1</backup-request-retries>
          <backup-request-retry-interval>5000</backup-request-retry-interval>
          <backup-port-offset>150</backup-port-offset>
          <excludes>
            <connector-ref>remote-connector</connector-ref>
          </excludes>
        </colocated>
      </shared-store>
    </ha-policy>
  </core>
</configuration>

```

```

        </excludes>
        <master>
            <failover-on-shutdown>true</failover-on-shutdown>
        </master>
        <slave>
            <failover-on-shutdown>true</failover-on-shutdown>
            <allow-failback>true</allow-failback>
        </slave>
        </colocated>
    </shared-store>
</ha-policy>
...
</core>
</configuration>

```

request-backup

By setting this property to **true**, this broker will request a backup broker to be created by another live broker in the cluster.

max-backups

The number of backup brokers that this broker can create. If you set this property to **0**, this broker will not accept backup requests from other brokers in the cluster.

backup-request-retries

The number of times this broker should try to request a backup broker to be created. The default is **-1**, which means unlimited tries.

backup-request-retry-interval

The amount of time in milliseconds that the broker should wait before retrying a request to create a backup broker. The default is **5000**, or 5 seconds.

backup-port-offset

The port offset to use for the acceptors and connectors for a new backup broker. If this broker receives a request to create a backup for another broker in the cluster, it will create the backup broker with the ports offset by this amount. The default is **100**.

excludes (optional)

Excludes connectors from the backup port offset. If you have configured any connectors for external brokers that should be excluded from the backup port offset, add a **<connector-ref>** for each of the connectors.

master

The shared store or replication failover configuration for this broker.

slave

The shared store or replication failover configuration for this broker's backup.

- Repeat this procedure for each remaining broker in the cluster.

Additional resources

- For examples of broker clusters that use colocated backups, see the [HA example programs](#).

16.3.4. Configuring clients to fail over

After configuring high availability in a broker cluster, you configure your clients to fail over. Client failover ensures that if a broker fails, the clients connected to it can reconnect to another broker in the cluster with minimal downtime.

NOTE

In the event of transient network problems, AMQ Broker automatically reattaches connections to the same broker. This is similar to failover, except that the client reconnects to the same broker.

You can configure two different types of client failover:

Automatic client failover

The client receives information about the broker cluster when it first connects. If the broker to which it is connected fails, the client automatically reconnects to the broker's backup, and the backup broker re-creates any sessions and consumers that existed on each connection before failover.

Application-level client failover

As an alternative to automatic client failover, you can instead code your client applications with your own custom reconnection logic in a failure handler.

Procedure

- Use AMQ Core Protocol JMS to configure your client application with automatic or application-level failover.
For more information, see [Using the AMQ Core Protocol JMS Client](#).

16.4. ENABLING MESSAGE REDISTRIBUTION

If your broker cluster uses on-demand message load balancing, you should enable message redistribution to prevent messages from being "stuck" in a queue that does not have a consumer to consume them.

Broker clusters use load balancing to distribute the message load across the cluster. When configuring load balancing in the cluster connection, if you set **message-load-balancing** to **ON_DEMAND**, the broker will only forward messages to other brokers that have matching consumers. This ensures that messages are not moved to queues that do not have any consumers to consume them. However, if the consumers attached to a queue close after the messages are forwarded to the broker, those messages will be "stuck" in the queue and not consumed. This issue is sometimes called *starvation*.

Message redistribution prevents starvation by automatically redistributing the messages from queues that have no consumers to brokers in the cluster that do have matching consumers.

Procedure

1. Open the `<broker-instance-dir>/etc/broker.xml` configuration file.
2. In the `<cluster-connection>` element, verify that `<message-load-balancing>` is set to `<ON_DEMAND>`.

```
<configuration>
  <core>
    ...
  <cluster-connections>
    <cluster-connection name="my-cluster">
```

```

    ...
    <message-load-balancing>ON_DEMAND</message-load-balancing>
    ...
  </cluster-connection>
</cluster-connections>
</core>
</configuration>

```

3. Within the **<address-settings>** element, set the redistribution delay for a queue or set of queues.

In this example, messages load balanced to **my.queue** will be redistributed 5000 milliseconds (5 seconds) after the last consumer closes.

```

<configuration>
  <core>
    ...
    <address-settings>
      <address-setting match="my.queue">
        <redistribution-delay>5000</redistribution-delay>
      </address-setting>
    </address-settings>
    ...
  </core>
</configuration>

```

address-setting

Set the **match** attribute to be the name of the queue for which you want messages to be redistributed. You can use the broker wildcard syntax to specify a range of queues. For more information, see [the section called "AMQ Broker Wildcard Syntax"](#).

redistribution-delay

The amount of time (in milliseconds) that the broker should wait after this queue's final consumer closes before redistributing messages to other brokers in the cluster. If you set this to **0**, messages will be redistributed immediately. However, you should typically set a delay before redistributing - it is common for a consumer to close but another one to be quickly created on the same queue.

4. Repeat this procedure on each additional broker.

Additional resources

- For an example of a broker cluster configuration that redistributes messages, see the [queue-message-redistribution AMQ Broker example program](#).

16.5. CONFIGURING CLUSTERED MESSAGE GROUPING

Message grouping enables clients to send groups of messages of a particular type to be processed serially by the same consumer. By adding a grouping handler to each broker in the cluster, you ensure that clients can send grouped messages to any broker in the cluster and still have those messages consumed in the correct order by the same consumer.

There are two types of grouping handlers: *local handlers* and *remote handlers*. They enable the broker cluster to route all of the messages in a particular group to the appropriate queue so that the intended consumer can consume them in the correct order.

Prerequisites

- There should be at least one consumer on each broker in the cluster.
When a message is pinned to a consumer on a queue, all messages with the same group ID will be routed to that queue. If the consumer is removed, the queue will continue to receive the messages even if there are no consumers.

Procedure

1. Configure a local handler on one broker in the cluster.
If you are using high availability, this should be a master broker.
 - a. Open the broker's `<broker-instance-dir>/etc/broker.xml` configuration file.
 - b. Within the `<core>` element, add a local handler:
The local handler serves as an arbiter for the remote handlers. It stores route information and communicates it to the other brokers.

```
<configuration>
  <core>
    ...
    <grouping-handler name="my-grouping-handler">
      <type>LOCAL</type>
      <timeout>10000</timeout>
    </grouping-handler>
    ...
  </core>
</configuration>
```

grouping-handler

Use the **name** attribute to specify a unique name for the grouping handler.

type

Set this to **LOCAL**.

timeout

The amount of time to wait (in milliseconds) for a decision to be made about where to route the message. The default is 5000 milliseconds (5 seconds). If the timeout is reached before a routing decision is made, an exception is thrown, which ensures strict message ordering.

When the broker receives a message with a group ID, it proposes a route to a queue to which the consumer is attached. If the route is accepted by the grouping handlers on the other brokers in the cluster, then the route is established: all brokers in the cluster will forward messages with this group ID to that queue. If the broker's route proposal is rejected, then it proposes an alternate route, repeating the process until a route is accepted.

2. If you are using high availability, copy the local handler configuration to the master broker's slave broker.
Copying the local handler configuration to the slave broker prevents a single point of failure for the local handler.
3. On each remaining broker in the cluster, configure a remote handler.
 - a. Open the broker's `<broker-instance-dir>/etc/broker.xml` configuration file.

- b. Within the `<core>` element, add a remote handler:

```
<configuration>
  <core>
    ...
    <grouping-handler name="my-grouping-handler">
      <type>REMOTE</type>
      <timeout>5000</timeout>
    </grouping-handler>
    ...
  </core>
</configuration>
```

grouping-handler

Use the **name** attribute to specify a unique name for the grouping handler.

type

Set this to **REMOTE**.

timeout

The amount of time to wait (in milliseconds) for a decision to be made about where to route the message. The default is 5000 milliseconds (5 seconds). Set this value to at least half of the value of the local handler.

Additional resources

- For an example of a broker cluster configured for message grouping, see the [clustered-grouping AMQ Broker example program](#).

16.6. CONNECTING CLIENTS TO A BROKER CLUSTER

You can use the AMQ JMS clients to connect to the cluster. By using JMS, you can configure your messaging clients to discover the list of brokers dynamically or statically. You can also configure client-side load balancing to distribute the client sessions created from the connection across the cluster.

Procedure

- Use AMQ Core Protocol JMS to configure your client application to connect to the broker cluster.
For more information, see [Using the AMQ Core Protocol JMS Client](#).

CHAPTER 17. LOGGING

AMQ Broker uses the JBoss Logging framework to do its logging and is configurable via the **`BROKER_INSTANCE_DIR/etc/logging.properties`** configuration file. This configuration file is a list of key value pairs.

There are six loggers available, which are configured by the **`loggers`** key.

```
loggers=org.jboss.logging,org.apache.activemq.artemis.core.server,org.apache.activemq.artemis.utils,org.apache.activemq.artemis.journal,org.apache.activemq.artemis.jms.server,org.apache.activemq.artemis.integration.bootstrap
```

Table 17.1. Loggers

Logger	Description
<code>org.jboss.logging</code>	Logs any calls not handled by the Brokers loggers
<code>org.apache.activemq.artemis.core.server</code>	Logs the Broker core
<code>org.apache.activemq.artemis.utils</code>	Logs utility calls
<code>org.apache.activemq.artemis.journal</code>	Logs Journal calls
<code>org.apache.activemq.artemis.jms</code>	Logs JMS calls
<code>org.apache.activemq.artemis.integration.bootstrap</code>	Logs bootstrap calls

By default there are two loggers configured by default by the **`logger.handlers`** key.

```
logger.handlers=FILE,CONSOLE
```

As the names suggest these log to the console and to a file.

17.1. CHANGING THE LOGGING LEVEL

The default logging level for all loggers is **`INFO`** and is configured on the root logger.

```
logger.level=INFO
```

All other loggers specified can be configured individually via the logger name.

```
logger.org.apache.activemq.artemis.core.server.level=INFO
logger.org.apache.activemq.artemis.journal.level=INFO
logger.org.apache.activemq.artemis.utils.level=INFO
logger.org.apache.activemq.artemis.jms.level=INFO
logger.org.apache.activemq.artemis.integration.bootstrap.level=INFO
```

**NOTE**

The root logger configuration will always be the finest logging logged even if the other logs have a finer logging configuration.

Table 17.2. Available Logging Levels

Level	Description
FATAL	Use the FATAL level priority for events that indicate a critical service failure. If a service issues a FATAL error it is completely unable to service requests of any kind.
ERROR	Use the ERROR level priority for events that indicate a disruption in a request or the ability to service a request. A service should have some capacity to continue to service requests in the presence of ERRORS.
WARN	Use the WARN level priority for events that may indicate a non-critical service error. Resumable errors, or minor breaches in request expectations fall into this category. The distinction between WARN and ERROR may be hard to discern and so it is up to the developer to judge. The simplest criterion is would this failure result in a user support call. If it would use ERROR. If it would not use WARN.
INFO	Use the INFO level priority for service life-cycle events and other crucial related information. Looking at the INFO messages for a given service category should tell you exactly what state the service is in.
DEBUG	Use the DEBUG level priority for log messages that convey extra information regarding life-cycle events. Developer or in depth information required for support is the basis for this priority. The important point is that when the DEBUG level priority is enabled, the JBoss server log should not grow proportionally with the number of server requests. Looking at the DEBUG and INFO messages for a given service category should tell you exactly what state the service is in, as well as what server resources it is using: ports, interfaces, log files, and so on.

Level	Description
TRACE	Use TRACE the level priority for log messages that are directly associated with activity that corresponds requests. Further, such messages should not be submitted to a Logger unless the Logger category priority threshold indicates that the message will be rendered. Use the <code>Logger.isTraceEnabled()</code> method to determine if the category priority threshold is enabled. The point of the TRACE priority is to allow for deep probing of the JBoss server behavior when necessary. When the TRACE level priority is enabled, you can expect the number of messages in the JBoss server log to grow at least a $x N$, where N is the number of requests received by the server, a some constant. The server log may well grow as power of N depending on the request-handling layer being traced.

17.2. CONFIGURING CONSOLE LOGGING

Console Logging can be configured via the following keys.

```

handler.CONSOLE=org.jboss.logmanager.handlers.ConsoleHandler
handler.CONSOLE.properties=autoFlush
handler.CONSOLE.level=DEBUG
handler.CONSOLE.autoFlush=true
handler.CONSOLE.formatter=PATTERN

```

NOTE

handler.CONSOLE refers to the name given in the **logger.handlers** key.

Table 17.3. Available Console Configuration

Property	Description
name	The handler's name.
encoding	The character encoding used by this Handler.
level	The log level specifying which message levels will be logged by this. Message levels lower than this value will be discarded.
formatter	Defines a formatter. See Section 17.4, "Configuring the Logging Format" .
autoflush	Automatically flush after each write.

Property	Description
target	Defines the target of the console handler. The value can either be <code>SYSTEM_OUT</code> or <code>SYSTEM_ERR</code> .

17.3. CONFIGURING FILE LOGGING

File Logging can be configured via the following keys.

```

handler.FILE=org.jboss.logmanager.handlers.PeriodicRotatingFileHandler
handler.FILE.level=DEBUG
handler.FILE.properties=suffix,append,autoFlush,fileName
handler.FILE.suffix=.yyyy-MM-dd
handler.FILE.append=true
handler.FILE.autoFlush=true
handler.FILE.fileName=${artemis.instance}/log/artemis.log
handler.FILE.formatter=PATTERN

```

NOTE

handler.FILE refers to the name given in the **logger.handlers** key.

Table 17.4. Available Console Configuration

Property	Description
name	The handler's name.
encoding	The character encoding used by this Handler.
level	The log level specifying which message levels will be logged by this. Message levels lower than this value will be discarded.
formatter	Defines a formatter. See Section 17.4, "Configuring the Logging Format" .
autoflush	Automatically flush after each write.
append	Specify whether to append to the target file.
file	The file description consisting of the path and optional relative to path.

17.4. CONFIGURING THE LOGGING FORMAT

The formatter describes how log messages should be shown. The following is the default configuration.

■

```
formatter.PATTERN=org.jboss.logmanager.formatters.PatternFormatter
formatter.PATTERN.properties=pattern
formatter.PATTERN.pattern=%d{HH:mm:ss,SSS} %-5p [%c] %s%E%n
```

Where **%s** is the message and **%E** is the exception if one exists.

The format is the same as the Log4J format. A full description can be found [here](#).

17.5. CLIENT OR EMBEDDED SERVER LOGGING

Firstly, if you want to enable logging on the client side you need to include the JBoss logging JARs in your client's class path. If you are using Maven, add the following dependencies:

```
<dependency>
  <groupId>org.jboss.logmanager</groupId>
  <artifactId>jboss-logmanager</artifactId>
  <version>1.5.3.Final</version>
</dependency>
<dependency>
  <groupId>org.apache.activemq</groupId>
  <artifactId>artemis-core-client</artifactId>
  <version>1.0.0.Final</version>
</dependency>
```

There are two properties you need to set when starting your Java program. The first is to set the Log Manager to use the JBoss Log Manager. This is done by setting the **-Djava.util.logging.manager** property. For example:

```
-Djava.util.logging.manager=org.jboss.logmanager.LogManager
```

The second is to set the location of the **logging.properties** file to use. This is done by setting the **-Dlogging.configuration** property with a valid URL. For example:

```
-Dlogging.configuration=file:///home/user/projects/myProject/logging.properties
```

The following is a typical **logging.properties** file for a client:

```
# Root logger option
loggers=org.jboss.logging,org.apache.activemq.artemis.core.server,org.apache.activemq.artemis.utils,org.apache.activemq.artemis.journal,org.apache.activemq.artemis.jms,org.apache.activemq.artemis.ra

# Root logger level
logger.level=INFO
# ActiveMQ Artemis logger levels
logger.org.apache.activemq.artemis.core.server.level=INFO
logger.org.apache.activemq.artemis.utils.level=INFO
logger.org.apache.activemq.artemis.jms.level=DEBUG

# Root logger handlers
logger.handlers=FILE,CONSOLE

# Console handler configuration
handler.CONSOLE=org.jboss.logmanager.handlers.ConsoleHandler
handler.CONSOLE.properties=autoFlush
```

```

handler.CONSOLE.level=FINE
handler.CONSOLE.autoFlush=true
handler.CONSOLE.formatter=PATTERN

# File handler configuration
handler.FILE=org.jboss.logmanager.handlers.FileHandler
handler.FILE.level=FINE
handler.FILE.properties=autoFlush,fileName
handler.FILE.autoFlush=true
handler.FILE.fileName=activemq.log
handler.FILE.formatter=PATTERN

# Formatter pattern configuration
formatter.PATTERN=org.jboss.logmanager.formatters.PatternFormatter
formatter.PATTERN.properties=pattern
formatter.PATTERN.pattern=%d{HH:mm:ss,SSS} %-5p [%c] %s%E%n

```

17.6. AMQ BROKER PLUG-INS SUPPORT

AMQ supports custom plug-ins. You can use plug-ins to log information about many different types of events that would otherwise only be available through debug logs. Multiple plug-ins can be registered, tied, and executed together. The plug-ins will be executed based on the order of the registration, that is, the first plug-in registered is always executed first.

You can create custom plug-ins and implement them using the **ActiveMQServerPlugin** interface. This interface ensures that the plug-in is on the classpath, and is registered with the broker. As all the interface methods are implemented by default, you have to add only the required behavior that needs to be implemented.

17.6.1. Adding Plug-ins to the Classpath

Add the custom created broker plug-ins to the broker runtime by adding the relevant jars to the **BROKER_INSTANCE_DIR/lib** directory.

If you are using an embedded system then place the jar under the regular classpath of your embedded application.

17.6.2. Registering a Plug-in

You must register a plug-in by adding the **broker-plugins** element in the **broker.xml** file. You can specify the plug-in configuration value using the **property** child elements. These properties will be read and passed into the plug-in's `init (Map<String, String>)` operation after the plug-in has been instantiated.

```

<broker-plugins>
  <broker-plugin class-name="some.plugin.UserPlugin">
    <property key="property1" value="val_1" />
    <property key="property2" value="val_2" />
  </broker-plugin>
</broker-plugins>

```

17.6.3. Registering a Plug-in Programmatically

To register a plug-in programmatically, use the **registerBrokerPlugin()** method and pass in a new instance of your plug-in. The example below shows the registration of the **UserPlugin** plugin:

```
Configuration config = new ConfigurationImpl();
config.registerBrokerPlugin(new UserPlugin());
```

17.6.4. Logging Specific Events

By default, AMQ broker provides the **LoggingActiveMQServerPlugin** plug-in to log specific broker events. The **LoggingActiveMQServerPlug-in** plug-in is commented out by default and does not log any information. The following table provides information about the plug-in properties and its description. Set the configuration property value to **true** to log events.

Property	Description
LOG_CONNECTION_EVENTS	Logs information when a connection is created or destroyed.
LOG_SESSION_EVENTS	Logs information when a session is created or closed.
LOG_CONSUMER_EVENTS	Logs information when a consumer is created or closed.
LOG_DELIVERING_EVENTS	Logs information when message is delivered to a consumer and when a message is acknowledged by a consumer.
LOG_SENDING_EVENTS	Logs information when a message has been sent to an address and when a message has been routed within the broker.
LOG_INTERNAL_EVENTS	Logs information when a queue created or destroyed, when a message is expired, when a bridge is deployed, and when a critical failure occurs.
LOG_ALL_EVENTS	Logs information for all the above events.

To configure the **LoggingActiveMQServerPlugin** plugin to log connection events, uncomment the **<broker-plugins>** section in the **broker.xml** file. The value of all the events is set to **true** in the commented default example.

```
<configuration ...>
...
<!-- Uncomment the following if you want to use the Standard LoggingActiveMQServerPlugin plugin
to log in events -->
  <broker-plugins>
    <broker-plugin class-
name="org.apache.activemq.artemis.core.server.plugin.impl.LoggingActiveMQServerPlugin">
      <property key="LOG_ALL_EVENTS" value="true"/>
      <property key="LOG_CONNECTION_EVENTS" value="true"/>
```

```
<property key="LOG_SESSION_EVENTS" value="true"/>
<property key="LOG_CONSUMER_EVENTS" value="true"/>
<property key="LOG_DELIVERING_EVENTS" value="true"/>
<property key="LOG_SENDING_EVENTS" value="true"/>
<property key="LOG_INTERNAL_EVENTS" value="true"/>
</broker-plugin>
</broker-plugins>
...
</configuration>
```

After changing the configuration parameters inside the **<broker-plugins>** section of the **broker.xml** file, you must restart the broker to reload the configuration updates. These configuration changes will not be reloaded by the **configuration-file-refresh-period** setting.

When the log level is set to **INFO**, an entry is logged after the event has occurred. If the log level is set to **DEBUG**, log entries are generated for both before and after the event has occurred. For example, it logs **beforeCreateConsumer()** and **afterCreateConsumer()**. If the log Level is set to **DEBUG**, it logs more information for a notification when available.

APPENDIX A. ACCEPTOR AND CONNECTOR CONFIGURATION PARAMETERS

The tables below detail some of the available parameters used to configure Netty network connections. Parameters and their values are appended to the URI of the connection string. See [Network Connections: Acceptors and Connectors](#) for more information. Each table lists the parameters by name and notes whether they can be used with acceptors or connectors or with both. You can use some parameters, for example, only with acceptors.

NOTE

All Netty parameters are defined in the class `org.apache.activemq.artemis.core.remoting.impl.netty.TransportConstants`. Source code is available for download on the [customer portal](#).

Table A.1. Netty TCP Parameters

Parameter	Use with...	Description
batchDelay	Both	Before writing packets to the acceptor or connector, the broker can be configured to batch up writes for a maximum of batchDelay milliseconds. This can increase overall throughput for very small messages. It does so at the expense of an increase in average latency for message transfer. The default value is 0 ms.
connectionsAllowed	Acceptors	Limits the number of connections that the acceptor will allow. When this limit is reached, a DEBUG-level message is issued to the log and the connection is refused. The type of client in use determines what happens when the connection is refused.
directDeliver	Both	When a message arrives on the server and is delivered to waiting consumers, by default, the delivery is done on the same thread as that on which the message arrived. This gives good latency in environments with relatively small messages and a small number of consumers, but at the cost of overall throughput and scalability - especially on multi-core machines. If you want the lowest latency and a possible reduction in throughput then you can use the default value for directDeliver , which is true . If you are willing to take some small extra hit on latency but want the highest throughput set directDeliver to false .

Parameter	Use with...	Description
handshake-timeout	Acceptors	<p>Prevents an unauthorized client to open a large number of connections and keep them open. Because each connection requires a file handle, it consumes resources that are then unavailable to other clients.</p> <p>This timeout limits the amount of time a connection can consume resources without having been authenticated. After the connection is authenticated, you can use resource limit settings to limit resource consumption.</p> <p>The default value is set to 10 seconds. You can set it to any other integer value. You can turn off this option by setting it to 0 or negative integer.</p> <p>After you edit the timeout value, you must restart the broker.</p>
localAddress	Connectors	Specifies which local address the client will use when connecting to the remote address. This is typically used in the Application Server or when running Embedded to control which address is used for outbound connections. If the local-address is not set then the connector will use any local address available.
localPort	Connectors	Specifies which local port the client will use when connecting to the remote address. This is typically used in the Application Server or when running Embedded to control which port is used for outbound connections. If the default is used, which is 0, then the connector will let the system pick up an ephemeral port. Valid ports are 0 to 65535
nioRemotingThreads	Both	<p>When configured to use NIO, the broker will by default use a number of threads equal to three times the number of cores (or hyper-threads) as reported by Runtime.getRuntime().availableProcessors() for processing incoming packets. If you want to override this value, you can set the number of threads by specifying this parameter. The default value for this parameter is -1, which means use the value derived from Runtime.getRuntime().availableProcessors() * 3.</p>
tcpNoDelay	Both	If this is true then Nagle's algorithm will be disabled. This is a Java (client) socket option . The default value is true .
tcpReceiveBufferSize	Both	Determines the size of the TCP receive buffer in bytes. The default value is 32768 .

Parameter	Use with...	Description
tcpSendBufferSize	Both	<p>Determines the size of the TCP send buffer in bytes. The default value is 32768.</p> <p>TCP buffer sizes should be tuned according to the bandwidth and latency of your network.</p> <p>In summary TCP send/receive buffer sizes should be calculated as:</p> <p>buffer_size = bandwidth * RTT.</p> <p>Where bandwidth is in bytes per second and network round trip time (RTT) is in seconds. RTT can be easily measured using the ping utility.</p> <p>For fast networks you may want to increase the buffer sizes from the defaults.</p>

Table A.2. Netty HTTP Parameters

Parameter	Use with...	Description
httpClientIdleTime	Acceptors	How long a client can be idle before sending an empty HTTP request to keep the connection alive.
httpClientIdleScanPeriod	Acceptors	How often, in milliseconds, to scan for idle clients.
httpEnabled	Acceptors	No longer required. With single port support the broker will now automatically detect if HTTP is being used and configure itself.
httpRequiresSessionId	Both	If true the client will wait after the first call to receive a session id. Used when an HTTP connector is connecting to a servlet acceptor. This configuration is not recommended.
httpResponseTime	Acceptors	How long the server can wait before sending an empty HTTP response to keep the connection alive.
httpServerScanPeriod	Acceptors	How often, in milliseconds, to scan for clients needing responses.

Table A.3. Netty TLS/SSL Parameters

Parameter	Use with...	Description
enabledCipherSuites	Both	Comma separated list of cipher suites used for SSL communication. The default value is empty which means the JVM's default will be used.

Parameter	Use with...	Description
enabledProtocols	Both	Comma separated list of protocols used for SSL communication. The default value is empty which means the JVM's default will be used.
keyStorePassword	Both	<p>When used on an acceptor this is the password for the server-side keystore.</p> <p>When used on a connector this is the password for the client-side keystore. This is only relevant for a connector if you are using 2-way SSL (that is, mutual authentication). Although this value can be configured on the server, it is downloaded and used by the client. If the client needs to use a different password from that set on the server then it can override the server-side setting by either using the customary javax.net.ssl.keyStorePassword system property or the ActiveMQ-specific org.apache.activemq.ssl.keyStorePassword system property. The ActiveMQ-specific system property is useful if another component on client is already making use of the standard, Java system property.</p>
keyStorePath	Both	<p>When used on an acceptor this is the path to the SSL key store on the server which holds the server's certificates (whether self-signed or signed by an authority).</p> <p>When used on a connector this is the path to the client-side SSL key store which holds the client certificates. This is only relevant for a connector if you are using 2-way SSL (that is, mutual authentication). Although this value is configured on the server, it is downloaded and used by the client. If the client needs to use a different path from that set on the server then it can override the server-side setting by either using the customary javax.net.ssl.keyStore system property or the ActiveMQ-specific org.apache.activemq.ssl.keyStore system property. The ActiveMQ-specific system property is useful if another component on client is already making use of the standard, Java system property.</p>
needClientAuth	Acceptors	Tells a client connecting to this acceptor that 2-way SSL is required. Valid values are true or false . Default is false .
sslEnabled	Both	Must be true to enable SSL. Default is false .

Parameter	Use with...	Description
trustStorePassword	Both	<p>When used on an acceptor this is the password for the server-side trust store. This is only relevant for an acceptor if you are using 2-way SSL (that is, mutual authentication).</p> <p>When used on a connector this is the password for the client-side truststore. Although this value can be configured on the server, it is downloaded and used by the client. If the client needs to use a different password from that set on the server then it can override the server-side setting by either using the customary javax.net.ssl.trustStorePassword system property or the ActiveMQ-specific org.apache.activemq.ssl.trustStorePassword system property. The ActiveMQ-specific system property is useful if another component on client is already making use of the standard, Java system property.</p>
trustStorePath	Both	<p>When used on an acceptor this is the path to the server-side SSL key store that holds the keys of all the clients that the server trusts. This is only relevant for an acceptor if you are using 2-way SSL (that is, mutual authentication).</p> <p>When used on a connector this is the path to the client-side SSL key store which holds the public keys of all the servers that the client trusts. Although this value can be configured on the server, it is downloaded and used by the client. If the client needs to use a different path from that set on the server then it can override the server-side setting by either using the customary javax.net.ssl.trustStore system property or the ActiveMQ-specific org.apache.activemq.ssl.trustStore system property. The ActiveMQ-specific system property is useful if another component on client is already making use of the standard, Java system property.</p>
verifyHost	Both	<p>When used on an acceptor the CN of the connecting client's SSL certificate will be compared to its hostname to verify they match. This is useful only for 2-way SSL.</p> <p>When used on a connector the CN of the server's SSL certificate will be compared to its hostname to verify they match. This is useful for both 1-way and 2-way SSL.</p> <p>Valid values are true or false. Default is false.</p>

APPENDIX B. ADDRESS SETTING CONFIGURATION ELEMENTS

The table below lists all of the configuration elements of an **address-setting**. Note that some elements are marked DEPRECATED. Use the suggested replacement to avoid potential issues.

Table B.1. Address Setting Elements

Name	Description
address-full-policy	<p>Determines what happens when an address configured with a max-size-bytes becomes full. The available policies are:</p> <p>PAGE: messages sent to a full address will be paged to disk.</p> <p>DROP: messages sent to a full address will be silently dropped.</p> <p>FAIL: messages sent to a full address will be dropped and the message producers will receive an exception.</p> <p>BLOCK: message producers will block when they try and send any further messages.</p> <p> NOTE</p> <p>The BLOCK policy works only for the AMQP, OpenWire, and Core protocols because they feature flow control.</p>
auto-create-addresses	Whether to automatically create addresses when a client sends a message to or attempts to consume a message from a queue mapped to an address that does not exist a queue. The default value is true .
auto-create-jms-queues	DEPRECATED: Use auto-create-queues instead. Determines whether this broker should automatically create a JMS queue corresponding to the address settings match when a JMS producer or a consumer tries to use such a queue. The default value is false .
auto-create-jms-topics	DEPRECATED: Use auto-create-queues instead. Determines whether this broker should automatically create a JMS topic corresponding to the address settings match when a JMS producer or a consumer tries to use such a queue. The default value is false .
auto-create-queues	Whether to automatically create a queue when a client sends a message to or attempts to consume a message from a queue. The default value is true .
auto-delete-addresses	Whether to delete auto-created addresses when the broker no longer has any queues. The default value is true .
auto-delete-jms-queues	DEPRECATED: Use auto-delete-queues instead. Determines whether AMQ Broker should automatically delete auto-created JMS queues when they have no consumers and no messages. The default value is false .

Name	Description
auto-delete-jms-topics	DEPRECATED: Use auto-delete-queues instead. Determines whether AMQ Broker should automatically delete auto-created JMS topics when they have no consumers and no messages. The default value is false .
auto-delete-queues	Whether to delete auto-created queues when the queue has no consumers and no messages. The default value is true .
config-delete-addresses	<p>When the configuration file is reloaded, this setting specifies how to handle an address (and its queues) that has been deleted from the configuration file. You can specify the following values:</p> <p>OFF (default) The address is not deleted when the configuration file is reloaded.</p> <p>FORCE The address and its queues are deleted when the configuration file is reloaded. If there are any messages in the queues, they are removed also.</p>
config-delete-queues	<p>When the configuration file is reloaded, this setting specifies how to handle queues that have been deleted from the configuration file. You can specify the following values:</p> <p>OFF (default) The queue is not deleted when the configuration file is reloaded.</p> <p>FORCE The queue is deleted when the configuration file is reloaded. If there are any messages in the queue, they are removed also.</p>
dead-letter-address	The address to which the broker sends dead messages.
default-address-routing-type	The routing-type used on auto-created addresses. The default value is MULTICAST .
default-max-consumers	The maximum number of consumers allowed on this queue at any one time. The default value is 200 .
default-purge-on-no-consumers	Whether to purge the contents of the queue once there are no consumers. The default value is false .
default-queue-routing-type	The routing-type used on auto-created queues. The default value is MULTICAST .
expiry-address	The address that will receive expired messages.
expiry-delay	Defines the expiration time in milliseconds that will be used for messages using the default expiration time. The default value is -1 , which means no expiration time.

Name	Description
last-value-queue	Whether a queue uses only last values or not. The default value is false .
management-browse-page-size	How many messages a management resource can browse. The default value is 200 .
max-delivery-attempts	how many times to attempt to deliver a message before sending to dead letter address. The default is 10 .
max-redelivery-delay	Maximum value for the redelivery-delay, in milliseconds.
max-size-bytes	The maximum memory size for this address, specified in bytes. Used when the address-full-policy is PAGING , BLOCK , or FAIL , this value is specified in byte notation such as "K", "Mb", and "GB". The default value is -1 , which denotes infinite bytes. This parameter is used to protect broker memory by limiting the amount of memory consumed by a particular address space. This setting does not represent the total amount of bytes sent by the client that are currently stored in broker address space. It is an estimate of broker memory utilization. This value can vary depending on runtime conditions and certain workloads. It is recommended that you allocate the maximum amount of memory that can be afforded per address space. Under typical workloads, the broker requires approximately 150% to 200% of the payload size of the outstanding messages in memory.
max-size-bytes-reject-threshold	Used when the address-full-policy is BLOCK . The maximum size, in bytes, that an address can reach before the broker begins to reject messages. Works in combination with max-size-bytes for the AMQP protocol only. The default value is -1 , which means no limit.
message-counter-history-day-limit	How many days to keep a message counter history for this address. The default value is 0 .
page-max-cache-size	The number of page files to keep in memory to optimize I/O during paging navigation. The default value is 5 .
page-size-bytes	The paging size in bytes. Also supports byte notation like K , Mb , and GB . The default value is 10485760 bytes, almost 10.5 MB.
redelivery-delay	The time, in milliseconds, to wait before redelivering a cancelled message. The default value is 0 .
redelivery-delay-multiplier	Multiplier to apply to the redelivery-delay parameter. The default value is 1.0 .
redistribution-delay	Defines how long to wait in milliseconds after the last consumer is closed on a queue before redistributing any messages. The default value is -1 .

Name	Description
send-to-dla-on-no-route	When set to true , a message will be sent to the configured dead letter address if it cannot be routed to any queues. The default value is false .
slow-consumer-check-period	How often to check, in seconds, for slow consumers. The default value is 5 .
slow-consumer-policy	Determines what happens when a slow consumer is identified. Valid options are KILL or NOTIFY . KILL kills the consumer's connection, which impacts any client threads using that same connection. NOTIFY sends a CONSUMER_SLOW management notification to the client. The default value is NOTIFY .
slow-consumer-threshold	The minimum rate of message consumption allowed before a consumer is considered slow. Measured in messages-per-second. The default value is -1 , which is unbounded.

APPENDIX C. CLUSTER CONNECTION CONFIGURATION ELEMENTS

The table below lists all of the configuration elements of a **cluster-connection**.

Table C.1. Cluster Connection Configuration Elements

Name	Description
address	<p>Each cluster connection applies only to addresses that match the value specified in the address field. If no address is specified, then all addresses will be load balanced.</p> <p>The address field also supports comma separated lists of addresses. Use exclude syntax, ! to prevent an address from being matched. Below are some example addresses:</p> <p>jms.eu Matches all addresses starting with jms.eu.</p> <p>!jms.eu Matches all addresses except for those starting with jms.eu</p> <p>jms.eu.uk,jms.eu.de Matches all addresses starting with either jms.eu.uk or jms.eu.de</p> <p>jms.eu,!jms.eu.uk Matches all addresses starting with jms.eu, but not those starting with jms.eu.uk</p> <div style="display: flex; align-items: flex-start; margin-top: 10px;"> <div style="flex: 1;">  </div> <div style="flex: 2;"> <p>NOTE</p> <p>You should not have multiple cluster connections with overlapping addresses (for example, "europe" and "europe.news"), because the same messages could be distributed between more than one cluster connection, possibly resulting in duplicate deliveries.</p> </div> </div>
call-failover-timeout	Use when a call is made during a failover attempt. The default is -1 , or no timeout.
call-timeout	When a packet is sent over a cluster connection, and it is a blocking call, call-timeout determines how long the broker will wait (in milliseconds) for the reply before throwing an exception. The default is 30000 .
check-period	The interval, in milliseconds, between checks to see if the cluster connection has failed to receive pings from another broker. The default is 30000 .
confirmation-window-size	The size, in bytes, of the window used for sending confirmations from the broker connected to. When the broker receives confirmation-window-size bytes, it notifies its client. The default is 1048576 . A value of -1 means no window.

Name	Description
connector-ref	Identifies the connector that will be transmitted to other brokers in the cluster so that they have the correct cluster topology. This parameter is mandatory.
connection-ttl	Determines how long a cluster connection should stay alive if it stops receiving messages from a specific broker in the cluster. The default is 60000 .
discovery-group-ref	Points to a discovery-group to be used to communicate with other brokers in the cluster. This element must include the attribute discovery-group-name , which must match the name attribute of a previously configured discovery-group .
initial-connect-attempts	Sets the number of times the system will try to connect a broker in the cluster initially. If the max-retry is achieved, this broker will be considered permanently down, and the system will not route messages to this broker. The default is -1 , which means infinite retries.
max-hops	Configures the broker to load balance messages to brokers which might be connected to it only indirectly with other brokers as intermediates in a chain. This allows for more complex topologies while still providing message load-balancing. The default value is 1 , which means messages are distributed only to other brokers directly connected to this broker. This parameter is optional.
max-retry-interval	The maximum delay for retries, in milliseconds. The default is 2000 .
message-load-balancing	<p>Determines whether and how messages will be distributed between other brokers in the cluster. Include the message-load-balancing element to enable load balancing. The default value is ON_DEMAND. You can provide a value as well. Valid values are:</p> <p>OFF Disables load balancing.</p> <p>STRICT Forwards messages to all brokers that have a matching queue, whether or not the queue has an active consumer or a matching selector.</p> <p>ON_DEMAND Ensures that messages are forwarded only to brokers that have active consumers or a matching selector.</p>
min-large-message-size	If a message size, in bytes, is larger than min-large-message-size , it will be split into multiple segments when sent over the network to other cluster members. The default is 102400 .

Name	Description
notification-attempts	Sets how many times the cluster connection should broadcast itself when connecting to the cluster. The default is 2 .
notification-interval	Sets how often, in milliseconds, the cluster connection should broadcast itself when attaching to the cluster. The default is 1000 .
producer-window-size	The size, in bytes, for producer flow control over cluster connection. By default, it is disabled, but you may want to set a value if you are using really large messages in cluster. A value of -1 means no window.
reconnect-attempts	Sets the number of times the system will try to reconnect to a broker in the cluster. If the max-retry is achieved, this broker will be considered permanently down and the system will stop routing messages to this broker. The default is -1 , which means infinite retries.
retry-interval	Determines the interval, in milliseconds, between retry attempts. If the cluster connection is created and the target broker has not been started or is booting, then the cluster connections from other brokers will retry connecting to the target until it comes back up. This parameter is optional. The default value is 500 milliseconds.
retry-interval-multiplier	The multiplier used to increase the retry-interval after each reconnect attempt. The default is 1.
use-duplicate-detection	Cluster connections use bridges to link the brokers, and bridges can be configured to add a duplicate ID property in each message that is forwarded. If the target broker of the bridge crashes and then recovers, messages might be resent from the source broker. By setting use-duplicate-detection to true , any duplicate messages will be filtered out and ignored on receipt at the target broker. The default is true .

APPENDIX D. COMMAND-LINE TOOLS

AMQ Broker includes a set of command-line interface (CLI) tools so you can manage your messaging journal. The table below lists the name for each tool and its description.

Tool	Description
exp	Exports the message data using a special and independent XML format.
imp	Imports the journal to a running broker using the output provided by exp .
data	Prints reports about journal records and compacts their data.
encode	Shows an internal format of the journal encoded to String.
decode	Imports the internal journal format from encode.

For a full list of commands available for each tool, use the **help** parameter followed by the tool's name. In the example below, the CLI output lists all the commands available to the **data** tool after the user entered the command `./artemis help data`.

```
$ ./artemis help data
```

NAME

```
artemis data - data tools group
(print|imp|exp|encode|decode|compact) (example ./artemis data print)
```

SYNOPSIS

```
artemis data
artemis data compact [--broker <brokerConfig>] [--verbose]
  [--paging <paging>] [--journal <journal>]
  [--large-messages <largeMessges>] [--bindings <binding>]
artemis data decode [--broker <brokerConfig>] [--suffix <suffix>]
  [--verbose] [--paging <paging>] [--prefix <prefix>] [--file-size <size>]
  [--directory <directory>] --input <input> [--journal <journal>]
  [--large-messages <largeMessges>] [--bindings <binding>]
artemis data encode [--directory <directory>] [--broker <brokerConfig>]
  [--suffix <suffix>] [--verbose] [--paging <paging>] [--prefix <prefix>]
  [--file-size <size>] [--journal <journal>]
  [--large-messages <largeMessges>] [--bindings <binding>]
artemis data exp [--broker <brokerConfig>] [--verbose]
  [--paging <paging>] [--journal <journal>]
  [--large-messages <largeMessges>] [--bindings <binding>]
artemis data imp [--host <host>] [--verbose] [--port <port>]
  [--password <password>] [--transaction] --input <input> [--user <user>]
artemis data print [--broker <brokerConfig>] [--verbose]
  [--paging <paging>] [--journal <journal>]
  [--large-messages <largeMessges>] [--bindings <binding>]
```

COMMANDS

```
With no arguments, Display help information
```

```
print
  Print data records information (WARNING: don't use while a
  production server is running)
...

```

You can use the help at the tool for more information on how to execute each of the tool's commands. For example, the CLI lists more information about the **data print** command after the user enters the **./artemis help data print**.

```
$ ./artemis help data print
```

NAME

```
artemis data print - Print data records information (WARNING: don't use
while a production server is running)
```

SYNOPSIS

```
artemis data print [--bindings <binding>] [--journal <journal>]
  [--paging <paging>]
```

OPTIONS

```
--bindings <binding>
  The folder used for bindings (default ../data/bindings)

--journal <journal>
  The folder used for messages journal (default ../data/journal)

--paging <paging>
  The folder used for paging (default ../data/paging)
```

APPENDIX E. MESSAGING JOURNAL CONFIGURATION ELEMENTS

The table below lists all of the configuration elements related to the AMQ Broker messaging journal.

Table E.1. Address Setting Elements

Name	Description
journal-directory	<p>The directory where the message journal is located. The default value is <i>BROKER_INSTANCE_DIR/data/journal</i>.</p> <p>For the best performance, the journal should be located on its own physical volume in order to minimize disk head movement. If the journal is on a volume that is shared with other processes that may be writing other files (for example, bindings journal, database, or transaction coordinator) then the disk head may well be moving rapidly between these files as it writes them, thus drastically reducing performance.</p> <p>When using a SAN, each journal instance should be given its own LUN (logical unit).</p>
create-journal-dir	<p>If set to true, the journal directory will be automatically created at the location specified in journal-directory if it does not already exist. The default value is true.</p>
journal-type	<p>Valid values are NIO or ASYNCIO.</p> <p>If set to NIO, the broker uses Java NIO interface to its journal. Set to ASYNCIO, and the broker will use the Linux asynchronous IO journal. If you choose ASYNCIO but are not running Linux or you do not have libaio installed then the broker will detect this and automatically fall back to using NIO.</p>
journal-sync-transactional	<p>If set to true, the broker flushes all transaction data to disk on transaction boundaries (that is, commit, prepare, and rollback). The default value is true.</p>
journal-sync-non-transactional	<p>If set to true, the broker flushes non-transactional message data (sends and acknowledgements) to disk each time. The default value is true.</p>
journal-file-size	<p>The size of each journal file in bytes. The default value is 10485760 bytes (10MiB).</p>
journal-min-files	<p>The minimum number of files the broker pre-creates when starting. Files are pre-created only if there is no existing message data.</p> <p>Depending on how much data you expect your queues to contain at steady state, you should tune this number of files to match the total amount of data expected.</p>

Name	Description
journal-pool-files	<p>The system will create as many files as needed; however, when reclaiming files it will shrink back to journal-pool-files.</p> <p>The default value is -1, meaning it will never delete files on the journal once created. The system cannot grow infinitely, however, as you are still required to use paging for destinations that can grow indefinitely.</p>
journal-max-io	<p>Controls the maximum number of write requests that can be in the IO queue at any one time. If the queue becomes full then writes will block until space is freed up.</p> <p>When using NIO, this value should always be 1. When using AIO, the default value is 500. The total max AIO can't be higher than the value set at the OS level (<code>/proc/sys/fs/aio-max-nr</code>), which is usually at 65536.</p>
journal-buffer-timeout	<p>Controls the timeout for when the buffer will be flushed. AIO can typically withstand with a higher flush rate than NIO, so the system maintains different default values for both NIO and AIO.</p> <p>The default value for NIO is 3333333 nanoseconds, or 300 times per second, and the default value for AIO is 50000 nanoseconds, or 2000 times per second.</p> <div data-bbox="555 1039 663 1236" style="float: left; margin-right: 10px;">  </div> <p>NOTE</p> <p>By increasing the timeout value, you might be able to increase system throughput at the expense of latency, since the default values are chosen to give a reasonable balance between throughput and latency.</p>
journal-buffer-size	<p>The size of the timed buffer on AIO. The default value is 490KiB.</p>
journal-compact-min-files	<p>The minimal number of files necessary before the broker compacts the journal. The compacting algorithm will not start until you have at least journal-compact-min-files. The default value is 10.</p> <div data-bbox="555 1554 663 1688" style="float: left; margin-right: 10px;">  </div> <p>NOTE</p> <p>Setting the value to 0 will disable compacting and could be dangerous because the journal could grow indefinitely.</p>
journal-compact-percentage	<p>The threshold to start compacting. Journal data will be compacted if less than journal-compact-percentage is determined to be live data. Note also that compacting will not start until you have at least journal-compact-min-files data files on the journal. The default value is 30.</p>

APPENDIX F. REPLICATION HIGH AVAILABILITY CONFIGURATION ELEMENTS

The following tables list the valid **ha-policy** configuration elements when using a replication HA policy.

Table F.1. Configuration Elements Available when Using Replication High Availability

Name	Description
check-for-live-server	Applies to master brokers only. Determines whether the master checks the cluster for another master server using its own server ID when starting up. Set to true if you want to fail back to the original master broker. The default is false .
cluster-name	Name of the cluster configuration to use for replication. This setting is only necessary if you configure multiple cluster connections. If configured, the the cluster configuration with this name will be used when connecting to the cluster. If unset, the first cluster connection defined in the configuration is used.
group-name	If set, slave brokers will only pair with master brokers with the matching group-name .
initial-replication-sync-timeout	<p>The amount of time the replicating broker will wait at the completion of the initial replication process for the replica to acknowledge it has received all the necessary data. The default is 30,000 milliseconds, or 30 seconds.</p> <div style="display: flex; align-items: flex-start;"> <div style="flex: 1;">  </div> <div style="flex: 2;"> <p>NOTE</p> <p>During this interval any journal related operations will be blocked.</p> </div> </div>
max-saved-replicated-journals-size	Applies to slave brokers only. Specifies how many times a slave broker can restart after moving its files on start. Once there are this number of slave journal files the broker will stop permanently after if fails back. The default is 2 .
allow-failback	Applies to slave brokers only. Determines whether the slave broker will automatically restart and resume its original role when another broker places a request to take over its place. The default is true .
