           exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_NAMESPACE_NAME,
"test");
           exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENT_NAME,
"event1");
        }
     });
  to("kubernetes-events:///?kubernetesClient=#kubernetesClient&operation=getEvent").
  to("mock:result");
```

This operation returns the event matching the criteria from your cluster. The type of the event is **io.fabric8.kubernetes.api.model.events.v1.Event**.

This operation expects two message headers which are **CamelKubernetesNamespaceName** and **CamelKubernetesEventName**, the first one needs to be set to the name of the target namespace and second one needs to be set to the target name of event.

If no matching event could be found, **null** is returned.

- createEvent: this operation creates a new event.

```
from("direct:get").process(new Processor() {

        @Override
        public void process(Exchange exchange) throws Exception {
            exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_NAMESPACE_NAME,
"default");
            exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENT_NAME,
"test1");
            Map<String, String> labels = new HashMap<>();
            labels.put("this", "rocks");
            exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENTS_LABELS,
labels);

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION_PRODUCER,
"Some Action");
            exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENT_TYPE,
"Normal");
            exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENT_REASON,
"Some Reason");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENT_REPORTING_CONTROL
LER, "Some-Reporting-Controller");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENT_REPORTING_INSTANCE
, "Some-Reporting-Instance");
        }
    });
  to("kubernetes-events:///?kubernetesClient=#kubernetesClient&operation=createEvent").
  to("mock:result");
```

This operation publishes a new event in your cluster. An event can be created in two ways either from message headers or directly from an **io.fabric8.kubernetes.api.model.events.v1.EventBuilder**.

Whatever the way used to create the event:

- The operation expects two message headers which are **CamelKubernetesNamespaceName** and **CamelKubernetesEventName**, to set respectively the name of namespace and the name of the produced event.

- The operation supports the message header **CamelKubernetesEventsLabels** to set the labels to the produced event.

The message headers that can be used to create an event are **CamelKubernetesEventTime**, **CamelKubernetesEventAction**, **CamelKubernetesEventType**, **CamelKubernetesEventReason**, **CamelKubernetesEventNote**,**CamelKubernetesEventRegarding**, **CamelKubernetesEventRelated**, **CamelKubernetesEventReportingController** and **CamelKubernetesEventReportingInstance**.

In case the supported message headers are not enough for a specific use case, it is still possible to set the message body with an object of type **io.fabric8.kubernetes.api.model.events.v1.EventBuilder** representing a prefilled builder to use when creating the event. Please note that the labels, name of event and name of namespace are always set from the message headers, even when the builder is provided.

- updateEvent: this operation updates an existing event.

The behavior is exactly the same as **createEvent**, only the name of the operation is different.

- deleteEvent: this operation deletes an existing event.

```
from("direct:get").process(new Processor() {

        @Override
        public void process(Exchange exchange) throws Exception {
            exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_NAMESPACE_NAME,
"default");
            exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_EVENT_NAME,
"test1");
        }
    });
  to("kubernetes-events:///?kubernetesClient=#kubernetesClient&operation=deleteEvent").
  to("mock:result");
```

This operation removes an existing event from your cluster. It returns a **boolean** to indicate whether the operation was successful or not.

This operation expects two message headers which are **CamelKubernetesNamespaceName** and **CamelKubernetesEventName**, the first one needs to be set to the name of the target namespace and second one needs to be set to the target name of event.

65.8. KUBERNETES EVENTS CONSUMER EXAMPLE

```
fromF("kubernetes-events://%s?oauthToken=%s", host, authToken)
  .setHeader(KubernetesConstants.KUBERNETES_NAMESPACE_NAME, constant("default"))
  .setHeader(KubernetesConstants.KUBERNETES_EVENT_NAME, constant("test"))
  .process(new KubernertesProcessor()).to("mock:result");

  public class KubernertesProcessor implements Processor {
    @Override
    public void process(Exchange exchange) throws Exception {
        Message in = exchange.getIn();
        Event cm = exchange.getIn().getBody(Event.class);
        log.info("Got event with event name: " + cm.getMetadata().getName() + " and action " +
in.getHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION));
    }
  }
```

This consumer returns a message per event received on the namespace "default" for the event "test". It also set the action (**io.fabric8.kubernetes.client.Watcher.Action**) in the message header **CamelKubernetesEventAction** and the timestamp (**long**) in the message header **CamelKubernetesEventTimestamp**.

65.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map

Name	Description	Default	Type
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long

Name	Description	Default	Type
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 66. KUBERNETES HPA

Since Camel 2.23

Both producer and consumer are supported

The Kubernetes HPA component is one of the Kubernetes Components which provides a producer to execute kubernetes Horizontal Pod Autoscaler operations and a consumer to consume events related to Horizontal Pod Autoscaler objects.

66.1. DEPENDENCIES

When using **kubernetes-hpa** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

66.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

66.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

66.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

66.3. COMPONENT OPTIONS

The Kubernetes HPA component supports 4 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (common)	**Autowired** To use an existing kubernetes client.		KubernetesClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

66.4. ENDPOINT OPTIONS

The Kubernetes HPA endpoint is configured using URI syntax:

```
kubernetes-hpa:masterUrl
```

with the following path and query parameters:

66.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (common)	**Required** Kubernetes Master url.		String

66.4.2. Query Parameters (33 parameters)

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use.		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (common)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (common)	The namespace.		String
portName (common)	The port name, used for ServiceCall EIP.		String
portProtocol (common)	The port protocol, used for ServiceCall EIP.	tcp	String
crdGroup (consumer)	The Consumer CRD Resource Group we would like to watch.		String
crdName (consumer)	The Consumer CRD Resource name we would like to watch.		String
crdPlural (consumer)	The Consumer CRD Resource Plural we would like to watch.		String
crdScope (consumer)	The Consumer CRD Resource Scope we would like to watch.		String
crdVersion (consumer)	The Consumer CRD Resource Version we would like to watch.		String
labelKey (consumer)	The Consumer Label key when watching at some resources.		String

Name	Description	Default	Type
labelValue (consumer)	The Consumer Label value when watching at some resources.		String
poolSize (consumer)	The Consumer pool size.	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

66.5. MESSAGE HEADERS

The Kubernetes HPA component supports 7 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String
CamelKubernetesHPAName (producer) Constant: KUBERNETES_HPA_NAME	The HPA name.		String
CamelKubernetesHPASpec (producer) Constant: KUBERNETES_HPA_SPEC	The spec for a HPA.		HorizontalPodAutoscalerSpec
CamelKubernetesHPALabels (producer) Constant: KUBERNETES_HPA_LABELS	The HPA labels.		Map

Name	Description	Default	Type
CamelKubernetesEventAction (consumer) Constant: KUBERNETES_EVENT_ACTION	Action watched by the consumer. Enum values: • ADDED • MODIFIED • DELETED • ERROR • BOOKMARK		Action
CamelKubernetesEventTimestamp (consumer) Constant: KUBERNETES_EVENT_TIMESTAMP	Timestamp of the action watched by the consumer.		long

66.6. SUPPORTED PRODUCER OPERATION

- listHPA
- listHPAByLabels
- getHPA
- createHPA
- updateHPA
- deleteHPA

66.7. KUBERNETES HPA PRODUCER EXAMPLES

- listHPA: this operation lists the HPAs on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-hpa:///?kubernetesClient=#kubernetesClient&operation=listHPA").
    to("mock:result");
```

This operation returns a List of HPAs from your cluster.

- listDeploymentsByLabels: this operation lists the HPAs by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
```

```
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");
                exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_HPA_LABELS, labels);
            }
        });
    toF("kubernetes-hpa:///?kubernetesClient=#kubernetesClient&operation=listHPAByLabels").
    to("mock:result");
```

This operation returns a List of HPAs from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

66.8. KUBERNETES HPA CONSUMER EXAMPLE

```
fromF("kubernetes-hpa://%s?oauthToken=%s&namespace=default&resourceName=test", host,
authToken).process(new KubernertesProcessor()).to("mock:result");
    public class KubernertesProcessor implements Processor {
        @Override
        public void process(Exchange exchange) throws Exception {
            Message in = exchange.getIn();
            HorizontalPodAutoscaler hpa = exchange.getIn().getBody(HorizontalPodAutoscaler.class);
            log.info("Got event with hpa name: " + hpa.getMetadata().getName() + " and action " +
in.getHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION));
        }
    }
```

This consumer returns a list of events on the namespace default for the hpa test.

66.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer

Name	Description	Default	Type
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 67. KUBERNETES JOB

Since Camel 2.23

Both producer and consumer are supported

The Kubernetes Job component isone of the Kubernetes Components which provides a producer to execute kubernetes Job operations and a consumer to consume events related to Job objects.

67.1. DEPENDENCIES

When using **kubernetes-job** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

67.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

67.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

67.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

67.3. COMPONENT OPTIONS

The Kubernetes Job component supports 4 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (common)	**Autowired** To use an existing kubernetes client.		KubernetesClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

67.4. ENDPOINT OPTIONS

The Kubernetes Job endpoint is configured using URI syntax:

```
kubernetes-job:masterUrl
```

with the following path and query parameters:

67.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (common)	**Required** Kubernetes Master url.		String

67.4.2. Query Parameters (33 parameters)

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use.		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (common)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (common)	The namespace.		String
portName (common)	The port name, used for ServiceCall EIP.		String
portProtocol (common)	The port protocol, used for ServiceCall EIP.	tcp	String
crdGroup (consumer)	The Consumer CRD Resource Group we would like to watch.		String
crdName (consumer)	The Consumer CRD Resource name we would like to watch.		String
crdPlural (consumer)	The Consumer CRD Resource Plural we would like to watch.		String
crdScope (consumer)	The Consumer CRD Resource Scope we would like to watch.		String
crdVersion (consumer)	The Consumer CRD Resource Version we would like to watch.		String
labelKey (consumer)	The Consumer Label key when watching at some resources.		String

Name	Description	Default	Type
labelValue (consumer)	The Consumer Label value when watching at some resources.		String
poolSize (consumer)	The Consumer pool size.	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

67.5. MESSAGE HEADERS

The Kubernetes Job component supports 5 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String
CamelKubernetesJobName (producer) Constant: KUBERNETES_JOB_NAME	The Job name.		String
CamelKubernetesJobSpec (producer) Constant: KUBERNETES_JOB_SPEC	The spec for a Job.		JobSpec
CamelKubernetesJobLabels (producer) Constant: KUBERNETES_JOB_LABELS	The Job labels.		Map

67.6. SUPPORTED PRODUCER OPERATION

- listJob
- listJobByLabels
- getJob
- createJob

- updateJob
- deleteJob

67.7. KUBERNETES JOB PRODUCER EXAMPLES

- listJob: this operation list the jobs on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-job:///?kubernetesClient=#kubernetesClient&operation=listJob").
    to("mock:result");
```

This operation returns a List of Job from your cluster.

- listJobByLabels: this operation list the jobs by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");
                exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_JOB_LABELS, labels);
            }
        });
    toF("kubernetes-job:///?kubernetesClient=#kubernetesClient&operation=listJobByLabels").
    to("mock:result");
```

This operation returns a List of Jobs from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

- createJob: This operation creates a job on a Kubernetes Cluster.

Example (see Create Job example for more information)

```
import java.util.ArrayList;
import java.util.Date;
import java.util.HashMap;
import java.util.List;

        PodSpec ps = new PodSpec();
        ps.setRestartPolicy("Never");
        ps.setContainers(generateContainers());
        pts.setSpec(ps);

        ObjectMeta metadata = new ObjectMeta();
        Map<String, String> annotations = new HashMap<String, String>();
        annotations.put("jobMetadataAnnotation1", "random value");
```

```
        metadata.setAnnotations(annotations);

        Map<String, String> podlabels = new HashMap<String, String>();
        podlabels.put("podLabelKey1", "value1");
        podlabels.put("podLabelKey2", "value2");
        podlabels.put("app", "podFromCamelApp");
        metadata.setLabels(podlabels);

        pts.setMetadata(metadata);
        js.setTemplate(pts);
        return js;
    }

    private List<Container> generateContainers() {
        Container container = new Container();
        container.setName("pi");
        container.setImage("perl");
        List<String> command = new ArrayList<String>();
        command.add("echo");
        command.add("Job created from Apache Camel code at " + (new Date()));
        container.setCommand(command);
        List<Container> containers = new ArrayList<Container>();
        containers.add(container);
        return containers;
    }
}
```

67.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean

Name	Description	Default	Type
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 68. KUBERNETES NAMESPACES

Since Camel 2.17

Both producer and consumer are supported

The Kubernetes Namespaces component is one of the Kubernetes Components which provides a producer to execute Kubernetes Namespace operations and a consumer to consume events related to Namespace events.

68.1. DEPENDENCIES

When using **kubernetes-namespaces** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

68.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

68.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

68.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

68.3. COMPONENT OPTIONS

The Kubernetes Namespaces component supports 4 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (common)	**Autowired** To use an existing kubernetes client.		KubernetesClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

68.4. ENDPOINT OPTIONS

The Kubernetes Namespaces endpoint is configured using URI syntax:

```
kubernetes-namespaces:masterUrl
```

with the following path and query parameters:

68.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (common)	**Required** Kubernetes Master url.		String

68.4.2. Query Parameters (33 parameters)

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use.		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (common)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (common)	The namespace.		String
portName (common)	The port name, used for ServiceCall EIP.		String
portProtocol (common)	The port protocol, used for ServiceCall EIP.	tcp	String
crdGroup (consumer)	The Consumer CRD Resource Group we would like to watch.		String
crdName (consumer)	The Consumer CRD Resource name we would like to watch.		String
crdPlural (consumer)	The Consumer CRD Resource Plural we would like to watch.		String
crdScope (consumer)	The Consumer CRD Resource Scope we would like to watch.		String
crdVersion (consumer)	The Consumer CRD Resource Version we would like to watch.		String
labelKey (consumer)	The Consumer Label key when watching at some resources.		String

Name	Description	Default	Type
labelValue (consumer)	The Consumer Label value when watching at some resources.		String
poolSize (consumer)	The Consumer pool size.	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

68.5. MESSAGE HEADERS

The Kubernetes Namespaces component supports 5 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String
CamelKubernetesNamespaceLabels (producer) Constant: KUBERNETES_NAMESPACE_LABELS	The namespace labels.		Map
CamelKubernetesEventAction (consumer) Constant: KUBERNETES_EVENT_ACTION	Action watched by the consumer. Enum values: • ADDED • MODIFIED • DELETED • ERROR • BOOKMARK		Action
CamelKubernetesEventTimestamp (consumer) Constant: KUBERNETES_EVENT_TIMESTAMP	Timestamp of the action watched by the consumer.		long

68.6. SUPPORTED PRODUCER OPERATION

- listNamespaces

- listNamespacesByLabels
- getNamespace
- createNamespace
- updateNamespace
- deleteNamespace

68.7. KUBERNETES NAMESPACES PRODUCER EXAMPLES

- listNamespaces: this operation list the namespaces on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-deployments:///?
kubernetesClient=#kubernetesClient&operation=listNamespaces").
    to("mock:result");
```

This operation returns a List of namespaces from your cluster.

- listNamespacesByLabels: this operation list the namespaces by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_NAMESPACES_LABELS,
labels);
            }
        });
    toF("kubernetes-deployments:///?
kubernetesClient=#kubernetesClient&operation=listNamespacesByLabels").
    to("mock:result");
```

This operation returns a List of Namespaces from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

68.8. KUBERNETES NAMESPACES CONSUMER EXAMPLE

```
fromF("kubernetes-namespaces://%s?oauthToken=%s&namespace=default", host,
authToken).process(new KubernertesProcessor()).to("mock:result");
    public class KubernertesProcessor implements Processor {
        @Override
        public void process(Exchange exchange) throws Exception {
            Message in = exchange.getIn();
            Namespace ns = exchange.getIn().getBody(Namespace.class);
            log.info("Got event with configmap name: " + ns.getMetadata().getName() + " and action " +
in.getHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION));
        }
    }
```

This consumer returns a list of events on the namespace default.

68.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer

Name	Description	Default	Type
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 69. KUBERNETES NODES

Since Camel 2.17

Both producer and consumer are supported

The Kubernetes Nodes component is one of the Kubernetes Components which provides a producer to execute Kubernetes Node operations and a consumer to consume events related to Node objects.

69.1. DEPENDENCIES

When using **kubernetes-nodes** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

69.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

69.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

69.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

69.3. COMPONENT OPTIONS

The Kubernetes Nodes component supports 4 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (common)	**Autowired** To use an existing kubernetes client.		KubernetesClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

69.4. ENDPOINT OPTIONS

The Kubernetes Nodes endpoint is configured using URI syntax:

```
kubernetes-nodes:masterUrl
```

with the following path and query parameters:

69.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (common)	**Required** Kubernetes Master url.		String

69.4.2. Query Parameters (33 parameters)

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use.		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (common)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (common)	The namespace.		String
portName (common)	The port name, used for ServiceCall EIP.		String
portProtocol (common)	The port protocol, used for ServiceCall EIP.	tcp	String
crdGroup (consumer)	The Consumer CRD Resource Group we would like to watch.		String
crdName (consumer)	The Consumer CRD Resource name we would like to watch.		String
crdPlural (consumer)	The Consumer CRD Resource Plural we would like to watch.		String
crdScope (consumer)	The Consumer CRD Resource Scope we would like to watch.		String
crdVersion (consumer)	The Consumer CRD Resource Version we would like to watch.		String
labelKey (consumer)	The Consumer Label key when watching at some resources.		String

Name	Description	Default	Type
labelValue (consumer)	The Consumer Label value when watching at some resources.		String
poolSize (consumer)	The Consumer pool size.	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

69.5. MESSAGE HEADERS

The Kubernetes Nodes component supports 6 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNodesLabels (producer) Constant: KUBERNETES_NODES_LABELS	The node labels.		Map
CamelKubernetesNodeName (producer) Constant: KUBERNETES_NODE_NAME	The node name.		String
CamelKubernetesNodeSpec (producer) Constant: KUBERNETES_NODE_SPEC	The spec for a node.		NodeSpec
CamelKubernetesEventAction (consumer) Constant: KUBERNETES_EVENT_ACTION	Action watched by the consumer. Enum values: • ADDED • MODIFIED • DELETED • ERROR • BOOKMARK		Action

Name	Description	Default	Type
CamelKubernetesEventTimestamp (consumer) Constant: KUBERNETES_EVENT_TIMESTAMP	Timestamp of the action watched by the consumer.		long

69.6. SUPPORTED PRODUCER OPERATION

- listNodes
- listNodesByLabels
- getNode
- createNode
- updateNode
- deleteNode

69.7. KUBERNETES NODES PRODUCER EXAMPLES

- listNodes: this operation list the nodes on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-nodes:///?kubernetesClient=#kubernetesClient&operation=listNodes").
    to("mock:result");
```

This operation returns a List of Nodes from your cluster.

- listNodesByLabels: this operation list the nodes by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");
                exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_NODES_LABELS,
labels);
            }
        });
    toF("kubernetes-deployments:///?
kubernetesClient=#kubernetesClient&operation=listNodesByLabels").
    to("mock:result");
```

This operation returns a List of Nodes from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

69.8. KUBERNETES NODES CONSUMER EXAMPLE

```
fromF("kubernetes-nodes:///%s?oauthToken=%s&resourceName=test", host,
authToken).process(new KubernertesProcessor()).to("mock:result");
    public class KubernertesProcessor implements Processor {
        @Override
        public void process(Exchange exchange) throws Exception {
            Message in = exchange.getIn();
            Node node = exchange.getIn().getBody(Node.class);
            log.info("Got event with configmap name: " + node.getMetadata().getName() + " and action " +
in.getHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION));
        }
    }
```

This consumer returns a list of events for the node test.

69.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String

Name	Description	Default	Type
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 70. KUBERNETES PERSISTENT VOLUME

Since Camel 2.17

Only producer is supported

The Kubernetes Persistent Volume component is one of the Kubernetes Components which provides a producer to execute Kubernetes Persistent Volume operations.

70.1. DEPENDENCIES

When using **kubernetes-persistent-volumes** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

70.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

70.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

70.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

70.3. COMPONENT OPTIONS

The Kubernetes Persistent Volume component supports 3 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (producer)	**Autowired** To use an existing kubernetes client.		KubernetesClient
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

70.4. ENDPOINT OPTIONS

The Kubernetes Persistent Volume endpoint is configured using URI syntax:

```
kubernetes-persistent-volumes:masterUrl
```

with the following path and query parameters:

70.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (producer)	**Required** Kubernetes Master url.		String

70.4.2. Query Parameters (21 parameters)

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use.		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (producer)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (producer)	The namespace.		String
operation (producer)	Producer operation to do on Kubernetes.		String
portName (producer)	The port name, used for ServiceCall EIP.		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP.	tcp	String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String

Name	Description	Default	Type
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

70.5. MESSAGE HEADERS

The Kubernetes Persistent Volume component supports 3 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String

Name	Description	Default	Type
CamelKubernetesPersistentVolumesLabels (producer) Constant: KUBERNETES_PERSISTENT_VOLUMES_LABELS	The persistent volume labels.		Map
CamelKubernetesPersistentVolumeName (producer) Constant: KUBERNETES_PERSISTENT_VOLUME_NAME	The persistent volume name.		String

70.6. SUPPORTED PRODUCER OPERATION

- listPersistentVolumes
- listPersistentVolumesByLabels
- getPersistentVolume

70.7. KUBERNETES PERSISTENT VOLUMES PRODUCER EXAMPLES

- listPersistentVolumes: this operation lists the pv on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-persistent-volumes:///?
kubernetesClient=#kubernetesClient&operation=listPersistentVolumes").
    to("mock:result");
```

This operation returns a List of pv from your cluster.

- listPersistentVolumesByLabels: this operation lists the pv by labels on a kubernetes cluster

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_PERSISTENT_VOLUMES_LABEL
S, labels);
            }
```

```
        });
    toF("kubernetes-persistent-volumes:///?
kubernetesClient=#kubernetesClient&operation=listPersistentVolumesByLabels").
    to("mock:result");
```

This operation returns a List of pv from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

70.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String

Name	Description	Default	Type
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 71. KUBERNETES PERSISTENT VOLUME CLAIM

Since Camel 2.17

Only producer is supported

The Kubernetes Persistent Volume Claim component is one of the Kubernetes Components which provides a producer to execute Kubernetes Persistent Volume Claims operations.

71.1. DEPENDENCIES

When using **kubernetes-persistent-volumes-claims** with Red Hat build of Apache Camel for Spring Boot,use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

71.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

71.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

71.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

71.3. COMPONENT OPTIONS

The Kubernetes Persistent Volume Claim component supports 3 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (producer)	**Autowired** To use an existing kubernetes client.		KubernetesClient
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

71.4. ENDPOINT OPTIONS

The Kubernetes Persistent Volume Claim endpoint is configured using URI syntax:

```
kubernetes-persistent-volumes-claims:masterUrl
```

with the following path and query parameters:

71.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (producer)	**Required** Kubernetes Master url.		String

71.4.2. Query Parameters (21 parameters)

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use.		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (producer)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (producer)	The namespace.		String
operation (producer)	Producer operation to do on Kubernetes.		String
portName (producer)	The port name, used for ServiceCall EIP.		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP.	tcp	String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String

Name	Description	Default	Type
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

71.5. MESSAGE HEADERS

The Kubernetes Persistent Volume Claim component supports 5 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String

Name	Description	Default	Type
CamelKubernetesPersistentVolumesClaimsLabels (producer) Constant: KUBERNETES_PERSISTENT_VOLUMES_CLAIMS_LABELS	The persistent volume claim labels.		Map
CamelKubernetesPersistentVolumeClaimName (producer) Constant: KUBERNETES_PERSISTENT_VOLUME_CLAIM_NAME	The persistent volume claim name.		String
CamelKubernetesPersistentVolumeClaimSpec (producer) Constant: KUBERNETES_PERSISTENT_VOLUME_CLAIM_SPEC	The spec for a persistent volume claim.		PersistentVolumeClaimSpec

71.6. SUPPORTED PRODUCER OPERATION

- listPersistentVolumesClaims
- listPersistentVolumesClaimsByLabels
- getPersistentVolumeClaim
- createPersistentVolumeClaim
- updatePersistentVolumeClaim
- deletePersistentVolumeClaim

71.7. KUBERNETES PERSISTENT VOLUME CLAIMS PRODUCER EXAMPLES

- listPersistentVolumesClaims: this operation lists the pvc on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-persistent-volumes-claims:///?
kubernetesClient=#kubernetesClient&operation=listPersistentVolumesClaims").
    to("mock:result");
```

This operation returns a List of pvc from your cluster.

- listPersistentVolumesClaimsByLabels: this operation lists the pvc by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_PERSISTENT_VOLUMES_CLAIM
S_LABELS, labels);
            }
        });
    toF("kubernetes-persistent-volumes-claims:///?
kubernetesClient=#kubernetesClient&operation=listPersistentVolumesClaimsByLabels").
    to("mock:result");
```

This operation returns a List of pvc from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

71.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean

Name	Description	Default	Type
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 72. KUBERNETES PODS

Since Camel 2.17

Both producer and consumer are supported

The Kubernetes Pods component is one of the Kubernetes Components which provides a producer to execute Kubernetes Pods operations and a consumer to consume events related to Pod Objects.

72.1. DEPENDENCIES

When using **kubernetes-pods** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

72.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

72.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

72.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

72.3. COMPONENT OPTIONS

The Kubernetes Pods component supports 4 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (common)	**Autowired** To use an existing kubernetes client.		KubernetesClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

72.4. ENDPOINT OPTIONS

The Kubernetes Pods endpoint is configured using URI syntax:

```
kubernetes-pods:masterUrl
```

with the following path and query parameters:

72.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (common)	**Required** Kubernetes Master url.		String

72.4.2. Query Parameters (33 parameters)

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use.		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (common)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (common)	The namespace.		String
portName (common)	The port name, used for ServiceCall EIP.		String
portProtocol (common)	The port protocol, used for ServiceCall EIP.	tcp	String
crdGroup (consumer)	The Consumer CRD Resource Group we would like to watch.		String
crdName (consumer)	The Consumer CRD Resource name we would like to watch.		String
crdPlural (consumer)	The Consumer CRD Resource Plural we would like to watch.		String
crdScope (consumer)	The Consumer CRD Resource Scope we would like to watch.		String
crdVersion (consumer)	The Consumer CRD Resource Version we would like to watch.		String
labelKey (consumer)	The Consumer Label key when watching at some resources.		String

Name	Description	Default	Type
labelValue (consumer)	The Consumer Label value when watching at some resources.		String
poolSize (consumer)	The Consumer pool size.	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

72.5. MESSAGE HEADERS

The Kubernetes Pods component supports 7 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String
CamelKubernetesPodsLabels (producer) Constant: KUBERNETES_PODS_LABELS	The pod labels.		Map
CamelKubernetesPodName (producer) Constant: KUBERNETES_POD_NAME	The pod name.		String
CamelKubernetesPodSpec (producer) Constant: KUBERNETES_POD_SPEC	The spec for a pod.		PodSpec

Name	Description	Default	Type
CamelKubernetesEventAction (consumer) Constant: KUBERNETES_EVENT_ACTION	Action watched by the consumer. Enum values: • ADDED • MODIFIED • DELETED • ERROR • BOOKMARK		Action
CamelKubernetesEventTimestamp (consumer) Constant: KUBERNETES_EVENT_TIMESTAMP	Timestamp of the action watched by the consumer.		long

72.6. SUPPORTED PRODUCER OPERATION

- listPods
- listPodsByLabels
- getPod
- createPod
- updatePod
- deletePod

72.7. KUBERNETES PODS PRODUCER EXAMPLES

- listPods: this operation list the pods on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-pods:///?kubernetesClient=#kubernetesClient&operation=listPods").
    to("mock:result");
```

This operation returns a List of Pods from your cluster.

- listPodsByLabels: this operation list the pods by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
```

```
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");
                exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_PODS_LABELS,
labels);
            }
        });
    toF("kubernetes-pods:///?kubernetesClient=#kubernetesClient&operation=listPodsByLabels").
    to("mock:result");
```

This operation returns a List of Pods from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

72.8. KUBERNETES PODS CONSUMER EXAMPLE

```
fromF("kubernetes-pods://%s?oauthToken=%s&namespace=default&resourceName=test", host,
authToken).process(new KubernertesProcessor()).to("mock:result");
    public class KubernertesProcessor implements Processor {
        @Override
        public void process(Exchange exchange) throws Exception {
            Message in = exchange.getIn();
            Pod pod = exchange.getIn().getBody(Pod.class);
            log.info("Got event with configmap name: " + pod.getMetadata().getName() + " and action " +
in.getHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION));
        }
    }
```

This consumer returns a list of events on the namespace default for the pod test.

72.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer

Name	Description	Default	Type
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 73. KUBERNETES REPLICATION CONTROLLER

Since Camel 2.17

Both producer and consumer are supported

The Kubernetes Replication Controller component is one of the Kubernetes Components which provides a producer to execute Kubernetes Replication controller operations and a consumer to consume events related to Replication Controller objects.

73.1. DEPENDENCIES

When using **kubernetes-replication-controllers** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

73.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

73.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

73.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

73.3. COMPONENT OPTIONS

The Kubernetes Replication Controller component supports 4 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (common)	**Autowired** To use an existing kubernetes client.		KubernetesClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

73.4. ENDPOINT OPTIONS

The Kubernetes Replication Controller endpoint is configured using URI syntax:

```
kubernetes-replication-controllers:masterUrl
```

with the following path and query parameters:

73.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (common)	**Required** Kubernetes Master url.		String

73.4.2. Query Parameters (33 parameters)

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use.		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (common)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (common)	The namespace.		String
portName (common)	The port name, used for ServiceCall EIP.		String
portProtocol (common)	The port protocol, used for ServiceCall EIP.	tcp	String
crdGroup (consumer)	The Consumer CRD Resource Group we would like to watch.		String
crdName (consumer)	The Consumer CRD Resource name we would like to watch.		String
crdPlural (consumer)	The Consumer CRD Resource Plural we would like to watch.		String
crdScope (consumer)	The Consumer CRD Resource Scope we would like to watch.		String
crdVersion (consumer)	The Consumer CRD Resource Version we would like to watch.		String
labelKey (consumer)	The Consumer Label key when watching at some resources.		String

Name	Description	Default	Type
labelValue (consumer)	The Consumer Label value when watching at some resources.		String
poolSize (consumer)	The Consumer pool size.	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

73.5. MESSAGE HEADERS

The Kubernetes Replication Controller component supports 8 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String
CamelKubernetesReplicationControllersLabels (producer) Constant: KUBERNETES_REPLICATION_CONTROLLERS_LABELS	The replication controller labels.		Map
CamelKubernetesReplicationControllerName (producer) Constant: KUBERNETES_REPLICATION_CONTROLLER_NAME	The replication controller name.		String
CamelKubernetesReplicationControllerSpec (producer) Constant: KUBERNETES_REPLICATION_CONTROLLER_SPEC	The spec for a replication controller.		ReplicationControllerSpec

Name	Description	Default	Type
CamelKubernetesReplicationControllerReplicas (producer) Constant: KUBERNETES_REPLICATION_CONTROLLER_REPLICAS	The number of replicas for a replication controller during the Scale operation.		Integer
CamelKubernetesEventAction (consumer) Constant: KUBERNETES_EVENT_ACTION	Action watched by the consumer. Enum values: • ADDED • MODIFIED • DELETED • ERROR • BOOKMARK		Action
CamelKubernetesEventTimestamp (consumer) Constant: KUBERNETES_EVENT_TIMESTAMP	Timestamp of the action watched by the consumer.		long

73.6. SUPPORTED PRODUCER OPERATION

- listReplicationControllers
- listReplicationControllersByLabels
- getReplicationController
- createReplicationController
- updateReplicationController
- deleteReplicationController
- scaleReplicationController

73.7. KUBERNETES REPLICATION CONTROLLERS PRODUCER EXAMPLES

- listReplicationControllers: this operation list the RCs on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-replication-controllers:///?
kubernetesClient=#kubernetesClient&operation=listReplicationControllers").
    to("mock:result");
```

This operation returns a List of RCs from your cluster.

- listReplicationControllersByLabels: this operation list the RCs by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_REPLICATION_CONTROLLERS_
LABELS, labels);
            }
        });
    toF("kubernetes-replication-controllers:///?
kubernetesClient=#kubernetesClient&operation=listReplicationControllersByLabels").
    to("mock:result");
```

This operation returns a List of RCs from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

73.8. KUBERNETES REPLICATION CONTROLLERS CONSUMER EXAMPLE

```
fromF("kubernetes-replication-controllers://%s?
oauthToken=%s&namespace=default&resourceName=test", host, authToken).process(new
KubernertesProcessor()).to("mock:result");
    public class KubernertesProcessor implements Processor {
        @Override
        public void process(Exchange exchange) throws Exception {
            Message in = exchange.getIn();
            ReplicationController rc = exchange.getIn().getBody(ReplicationController.class);
            log.info("Got event with configmap name: " + rc.getMetadata().getName() + " and action " +
in.getHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION));
        }
    }
```

This consumer returns a list of events on the namespace default for the rc test.

73.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long

Name	Description	Default	Type
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 74. KUBERNETES RESOURCES QUOTA

Since Camel 2.17

Only producer is supported

The Kubernetes Resources Quota component is one of the Kubernetes Components which provides a producer to execute Kubernetes Resource Quota operations.

74.1. DEPENDENCIES

When using **kubernetes-resources-quota** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

74.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

74.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

74.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

74.3. COMPONENT OPTIONS

The Kubernetes Resources Quota component supports 3 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (producer)	**Autowired** To use an existing kubernetes client.		KubernetesClient
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

74.4. ENDPOINT OPTIONS

The Kubernetes Resources Quota endpoint is configured using URI syntax:

```
kubernetes-resources-quota:masterUrl
```

with the following path and query parameters:

74.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (producer)	**Required** Kubernetes Master url.		String

74.4.2. Query Parameters (21 parameters)

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use.		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (producer)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (producer)	The namespace.		String
operation (producer)	Producer operation to do on Kubernetes.		String
portName (producer)	The port name, used for ServiceCall EIP.		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP.	tcp	String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String

Name	Description	Default	Type
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

74.5. MESSAGE HEADERS

The Kubernetes Resources Quota component supports 5 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String

Name	Description	Default	Type
CamelKubernetesResourcesQuotaLabels (producer) Constant: KUBERNETES_RESOURCES_QUOTA_LABELS	The resource quota labels.		Map
CamelKubernetesResourcesQuotaName (producer) Constant: KUBERNETES_RESOURCES_QUOTA_NAME	The resource quota name.		String
CamelKubernetesResourceQuotaSpec (producer) Constant: KUBERNETES_RESOURCE_QUOTA_SPEC	The spec for a resource quota.		ResourceQuotaSpec

74.6. SUPPORTED PRODUCER OPERATION

- listResourcesQuota
- listResourcesQuotaByLabels
- getResourcesQuota
- createResourcesQuota
- updateResourceQuota
- deleteResourcesQuota

74.7. KUBERNETES RESOURCE QUOTA PRODUCER EXAMPLES

- listResourcesQuota: this operation list the Resource Quotas on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-resources-quota:///?
kubernetesClient=#kubernetesClient&operation=listResourcesQuota").
    to("mock:result");
```

This operation returns a List of Resource Quotas from your cluster.

- listResourcesQuotaByLabels: this operation list the Resource Quotas by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_RESOURCES_QUOTA_LABELS,
labels);
            }
        });
    toF("kubernetes-resources-quota:///?
kubernetesClient=#kubernetesClient&operation=listResourcesQuotaByLabels").
    to("mock:result");
```

This operation returns a List of Resource Quotas from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

74.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String

Name	Description	Default	Type
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 75. KUBERNETES SECRETS

Since Camel 2.17

Only producer is supported

The Kubernetes Secrets component is one of the Kubernetes Components which provides a producer to execute Kubernetes Secrets operations.

75.1. DEPENDENCIES

When using **kubernetes-secrets** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

75.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

75.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

75.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

75.3. COMPONENT OPTIONS

The Kubernetes Secrets component supports 3 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (producer)	**Autowired** To use an existing kubernetes client.		KubernetesClient
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

75.4. ENDPOINT OPTIONS

The Kubernetes Secrets endpoint is configured using URI syntax:

```
kubernetes-secrets:masterUrl
```

with the following path and query parameters:

75.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (producer)	**Required** Kubernetes Master url.		String

75.4.2. Query Parameters (21 parameters)

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use.		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (producer)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (producer)	The namespace.		String
operation (producer)	Producer operation to do on Kubernetes.		String
portName (producer)	The port name, used for ServiceCall EIP.		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP.	tcp	String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String

Name	Description	Default	Type
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

75.5. MESSAGE HEADERS

The Kubernetes Secrets component supports 5 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String

Name	Description	Default	Type
CamelKubernetesSecretsLabels (producer) Constant: KUBERNETES_SECRETS_LABELS	The secret labels.		Map
CamelKubernetesSecretName (producer) Constant: KUBERNETES_SECRET_NAME	The secret name.		String
CamelKubernetesSecret (producer) Constant: KUBERNETES_SECRET	A secret object.		Secret

75.6. SUPPORTED PRODUCER OPERATION

- listSecrets
- listSecretsByLabels
- getSecret
- createSecret
- updateSecret
- deleteSecret

75.7. KUBERNETES SECRETS PRODUCER EXAMPLES

- listSecrets: this operation list the secrets on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-secrets:///?kubernetesClient=#kubernetesClient&operation=listSecrets").
    to("mock:result");
```

This operation returns a List of secrets from your cluster.

- listSecretsByLabels: this operation list the Secrets by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");
                exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_SECRETS_LABELS,
labels);
            }
        });
    toF("kubernetes-secrets:///?kubernetesClient=#kubernetesClient&operation=listSecretsByLabels").
    to("mock:result");
```

This operation returns a List of Secrets from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

75.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String

Name	Description	Default	Type
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 76. KUBERNETES SERVICE ACCOUNT

Since Camel 2.17

Only producer is supported

The Kubernetes Service Account component is one of the Kubernetes Components which provides a producer to execute Kubernetes Service Account operations.

76.1. DEPENDENCIES

When using **kubernetes-service-accounts** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

76.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

76.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

76.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

76.3. COMPONENT OPTIONS

The Kubernetes Service Account component supports 3 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (producer)	**Autowired** To use an existing kubernetes client.		KubernetesClient
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

76.4. ENDPOINT OPTIONS

The Kubernetes Service Account endpoint is configured using URI syntax:

```
kubernetes-service-accounts:masterUrl
```

with the following path and query parameters:

76.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (producer)	**Required** Kubernetes Master url.		String

76.4.2. Query Parameters (21 parameters)

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use.		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (producer)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (producer)	The namespace.		String
operation (producer)	Producer operation to do on Kubernetes.		String
portName (producer)	The port name, used for ServiceCall EIP.		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP.	tcp	String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String

Name	Description	Default	Type
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

76.5. MESSAGE HEADERS

The Kubernetes Service Account component supports 5 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String

Name	Description	Default	Type
CamelKubernetesServiceAccountsLabels (producer) Constant: KUBERNETES_SERVICE_ACCOUNTS_LABELS	The service account labels.		Map
CamelKubernetesServiceAccountName (producer) Constant: KUBERNETES_SERVICE_ACCOUNT_NAME	The service account name.		String
CamelKubernetesServiceAccount (producer) Constant: KUBERNETES_SERVICE_ACCOUNT	A service account object.		ServiceAccount

76.6. SUPPORTED PRODUCER OPERATION

- listServiceAccounts
- listServiceAccountsByLabels
- getServiceAccount
- createServiceAccount
- updateServiceAccount
- deleteServiceAccount

76.7. KUBERNETES SERVICEACCOUNTS PRODUCE EXAMPLES

- listServiceAccounts: this operation lists the service account on a kubernetes cluster.

```
from("direct:list").
    toF("kubernetes-service-accounts:///?
kubernetesClient=#kubernetesClient&operation=listServiceAccounts").
    to("mock:result");
```

This operation returns a List of services from your cluster.

- listServiceAccountsByLabels: this operation lists the service account by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_SERVICE_ACCOUNTS_LABELS,
labels);
            }
        });
    toF("kubernetes-service-accounts:///?
kubernetesClient=#kubernetesClient&operation=listServiceAccountsByLabels").
    to("mock:result");
```

This operation returns a List of Services from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

76.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String

Name	Description	Default	Type
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 77. KUBERNETES SERVICES

Since Camel 2.17

Both producer and consumer are supported

The Kubernetes Services component is one of the Kubernetes Components which provides a producer to execute Kubernetes Service operations and a consumer to consume events related to Service objects.

77.1. DEPENDENCIES

When using **kubernetes-services** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

77.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

77.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

77.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

77.3. COMPONENT OPTIONS

The Kubernetes Services component supports 4 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (common)	**Autowired** To use an existing kubernetes client.		KubernetesClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

77.4. ENDPOINT OPTIONS

The Kubernetes Services endpoint is configured using URI syntax:

```
kubernetes-services:masterUrl
```

with the following path and query parameters:

77.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (common)	**Required** Kubernetes Master url.		String

77.4.2. Query Parameters (33 parameters)

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use.		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (common)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (common)	The namespace.		String
portName (common)	The port name, used for ServiceCall EIP.		String
portProtocol (common)	The port protocol, used for ServiceCall EIP.	tcp	String
crdGroup (consumer)	The Consumer CRD Resource Group we would like to watch.		String
crdName (consumer)	The Consumer CRD Resource name we would like to watch.		String
crdPlural (consumer)	The Consumer CRD Resource Plural we would like to watch.		String
crdScope (consumer)	The Consumer CRD Resource Scope we would like to watch.		String
crdVersion (consumer)	The Consumer CRD Resource Version we would like to watch.		String
labelKey (consumer)	The Consumer Label key when watching at some resources.		String

Name	Description	Default	Type
labelValue (consumer)	The Consumer Label value when watching at some resources.		String
poolSize (consumer)	The Consumer pool size.	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

77.5. MESSAGE HEADERS

The Kubernetes Services component supports 7 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String
CamelKubernetesServiceLabels (producer) Constant: KUBERNETES_SERVICE_LABELS	The service labels.		Map
CamelKubernetesServiceName (producer) Constant: KUBERNETES_SERVICE_NAME	The service name.		String
CamelKubernetesServiceSpec (producer) Constant: KUBERNETES_SERVICE_SPEC	The spec of a service.		ServiceSpec

Name	Description	Default	Type
CamelKubernetesEventAction (consumer) Constant: KUBERNETES_EVENT_ACTION	Action watched by the consumer. Enum values: • ADDED • MODIFIED • DELETED • ERROR • BOOKMARK		Action
CamelKubernetesEventTimestamp (consumer) Constant: KUBERNETES_EVENT_TIMESTAMP	Timestamp of the action watched by the consumer.		long

77.6. SUPPORTED PRODUCER OPERATION

- listServices
- listServicesByLabels
- getService
- createService
- deleteService

77.7. KUBERNETES SERVICES PRODUCER EXAMPLES

- listServices: this operation list the services on a kubernetes cluster.

```
from("direct:list").
   toF("kubernetes-services:///?kubernetesClient=#kubernetesClient&operation=listServices").
   to("mock:result");
```

This operation returns a List of services from your cluster.

- listServicesByLabels: this operation list the deployments by labels on a kubernetes cluster.

```
from("direct:listByLabels").process(new Processor() {
        @Override
        public void process(Exchange exchange) throws Exception {
```

```
            Map<String, String> labels = new HashMap<>();
            labels.put("key1", "value1");
            labels.put("key2", "value2");
            exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_SERVICE_LABELS,
labels);
        }
    });
  toF("kubernetes-services:///?
kubernetesClient=#kubernetesClient&operation=listServicesByLabels").
  to("mock:result");
```

This operation returns a List of Services from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

77.8. KUBERNETES SERVICES CONSUMER EXAMPLE

```
fromF("kubernetes-services://%s?oauthToken=%s&namespace=default&resourceName=test", host,
authToken).process(new KubernertesProcessor()).to("mock:result");

  public class KubernertesProcessor implements Processor {
    @Override
    public void process(Exchange exchange) throws Exception {
      Message in = exchange.getIn();
      Service sv = exchange.getIn().getBody(Service.class);
      log.info("Got event with configmap name: " + sv.getMetadata().getName() + " and action " +
in.getHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION));
    }
  }
```

This consumer returns a list of events on the namespace default for the service test.

77.8.1. Spring Boot Auto-Configuration

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer

Name	Description	Default	Type
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 78. OPENSHIFT BUILDS

Since Camel 2.17

Only producer is supported

The Openshift Builds component is one of the Kubernetes Components which provides a producer to execute Openshift builds operations.

78.1. DEPENDENCIES

When using **openshift-builds** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

78.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

78.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

78.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

78.3. COMPONENT OPTIONS

The Openshift Builds component supports 3 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (producer)	**Autowired** To use an existing kubernetes client.		KubernetesClient
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

78.4. ENDPOINT OPTIONS

The Openshift Builds endpoint is configured using URI syntax:

```
openshift-builds:masterUrl
```

with the following path and query parameters:

78.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (producer)	**Required** Kubernetes Master url.		String

78.4.2. Query Parameters (21 parameters)

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use.		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (producer)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (producer)	The namespace.		String
operation (producer)	Producer operation to do on Kubernetes.		String
portName (producer)	The port name, used for ServiceCall EIP.		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP.	tcp	String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String

Name	Description	Default	Type
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

78.5. MESSAGE HEADERS

The Openshift Builds component supports 4 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String

Name	Description	Default	Type
CamelKubernetesBuildsLabels (producer) Constant: KUBERNETES_BUILDS_LABELS	The Openshift build labels.		Map
CamelKubernetesBuildName (producer) Constant: KUBERNETES_BUILD_NAME	The Openshift build name.		String

78.6. SUPPORTED PRODUCER OPERATION

- listBuilds
- listBuildsByLabels
- getBuild

78.7. OPENSHIFT BUILDS PRODUCER EXAMPLES

- listBuilds: this operation list the Builds on an Openshift cluster.

```
from("direct:list").
    toF("openshift-builds:///?kubernetesClient=#kubernetesClient&operation=listBuilds").
    to("mock:result");
```

This operation returns a List of Builds from your Openshift cluster.

- listBuildsByLabels: this operation list the builds by labels on an Openshift cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");
                exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_BUILDS_LABELS,
labels);
            }
        });
    toF("openshift-builds:///?kubernetesClient=#kubernetesClient&operation=listBuildsByLabels").
    to("mock:result");
```

This operation returns a List of Builds from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

78.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer

Name	Description	Default	Type
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 79. OPENSHIFT BUILD CONFIG

Since Camel 2.17

Only producer is supported

The OpenShift Build Config component is one of the Kubernetes Components which provides a producer to execute Openshift Build Configs operations.

79.1. DEPENDENCIES

When using **openshift-build-configs** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

79.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

79.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

79.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

79.3. COMPONENT OPTIONS

The Openshift Build Config component supports 3 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (producer)	**Autowired** To use an existing kubernetes client.		KubernetesClient
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

79.4. ENDPOINT OPTIONS

The Openshift Build Config endpoint is configured using URI syntax:

```
openshift-build-configs:masterUrl
```

with the following path and query parameters:

79.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (producer)	**Required** Kubernetes Master url.		String

79.4.2. Query Parameters (21 parameters)

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use.		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (producer)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (producer)	The namespace.		String
operation (producer)	Producer operation to do on Kubernetes.		String
portName (producer)	The port name, used for ServiceCall EIP.		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP.	tcp	String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String

Name	Description	Default	Type
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

79.5. MESSAGE HEADERS

The Openshift Build Config component supports 4 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String

Name	Description	Default	Type
CamelKubernetesBuildConfigsLabels (producer) Constant: KUBERNETES_BUILD_CONFIGS_LABELS	The Openshift Config Build labels.		Map
CamelKubernetesBuildConfigName (producer) Constant: KUBERNETES_BUILD_CONFIG_NAME	The Openshift Config Build name.		String

79.6. SUPPORTED PRODUCER OPERATION

- listBuildConfigs
- listBuildConfigsByLabels
- getBuildConfig

79.7. OPENSHIFT BUILD CONFIGS PRODUCER EXAMPLES

- listBuilds: this operation list the Build Configs on an Openshift cluster.

```
from("direct:list").
   toF("openshift-build-configs:///?kubernetesClient=#kubernetesClient&operation=listBuildConfigs").
   to("mock:result");
```

This operation returns a List of Builds from your Openshift cluster.

- listBuildsByLabels: this operation list the build configs by labels on an Openshift cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
               Map<String, String> labels = new HashMap<>();
               labels.put("key1", "value1");
               labels.put("key2", "value2");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_BUILD_CONFIGS_LABELS,
labels);
            }
        });
```

```
    toF("openshift-build-configs:///?
kubernetesClient=#kubernetesClient&operation=listBuildConfigsByLabels").
    to("mock:result");
```

This operation returns a List of Build configs from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

79.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String

Name	Description	Default	Type
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 80. OPENSHIFT DEPLOYMENT CONFIGS

Since Camel 3.18

Both producer and consumer are supported

The Openshift Deployment Configs component is one of the Kubernetes Components which provides a producer to execute Openshift Deployment Configs operations and a consumer to consume events related to Deployment Configs objects.

80.1. DEPENDENCIES

When using **openshift-deploymentconfigs** with Red Hat build of Apache Camel for Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kubernetes-starter</artifactId>
</dependency>
```

80.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

80.2.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

80.2.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

80.3. COMPONENT OPTIONS

The Openshift Deployment Configs component supports 4 options, which are listed below.

Name	Description	Default	Type
kubernetesClient (common)	**Autowired** To use an existing kubernetes client.		KubernetesClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

80.4. ENDPOINT OPTIONS

The Openshift Deployment Configs endpoint is configured using URI syntax:

```
openshift-deploymentconfigs:masterUrl
```

with the following path and query parameters:

80.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
masterUrl (common)	**Required** Kubernetes Master url.		String

80.4.2. Query Parameters (33 parameters)

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use.		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP.		String
kubernetesClient (common)	Default KubernetesClient to use if provided.		KubernetesClient
namespace (common)	The namespace.		String
portName (common)	The port name, used for ServiceCall EIP.		String
portProtocol (common)	The port protocol, used for ServiceCall EIP.	tcp	String
crdGroup (consumer)	The Consumer CRD Resource Group we would like to watch.		String
crdName (consumer)	The Consumer CRD Resource name we would like to watch.		String
crdPlural (consumer)	The Consumer CRD Resource Plural we would like to watch.		String
crdScope (consumer)	The Consumer CRD Resource Scope we would like to watch.		String
crdVersion (consumer)	The Consumer CRD Resource Version we would like to watch.		String
labelKey (consumer)	The Consumer Label key when watching at some resources.		String

Name	Description	Default	Type
labelValue (consumer)	The Consumer Label value when watching at some resources.		String
poolSize (consumer)	The Consumer pool size.	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
caCertData (security)	The CA Cert Data.		String
caCertFile (security)	The CA Cert File.		String
clientCertData (security)	The Client Cert Data.		String
clientCertFile (security)	The Client Cert File.		String
clientKeyAlgo (security)	The Key Algorithm used by the client.		String
clientKeyData (security)	The Client Key data.		String
clientKeyFile (security)	The Client Key file.		String
clientKeyPassphrase (security)	The Client Key Passphrase.		String
oauthToken (security)	The Auth Token.		String
password (security)	Password to connect to Kubernetes.		String
trustCerts (security)	Define if the certs we used are trusted anyway or not.		Boolean
username (security)	Username to connect to Kubernetes.		String

80.5. MESSAGE HEADERS

The Openshift Deployment Configs component supports 8 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKubernetesOperation (producer) Constant: KUBERNETES_OPERATION	The Producer operation.		String
CamelKubernetesNamespaceName (producer) Constant: KUBERNETES_NAMESPACE_NAME	The namespace name.		String
CamelKubernetesDeploymentsLabels (producer) Constant: KUBERNETES_DEPLOYMENTS_LABELS	The deployment labels.		Map
CamelKubernetesDeploymentName (producer) Constant: KUBERNETES_DEPLOYMENT_NAME	The deployment name.		String
CamelKubernetesDeploymentReplicas (producer) Constant: KUBERNETES_DEPLOYMENT_REPLICAS	The desired instance count.		Integer
CamelKubernetesDeploymentConfigSpec (producer) Constant: KUBERNETES_DEPLOYMENT_CONFIG_SPEC	The spec for a deployment config.		DeploymentConfigSpec

Name	Description	Default	Type
CamelKubernetesEventAction (consumer) Constant: KUBERNETES_EVENT_ACTION	Action watched by the consumer. Enum values: • ADDED • MODIFIED • DELETED • ERROR • BOOKMARK		Action
CamelKubernetesEventTimestamp (consumer) Constant: KUBERNETES_EVENT_TIMESTAMP	Timestamp of the action watched by the consumer.		long

80.6. SUPPORTED PRODUCER OPERATION

- listDeploymentConfigs
- listDeploymentsConfigsByLabels
- getDeploymentConfig
- createDeploymentConfig
- updateDeploymentConfig
- deleteDeploymentConfig
- scaleDeploymentConfig

80.7. OPENSHIFT DEPLOYMENT CONFIGS PRODUCER EXAMPLES

- listDeploymentConfigs: this operation list the deployments on a Openshift cluster.

```
from("direct:list").
    toF("openshift-deploymentconfigs:///?
kubernetesClient=#kubernetesClient&operation=listDeploymentConfigs").
    to("mock:result");
```

This operation returns a List of Deployment Configs from your cluster.

- listDeploymentConfigsByLabels: this operation list the deployment configs by labels on a Openshift cluster.

```
from("direct:listByLabels").process(new Processor() {
            @Override
            public void process(Exchange exchange) throws Exception {
                Map<String, String> labels = new HashMap<>();
                labels.put("key1", "value1");
                labels.put("key2", "value2");

exchange.getIn().setHeader(KubernetesConstants.KUBERNETES_DEPLOYMENTS_LABELS,
labels);
            }
        });
    toF("openshift-deploymentconfigs:///?
kubernetesClient=#kubernetesClient&operation=listDeploymentConfigsByLabels").
    to("mock:result");
```

This operation returns a List of Deployment Configs from your cluster, using a label selector (with key1 and key2, with value value1 and value2).

80.8. OPENSHIFT DEPLOYMENT CONFIGS CONSUMER EXAMPLE

```
fromF("openshift-deploymentconfigs://%s?
oauthToken=%s&namespace=default&resourceName=test", host, authToken).process(new
OpenshiftProcessor()).to("mock:result");
    public class OpenshiftProcessor implements Processor {
        @Override
        public void process(Exchange exchange) throws Exception {
            Message in = exchange.getIn();
            DeploymentConfig dp = exchange.getIn().getBody(DeploymentConfig.class);
            log.info("Got event with configmap name: " + dp.getMetadata().getName() + " and action " +
in.getHeader(KubernetesConstants.KUBERNETES_EVENT_ACTION));
        }
    }
```

This consumer returns a list of events on the namespace default for the deployment config test.

80.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 102 options, which are listed below.

Name	Description	Default	Type
camel.cluster.kubernetes.attributes	Custom service attributes.		Map
camel.cluster.kubernetes.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map

Name	Description	Default	Type
camel.cluster.kubernetes.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String
camel.cluster.kubernetes.connection-timeout-millis	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
camel.cluster.kubernetes.enabled	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
camel.cluster.kubernetes.id	Cluster Service ID.		String
camel.cluster.kubernetes.jitter-factor	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
camel.cluster.kubernetes.kubernetes-namespace	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default).		String
camel.cluster.kubernetes.lease-duration-millis	The default duration of the lease for the current leader.		Long
camel.cluster.kubernetes.master-url	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
camel.cluster.kubernetes.order	Service lookup order/priority.		Integer
camel.cluster.kubernetes.pod-name	Set the name of the current pod (autodetected from container host name by default).		String
camel.cluster.kubernetes.renew-deadline-millis	The deadline after which the leader must stop its services because it may have lost the leadership.		Long
camel.cluster.kubernetes.retry-period-millis	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long

Name	Description	Default	Type
camel.component.kubernetes-config-maps.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-config-maps.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-config-maps.enabled	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
camel.component.kubernetes-config-maps.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-config-maps.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-custom-resources.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-custom-resources.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-custom-resources.enabled	Whether to enable auto configuration of the kubernetes-custom-resources component. This is enabled by default.		Boolean
camel.component.kubernetes-custom-resources.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-custom-resources.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-deployments.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean
camel.component.kubernetes-deployments.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-deployments.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-events.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-events.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-events.enabled	Whether to enable auto configuration of the kubernetes-events component. This is enabled by default.		Boolean
camel.component.kubernetes-events.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-events.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-hpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-hpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean
camel.component.kubernetes-hpa.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-hpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-job.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-job.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean
camel.component.kubernetes-job.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-job.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-namespaces.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-namespaces.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean
camel.component.kubernetes-namespaces.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-namespaces.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-nodes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-nodes.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean
camel.component.kubernetes-nodes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-nodes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes-claims.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes-claims.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
camel.component.kubernetes-persistent-volumes-claims.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes-claims.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-persistent-volumes.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-persistent-volumes.enabled	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-persistent-volumes.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-persistent-volumes.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-pods.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-pods.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean
camel.component.kubernetes-pods.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-pods.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-replication-controllers.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-replication-controllers.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean
camel.component.kubernetes-replication-controllers.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-resources-quota.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-resources-quota.enabled	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
camel.component.kubernetes-resources-quota.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-resources-quota.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.kubernetes-secrets.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-secrets.enabled	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
camel.component.kubernetes-secrets.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.kubernetes-secrets.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-service-accounts.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-service-accounts.enabled	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
camel.component.kubernetes-service-accounts.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-service-accounts.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kubernetes-services.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kubernetes-services.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean
camel.component.kubernetes-services.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.kubernetes-services.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-build-configs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-build-configs.enabled	Whether to enable auto configuration of the openshift-build-configs component. This is enabled by default.		Boolean
camel.component.openshift-build-configs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-build-configs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-builds.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.openshift-builds.enabled	Whether to enable auto configuration of the openshift-builds component. This is enabled by default.		Boolean
camel.component.openshift-builds.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient
camel.component.openshift-builds.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.openshift-deploymentconfigs.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.openshift-deploymentconfigs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.openshift-deploymentconfigs.enabled	Whether to enable auto configuration of the openshift-deploymentconfigs component. This is enabled by default.		Boolean
camel.component.openshift-deploymentconfigs.kubernetes-client	To use an existing kubernetes client. The option is a io.fabric8.kubernetes.client.KubernetesClient type.		KubernetesClient

Name	Description	Default	Type
camel.component.openshift-deploymentconfigs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 81. KUDU

Since Camel 3.0

Only producer is supported

The Kudu component supports storing and retrieving data from/to Apache Kudu, a free and open source column-oriented data store of the Apache Hadoop ecosystem.

81.1. DEPENDENCIES

When using **kudu** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-kudu-starter</artifactId>
</dependency>
```

81.2. PREREQUISITES

You must have a valid Kudu instance running. More information are available at Apache Kudu.

81.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

81.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

81.3.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

81.4. COMPONENT OPTIONS

The Kudu component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). This allows CamelContext and routes to start in situations where a producer failing would cause the route to fail. With lazy startup, the startup failures can be handled during routing messages via Camel's routing error handlers.  **NOTE** When the first message is processed, it may take some time to create and start the producer which will increase the total processing time.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

81.5. ENDPOINT OPTIONS

The Kudu endpoint is configured using URI syntax:

```
kudu:host:port/tableName
```

with the following path and query parameters:

81.5.1. Path Parameters (3 parameters)

Name	Description	Default	Type
host (common)	Host of the server to connect to.		String
port (common)	Port of the server to connect to.		String
tableName (common)	Table to connect to.		String

81.5.2. Query Parameters (2 parameters)

Name	Description	Default	Type
operation (producer)	Operation to perform. Enum values: • INSERT • DELETE • UPDATE • UPSERT • CREATE_TABLE • SCAN		KuduOperations
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

81.6. MESSAGE HEADERS

The Kudu component supports 5 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelKuduSchema (producer) Constant:CAMEL_KUDU_SCHEMA	The schema.		Schema
CamelKuduTableOptions (producer) Constant:CAMEL_KUDU_TABLE_OPTIONS	The create table options.		CreateTableOptions
CamelKuduScanColumnNames (producer) Constant:CAMEL_KUDU_SCAN_COLUMN_NAMES	The projected column names for scan operation.		List
CamelKuduScanPredicate (producer) Constant:CAMEL_KUDU_SCAN_PREDICATE	The predicate for scan operation.		KuduPredicate
CamelKuduScanLimit (producer) Constant:CAMEL_KUDU_SCAN_LIMIT	The limit on the number of rows for scan operation.		long

81.7. INPUT BODY FORMATS

81.7.1. Insert, delete, update, and upsert

The input body format has to be a java.util.Map<String, Object>. This map will represent a row of the table whose elements are columns, where the key is the column name and the value is the value of the column.

81.8. OUTPUT BODY FORMATS

81.8.1. Scan

The output body format will be a java.util.List<java.util.Map<String, Object>>. Each element of the list will be a different row of the table. Each row is a Map<String, Object> whose elements will be each pair of column name and column value for that row.

81.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.kudu.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kudu.enabled	Whether to enable auto configuration of the kudu component. This is enabled by default.		Boolean
camel.component.kudu.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 82. LANGUAGE

Only producer is supported

The Language component allows you to send Exchange to an endpoint which executes a script by any of the supported Languages in Camel. By having a component to execute language scripts, it allows more dynamic routing capabilities. For example by using the Routing Slip or Dynamic Router EIPs you can send messages to language endpoints where the script is dynamic defined as well.

This component is provided out of the box in camel-core and hence no additional JARs is needed. You only have to include additional Camel components if the language of choice mandates it, such as using Groovy or JavaScript languages.

82.1. DEPENDENCIES

When using **language** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-language-starter</artifactId>
</dependency>
```

82.2. URI FORMAT

```
language://languageName[:script][?options]
```

You can refer to an external resource for the script using same notation as supported by the other Languages in Camel.

```
language://languageName:resource:scheme:location][?options]
```

82.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

82.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

82.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

82.4. COMPONENT OPTIONS

The Language component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

82.5. ENDPOINT OPTIONS

The Language endpoint is configured using URI syntax:

```
language:languageName:resourceUri
```

with the following path and query parameters:

82.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
languageName (producer)	**Required** Sets the name of the language to use. Enum values: • bean • constant • exchangeProperty • file • groovy • header • javascript • jsonpath • mvel • ognl • ref • simple • spel • sql • terser • tokenize • xpath • xquery • xtokenize		String
resourceUri (producer)	Path to the resource, or a reference to lookup a bean in the Registry to use as the resource.		String

82.5.2. Query Parameters (7 parameters)

Name	Description	Default	Type

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so impose a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
binary (producer)	Whether the script is binary content or text content. By default the script is read as text content (eg java.lang.String).	false	boolean
cacheScript (producer)	Whether to cache the compiled script and reuse Notice reusing the script can cause side effects from processing one Camel org.apache.camel.Exchange to the next org.apache.camel.Exchange.	false	boolean
contentCache (producer)	Sets whether to use resource content cache or not.	true	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
script (producer)	Sets the script to execute.		String
transform (producer)	Whether or not the result of the script should be used as message body. This options is default true.	true	boolean

82.6. MESSAGE HEADERS

The following message headers can be used to affect the behavior of the component

Header	Description
CamelLanguageScript	The script to execute provided in the header. Takes precedence over script configured on the endpoint.

82.7. EXAMPLES

For example you can use the Simple language to Message Translator a message.

You can also provide the script as a header as shown below. Here we use XPath language to extract the text from the <foo> tag.

```
Object out = producer.requestBodyAndHeader("language:xpath", "<foo>Hello World</foo>",
Exchange.LANGUAGE_SCRIPT, "/foo/text()");
assertEquals("Hello World", out);
```

82.8. LOADING SCRIPTS FROM RESOURCES

You can specify a resource uri for a script to load in either the endpoint uri, or in the **Exchange.LANGUAGE_SCRIPT** header. The uri must start with one of the following schemes: file:, classpath:, or http:

By default the script is loaded once and cached. However you can disable the **contentCache** option and have the script loaded on each evaluation. For example if the file myscript.txt is changed on disk, then the updated script is used:

You can refer to the resource similar to the other Languages in Camel by prefixing with "resource:" as shown below.

82.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.language.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.language.enabled	Whether to enable auto configuration of the language component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.language.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 83. LDAP

Since Camel 1.5

Only producer is supported

The LDAP component allows you to perform searches in LDAP servers using filters as the message payload. This component uses standard JNDI (**javax.naming** package) to access the server.

83.1. DEPENDENCIES

When using **ldap** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-ldap-starter</artifactId>
</dependency>
```

83.2. URI FORMAT

```
ldap:ldapServerBean[?options]
```

The **ldapServerBean** in the URI refers to a DirContext bean in the registry. The LDAP component only supports producer endpoints, which means that an **ldap** URI cannot appear in the **from** at the start of a route.

83.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

83.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

83.3.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

83.4. COMPONENT OPTIONS

The LDAP component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

83.5. ENDPOINT OPTIONS

The LDAP endpoint is configured using URI syntax:

```
ldap:dirContextName
```

with the following path and query parameters:

83.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type

Name	Description	Default	Type
dirContextName (producer)	**Required** Name of either a javax.naming.directory.DirContext, or java.util.Hashtable, or Map bean to lookup in the registry. If the bean is either a Hashtable or Map then a new javax.naming.directory.DirContext instance is created for each use. If the bean is a javax.naming.directory.DirContext then the bean is used as given. The latter may not be possible in all situations where the javax.naming.directory.DirContext must not be shared, and in those situations it can be better to use java.util.Hashtable or Map instead.		String

83.5.2. Query Parameters (5 parameters)

Name	Description	Default	Type
base (producer)	The base DN for searches.	ou=system	String
pageSize (producer)	When specified the ldap module uses paging to retrieve all results (most LDAP Servers throw an exception when trying to retrieve more than 1000 entries in one query). To be able to use this a LdapContext (subclass of DirContext) has to be passed in as ldapServerBean (otherwise an exception is thrown).		Integer
returnedAttributes (producer)	Comma-separated list of attributes that should be set in each entry of the result.		String
scope (producer)	Specifies how deeply to search the tree of entries, starting at the base DN. Enum values: • object • onelevel • subtree	subtree	String

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

83.6. RESULT

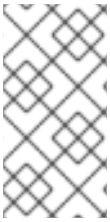
The result is returned to Out body as a **List<javax.naming.directory.SearchResult>** object.

83.7. DIRCONTEXT

The URI, **ldap:ldapserver**, references a Spring bean with the ID, **ldapserver**. The **ldapserver** bean may be defined as follows:

```
<bean id="ldapserver" class="javax.naming.directory.InitialDirContext" scope="prototype">
  <constructor-arg>
    <props>
      <prop key="java.naming.factory.initial">com.sun.jndi.ldap.LdapCtxFactory</prop>
      <prop key="java.naming.provider.url">ldap://localhost:10389</prop>
      <prop key="java.naming.security.authentication">none</prop>
    </props>
  </constructor-arg>
</bean>
```

The preceding example declares a regular Sun based LDAP **DirContext** that connects anonymously to a locally hosted LDAP server.



NOTE

DirContext objects are **not** required to support concurrency by contract. It is therefore important that the directory context is declared with the setting, **scope="prototype"**, in the **bean** definition or that the context supports concurrency. In the Spring framework, **prototype** scoped objects are instantiated each time they are looked up.

83.8. SECURITY CONCERNS RELATED TO LDAP INJECTION

NOTE

The camel-ldap component uses the message body as filter the search results. Therefore, the message body should be protected from LDAP injection. To assist with this, you can use **org.apache.camel.component.ldap.LdapHelper** utility class that has method(s) to escape string values to be LDAP injection safe.

See LDAP Injection for more information.

83.9. SAMPLES

Following on from the Spring configuration above, the code sample below sends an LDAP request to filter search a group for a member. The Common Name is then extracted from the response.

```
ProducerTemplate template = exchange.getContext().createProducerTemplate();

Collection<SearchResult> results = template.requestBody(
    "ldap:ldapserver?base=ou=mygroup,ou=groups,ou=system",
    "(member=uid=huntc,ou=users,ou=system)", Collection.class);

if (results.size() > 0) {
  // Extract what we need from the device's profile

  Iterator resultIter = results.iterator();
  SearchResult searchResult = (SearchResult) resultIter.next();
  Attributes attributes = searchResult.getAttributes();
  Attribute deviceCNAttr = attributes.get("cn");
  String deviceCN = (String) deviceCNAttr.get();
  // ...
}
```

If no specific filter is required - for example, you just need to look up a single entry - specify a wildcard filter expression. For example, if the LDAP entry has a Common Name, use a filter expression like:

```
(cn=*)
```

83.9.1. Binding using credentials

A Camel end user donated this sample code he used to bind to the ldap server using credentials.

```
Properties props = new Properties();
props.setProperty(Context.INITIAL_CONTEXT_FACTORY, "com.sun.jndi.ldap.LdapCtxFactory");
props.setProperty(Context.PROVIDER_URL, "ldap://localhost:389");
props.setProperty(Context.URL_PKG_PREFIXES, "com.sun.jndi.url");
props.setProperty(Context.REFERRAL, "ignore");
props.setProperty(Context.SECURITY_AUTHENTICATION, "simple");
props.setProperty(Context.SECURITY_PRINCIPAL, "cn=Manager");
props.setProperty(Context.SECURITY_CREDENTIALS, "secret");

DefaultRegistry reg = new DefaultRegistry();
reg.bind("myldap", new InitialLdapContext(props, null));

CamelContext context = new DefaultCamelContext(reg);
context.addRoutes(
```

```
    new RouteBuilder() {
        @Override
        public void configure() throws Exception {
            from("direct:start").to("ldap:myldap?base=ou=test");
        }
    }
);
context.start();

ProducerTemplate template = context.createProducerTemplate();

Endpoint endpoint = context.getEndpoint("direct:start");
Exchange exchange = endpoint.createExchange();
exchange.getIn().setBody("(uid=test)");
Exchange out = template.send(endpoint, exchange);

Collection<SearchResult> data = out.getMessage().getBody(Collection.class);
assert data != null;
assert !data.isEmpty();

System.out.println(out.getMessage().getBody());

context.stop();
```

83.10. CONFIGURING SSL

All that is required is to create a custom socket factory and reference it in the InitialDirContext bean - see below sample.

SSL Configuration

```
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:context="http://www.springframework.org/schema/context"
    xsi:schemaLocation="http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
    http://www.springframework.org/schema/context
http://www.springframework.org/schema/context/spring-context.xsd
    http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-spring.xsd">

    <sslContextParameters xmlns="http://camel.apache.org/schema/spring"
id="sslContextParameters" >
        <keyManagers keyPassword="{{keystore.pwd}}">
            <keyStore resource="{{keystore.url}}" password="{{keystore.pwd}}"/>
        </keyManagers>
    </sslContextParameters>

    <bean id="customSocketFactory" class="com.example.ldap.CustomSocketFactory">
        <constructor-arg index="0" ref="sslContextParameters"/>
    </bean>

    <bean id="ldapserver" class="javax.naming.directory.InitialDirContext" scope="prototype">
        <constructor-arg>
            <props>
```

```
            <prop key="java.naming.factory.initial">com.sun.jndi.ldap.LdapCtxFactory</prop>
            <prop key="java.naming.provider.url">ldaps://127.0.0.1:10636</prop>
            <prop key="java.naming.security.protocol">ssl</prop>
            <prop key="java.naming.security.authentication">none</prop>
            <prop
key="java.naming.ldap.factory.socket">com.example.ldap.CustomSocketFactory</prop>
        </props>
    </constructor-arg>
  </bean>
</beans>
```

Custom Socket Factory

```
package com.example.ldap;

import java.io.IOException;
import java.net.InetAddress;
import java.net.Socket;
import java.security.KeyStore;

import javax.net.SocketFactory;
import javax.net.ssl.SSLContext;
import javax.net.ssl.SSLSocketFactory;
import javax.net.ssl.TrustManagerFactory;

import org.apache.camel.support.jsse.SSLContextParameters;

/**
 * The CustomSocketFactory. Loads the KeyStore and creates an instance of SSLSocketFactory
 */
public class CustomSocketFactory extends SSLSocketFactory {

    private static SSLSocketFactory socketFactory;

    /**
     * Called by the getDefault() method.
     */
    public CustomSocketFactory() {
    }

    /**
     * Called by Spring Boot DI to initialize an instance of SocketFactory
     */
    public CustomSocketFactory(SSLContextParameters sslContextParameters) {
        try {
            KeyStore keyStore =
sslContextParameters.getKeyManagers().getKeyStore().createKeyStore();
            TrustManagerFactory tmf = TrustManagerFactory.getInstance("SunX509");
            tmf.init(keyStore);
            SSLContext ctx = SSLContext.getInstance("TLS");
            ctx.init(null, tmf.getTrustManagers(), null);
            socketFactory = ctx.getSocketFactory();
        } catch (Exception ex) {
            ex.printStackTrace(System.err);
        }
    }
```

```
    /**
     * Getter for the SocketFactory
     */
    public static SocketFactory getDefault() {
        return new CustomSocketFactory();
    }

    @Override
    public String[] getDefaultCipherSuites() {
        return socketFactory.getDefaultCipherSuites();
    }

    @Override
    public String[] getSupportedCipherSuites() {
        return socketFactory.getSupportedCipherSuites();
    }

    @Override
    public Socket createSocket(Socket socket, String string, int i, boolean bln) throws IOException {
        return socketFactory.createSocket(socket, string, i, bln);
    }

    @Override
    public Socket createSocket(String string, int i) throws IOException {
        return socketFactory.createSocket(string, i);
    }

    @Override
    public Socket createSocket(String string, int i, InetAddress ia, int i1) throws IOException {
        return socketFactory.createSocket(string, i, ia, i1);
    }

    @Override
    public Socket createSocket(InetAddress ia, int i) throws IOException {
        return socketFactory.createSocket(ia, i);
    }

    @Override
    public Socket createSocket(InetAddress ia, int i, InetAddress ia1, int i1) throws IOException {
        return socketFactory.createSocket(ia, i, ia1, i1);
    }
}
```

83.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type

Name	Description	Default	Type
camel.component.ldap.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.ldap.enabled	Whether to enable auto configuration of the ldap component. This is enabled by default.		Boolean
camel.component.ldap.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 84. LOG

Only producer is supported

The Log component logs message exchanges to the underlying logging mechanism.

Camel uses SLF4J which allows you to configure logging via, among others:

- Log4j
- Logback
- Java Util Logging

84.1. DEPENDENCIES

When using **log** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-log-starter</artifactId>
</dependency>
```

84.2. URI FORMAT

```
log:loggingCategory[?options]
```

Where **loggingCategory** is the name of the logging category to use. You can append query options to the URI in the following format,

?option=value&option=value&…

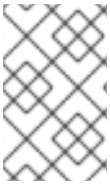
NOTE

Using Logger instance from the Registry
If there's single instance of **org.slf4j.Logger** found in the Registry, the **loggingCategory** is no longer used to create logger instance. The registered instance is used instead. Also it is possible to reference particular **Logger** instance using **?logger=#myLogger** URI parameter. Eventually, if there's no registered and URI **logger** parameter, the logger instance is created using **loggingCategory**.

For example, a log endpoint typically specifies the logging level using the **level** option, as follows:

```
log:org.apache.camel.example?level=DEBUG
```

The default logger logs every exchange (*regular logging*). But Camel also ships with the **Throughput** logger, which is used whenever the **groupSize** option is specified.



NOTE

Also a log in the DSL
There is also a **log** directly in the DSL, but it has a different purpose. Its meant for lightweight and human logs. See more details at LogEIP.

84.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

84.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

84.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

84.4. COMPONENT OPTIONS

The Log component supports 3 options, which are listed below.

Name	Description	Default	Type

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
exchangeFormatter (advanced)	**Autowired** Sets a custom ExchangeFormatter to convert the Exchange to a String suitable for logging. If not specified, we default to DefaultExchangeFormatter.		ExchangeFormatter

84.5. ENDPOINT OPTIONS

The Log endpoint is configured using URI syntax:

```
log:loggerName
```

with the following path and query parameters:

84.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
loggerName (producer)	**Required** Name of the logging category to use.		String

84.5.2. Query Parameters (27 parameters)

Name	Description	Default	Type
groupActiveOnly (producer)	If true, will hide stats when no new messages have been received for a time interval, if false, show stats regardless of message traffic.	true	Boolean
groupDelay (producer)	Set the initial delay for stats (in millis).		Long
groupInterval (producer)	If specified will group message stats by this time interval (in millis).		Long
groupSize (producer)	An integer that specifies a group size for throughput logging.		Integer
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
level (producer)	Logging level to use. The default value is INFO. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	INFO	String
logMask (producer)	If true, mask sensitive information like password or passphrase in the log.		Boolean
marker (producer)	An optional Marker name to use.		String
exchangeFormatter (advanced)	To use a custom exchange formatter.		ExchangeFormatter

Name	Description	Default	Type
maxChars (formatting)	Limits the number of characters logged per line.	10000	int
multiline (formatting)	If enabled then each information is outputted on a newline.	false	boolean
showAll (formatting)	Quick option for turning all options on. (multiline, maxChars has to be manually set if to be used).	false	boolean
showAllProperties (formatting)	Show all of the exchange properties (both internal and custom).	false	boolean
showBody (formatting)	Show the message body.	true	boolean
showBodyType (formatting)	Show the body Java type.	true	boolean
showCaughtException (formatting)	If the exchange has a caught exception, show the exception message (no stack trace). A caught exception is stored as a property on the exchange (using the key org.apache.camel.Exchange#EXCEPTION_CAUGHT) and for instance a doCatch can catch exceptions.	false	boolean
showException (formatting)	If the exchange has an exception, show the exception message (no stacktrace).	false	boolean
showExchangeId (formatting)	Show the unique exchange ID.	false	boolean
showExchangePattern (formatting)	Shows the Message Exchange Pattern (or MEP for short).	true	boolean
showFiles (formatting)	If enabled Camel will output files.	false	boolean
showFuture (formatting)	If enabled Camel will on Future objects wait for it to complete to obtain the payload to be logged.	false	boolean
showHeaders (formatting)	Show the message headers.	false	boolean
showProperties (formatting)	Show the exchange properties (only custom). Use showAllProperties to show both internal and custom properties.	false	boolean

Name	Description	Default	Type
showStackTrace (formatting)	Show the stack trace, if an exchange has an exception. Only effective if one of showAll, showException or showCaughtException are enabled.	false	boolean
showStreams (formatting)	Whether Camel should show stream bodies or not (eg such as java.io.InputStream). Beware if you enable this option then you may not be able later to access the message body as the stream have already been read by this logger. To remedy this you will have to use Stream Caching.	false	boolean
skipBodyLineSeparator (formatting)	Whether to skip line separators when logging the message body. This allows to log the message body in one line, setting this option to false will preserve any line separators from the body, which then will log the body as is.	true	boolean
style (formatting)	Sets the outputs style to use. Enum values: • Default • Tab • Fixed	Default	OutputStyle

84.6. REGULAR LOGGER SAMPLE

In the route below we log the incoming orders at **DEBUG** level before the order is processed:

```
from("activemq:orders").to("log:com.mycompany.order?level=DEBUG").to("bean:processOrder");
```

Or using Spring XML to define the route:

```
<route>
  <from uri="activemq:orders"/>
  <to uri="log:com.mycompany.order?level=DEBUG"/>
  <to uri="bean:processOrder"/>
</route>
```

84.7. REGULAR LOGGER WITH FORMATTER SAMPLE

In the route below we log the incoming orders at **INFO** level before the order is processed.

```
from("activemq:orders").
    to("log:com.mycompany.order?showAll=true&multiline=true").to("bean:processOrder");
```

84.8. THROUGHPUT LOGGER WITH GROUPSIZE SAMPLE

In the route below we log the throughput of the incoming orders at **DEBUG** level grouped by 10 messages.

```
from("activemq:orders").
    to("log:com.mycompany.order?level=DEBUG&groupSize=10").to("bean:processOrder");
```

84.9. THROUGHPUT LOGGER WITH GROUPINTERVAL SAMPLE

This route will result in message stats logged every 10s, with an initial 60s delay and stats should be displayed even if there isn't any message traffic.

```
from("activemq:orders").
    to("log:com.mycompany.order?
level=DEBUG&groupInterval=10000&groupDelay=60000&groupActiveOnly=false").to("bean:process
Order");
```

The following will be logged:

```
"Received: 1000 new messages, with total 2000 so far. Last group took: 10000 millis which is: 100
messages per second. average: 100"
```

84.10. MASKING SENSITIVE INFORMATION LIKE PASSWORD

You can enable security masking for logging by setting **logMask** flag to **true**. Note that this option also affects Log EIP.

To enable mask in Java DSL at CamelContext level:

```
camelContext.setLogMask(true);
```

And in XML:

```
<camelContext logMask="true">
```

You can also turn it on|off at endpoint level. To enable mask in Java DSL at endpoint level, add logMask=true option in the URI for the log endpoint:

```
from("direct:start").to("log:foo?logMask=true");
```

And in XML:

```
<route>
  <from uri="direct:foo"/>
  <to uri="log:foo?logMask=true"/>
</route>
```

org.apache.camel.support.processor.DefaultMaskingFormatter is used for the masking by default. If you want to use a custom masking formatter, put it into registry with the name **CamelCustomLogMask**. Note that the masking formatter must implement **org.apache.camel.spi.MaskingFormatter**.

84.11. FULL CUSTOMIZATION OF THE LOGGING OUTPUT

With the options outlined in the section, you can control much of the output of the logger. However, log lines will always follow this structure:

```
Exchange[Id:ID-machine-local-50656-1234567901234-1-2, ExchangePattern:InOut,
Properties:{CamelToEndpoint=log://org.apache.camel.component.log.TEST?showAll=true,
CamelCreatedTimestamp=Thu Mar 28 00:00:00 WET 2013},
Headers:{breadcrumbId=ID-machine-local-50656-1234567901234-1-1}, BodyType:String, Body:Hello
World, Out: null]
```

This format is unsuitable in some cases, perhaps because you need to...

- Filter the headers and properties that are printed, to strike a balance between insight and verbosity.
- Adjust the log message to whatever you deem most readable.
- Tailor log messages for digestion by log mining systems, e.g. Splunk.
- Print specific body types differently.

Whenever you require absolute customization, you can create a class that implements the interface. Within the **format(Exchange)** method you have access to the full Exchange, so you can select and extract the precise information you need, format it in a custom manner and return it. The return value will become the final log message.

You can have the Log component pick up your custom **ExchangeFormatter** in either of two ways:

Explicitly instantiating the LogComponent in your Registry:

```
<bean name="log" class="org.apache.camel.component.log.LogComponent">
  <property name="exchangeFormatter" ref="myCustomFormatter" />
</bean>
```

84.11.1. Convention over configuration

Simply by registering a bean with the name **logFormatter**; the Log Component is intelligent enough to pick it up automatically.

```
<bean name="logFormatter" class="com.xyz.MyCustomExchangeFormatter" />
```

NOTE

The **ExchangeFormatter** gets applied to **all Log endpoints within that Camel Context** If you need different ExchangeFormatters for different endpoints, just instantiate the LogComponent as many times as needed, and use the relevant bean name as the endpoint prefix.

When using a custom log formatter, you can specify parameters in the log uri, which gets configured on the custom log formatter. Though when you do that you should define the "logFormatter" as prototype scoped so its not shared if you have different parameters, for example,

```
<bean name="logFormatter" class="com.xyz.MyCustomExchangeFormatter" scope="prototype"/>
```

And then we can have Camel routes using the log uri with different options:

```
<to uri="log:foo?param1=foo&amp;param2=100"/>

<to uri="log:bar?param1=bar&amp;param2=200"/>
```

84.12. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.log.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.log.enabled	Whether to enable auto configuration of the log component. This is enabled by default.		Boolean
camel.component.log.exchange-formatter	Sets a custom ExchangeFormatter to convert the Exchange to a String suitable for logging. If not specified, we default to DefaultExchangeFormatter. The option is a org.apache.camel.spi.ExchangeFormatter type.		ExchangeFormatter
camel.component.log.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 85. LRA

Since Camel 2.21

The LRA module provides bindings of the Saga EIP with any MicroProfile compatible LRA Coordinator.

85.1. DEPENDENCIES

When using **lra** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-lra-starter</artifactId>
</dependency>
```

85.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.lra.coordinator-context-path	The context path of the LRA coordinator service.		String
camel.lra.coordinator-url	The base URL of the LRA coordinator service (e.g.).		String
camel.lra.enabled	Global option to enable/disable component auto-configuration, default is true.	true	Boolean
camel.lra.local-participant-context-path	The context path of the local participant callback services.		String
camel.lra.local-participant-url	The local URL where the coordinator should send callbacks to (e.g.).		String

CHAPTER 86. MAIL

Both producer and consumer are supported

The Mail component provides access to Email via Spring's Mail support and the underlying JavaMail system.

NOTE

POP3 or IMAP
POP3 has some limitations and end users are encouraged to use IMAP if possible.

NOTE

Using mock-mail for testing
You can use a mock framework for unit testing, which allows you to test without the need for a real mail server. However you should remember to not include the mock-mail when you go into production or other environments where you need to send mails to a real mail server. Just the presence of the mock-javamail.jar on the classpath means that it will kick in and avoid sending the mails.

86.1. DEPENDENCIES

When using **camel-mail** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-mail-starter</artifactId>
</dependency>
```

86.2. URI FORMAT

Mail endpoints can have one of the following URI formats (for the protocols, SMTP, POP3, or IMAP, respectively):

```
smtp://[username@]host[:port][?options]
pop3://[username@]host[:port][?options]
imap://[username@]host[:port][?options]
```

The mail component also supports secure variants of these protocols (layered over SSL). You can enable the secure protocols by adding **s** to the scheme:

```
smtps://[username@]host[:port][?options]
pop3s://[username@]host[:port][?options]
imaps://[username@]host[:port][?options]
```

86.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level

- Endpoint level

86.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

86.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

86.4. COMPONENT OPTIONS

The Mail component supports 43 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
closeFolder (consumer)	Whether the consumer should close the folder after polling. Setting this option to false and having disconnect=false as well, then the consumer keep the folder open between polls.	true	boolean

Name	Description	Default	Type
copyTo (consumer)	After processing a mail message, it can be copied to a mail folder with the given name. You can override this configuration value, with a header with the key copyTo, allowing you to copy messages to folder names configured at runtime.		String
decodeFilename (consumer)	If set to true, the MimeUtility.decodeText method will be used to decode the filename. This is similar to setting JVM system property mail.mime.encodefilename.	false	boolean
delete (consumer)	Deletes the messages after they have been processed. This is done by setting the DELETED flag on the mail message. If false, the SEEN flag is set instead. As of Camel 2.10 you can override this configuration option by setting a header with the key delete to determine if the mail should be deleted or not.	false	boolean
disconnect (consumer)	Whether the consumer should disconnect after polling. If enabled this forces Camel to connect on each poll.	false	boolean
handleFailedMessage (consumer)	If the mail consumer cannot retrieve a given mail message, then this option allows to handle the caused exception by the consumer's error handler. By enable the bridge error handler on the consumer, then the Camel routing error handler can handle the exception instead. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	boolean
mimeDecodeHeaders (consumer)	This option enables transparent MIME decoding and unfolding for mail headers.	false	boolean
moveTo (consumer)	After processing a mail message, it can be moved to a mail folder with the given name. You can override this configuration value, with a header with the key moveTo, allowing you to move messages to folder names configured at runtime.		String
peek (consumer)	Will mark the javax.mail.Message as peeked before processing the mail message. This applies to IMAPMessage messages types only. By using peek the mail will not be eager marked as SEEN on the mail server, which allows us to rollback the mail message if there is an error processing in Camel.	true	boolean

Name	Description	Default	Type
skipFailedMessage (consumer)	If the mail consumer cannot retrieve a given mail message, then this option allows to skip the message and move on to retrieve the next mail message. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	boolean
unseen (consumer)	Whether to limit by unseen mails only.	true	boolean
fetchSize (consumer (advanced))	Sets the maximum number of messages to consume during a poll. This can be used to avoid overloading a mail server, if a mailbox folder contains a lot of messages. Default value of -1 means no fetch size and all messages will be consumed. Setting the value to 0 is a special corner case, where Camel will not consume any messages at all.	-1	int
folderName (consumer (advanced))	The folder to poll.	INBOX	String
mapMailMessage (consumer (advanced))	Specifies whether Camel should map the received mail message to Camel body/headers/attachments. If set to true, the body of the mail message is mapped to the body of the Camel IN message, the mail headers are mapped to IN headers, and the attachments to Camel IN attachment message. If this option is set to false then the IN message contains a raw javax.mail.Message. You can retrieve this raw message by calling exchange.getIn().getBody(javax.mail.Message.class).	true	boolean
bcc (producer)	Sets the BCC email address. Separate multiple email addresses with comma.		String
cc (producer)	Sets the CC email address. Separate multiple email addresses with comma.		String
from (producer)	The from email address.	camel@localhost	String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
replyTo (producer)	The Reply-To recipients (the receivers of the response mail). Separate multiple email addresses with a comma.		String
subject (producer)	The Subject of the message being sent. Note: Setting the subject in the header takes precedence over this option.		String
to (producer)	Sets the To email address. Separate multiple email addresses with comma.		String
javaMailSender (producer (advanced))	To use a custom org.apache.camel.component.mail.JavaMailSender for sending emails.		JavaMailSender
additionalJavaMailProperties (advanced)	Sets additional java mail properties, that will append/override any default properties that is set based on all the other options. This is useful if you need to add some special options but want to keep the others as is.		Properties
alternativeBodyHeader (advanced)	Specifies the key to an IN message header that contains an alternative email body. For example, if you send emails in text/html format and want to provide an alternative mail body for non-HTML email clients, set the alternative mail body with this key as a header.	CamelMailAlternativeBody	String
attachmentsContentTransferEncodingResolver (advanced)	To use a custom AttachmentsContentTransferEncodingResolver to resolve what content-type-encoding to use for attachments.		AttachmentsContentTransferEncodingResolver

Name	Description	Default	Type
authenticator (advanced)	The authenticator for login. If set then the password and username are ignored. Can be used for tokens which can expire and therefore must be read dynamically.		MailAuthenticator
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
configuration (advanced)	Sets the Mail configuration.		MailConfiguration
connectionTimeout (advanced)	The connection timeout in milliseconds.	30000	int
contentType (advanced)	The mail message content type. Use text/html for HTML mails.	text/plain	String
contentTypeResolver (advanced)	Resolver to determine Content-Type for file attachments.		ContentTypeResolver
debugMode (advanced)	Enable debug mode on the underlying mail framework. The SUN Mail framework logs the debug messages to System.out by default.	false	boolean
ignoreUnsupportedCharset (advanced)	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	boolean
ignoreUriScheme (advanced)	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	boolean
javaMailProperties (advanced)	Sets the java mail options. Will clear any default properties and only use the properties provided for this method.		Properties

Name	Description	Default	Type
session (advanced)	Specifies the mail session that camel should use for all mail interactions. Useful in scenarios where mail sessions are created and managed by some other resource, such as a JavaEE container. When using a custom mail session, then the hostname and port from the mail session will be used (if configured on the session).		Session
useInlineAttachments (advanced)	Whether to use disposition inline or attachment.	false	boolean
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
password (security)	The password for login. See also setAuthenticator(MailAuthenticator).		String
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
username (security)	The username for login. See also setAuthenticator(MailAuthenticator).		String

86.5. ENDPOINT OPTIONS

The Mail endpoint is configured using URI syntax:

```
imap:host:port
```

with the following path and query parameters:

86.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
host (common)	**Required** The mail server host name.		String
port (common)	The port number of the mail server.		int

86.5.2. Query Parameters (66 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
closeFolder (consumer)	Whether the consumer should close the folder after polling. Setting this option to false and having disconnect=false as well, then the consumer keep the folder open between polls.	true	boolean
copyTo (consumer)	After processing a mail message, it can be copied to a mail folder with the given name. You can override this configuration value, with a header with the key copyTo, allowing you to copy messages to folder names configured at runtime.		String
decodeFilename (consumer)	If set to true, the MimeUtility.decodeText method will be used to decode the filename. This is similar to setting JVM system property mail.mime.encodefilename.	false	boolean
delete (consumer)	Deletes the messages after they have been processed. This is done by setting the DELETED flag on the mail message. If false, the SEEN flag is set instead. As of Camel 2.10 you can override this configuration option by setting a header with the key delete to determine if the mail should be deleted or not.	false	boolean
disconnect (consumer)	Whether the consumer should disconnect after polling. If enabled this forces Camel to connect on each poll.	false	boolean
handleFailedMessage (consumer)	If the mail consumer cannot retrieve a given mail message, then this option allows to handle the caused exception by the consumer's error handler. By enable the bridge error handler on the consumer, then the Camel routing error handler can handle the exception instead. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	boolean

Name	Description	Default	Type
maxMessagesPerPoll (consumer)	Specifies the maximum number of messages to gather per poll. By default, no maximum is set. Can be used to set a limit of e.g. 1000 to avoid downloading thousands of files when the server starts up. Set a value of 0 or negative to disable this option.		int
mimeDecodeHeaders (consumer)	This option enables transparent MIME decoding and unfolding for mail headers.	false	boolean
moveTo (consumer)	After processing a mail message, it can be moved to a mail folder with the given name. You can override this configuration value, with a header with the key moveTo, allowing you to move messages to folder names configured at runtime.		String
peek (consumer)	Will mark the javax.mail.Message as peeked before processing the mail message. This applies to IMAPMessage messages types only. By using peek the mail will not be eager marked as SEEN on the mail server, which allows us to rollback the mail message if there is an error processing in Camel.	true	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
skipFailedMessage (consumer)	If the mail consumer cannot retrieve a given mail message, then this option allows to skip the message and move on to retrieve the next mail message. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	boolean
unseen (consumer)	Whether to limit by unseen mails only.	true	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
fetchSize (consumer (advanced))	Sets the maximum number of messages to consume during a poll. This can be used to avoid overloading a mail server, if a mailbox folder contains a lot of messages. Default value of -1 means no fetch size and all messages will be consumed. Setting the value to 0 is a special corner case, where Camel will not consume any messages at all.	-1	int
folderName (consumer (advanced))	The folder to poll.	INBOX	String
mailUidGenerator (consumer (advanced))	A pluggable MailUidGenerator that allows to use custom logic to generate UUID of the mail message.		MailUidGenerator
mapMailMessage (consumer (advanced))	Specifies whether Camel should map the received mail message to Camel body/headers/attachments. If set to true, the body of the mail message is mapped to the body of the Camel IN message, the mail headers are mapped to IN headers, and the attachments to Camel IN attachment message. If this option is set to false then the IN message contains a raw javax.mail.Message. You can retrieve this raw message by calling exchange.getIn().getBody(javax.mail.Message.class).	true	boolean
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
postProcessAction (consumer (advanced))	Refers to an MailBoxPostProcessAction for doing post processing tasks on the mailbox once the normal processing ended.		MailBoxPostProcessAction

Name	Description	Default	Type
bcc (producer)	Sets the BCC email address. Separate multiple email addresses with comma.		String
cc (producer)	Sets the CC email address. Separate multiple email addresses with comma.		String
from (producer)	The from email address.	camel@localhost	String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
replyTo (producer)	The Reply-To recipients (the receivers of the response mail). Separate multiple email addresses with a comma.		String
subject (producer)	The Subject of the message being sent. Note: Setting the subject in the header takes precedence over this option.		String
to (producer)	Sets the To email address. Separate multiple email addresses with comma.		String
javaMailSender (producer (advanced))	To use a custom org.apache.camel.component.mail.JavaMailSender for sending emails.		JavaMailSender
additionalJavaMailProperties (advanced)	Sets additional java mail properties, that will append/override any default properties that is set based on all the other options. This is useful if you need to add some special options but want to keep the others as is.		Properties

Name	Description	Default	Type
alternativeBodyHeader (advanced)	Specifies the key to an IN message header that contains an alternative email body. For example, if you send emails in text/html format and want to provide an alternative mail body for non-HTML email clients, set the alternative mail body with this key as a header.	CamelMailAlternativeBody	String
attachmentsContentTransferEncodingResolver (advanced)	To use a custom AttachmentsContentTransferEncodingResolver to resolve what content-type-encoding to use for attachments.		AttachmentsContentTransferEncodingResolver
authenticator (advanced)	The authenticator for login. If set then the password and username are ignored. Can be used for tokens which can expire and therefore must be read dynamically.		MailAuthenticator
binding (advanced)	Sets the binding used to convert from a Camel message to and from a Mail message.		MailBinding
connectionTimeout (advanced)	The connection timeout in milliseconds.	30000	int
contentType (advanced)	The mail message content type. Use text/html for HTML mails.	text/plain	String
contentTypeResolver (advanced)	Resolver to determine Content-Type for file attachments.		ContentTypeResolver
debugMode (advanced)	Enable debug mode on the underlying mail framework. The SUN Mail framework logs the debug messages to System.out by default.	false	boolean
headerFilterStrategy (advanced)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers.		HeaderFilterStrategy
ignoreUnsupportedCharset (advanced)	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	boolean

Name	Description	Default	Type
ignoreUriScheme (advanced)	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	boolean
javaMailProperties (advanced)	Sets the java mail options. Will clear any default properties and only use the properties provided for this method.		Properties
session (advanced)	Specifies the mail session that camel should use for all mail interactions. Useful in scenarios where mail sessions are created and managed by some other resource, such as a JavaEE container. When using a custom mail session, then the hostname and port from the mail session will be used (if configured on the session).		Session
useInlineAttachments (advanced)	Whether to use disposition inline or attachment.	false	boolean
idempotentRepository (filter)	A pluggable repository org.apache.camel.spi.IdempotentRepository which allows to cluster consuming from the same mailbox, and let the repository coordinate whether a mail message is valid for the consumer to process. By default no repository is in use.		IdempotentRepository
idempotentRepositoryRemoveOnCommit (filter)	When using idempotent repository, then when the mail message has been successfully processed and is committed, should the message id be removed from the idempotent repository (default) or be kept in the repository. By default its assumed the message id is unique and has no value to be kept in the repository, because the mail message will be marked as seen/moved or deleted to prevent it from being consumed again. And therefore having the message id stored in the idempotent repository has little value. However this option allows to store the message id, for whatever reason you may have.	true	boolean
searchTerm (filter)	Refers to a javax.mail.search.SearchTerm which allows to filter mails based on search criteria such as subject, body, from, sent after a certain date etc.		SearchTerm
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int

Name	Description	Default	Type
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	60000	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object

Name	Description	Default	Type
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
password (security)	The password for login. See also setAuthenticator(MailAuthenticator).		String
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters
username (security)	The username for login. See also setAuthenticator(MailAuthenticator).		String
sortTerm (sort)	Sorting order for messages. Only natively supported for IMAP. Emulated to some degree when using POP3 or when IMAP server does not have the SORT capability.		SortTerm[]

86.5.3. Sample endpoints

Typically, you specify a URI with login credentials as follows (taking SMTP as an example):

```
smtp://[username@]host[:port][?password=somepwd]
```

Alternatively, it is possible to specify both the user name and the password as query options:

```
smtp://host[:port]?password=somepwd&username=someuser
```

For example:

```
smtp://mycompany.mailserver:30?password=tiger&username=scott
```

86.5.4. Component alias names

- IMAP
- IMAPs
- POP3s
- SMTP
- SMTPs

86.5.5. Default ports

Default port numbers are supported. If the port number is omitted, Camel determines the port number to use based on the protocol.

Protocol	Default Port Number
SMTP	**25**
SMTPS	**465**
POP3	**110**
POP3S	**995**
IMAP	**143**
IMAPS	**993**

86.6. SSL SUPPORT

The underlying mail framework is responsible for providing SSL support. You may either configure SSL/TLS support by completely specifying the necessary Java Mail API configuration options, or you may provide a configured SSLContextParameters through the component or endpoint configuration.

86.6.1. Using the JSSE Configuration Utility

The mail component supports SSL/TLS configuration through the Camel JSSE Configuration Utility. This utility greatly decreases the amount of component specific code you need to write and is

configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the mail component.

Programmatic configuration of the endpoint

```
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/truststore.jks");
ksp.setPassword("keystorePassword");
TrustManagersParameters tmp = new TrustManagersParameters();
tmp.setKeyStore(ksp);
SSLContextParameters scp = new SSLContextParameters();
scp.setTrustManagers(tmp);
Registry registry = ...
registry.bind("sslContextParameters", scp);
...
from(...)
    .to("smtps://smtp.google.com?
username=user@gmail.com&password=password&sslContextParameters=#sslContextParameters");
```

Spring DSL based configuration of endpoint

```
...
<camel:sslContextParameters id="sslContextParameters">
  <camel:trustManagers>
    <camel:keyStore resource="/users/home/server/truststore.jks" password="keystorePassword"/>
  </camel:trustManagers>
</camel:sslContextParameters>...
...
<to uri="smtps://smtp.google.com?
username=user@gmail.com&password=password&sslContextParameters=#sslContextParameters"/
>...
```

86.6.2. Configuring JavaMail Directly

Camel uses Jakarta JavaMail, which only trusts certificates issued by well known Certificate Authorities (the default JVM trust configuration). If you issue your own certificates, you have to import the CA certificates into the JVM's Java trust/key store files, override the default JVM trust/key store files (see **SSLNOTES.txt** in JavaMail for details).

86.7. MAIL MESSAGE CONTENT

Camel uses the message exchange's IN body as the MimeMessage text content. The body is converted to String.class.

Camel copies all of the exchange's IN headers to the MimeMessage headers.

The subject of the MimeMessage can be configured using a header property on the IN message. The code below demonstrates this:

The same applies for other MimeMessage headers such as recipients, so you can use a header property as To:

When using the MailProducer the send the mail to server, you should be able to get the message id of the MimeMessage with the key CamelMailMessageId from the Camel message header.

86.8. HEADERS TAKE PRECEDENCE OVER PRE-CONFIGURED RECIPIENTS

The recipients specified in the message headers always take precedence over recipients pre-configured in the endpoint URI. The idea is that if you provide any recipients in the message headers, that is what you get. The recipients pre-configured in the endpoint URI are treated as a fallback.

In the sample code below, the email message is sent to **davsclaus@apache.org**, because it takes precedence over the pre-configured recipient, **info@mycompany.com**. Any **CC** and **BCC** settings in the endpoint URI are also ignored and those recipients will not receive any mail. The choice between headers and pre-configured settings is all or nothing: the mail component *either* takes the recipients exclusively from the headers or exclusively from the pre-configured settings. It is not possible to mix and match headers and pre-configured settings.

```
Map<String, Object> headers = new HashMap<String, Object>();
headers.put("to", "davsclaus@apache.org");

template.sendBodyAndHeaders("smtp://admin@localhost?to=info@mycompany.com", "Hello World",
headers);
```

86.9. MULTIPLE RECIPIENTS FOR EASIER CONFIGURATION

It is possible to set multiple recipients using a comma-separated or a semicolon-separated list. This applies both to header settings and to settings in an endpoint URI. For example:

```
Map<String, Object> headers = new HashMap<String, Object>();
headers.put("to", "davsclaus@apache.org ; jstrachan@apache.org ; ningjiang@apache.org");
```

The preceding example uses a semicolon, **;**, as the separator character.

86.10. SETTING SENDER NAME AND EMAIL

You can specify recipients in the format, **name <email>**, to include both the name and the email address of the recipient.

For example, you define the following headers on the a Message:

```
Map headers = new HashMap();
map.put("To", "Claus Ibsen <davsclaus@apache.org>");
map.put("From", "James Strachan <jstrachan@apache.org>");
map.put("Subject", "Camel is cool");
```

86.11. JAVAMAIL API (EX SUN JAVAMAIL)

JavaMail API is used under the hood for consuming and producing mails. We encourage end-users to consult these references when using either POP3 or IMAP protocol. Note particularly that POP3 has a much more limited set of features than IMAP.

- JavaMail POP3 API
- JavaMail IMAP API
- And generally about the MAIL Flags

86.12. SAMPLES

We start with a simple route that sends the messages received from a JMS queue as emails. The email account is the **admin** account on **mymailserver.com**.

```
from("jms://queue:subscription").to("smtp://admin@mymailserver.com?password=secret");
```

In the next sample, we poll a mailbox for new emails once every minute.

```
from("imap://admin@mymailserver.com?password=secret&unseen=true&delay=60000")
    .to("seda://mails");
```

86.13. SENDING MAIL WITH ATTACHMENT SAMPLE

NOTE

Attachments are not support by all Camel components
The *Attachments API* is based on the Java Activation Framework and is generally only used by the Mail API. Since many of the other Camel components do not support attachments, the attachments could potentially be lost as they propagate along the route. The rule of thumb, therefore, is to add attachments just before sending a message to the mail endpoint.

The mail component supports attachments. In the sample below, we send a mail message containing a plain text message with a logo file attachment.

86.14. SSL SAMPLE

In this sample, we want to poll our Google mail inbox for mails. To download mail onto a local mail client, Google mail requires you to enable and configure SSL. This is done by logging into your Google mail account and changing your settings to allow IMAP access. Google have extensive documentation on how to do this.

```
from("imaps://imap.gmail.com?
username=YOUR_USERNAME@gmail.com&password=YOUR_PASSWORD"
    + "&delete=false&unseen=true&delay=60000").to("log:newmail");
```

The preceding route polls the Google mail inbox for new mails once every minute and logs the received messages to the **newmail** logger category.
Running the sample with **DEBUG** logging enabled, we can monitor the progress in the logs:

```
2008-05-08 06:32:09,640 DEBUG MailConsumer - Connecting to MailStore
imaps//imap.gmail.com:993 (SSL enabled), folder=INBOX
2008-05-08 06:32:11,203 DEBUG MailConsumer - Polling mailfolder: imaps//imap.gmail.com:993
(SSL enabled), folder=INBOX
2008-05-08 06:32:11,640 DEBUG MailConsumer - Fetching 1 messages. Total 1 messages.
2008-05-08 06:32:12,171 DEBUG MailConsumer - Processing message: messageNumber=[332],
from=[James Bond <007@mi5.co.uk>], to=YOUR_USERNAME@gmail.com], subject=[...
2008-05-08 06:32:12,187 INFO  newmail - Exchange[MailMessage: messageNumber=[332], from=
[James Bond <007@mi5.co.uk>], to=YOUR_USERNAME@gmail.com], subject=[...
```

86.15. CONSUMING MAILS WITH ATTACHMENT SAMPLE

In this sample we poll a mailbox and store all attachments from the mails as files. First, we define a route to poll the mailbox. As this sample is based on google mail, it uses the same route as shown in the SSL sample:

```
from("imaps://imap.gmail.com?
username=YOUR_USERNAME@gmail.com&password=YOUR_PASSWORD"
    + "&delete=false&unseen=true&delay=60000").process(new MyMailProcessor());
```

Instead of logging the mail we use a processor where we can process the mail from java code:

```
public void process(Exchange exchange) throws Exception {
    // the API is a bit clunky so we need to loop
    AttachmentMessage attachmentMessage = exchange.getMessage(AttachmentMessage.class);
    Map<String, DataHandler> attachments = attachmentMessage.getAttachments();
    if (attachments.size() > 0) {
        for (String name : attachments.keySet()) {
            DataHandler dh = attachments.get(name);
            // get the file name
            String filename = dh.getName();

            // get the content and convert it to byte[]
            byte[] data = exchange.getContext().getTypeConverter()
                            .convertTo(byte[].class, dh.getInputStream());

            // write the data to a file
            FileOutputStream out = new FileOutputStream(filename);
            out.write(data);
            out.flush();
            out.close();
        }
    }
}
```

As you can see the API to handle attachments is a bit clunky but it's there so you can get the **javax.activation.DataHandler** so you can handle the attachments using standard API.

86.16. HOW TO SPLIT A MAIL MESSAGE WITH ATTACHMENTS

In this example we consume mail messages which may have a number of attachments. What we want to do is to use the Splitter EIP per individual attachment, to process the attachments separately. For example if the mail message has 5 attachments, we want the Splitter to process five messages, each having a single attachment. To do this we need to provide a custom Expression to the Splitter where we provide a List<Message> that contains the five messages with the single attachment.

The code is provided out of the box in Camel 2.10 onwards in the **camel-mail** component. The code is in the class: **org.apache.camel.component.mail.SplitAttachmentsExpression**, which you can find in the source code here.

In the Camel route you then need to use this Expression in the route as shown below:

If you use XML DSL then you need to declare a method call expression in the Splitter as shown below

```
<split>
  <method beanType="org.apache.camel.component.mail.SplitAttachmentsExpression"/>
  <to uri="mock:split"/>
</split>
```

You can also split the attachments as byte[] to be stored as the message body. This is done by creating the expression with boolean true

```
SplitAttachmentsExpression split = SplitAttachmentsExpression(true);
```

And then use the expression with the splitter EIP.

86.17. USING CUSTOM SEARCHTERM

You can configure a **searchTerm** on the **MailEndpoint** which allows you to filter out unwanted mails.

For example to filter mails to contain Camel in either Subject or Text you can do as follows:

```
<route>
  <from uri="imaps://mymailseerver?
username=foo&password=secret&searchTerm.subjectOrBody=Camel"/>
  <to uri="bean:myBean"/>
</route>
```

Notice we use the **"searchTerm.subjectOrBody"** as parameter key to indicate that we want to search on mail subject or body, to contain the word "Camel".
The class **org.apache.camel.component.mail.SimpleSearchTerm** has a number of options you can configure:

Or to get the new unseen emails going 24 hours back in time you can do. Notice the "now-24h" syntax. See the table below for more details.

```
<route>
  <from uri="imaps://mymailseerver?
username=foo&password=secret&searchTerm.fromSentDate=now-24h"/>
  <to uri="bean:myBean"/>
</route>
```

You can have multiple searchTerm in the endpoint uri configuration. They would then be combined together using AND operator, eg so both conditions must match. For example to get the last unseen emails going back 24 hours which has Camel in the mail subject you can do:

```
<route>
  <from uri="imaps://mymailseerver?
username=foo&password=secret&searchTerm.subject=Camel&searchTerm.fromSentDate=now-
24h"/>
  <to uri="bean:myBean"/>
</route>
```

The **SimpleSearchTerm** is designed to be easily configurable from a POJO, so you can also configure it using a <bean> style in XML

```
<bean id="mySearchTerm" class="org.apache.camel.component.mail.SimpleSearchTerm">
```

```
  <property name="subject" value="Order"/>
  <property name="to" value="acme-order@acme.com"/>
  <property name="fromSentDate" value="now"/>
 </bean>
```

You can then refer to this bean, using #beanId in your Camel route as shown:

```
<route>
  <from uri="imaps://mymailseerver?
username=foo&password=secret&searchTerm=#mySearchTerm"/>
  <to uri="bean:myBean"/>
</route>
```

In Java there is a builder class to build compound **SearchTerms** using the **org.apache.camel.component.mail.SearchTermBuilder** class. This allows you to build complex terms such as:

```
// we just want the unseen mails which is not spam
SearchTermBuilder builder = new SearchTermBuilder();

builder.unseen().body(Op.not, "Spam").subject(Op.not, "Spam")
  // which was sent from either foo or bar
  .from("foo@somewhere.com").from(Op.or, "bar@somewhere.com");
  // .. and we could continue building the terms

SearchTerm term = builder.build();
```

86.18. POLLING OPTIMIZATION

The parameter maxMessagePerPoll and fetchSize allow you to restrict the number message that should be processed for each poll. These parameters should help to prevent bad performance when working with folders that contain a lot of messages. In previous versions these parameters have been evaluated too late, so that big mailboxes could still cause performance problems. With Camel 3.1 these parameters are evaluated earlier during the poll to avoid these problems.

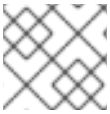
86.19. USING HEADERS WITH ADDITIONAL JAVA MAIL SENDER PROPERTIES

When sending mails, then you can provide dynamic java mail properties for the **JavaMailSender** from the Exchange as message headers with keys starting with **java.smtp.**.

You can set any of the **java.smtp** properties which you can find in the Java Mail documentation.

For example to provide a dynamic uuid in **java.smtp.from** (SMTP MAIL command):

```
  .setHeader("from", constant("reply2me@foo.com"));
  .setHeader("java.smtp.from", method(UUID.class, "randomUUID"));
  .to("smtp://mymailserver:1234");
```



NOTE

This is only supported when **not** using a custom **JavaMailSender**.

86.20. SPRING BOOT AUTO-CONFIGURATION

The component supports 50 options, which are listed below.

Name	Description	Default	Type
camel.component.mail.additional-java-mail-properties	Sets additional java mail properties, that will append/override any default properties that is set based on all the other options. This is useful if you need to add some special options but want to keep the others as is. The option is a java.util.Properties type.		Properties
camel.component.mail.alternative-body-header	Specifies the key to an IN message header that contains an alternative email body. For example, if you send emails in text/html format and want to provide an alternative mail body for non-HTML email clients, set the alternative mail body with this key as a header.	CamelMailAlternativeBody	String
camel.component.mail.attachments-content-transfer-encoding-resolver	To use a custom AttachmentsContentTransferEncodingResolver to resolve what content-type-encoding to use for attachments. The option is a org.apache.camel.component.mail.AttachmentsContentTransferEncodingResolver type.		AttachmentsContentTransferEncodingResolver
camel.component.mail.authenticator	The authenticator for login. If set then the password and username are ignored. Can be used for tokens which can expire and therefore must be read dynamically. The option is a org.apache.camel.component.mail.MailAuthenticator type.		MailAuthenticator
camel.component.mail.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.mail.bcc	Sets the BCC email address. Separate multiple email addresses with comma.		String

Name	Description	Default	Type
camel.component.mail.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.mail.cc	Sets the CC email address. Separate multiple email addresses with comma.		String
camel.component.mail.close-folder	Whether the consumer should close the folder after polling. Setting this option to false and having disconnect=false as well, then the consumer keep the folder open between polls.	true	Boolean
camel.component.mail.configuration	Sets the Mail configuration. The option is a org.apache.camel.component.mail.MailConfiguration type.		MailConfiguration
camel.component.mail.connection-timeout	The connection timeout in milliseconds.	30000	Integer
camel.component.mail.content-type	The mail message content type. Use text/html for HTML mails.	text/plain	String
camel.component.mail.content-type-resolver	Resolver to determine Content-Type for file attachments. The option is a org.apache.camel.component.mail.ContentTypeResolver type.		ContentTypeResolver
camel.component.mail.copy-to	After processing a mail message, it can be copied to a mail folder with the given name. You can override this configuration value, with a header with the key copyTo, allowing you to copy messages to folder names configured at runtime.		String
camel.component.mail.debug-mode	Enable debug mode on the underlying mail framework. The SUN Mail framework logs the debug messages to System.out by default.	false	Boolean

Name	Description	Default	Type
camel.component.mail.decode-filename	If set to true, the MimeUtility.decodeText method will be used to decode the filename. This is similar to setting JVM system property mail.mime.encodefilename.	false	Boolean
camel.component.mail.delete	Deletes the messages after they have been processed. This is done by setting the DELETED flag on the mail message. If false, the SEEN flag is set instead. As of Camel 2.10 you can override this configuration option by setting a header with the key delete to determine if the mail should be deleted or not.	false	Boolean
camel.component.mail.disconnect	Whether the consumer should disconnect after polling. If enabled this forces Camel to connect on each poll.	false	Boolean
camel.component.mail.enabled	Whether to enable auto configuration of the mail component. This is enabled by default.		Boolean
camel.component.mail.fetch-size	Sets the maximum number of messages to consume during a poll. This can be used to avoid overloading a mail server, if a mailbox folder contains a lot of messages. Default value of -1 means no fetch size and all messages will be consumed. Setting the value to 0 is a special corner case, where Camel will not consume any messages at all.	-1	Integer
camel.component.mail.folder-name	The folder to poll.	INBOX	String
camel.component.mail.from	The from email address.	camel@localhost	String
camel.component.mail.handle-failed-message	If the mail consumer cannot retrieve a given mail message, then this option allows to handle the caused exception by the consumer's error handler. By enable the bridge error handler on the consumer, then the Camel routing error handler can handle the exception instead. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	Boolean

Name	Description	Default	Type
camel.component.mail.header-filter-strategy	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		HeaderFilterStrategy
camel.component.mail.ignore-unsupported-charset	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	Boolean
camel.component.mail.ignore-uri-scheme	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	Boolean
camel.component.mail.java-mail-properties	Sets the java mail options. Will clear any default properties and only use the properties provided for this method. The option is a java.util.Properties type.		Properties
camel.component.mail.java-mail-sender	To use a custom org.apache.camel.component.mail.JavaMailSender for sending emails. The option is a org.apache.camel.component.mail.JavaMailSender type.		JavaMailSender
camel.component.mail.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.mail.map-mail-message	Specifies whether Camel should map the received mail message to Camel body/headers/attachments. If set to true, the body of the mail message is mapped to the body of the Camel IN message, the mail headers are mapped to IN headers, and the attachments to Camel IN attachment message. If this option is set to false then the IN message contains a raw javax.mail.Message. You can retrieve this raw message by calling exchange.getIn().getBody(javax.mail.Message.class).	true	Boolean
camel.component.mail.mime-decode-headers	This option enables transparent MIME decoding and unfolding for mail headers.	false	Boolean
camel.component.mail.move-to	After processing a mail message, it can be moved to a mail folder with the given name. You can override this configuration value, with a header with the key moveTo, allowing you to move messages to folder names configured at runtime.		String
camel.component.mail.password	The password for login. See also setAuthenticator(MailAuthenticator).		String
camel.component.mail.peek	Will mark the javax.mail.Message as peeked before processing the mail message. This applies to IMAPMessage messages types only. By using peek the mail will not be eager marked as SEEN on the mail server, which allows us to rollback the mail message if there is an error processing in Camel.	true	Boolean
camel.component.mail.reply-to	The Reply-To recipients (the receivers of the response mail). Separate multiple email addresses with a comma.		String
camel.component.mail.session	Specifies the mail session that camel should use for all mail interactions. Useful in scenarios where mail sessions are created and managed by some other resource, such as a JavaEE container. When using a custom mail session, then the hostname and port from the mail session will be used (if configured on the session). The option is a javax.mail.Session type.		Session

Name	Description	Default	Type
camel.component.mail.skip-failed-message	If the mail consumer cannot retrieve a given mail message, then this option allows to skip the message and move on to retrieve the next mail message. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	Boolean
camel.component.mail.ssl-context-parameters	To configure security using SSLContextParameters. The option is a org.apache.camel.support.jsse.SSLContextParameters type.		SSLContextParameters
camel.component.mail.subject	The Subject of the message being sent. Note: Setting the subject in the header takes precedence over this option.		String
camel.component.mail.to	Sets the To email address. Separate multiple email addresses with comma.		String
camel.component.mail.unseen	Whether to limit by unseen mails only.	true	Boolean
camel.component.mail.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.mail.use-inline-attachments	Whether to use disposition inline or attachment.	false	Boolean
camel.component.mail.username	The username for login. See also setAuthenticator(MailAuthenticator).		String
camel.dataformat.mime-multipart.binary-content	Defines whether the content of binary parts in the MIME multipart is binary (true) or Base-64 encoded (false) Default is false.	false	Boolean
camel.dataformat.mime-multipart.enabled	Whether to enable auto configuration of the mime-multipart data format. This is enabled by default.		Boolean
camel.dataformat.mime-multipart.headers-inline	Defines whether the MIME-Multipart headers are part of the message body (true) or are set as Camel headers (false). Default is false.	false	Boolean

Name	Description	Default	Type
camel.dataformat.mime-multipart.include-headers	A regex that defines which Camel headers are also included as MIME headers into the MIME multipart. This will only work if headersInline is set to true. Default is to include no headers.		String
camel.dataformat.mime-multipart.multipart-sub-type	Specify the subtype of the MIME Multipart. Default is mixed.	mixed	String
camel.dataformat.mime-multipart.multipart-without-attachment	Defines whether a message without attachment is also marshaled into a MIME Multipart (with only one body part). Default is false.	false	Boolean

CHAPTER 87. MAIL MICROSOFT OAUTH

Since Camel 3.18.4.

The Mail Microsoft OAuth2 provides an implementation of **org.apache.camel.component.mail.MailAuthenticator** to authenticate IMAP/POP/SMTP connections and access to Email via Spring's Mail support and the underlying JavaMail system.

87.1. DEPENDENCIES

Add the following dependency to your **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-mail-microsoft-oauth</artifactId>
</dependency>
```

Importing **camel-mail-microsoft-oauth** will automatically import camel-mail component.

87.2. MICROSOFT EXCHANGE ONLINE OAUTH2 MAIL AUTHENTICATOR IMAP SAMPLE

To use OAuth, an application must be registered with Azure Active Directory. Follow the instructions to register a new application.

Procedure

1. Enable the application to access Exchange mailboxes via client credentials flow. For more information, see Authenticate an IMAP, POP or SMTP connection using OAuth

2. Once everything is set up, declare and register in the registry, an instance of **org.apache.camel.component.mail.MicrosoftExchangeOnlineOAuth2MailAuthenticator**.

3. For Example, in a Spring Boot application:

```
@BindToRegistry("auth")
public MicrosoftExchangeOnlineOAuth2MailAuthenticator exchangeAuthenticator(){
  return new MicrosoftExchangeOnlineOAuth2MailAuthenticator(tenantId, clientId, clientSecret,
"jon@doe.com");
}
```

1. Then reference it in the Camel URI as follows:

```
from("imaps://outlook.office365.com:993"
            + "?authenticator=#auth"
            + "&mail.imaps.auth.mechanisms=XOAUTH2"
            + "&debugMode=true"
            + "&delete=false")
```

CHAPTER 88. MAPSTRUCT

Since Camel 3.19

Only producer is supported.

The camel-mapstruct component is used for converting POJOs using MapStruct.

88.1. DEPENDENCIES

When using **mapstruct** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-mapstruct-starter</artifactId>
</dependency>
```

88.2. URI FORMAT

```
mapstruct:className[?options]
```

Where **className** is the fully qualified class name of the POJO to convert to.

88.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

88.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

88.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

88.4. COMPONENT OPTIONS

The MapStruct component supports 4 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
mapperPackageName (producer)	**Required** Package name(s) where Camel should discover Mapstruct mapping classes. Multiple package names can be separated by comma.		String
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
mapStructConverter (advanced)	**Autowired** To use a custom MapStructConverter such as adapting to a special runtime.		MapStructMapperFinder

88.5. ENDPOINT OPTIONS

The MapStruct endpoint is configured using URI syntax:

```
mapstruct:className
```

with the following path and query parameters:

88.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
className (producer)	**Required** The fully qualified class name of the POJO that mapstruct should convert to (target).		String

88.5.2. Query Parameters (2 parameters)

Name	Description	Default	Type
mandatory (producer)	Whether there must exist a mapstruct converter to convert to the POJO.	true	boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

88.6. SETTING UP MAPSTRUCT

The camel-mapstruct component must be configured with one or more package names, for classpath scanning MapStruct **Mapper** classes. This is needed because the **Mapper** classes are to be used for converting POJOs with MapStruct.

For example, to set up two packages you can do as following:

```
MapstructComponent mc = context.getComponent("mapstruct", MapstructComponent.class);
mc.setMapperPackageName("com.foo.mapper,com.bar.mapper");
```

This can also be configured in **application.properties**:

```
camel.component.mapstruct.mapper-package-name = com.foo.mapper,com.bar.mapper
```

Camel will on startup scan these packages for classes which names ends with **Mapper**. These classes are then introspected to discover the mapping methods. These mapping methods are then registered into the Camel registry. This means that you can also use type converter to convert the POJOs with MapStruct, such as:

```
from("direct:foo")
  .convertBodyTo(MyFooDto.class);
```

Where **MyFooDto** is a POJO that MapStruct is able to convert to/from.

88.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.component.mapstruct.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.mapstruct.enabled	Whether to enable auto configuration of the mapstruct component. This is enabled by default.		Boolean
camel.component.mapstruct.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.mapstruct.map-struct-converter	To use a custom MapStructConverter such as adapting to a special runtime. The option is a org.apache.camel.component.mapstruct.MapStructMapperFinder type.		MapStructMapperFinder
camel.component.mapstruct.mapper-package-name	Package name(s) where Camel should discover Mapstruct mapping classes. Multiple package names can be separated by comma.		String

CHAPTER 89. MASTER

Only consumer is supported

The Camel-Master endpoint provides a way to ensure only a single consumer in a cluster consumes from a given endpoint; with automatic failover if that JVM dies.

This can be very useful if you need to consume from some legacy back end which either doesn't support concurrent consumption or due to commercial or stability reasons you can only have a single connection at any point in time.

89.1. DEPENDENCIES

When using **master** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

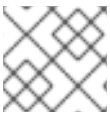
```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-master-starter</artifactId>
</dependency>
```

89.2. USING THE MASTER ENDPOINT

Just prefix any camel endpoint with **master:someName:** where *someName* is a logical name and is used to acquire the master lock. e.g.

```
from("master:cheese:jms:foo").to("activemq:wine");
```

In this example, there master component ensures that the route is only active in one node, at any given time, in the cluster. So if there are 8 nodes in the cluster, then the master component will elect one route to be the leader, and only this route will be active, and hence only this route will consume messages from **jms:foo**. In case this route is stopped or unexpected terminated, then the master component will detect this, and re-elect another node to be active, which will then become active and start consuming messages from **jms:foo**.



NOTE

Apache ActiveMQ 5.x has such feature out of the box called Exclusive Consumers.

89.3. URI FORMAT

```
master:namespace:endpoint[?options]
```

Where endpoint is any Camel endpoint you want to run in master/slave mode.

89.4. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

89.4.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

89.4.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

89.5. COMPONENT OPTIONS

The Master component supports 4 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
service (advanced)	Inject the service to use.		CamelClusterService
serviceSelector (advanced)	Inject the service selector used to lookup the CamelClusterService to use.		Selector

89.6. ENDPOINT OPTIONS

The Master endpoint is configured using URI syntax:

```
master:namespace:delegateUri
```

with the following path and query parameters:

89.6.1. Path Parameters (2 parameters)

Name	Description	Default	Type
namespace (consumer)	**Required** The name of the cluster namespace to use.		String
delegateUri (consumer)	**Required** The endpoint uri to use in master/slave mode.		String

89.6.2. Query Parameters (3 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern

89.7. EXAMPLE

You can protect a clustered Camel application to only consume files from one active node.

```
// the file endpoint we want to consume from
String url = "file:target/inbox?delete=true";

// use the camel master component in the clustered group named myGroup
// to run a master/slave mode in the following Camel url
from("master:myGroup:" + url)
    .log(name + " - Received file: ${file:name}")
    .delay(delay)
    .log(name + " - Done file:     ${file:name}")
    .to("file:target/outbox");
```

The master component leverages CamelClusterService you can configure using

- **Java**

```
ZooKeeperClusterService service = new ZooKeeperClusterService();
service.setId("camel-node-1");
service.setNodes("myzk:2181");
service.setBasePath("/camel/cluster");

context.addService(service)
```

- **Xml (Spring/Blueprint)**

```
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="
```

```
      http://www.springframework.org/schema/beans
      http://www.springframework.org/schema/beans/spring-beans.xsd
      http://camel.apache.org/schema/spring
      http://camel.apache.org/schema/spring/camel-spring.xsd">

  <bean id="cluster"
class="org.apache.camel.component.zookeeper.cluster.ZooKeeperClusterService">
    <property name="id" value="camel-node-1"/>
    <property name="basePath" value="/camel/cluster"/>
    <property name="nodes" value="myzk:2181"/>
  </bean>

  <camelContext xmlns="http://camel.apache.org/schema/spring" autoStartup="false">
    ...
  </camelContext>

</beans>
```

- **Spring boot**

```
camel.component.zookeeper.cluster.service.enabled   = true
camel.component.zookeeper.cluster.service.id        = camel-node-1
camel.component.zookeeper.cluster.service.base-path = /camel/cluster
camel.component.zookeeper.cluster.service.nodes     = myzk:2181
```

89.8. IMPLEMENTATIONS

Camel provides the following ClusterService implementations:

- camel-consul
- camel-file
- camel-infinispan
- camel-jgroups-raft
- camel-jgroups
- camel-kubernetes
- camel-zookeeper

89.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.component.master.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.master.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.master.enabled	Whether to enable auto configuration of the master component. This is enabled by default.		Boolean
camel.component.master.service	Inject the service to use. The option is a org.apache.camel.cluster.CamelClusterService type.		CamelClusterService
camel.component.master.service-selector	Inject the service selector used to lookup the CamelClusterService to use. The option is a org.apache.camel.cluster.CamelClusterService.Selector type.		CamelClusterService$Selector

CHAPTER 90. MICROMETER

Since Camel 2.22

Only producer is supported

The Micrometer component allows to collect various metrics directly from Camel routes. Supported metric types are counter, summary, and timer. Micrometer provides simple way to measure the behavior of an application. Configurable reporting backends (via Micrometer registries) enable different integration options for collecting and visualizing statistics.

The component also provides a **MicrometerRoutePolicyFactory** which allows to expose route statistics using Micrometer as well as **EventNotifier** implementations for counting routes and timing exchanges from their creation to their completion.

90.1. DEPENDENCIES

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-micrometer</artifactId>
</dependency>
```

At the same time update **dependencyManagement** section with:

```
<dependencyManagement>
    <dependencies>
        <dependency>
            <groupId>com.redhat.camel.springboot.platform</groupId>
            <artifactId>camel-spring-boot-bom</artifactId>
            <version>${camel-spring-boot-version}</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
    </dependencies>
</dependencyManagement>
```

90.2. URI FORMAT

```
micrometer:[ counter | summary | timer ]:metricname[?options]
```

90.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

90.3.1. Configuring component options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

90.3.2. Configuring endpoint options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL and DataFormat DSL as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

90.4. COMPONENT OPTIONS

The Micrometer component supports 3 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	False	Boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	True	Boolean

Name	Description	Default	Type
metricsRegistry (advanced)	To use a custom configured MetricRegistry.		MeterRegistry

90.5. ENDPOINT OPTIONS

The Micrometer endpoint is configured using URI syntax:

```
micrometer:metricsType:metricsName
```

with the following path and query parameters:

90.5.1. Path Parameters (3 parameters)

Name	Description	Default	Type
metricsType (producer)	**Required** Type of metrics. Enum values: • counter • summary • timer		Type
metricsName (producer)	**Required** Name of metrics.		String
tags (producer)	Tags of metrics.		Iterable

90.5.2. Query Parameters (6 parameters)

Name	Description	Default	Type
action (producer)	Action expression when using timer type. Enum values: • start • stop		String

Name	Description	Default	Type
decrement (producer)	Decrement value expression when using counter type.		String
increment (producer)	Increment value expression when using counter type.		boolean
metricsDescription (producer)	Description of metrics.		String
value (producer)	Value expression when using histogram type.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	False	Boolean

90.6. MESSAGE HEADERS

The Micrometer component supports 7 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelMetricsTimerAction (producer) Constant: HEADER_TIMER_ACTION	Override timer action in URI. Enum values: • start • stop		MicrometerTimerAction
CamelMetricsHistogramValue (producer) Constant: HEADER_HISTOGRAM_VALUE	Override histogram value in URI.		Long

Name	Description	Default	Type
CamelMetricsCounterDecrement (producer) Constant: HEADER_COUNTER_DECREMENT	Override decrement value in URI.		Double
CamelMetricsCounterIncrement (producer) Constant: HEADER_COUNTER_INCREMENT	Override increment value in URI.		Double
CamelMetricsName (producer) Constant: HEADER_METRIC_NAME	Override name value in URI.		String
CamelMetricsDescription (producer) Constant: HEADER_METRIC_DESCRIPTION	Override description value in URI.		String
CamelMetricsTags (producer) Constant: HEADER_METRIC_TAGS	To augment meter tags defined as URI parameters.		Iterable

90.7. METER REGISTRY

By default the Camel Micrometer component creates a **SimpleMeterRegistry** instance, suitable mainly for testing. You should define a dedicated registry by providing a **MeterRegistry** bean. Micrometer registries primarily determine the backend monitoring system to be used. A **CompositeMeterRegistry** can be used to address more than one monitoring target.

For example using Spring Java Configuration:

```
@Configuration
public static class MyConfig extends SingleRouteCamelConfiguration {

    @Bean
    @Override
    public RouteBuilder route() {
        return new RouteBuilder() {
            @Override
            public void configure() throws Exception {
                // define Camel routes here
            }
```

```
        };
    }

    @Bean(name = MicrometerConstants.METRICS_REGISTRY_NAME)
    public MeterRegistry getMeterRegistry() {
        CompositeMeterRegistry registry = ...;
        registry.add(...);
        // ...
        return registry;
    }
}
```

Or using CDI:

```
 @Override
    public void configure() {
      from("...")
          // Register the 'my-meter' meter in the MetricRegistry below
          .to("micrometer:meter:my-meter");
    }

    @Produces
    // If multiple MetricRegistry beans
    // @Named(MicrometerConstants.METRICS_REGISTRY_NAME)
    MetricRegistry registry() {
        CompositeMeterRegistry registry = ...;
        registry.add(...);
        // ...
        return registry;
    }
}
```

90.8. DEFAULT CAMEL METRICS

Some Camel specific metrics are available out of the box.

Name	Type	Description
camel.message.history	Timer	Sample of performance of each node in the route when message history is enabled
camel.routes.added	Gauge	Number of routes added
camel.routes.running	Gauge	Number of routes running
camel.exchanges.inflight	Gauge	Route inflight messages
camel.exchanges.total	Counter	Total number of processed exchanges

Name	Type	Description
camel.exchanges.succeeded	Counter	Number of successfully completed exchange
camel.exchanges.failed	Counter	Number of failed exchanges
camel.exchanges.failures.handled	Counter	Number of failures handled
camel.exchanges.external.redeliveries	Counter	Number of external initiated redeliveries (such as from JMS broker)
camel.exchange.event.notifier	Gauge + Summary	Metrics for message created, sent, completed, and failed events
camel.route.policy	Gauge + Summary	Route performance metrics
camel.route.policy.long.task	Gauge + Summary	Route long task metric

90.9. USAGE OF PRODUCERS

Each meter has type and name. Supported types are counter, distribution summary and timer. If no type is provided then a counter is used by default.

The meter name is a string that is evaluated as **Simple** expression. In addition to using the **CamelMetricsName** header (see below), this allows to select the meter depending on exchange data.

The optional **tags** URI parameter is a comma-separated string, consisting of **key=value** expressions. Both **key** and **value** are strings that are also evaluated as **Simple** expression. E.g. the URI parameter **tags=X=${header.Y}** would assign the current value of header **Y** to the key **X**.

90.9.1. Headers

The meter name defined in URI can be overridden by populating a header with name CamelMetricsName. The meter tags defined as URI parameters can be augmented by populating a header with name CamelMetricsTags.

For example:

```
from("direct:in")
    .setHeader(MicrometerConstants.HEADER_METRIC_NAME, constant("new.name"))
    .setHeader(MicrometerConstants.HEADER_METRIC_TAGS, constant(Tags.of("dynamic-key",
"dynamic-value")))
    .to("micrometer:counter:name.not.used?tags=key=value")
    .to("direct:out");
```

will update a counter with name **new.name** instead of **name.not.used** using the tag **dynamic-key** with value **dynamic-value** in addition to the tag **key** with value **value**.

All Metrics specific headers are removed from the message once the Micrometer endpoint finishes processing of exchange. While processing exchange Micrometer endpoint will catch all exceptions and write log entry using level **warn**.

90.10. COUNTER

```
micrometer:counter:name[?options]
```

90.10.1. Options

Name	Default	Description
increment		Double value to add to the counter
decrement		Double value to subtract from the counter

If neither **increment** or **decrement** is defined then counter value will be incremented by one. If **increment** and **decrement** are both defined only increment operation is called.

```
// update counter simple.counter by 7
from("direct:in")
    .to("micrometer:counter:simple.counter?increment=7")
    .to("direct:out");

// increment counter simple.counter by 1
from("direct:in")
    .to("micrometer:counter:simple.counter")
    .to("direct:out");
```

Both **increment** and **decrement** values are evaluated as **Simple** expressions with a Double result, e.g. if header **X** contains a value that evaluates to 3.0, the **simple.counter** counter is decremented by 3.0:

```
// decrement counter simple.counter by 3
from("direct:in")
    .to("micrometer:counter:simple.counter?decrement=${header.X}")
    .to("direct:out");
```

90.10.2. Headers

Like in camel-metrics, specific Message headers can be used to override increment and decrement values specified in the Micrometer endpoint URI.

Name	Description	Expected type
CamelMetricsCounterIncrement		Double value to add to the counter

Name	Description	Expected type
CamelMetricsCounterDecrement		Double value to subtract from the counter

```
from("direct:in")
    .setHeader(MicrometerConstants.HEADER_COUNTER_INCREMENT, constant(417.0D))
    .to("micrometer:counter:simple.counter?increment=7")
    .to("direct:out");
```

```
from("direct:in")
    .setHeader(MicrometerConstants.HEADER_COUNTER_INCREMENT, simple("${body.length}"))
    .to("micrometer:counter:body.length")
    .to("direct:out");
```

90.11. DISTRIBUTION SUMMARY

```
micrometer:summary:metricname[?options]
```

90.11.1. Options

Name	Default	Description
value		Value to use in histogram

If no **value** is not set, nothing is added to histogram and warning is logged.

```
// adds value 9923 to simple.histogram
from("direct:in")
    .to("micrometer:summary:simple.histogram?value=9923")
    .to("direct:out");

// nothing is added to simple.histogram; warning is logged
from("direct:in")
    .to("micrometer:summary:simple.histogram")
    .to("direct:out");
```

value is evaluated as **Simple** expressions with a Double result, e.g. if header **X** contains a value that evaluates to 3.0, this value is registered with the **simple.histogram**:

```
from("direct:in")
    .to("micrometer:summary:simple.histogram?value=${header.X}")
    .to("direct:out");
```

90.11.2. Headers

Like in **camel-metrics**, a specific Message header can be used to override the value specified in the Micrometer endpoint URI.

Name	Description	Expected type
CamelMetricsHistogramValue	Override histogram value in URI	Long

```
// adds value 992.0 to simple.histogram
from("direct:in")
    .setHeader(MicrometerConstants.HEADER_HISTOGRAM_VALUE, constant(992.0D))
    .to("micrometer:summary:simple.histogram?value=700")
    .to("direct:out")
```

90.12. TIMER

```
micrometer:timer:metricname[?options]
```

90.12.1. Options

Name	Default	Description
action		start or stop

If no **action** or invalid value is provided then warning is logged without any timer update. If action **start** is called on an already running timer or **stop** is called on an unknown timer, nothing is updated and warning is logged.

```
// measure time spent in route "direct:calculate"
from("direct:in")
    .to("micrometer:timer:simple.timer?action=start")
    .to("direct:calculate")
    .to("micrometer:timer:simple.timer?action=stop");
```

Timer.Sample objects are stored as Exchange properties between different Metrics component calls.

action is evaluated as a Simple expression returning a result of type **MicrometerTimerAction**.

90.12.2. Headers

Like in **camel-metrics**, a specific Message header can be used to override action value specified in the Micrometer endpoint URI.

Name	Description	Expected type
CamelMetricsTimerAction	Override timer action in URI	**org.apache.camel.component.micrometer.MicrometerTimerAction**

```
// sets timer action using header
from("direct:in")
    .setHeader(MicrometerConstants.HEADER_TIMER_ACTION, MicrometerTimerAction.start)
    .to("micrometer:timer:simple.timer")
    .to("direct:out");
```

90.13. USING MICROMETER ROUTE POLICY FACTORY

MicrometerRoutePolicyFactory allows to add a RoutePolicy for each route in order to exposes route utilization statistics using Micrometer. This factory can be used in Java and XML as the examples below demonstrates.

NOTE

Instead of using the **MicrometerRoutePolicyFactory** you can define a dedicated **MicrometerRoutePolicy** per route you want to instrument, in case you only want to instrument a few selected routes.

From Java you just add the factory to the CamelContext as shown below:

```
context.addRoutePolicyFactory(new MicrometerRoutePolicyFactory());
```

And from XML DSL you define a <bean> as follows:

```
 <!-- use camel-micrometer route policy to gather metrics for all routes -->
  <bean id="metricsRoutePolicyFactory"
class="org.apache.camel.component.micrometer.routepolicy.MicrometerRoutePolicyFactory"/>
```

The **MicrometerRoutePolicyFactory** and **MicrometerRoutePolicy** supports the following options:

Name	Default	Description
prettyPrint	false	Whether to use pretty print when outputting statistics in json format
meterRegistry		Allow to use a shared **MeterRegistry**. If none is provided then Camel will create a shared instance used by the this CamelContext.
durationUnit	TimeUnit.MILLISECONDS	The unit to use for duration in when dumping the statistics as json.
configuration	see below	MicrometerRoutePolicyConfiguration.class

The **MicrometerRoutePolicyConfiguration** supports the following options:

Name	Default	Description
additionalCounters	true	activates all additional counters

Name	Default	Description
exchangesSucceeded	true	activates counter for succeeded exchanges
exchangesFailed	true	activates counter for failed exchanges
exchangesTotal	true	activates counter for total count of exchanges
externalRedeliveries	true	activates counter for redeliveries of exchanges
failuresHandled	true	activates counter for handled failures
longTask	false	activates long task timer (current processing time for micrometer)
timerInitiator	null	Consumer<Timer.Builder> for custom initialize Timer
longTaskInitiator	null	Consumer<LongTaskTimer.Builder> for custom initialize LongTaskTimer

If JMX is enabled in the CamelContext, the MBean is registered in the **type=services** tree with **name=MicrometerRoutePolicy**.

90.14. USING MICROMETER MESSAGE HISTORY FACTORY

MicrometerMessageHistoryFactory allows to use metrics to capture Message History performance statistics while routing messages. It works by using a Micrometer Timer for each node in all the routes. This factory can be used in Java and XML as the examples below demonstrates.

From Java you just set the factory to the CamelContext as shown below:

```
context.setMessageHistoryFactory(new MicrometerMessageHistoryFactory());
```

And from XML DSL you define a <bean> as follows:

```
<!-- use camel-micrometer message history to gather metrics for all messages being routed -->
  <bean id="metricsMessageHistoryFactory"
class="org.apache.camel.component.micrometer.messagehistory.MicrometerMessageHistoryFactory"
/>
```

The following options is supported on the factory:

Name	Default	Description

Name	Default	Description
prettyPrint	false	Whether to use pretty print when outputting statistics in json format
meterRegistry		Allow to use a shared **MeterRegistry**. If none is provided then Camel will create a shared instance used by the this CamelContext.
durationUnit	TimeUnit.MILLISECONDS	The unit to use for duration in when dumping the statistics as json.

At runtime the metrics can be accessed from Java API or JMX which allows to gather the data as json output.

From Java code you can get the service from the CamelContext as shown:

```
MicrometerMessageHistoryService service =
context.hasService(MicrometerMessageHistoryService.class);
String json = service.dumpStatisticsAsJson();
```

If JMX is enabled in the CamelContext, the MBean is registered in the type=services tree with **name=MicrometerMessageHistory**.

90.15. MICROMETER EVENT NOTIFICATION

There is a **MicrometerRouteEventNotifier** (counting added and running routes) and a **MicrometerExchangeEventNotifier** (timing exchanges from their creation to their completion).

EventNotifiers can be added to the CamelContext, e.g.:

```
camelContext.getManagementStrategy().addEventNotifier(new MicrometerExchangeEventNotifier())
```

At runtime the metrics can be accessed from Java API or JMX which allows to gather the data as json output.

From Java code you can do get the service from the CamelContext as shown:

```
MicrometerEventNotifierService service = context.hasService(MicrometerEventNotifierService.class);
String json = service.dumpStatisticsAsJson();
```

If JMX is enabled in the CamelContext, the MBean is registered in the **type=services** tree with **name=MicrometerEventNotifier**.

90.16. INSTRUMENTING CAMEL THREAD POOLS

InstrumentedThreadPoolFactory allows you to gather performance information about Camel Thread Pools by injecting a **InstrumentedThreadPoolFactory** which collects information from inside of Camel. See more details at Advanced configuration of CamelContext using Spring.

90.17. EXPOSING MICROMETER STATISTICS IN JMX

Micrometer uses **MeterRegistry** implementations in order to publish statistics. While in production scenarios it is advisable to select a dedicated backend like Prometheus or Graphite, it may be sufficient for test or local deployments to publish statistics to JMX.

In order to achieve this, add the following dependency:

```
<dependency>
  <groupId>io.micrometer</groupId>
  <artifactId>micrometer-registry-jmx</artifactId>
  <version>${micrometer-version}</version>
</dependency>
```

and add a **JmxMeterRegistry** instance:

```
@Bean(name = MicrometerConstants.METRICS_REGISTRY_NAME)
public MeterRegistry getMeterRegistry() {
    CompositeMeterRegistry meterRegistry = new CompositeMeterRegistry();
    meterRegistry.add(...);
    meterRegistry.add(new JmxMeterRegistry(
      CamelJmxConfig.DEFAULT,
      Clock.SYSTEM,
      HierarchicalNameMapper.DEFAULT));
    return meterRegistry;
  }
}
```

The **HierarchicalNameMapper** strategy determines how meter name and tags are assembled into an MBean name.

90.18. USING CAMEL MICROMETER WITH SPRING BOOT

When you use **camel-micrometer-starter** with Spring Boot, then Spring Boot auto configuration will automatically enable metrics capture if a **io.micrometer.core.instrument.MeterRegistry** is available.

For example to capture data with Prometheus, you can add the following dependency:

```
<dependency>
  <groupId>io.micrometer</groupId>
  <artifactId>micrometer-registry-prometheus</artifactId>
</dependency>
```

See the following table for options to specify what metrics to capture, or to turn it off.

90.19. SPRING BOOT AUTO CONFIGURATION

Compared to the plain camel micrometer, micrometer component on Spring Boot provides 10 more options, which are listed below:

Name	Description	Default	Type
camel.component.micrometer.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	True	Boolean
camel.component.micrometer.enabled	Whether to enable auto configuration of the micrometer component. This is enabled by default.		Boolean
camel.component.micrometer.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	False	Boolean
camel.component.micrometer.metrics-registry	To use a custom configured MetricRegistry. The option is a io.micrometer.core.instrument.MeterRegistry type.		MeterRegistry
camel.metrics.enable-exchange-event-notifier	Set whether to enable the MicrometerExchangeEventNotifier for capturing metrics on exchange processing times.	True	Boolean

Name	Description	Default	Type
camel.metrics.enable-message-history	Set whether to enable the MicrometerMessageHistoryFactory for capturing metrics on individual route node processing times. Depending on the number of configured route nodes, there is the potential to create a large volume of metrics. Therefore, this option is disabled by default.	False	Boolean
camel.metrics.enable-route-event-notifier	Set whether to enable the MicrometerRouteEventNotifier for capturing metrics on the total number of routes and total number of routes running.	True	Boolean
camel.metrics.enable-route-policy	Set whether to enable the MicrometerRoutePolicyFactory for capturing metrics on route processing times.	True	Boolean
camel.metrics.uri-tag-dynamic	Whether to use static or dynamic values for URI tags in captured metrics. When using dynamic tags, then a REST service with base URL: /users/{id} will capture metrics with uri tag with the actual dynamic value such as: /users/123. However, this can lead to many tags as the URI is dynamic, so use this with care.	False	Boolean
camel.metrics.uri-tag-enabled	Whether HTTP uri tags should be enabled or not in captured metrics. If disabled then the uri tag, is likely not able to be resolved and will be marked as UNKNOWN.	True	Boolean

CHAPTER 91. MINIO

Since Camel 3.5

Both producer and consumer are supported

The Minio component supports storing and retrieving objects from/to Minio service.

91.1. PREREQUISITES

You must have valid credentials for authorized access to the buckets/folders. More information is available at Minio.

91.2. DEPENDENCIES

When using **minio** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-minio-starter</artifactId>
</dependency>
```

91.3. URI FORMAT

```
minio://bucketName[?options]
```

The bucket will be created if it doesn't already exist. You can append query options to the URI in the following format,

```
?options=value&option2=value&…
```

For example in order to read file **hello.txt** from the bucket **helloBucket**, use the following snippet:

```
from("minio://helloBucket?accessKey=yourAccessKey&secretKey=yourSecretKey&prefix=hello.txt")
  .to("file:/var/downloaded");
```

91.4. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

91.4.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

91.4.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

91.5. COMPONENT OPTIONS

The Minio component supports 47 options, which are listed below.

Name	Description	Default	Type
autoCreateBucket (common)	Setting the autocreation of the bucket if bucket name not exist.	true	boolean
configuration (common)	The component configuration.		MinioConfiguration
customHttpClient (common)	Set custom HTTP client for authenticated access.		OkHttpClient
endpoint (common)	Endpoint can be an URL, domain name, IPv4 address or IPv6 address.		String
minioClient (common)	**Autowired** Reference to a Minio Client object in the registry.		MinioClient
objectLock (common)	Set when creating new bucket.	false	boolean
policy (common)	The policy for this queue to set in the method.		String
proxyPort (common)	TCP/IP port number. 80 and 443 are used as defaults for HTTP and HTTPS.		Integer

Name	Description	Default	Type
region (common)	The region in which Minio client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1). You'll need to use the name Region.EU_WEST_1.id().		String
secure (common)	Flag to indicate to use secure connection to minio service or not.	false	boolean
serverSideEncryption (common)	Server-side encryption.		ServerSideEncryption
serverSideEncryptionCustomerKey (common)	Server-side encryption for source object while copy/move objects.		ServerSideEncryptionCustomerKey
autoCloseBody (consumer)	If this option is true and includeBody is true, then the MinioObject.close() method will be called on exchange completion. This option is strongly related to includeBody option. In case of setting includeBody to true and autocloseBody to false, it will be up to the caller to close the MinioObject stream. Setting autocloseBody to true, will close the MinioObject stream automatically.	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
bypassGovernanceMode (consumer)	Set this flag if you want to bypassGovernanceMode when deleting a particular object.	false	boolean

Name	Description	Default	Type
deleteAfterRead (consumer)	Delete objects from Minio after they have been retrieved. The delete is only performed if the Exchange is committed. If a rollback occurs, the object is not deleted. If this option is false, then the same objects will be retrieve over and over again on the polls. Therefore you need to use the Idempotent Consumer EIP in the route to filter out duplicates. You can filter using the MinioConstants#BUCKET_NAME and MinioConstants#OBJECT_NAME headers, or only the MinioConstants#OBJECT_NAME header.	true	boolean
delimiter (consumer)	The delimiter which is used in the ListObjectsRequest to only consume objects we are interested in.		String
destinationBucketName (consumer)	Source bucket name.		String
destinationObjectName (consumer)	Source object name.		String
includeBody (consumer)	If it is true, the exchange body will be set to a stream to the contents of the file. If false, the headers will be set with the Minio object metadata, but the body will be null. This option is strongly related to autocloseBody option. In case of setting includeBody to true and autocloseBody to false, it will be up to the caller to close the MinioObject stream. Setting autocloseBody to true, will close the MinioObject stream automatically.	true	boolean
includeFolders (consumer)	The flag which is used in the ListObjectsRequest to set include folders.	false	boolean
includeUserMetadata (consumer)	The flag which is used in the ListObjectsRequest to get objects with user meta data.	false	boolean
includeVersions (consumer)	The flag which is used in the ListObjectsRequest to get objects with versioning.	false	boolean
length (consumer)	Number of bytes of object data from offset.		long
matchETag (consumer)	Set match ETag parameter for get object(s).		String
maxConnections (consumer)	Set the maxConnections parameter in the minio client configuration.	60	int

Name	Description	Default	Type
maxMessagesPerPoll (consumer)	Gets the maximum number of messages as a limit to poll at each polling. Gets the maximum number of messages as a limit to poll at each polling. The default value is 10. Use 0 or a negative number to set it as unlimited.	10	int
modifiedSince (consumer)	Set modified since parameter for get object(s).		ZonedDateTime
moveAfterRead (consumer)	Move objects from bucket to a different bucket after they have been retrieved. To accomplish the operation the destinationBucket option must be set. The copy bucket operation is only performed if the Exchange is committed. If a rollback occurs, the object is not moved.	false	boolean
notMatchETag (consumer)	Set not match ETag parameter for get object(s).		String
objectName (consumer)	To get the object from the bucket with the given object name.		String
offset (consumer)	Start byte position of object data.		long
prefix (consumer)	Object name starts with prefix.		String
recursive (consumer)	List recursively than directory structure emulation.	false	boolean
startAfter (consumer)	list objects in bucket after this object name.		String
unModifiedSince (consumer)	Set un modified since parameter for get object(s).		ZonedDateTime
useVersion1 (consumer)	when true, version 1 of REST API is used.	false	boolean
versionId (consumer)	Set specific version_ID of a object when deleting the object.		String
deleteAfterWrite (producer)	Delete file object after the Minio file has been uploaded.	false	boolean
keyName (producer)	Setting the key name for an element in the bucket through endpoint parameter.		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
operation (producer)	The operation to do in case the user don't want to do only an upload. Enum values: • copyObject • listObjects • deleteObject • deleteObjects • deleteBucket • listBuckets • getObject • getObjectRange		MinioOperations
pojoRequest (producer)	If we want to use a POJO request as body or not.	false	boolean
storageClass (producer)	The storage class to set in the request.		String
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
accessKey (security)	Amazon AWS Secret Access Key or Minio Access Key. If not set camel will connect to service for anonymous access.		String

Name	Description	Default	Type
secretKey (security)	Amazon AWS Access Key Id or Minio Secret Key. If not set camel will connect to service for anonymous access.		String

91.6. ENDPOINT OPTIONS

The Minio endpoint is configured using URI syntax:

```
minio:bucketName
```

with the following path and query parameters:

91.6.1. Path Parameters (1 parameters)

Name	Description	Default	Type
bucketName (common)	**Required** Bucket name.		String

91.6.2. Query Parameters (63 parameters)

Name	Description	Default	Type
autoCreateBucket (common)	Setting the autocreation of the bucket if bucket name not exist.	true	boolean
customHttpClient (common)	Set custom HTTP client for authenticated access.		OkHttpClient
endpoint (common)	Endpoint can be an URL, domain name, IPv4 address or IPv6 address.		String
minioClient (common)	**Autowired** Reference to a Minio Client object in the registry.		MinioClient
objectLock (common)	Set when creating new bucket.	false	boolean
policy (common)	The policy for this queue to set in the method.		String
proxyPort (common)	TCP/IP port number. 80 and 443 are used as defaults for HTTP and HTTPS.		Integer

Name	Description	Default	Type
region (common)	The region in which Minio client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1). You'll need to use the name Region.EU_WEST_1.id().		String
secure (common)	Flag to indicate to use secure connection to minio service or not.	false	boolean
serverSideEncryption (common)	Server-side encryption.		ServerSideEncryption
serverSideEncryptionCustomerKey (common)	Server-side encryption for source object while copy/move objects.		ServerSideEncryptionCustomerKey
autoCloseBody (consumer)	If this option is true and includeBody is true, then the MinioObject.close() method will be called on exchange completion. This option is strongly related to includeBody option. In case of setting includeBody to true and autocloseBody to false, it will be up to the caller to close the MinioObject stream. Setting autocloseBody to true, will close the MinioObject stream automatically.	true	boolean
bypassGovernanceMode (consumer)	Set this flag if you want to bypassGovernanceMode when deleting a particular object.	false	boolean
deleteAfterRead (consumer)	Delete objects from Minio after they have been retrieved. The delete is only performed if the Exchange is committed. If a rollback occurs, the object is not deleted. If this option is false, then the same objects will be retrieve over and over again on the polls. Therefore you need to use the Idempotent Consumer EIP in the route to filter out duplicates. You can filter using the MinioConstants#BUCKET_NAME and MinioConstants#OBJECT_NAME headers, or only the MinioConstants#OBJECT_NAME header.	true	boolean
delimiter (consumer)	The delimiter which is used in the ListObjectsRequest to only consume objects we are interested in.		String
destinationBucketName (consumer)	Source bucket name.		String

Name	Description	Default	Type
destinationObjectName (consumer)	Source object name.		String
includeBody (consumer)	If it is true, the exchange body will be set to a stream to the contents of the file. If false, the headers will be set with the Minio object metadata, but the body will be null. This option is strongly related to autocloseBody option. In case of setting includeBody to true and autocloseBody to false, it will be up to the caller to close the MinioObject stream. Setting autocloseBody to true, will close the MinioObject stream automatically.	true	boolean
includeFolders (consumer)	The flag which is used in the ListObjectsRequest to set include folders.	false	boolean
includeUserMetadata (consumer)	The flag which is used in the ListObjectsRequest to get objects with user meta data.	false	boolean
includeVersions (consumer)	The flag which is used in the ListObjectsRequest to get objects with versioning.	false	boolean
length (consumer)	Number of bytes of object data from offset.		long
matchETag (consumer)	Set match ETag parameter for get object(s).		String
maxConnections (consumer)	Set the maxConnections parameter in the minio client configuration.	60	int
maxMessagesPerPoll (consumer)	Gets the maximum number of messages as a limit to poll at each polling. Gets the maximum number of messages as a limit to poll at each polling. The default value is 10. Use 0 or a negative number to set it as unlimited.	10	int
modifiedSince (consumer)	Set modified since parameter for get object(s).		ZonedDateTime
moveAfterRead (consumer)	Move objects from bucket to a different bucket after they have been retrieved. To accomplish the operation the destinationBucket option must be set. The copy bucket operation is only performed if the Exchange is committed. If a rollback occurs, the object is not moved.	false	boolean

Name	Description	Default	Type
notMatchETag (consumer)	Set not match ETag parameter for get object(s).		String
objectName (consumer)	To get the object from the bucket with the given object name.		String
offset (consumer)	Start byte position of object data.		long
prefix (consumer)	Object name starts with prefix.		String
recursive (consumer)	List recursively than directory structure emulation.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
startAfter (consumer)	list objects in bucket after this object name.		String
unModifiedSince (consumer)	Set un modified since parameter for get object(s).		ZonedDateTime
useVersion1 (consumer)	when true, version 1 of REST API is used.	false	boolean
versionId (consumer)	Set specific version_ID of a object when deleting the object.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
deleteAfterWrite (producer)	Delete file object after the Minio file has been uploaded.	false	boolean
keyName (producer)	Setting the key name for an element in the bucket through endpoint parameter.		String
operation (producer)	The operation to do in case the user don't want to do only an upload. Enum values: • copyObject • listObjects • deleteObject • deleteObjects • deleteBucket • listBuckets • getObject • getObjectRange		MinioOperations
pojoRequest (producer)	If we want to use a POJO request as body or not.	false	boolean
storageClass (producer)	The storage class to set in the request.		String

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
accessKey (security)	Amazon AWS Secret Access Key or Minio Access Key. If not set camel will connect to service for anonymous access.		String
secretKey (security)	Amazon AWS Access Key Id or Minio Secret Key. If not set camel will connect to service for anonymous access.		String

You have to provide the minioClient in the Registry or your accessKey and secretKey to access the Minio.

91.7. BATCH CONSUMER

This component implements the Batch Consumer.

This allows you for instance to know how many messages exists in this batch and for instance let the Aggregator aggregate this number of messages.

91.8. MESSAGE HEADERS

The Minio component supports 21 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelMinioBucketName (common) Constant: BUCKET_NAME	Producer: The bucket Name which this object will be stored or which will be used for the current operation. Consumer: The name of the bucket in which this object is contained.		String
CamelMinioDestinationBucketName (producer) Constant: DESTINATION_BUCKET_NAME	The bucket Destination Name which will be used for the current operation.		String

Name	Description	Default	Type
CamelMinioContentControl (common) Constant: CACHE_CONTROL	Producer: The content control of this object. Consumer: The optional Cache-Control HTTP header which allows the user to specify caching behavior along the HTTP request/reply chain.		String
CamelMinioContentDisposition (common) Constant: CONTENT_DISPOSITION	Producer: The content disposition of this object. Consumer: The optional Content-Disposition HTTP header, which specifies presentational information such as the recommended filename for the object to be saved as.		String
CamelMinioContentEncoding (common) Constant: CONTENT_ENCODING	Producer: The content encoding of this object. Consumer: The optional Content-Encoding HTTP header specifying what content encodings have been applied to the object and what decoding mechanisms must be applied in order to obtain the media-type referenced by the Content-Type field.		String
CamelMinioContentLength (common) Constant: CONTENT_LENGTH	Producer: The content length of this object. Consumer: The Content-Length HTTP header indicating the size of the associated object in bytes.		Long
CamelMinioContentMD5 (common) Constant: CONTENT_MD5	Producer: The md5 checksum of this object. Consumer: The base64 encoded 128-bit MD5 digest of the associated object (content - not including headers) according to RFC 1864. This data is used as a message integrity check to verify that the data received by Minio is the same data that the caller sent.		String
CamelMinioContentType (common) Constant: CONTENT_TYPE	Producer: The content type of this object. Consumer: The Content-Type HTTP header, which indicates the type of content stored in the associated object. The value of this header is a standard MIME type.		String

Name	Description	Default	Type
CamelMinioETag (common) Constant: E_TAG	Producer: The ETag value for the newly uploaded object. Consumer: The hex encoded 128-bit MD5 digest of the associated object according to RFC 1864. This data is used as an integrity check to verify that the data received by the caller is the same data that was sent by Minio.		String
CamelMinioObjectName (common) Constant: OBJECT_NAME	Producer: The key under which this object will be stored or which will be used for the current operation. Consumer: The key under which this object is stored.		String
CamelMinioDestinationObjectName (producer) Constant: DESTINATION_OBJECT_NAME	The Destination key which will be used for the current operation.		String
CamelMinioLastModified (common) Constant: LAST_MODIFIED	Producer: The last modified timestamp of this object. Consumer: The value of the Last-Modified header, indicating the date and time at which Minio last recorded a modification to the associated object.		Date
CamelMinioStorageClass (producer) Constant: STORAGE_CLASS	The storage class of this object.		String
CamelMinioVersionId (common) Constant: VERSION_ID	Producer: The version Id of the object to be stored or returned from the current operation. Consumer: The version ID of the associated Minio object if available. Version IDs are only assigned to objects when an object is uploaded to an Minio bucket that has object versioning enabled.		String
CamelMinioCannedAcl (producer) Constant: CANNED_ACL	The canned acl that will be applied to the object. see com.amazonaws.services.s3.model.CannedAccessControlList for allowed values.		String

Name	Description	Default	Type
CamelMinioOperation (producer) Constant: MINIO_OPERATION	The operation to perform. Enum values: • copyObject • listObjects • deleteObject • deleteObjects • deleteBucket • listBuckets • getObject • getPartialObject		MinioOperations
CamelMinioServerSideEncryption (common) Constant: SERVER_SIDE_ENCRYPTION	Producer: Sets the server-side encryption algorithm when encrypting the object using Minio-managed keys. For example use AES256. Consumer: The server-side encryption algorithm when encrypting the object using Minio-managed keys.		String
CamelMinioExpirationTime (common) Constant: EXPIRATION_TIME	The expiration time.		String
CamelMinioReplicationStatus (common) Constant: REPLICATION_STATUS	The replication status.		String
CamelMinioOffset (producer) Constant: OFFSET	The offset.		String

Name	Description	Default	Type
CamelMinioLength (producer) Constant: LENGTH	The length.		String

91.8.1. Minio Producer operations

Camel-Minio component provides the following operation on the producer side:

- copyObject
- deleteObject
- deleteObjects
- listBuckets
- deleteBucket
- listObjects
- getObject (this will return a MinioObject instance)
- getObjectRange (this will return a MinioObject instance)

91.8.2. Advanced Minio configuration

If your Camel Application is running behind a firewall or if you need to have more control over the **MinioClient** instance configuration, you can create your own instance and refer to it in your Camel minio component configuration:

```
from("minio://MyBucket?minioClient=#client&delay=5000&maxMessagesPerPoll=5")
.to("mock:result");
```

91.8.3. Minio Producer Operation examples

- CopyObject: this operation copy an object from one bucket to a different one

```
 from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(MinioConstants.DESTINATION_BUCKET_NAME,
"camelDestinationBucket");
        exchange.getIn().setHeader(MinioConstants.OBJECT_NAME, "camelKey");
        exchange.getIn().setHeader(MinioConstants.DESTINATION_OBJECT_NAME,
"camelDestinationKey");
    }
```

```
})
.to("minio://mycamelbucket?minioClient=#minioClient&operation=copyObject")
.to("mock:result");
```

This operation will copy the object with the name expressed in the header camelDestinationKey to the camelDestinationBucket bucket, from the bucket mycamelbucket.

- DeleteObject: this operation deletes an object from a bucket

```
from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(MinioConstants.OBJECT_NAME, "camelKey");
    }
})
.to("minio://mycamelbucket?minioClient=#minioClient&operation=deleteObject")
.to("mock:result");
```

This operation will delete the object camelKey from the bucket mycamelbucket.

- ListBuckets: this operation list the buckets for this account in this region

```
from("direct:start")
.to("minio://mycamelbucket?minioClient=#minioClient&operation=listBuckets")
.to("mock:result");
```

This operation will list the buckets for this account

- DeleteBucket: this operation delete the bucket specified as URI parameter or header

```
from("direct:start")
.to("minio://mycamelbucket?minioClient=#minioClient&operation=deleteBucket")
.to("mock:result");
```

This operation will delete the bucket mycamelbucket

- ListObjects: this operation list object in a specific bucket

```
from("direct:start")
.to("minio://mycamelbucket?minioClient=#minioClient&operation=listObjects")
.to("mock:result");
```

This operation will list the objects in the mycamelbucket bucket

- GetObject: this operation get a single object in a specific bucket

```
from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(MinioConstants.OBJECT_NAME, "camelKey");
    }
```

```
    })
    .to("minio://mycamelbucket?minioClient=#minioClient&operation=getObject")
    .to("mock:result");
```

This operation will return an MinioObject instance related to the camelKey object in mycamelbucket bucket.

- GetObjectRange: this operation get a single object range in a specific bucket

```
from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(MinioConstants.OBJECT_NAME, "camelKey");
        exchange.getIn().setHeader(MinioConstants.OFFSET, "0");
        exchange.getIn().setHeader(MinioConstants.LENGTH, "9");
    }
})
.to("minio://mycamelbucket?minioClient=#minioClient&operation=getObjectRange")
.to("mock:result");
```

This operation will return an MinioObject instance related to the camelKey object in mycamelbucket bucket, containing bytes from 0 to 9.

91.9. BUCKET AUTOCREATION

With the option **autoCreateBucket** users are able to avoid the autocreation of a Minio Bucket in case it doesn't exist. The default for this option is **true**. If set to false any operation on a not-existent bucket in Minio won't be successful, and an error will be returned.

91.10. AUTOMATIC DETECTION OF MINIO CLIENT IN REGISTRY

The component is capable of detecting the presence of a Minio bean into the registry. If it's the only instance of that type it will be used as client, and you won't have to define it as uri parameter, like the example above. This may be really useful for smarter configuration of the endpoint.

91.11. MOVING STUFF BETWEEN A BUCKET AND ANOTHER BUCKET

Some users like to consume stuff from a bucket and move the content in a different one without using the copyObject feature of this component. If this is case for you, don't forget to remove the bucketName header from the incoming exchange of the consumer, otherwise the file will always be overwritten on the same original bucket.

91.12. MOVEAFTERREAD CONSUMER OPTION

In addition to deleteAfterRead it has been added another option, moveAfterRead. With this option enabled the consumed object will be moved to a target destinationBucket instead of being only deleted. This will require specifying the destinationBucket option. As example:

```
  from("minio://mycamelbucket?
minioClient=#minioClient&moveAfterRead=true&destinationBucketName=myothercamelbucket")
  .to("mock:result");
```

In this case the objects consumed will be moved to myothercamelbucket bucket and deleted from the original one (because of deleteAfterRead set to true as default).

91.13. USING A POJO AS BODY

Sometimes build a Minio Request can be complex, because of multiple options. We introduce the possibility to use a POJO as body. In Minio there are multiple operations you can submit, as an example for List brokers request, you can do something like:

```
from("direct:minio")
    .setBody(ListObjectsArgs.builder()
                .bucket(bucketName)
                .recursive(getConfiguration().isRecursive())))
    .to("minio://test?minioClient=#minioClient&operation=listObjects&pojoRequest=true")
```

In this way you'll pass the request directly without the need of passing headers and options specifically related to this operation.

91.14. SPRING BOOT AUTO-CONFIGURATION

The component supports 48 options, which are listed below.

Name	Description	Default	Type
camel.component.minio.access-key	Amazon AWS Secret Access Key or Minio Access Key. If not set camel will connect to service for anonymous access.		String
camel.component.minio.auto-close-body	If this option is true and includeBody is true, then the MinioObject.close() method will be called on exchange completion. This option is strongly related to includeBody option. In case of setting includeBody to true and autocloseBody to false, it will be up to the caller to close the MinioObject stream. Setting autocloseBody to true, will close the MinioObject stream automatically.	true	Boolean
camel.component.minio.auto-create-bucket	Setting the autocreation of the bucket if bucket name not exist.	true	Boolean
camel.component.minio.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.minio.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.minio.bypass-governance-mode	Set this flag if you want to bypassGovernanceMode when deleting a particular object.	false	Boolean
camel.component.minio.configuration	The component configuration. The option is a org.apache.camel.component.minio.MinioConfiguration type.		MinioConfiguration
camel.component.minio.custom-http-client	Set custom HTTP client for authenticated access. The option is a okhttp3.OkHttpClient type.		OkHttpClient
camel.component.minio.delete-after-read	Delete objects from Minio after they have been retrieved. The delete is only performed if the Exchange is committed. If a rollback occurs, the object is not deleted. If this option is false, then the same objects will be retrieve over and over again on the polls. Therefore you need to use the Idempotent Consumer EIP in the route to filter out duplicates. You can filter using the MinioConstants#BUCKET_NAME and MinioConstants#OBJECT_NAME headers, or only the MinioConstants#OBJECT_NAME header.	true	Boolean
camel.component.minio.delete-after-write	Delete file object after the Minio file has been uploaded.	false	Boolean
camel.component.minio.delimiter	The delimiter which is used in the ListObjectsRequest to only consume objects we are interested in.		String
camel.component.minio.destination-bucket-name	Source bucket name.		String

Name	Description	Default	Type
camel.component.minio.destination-object-name	Source object name.		String
camel.component.minio.enabled	Whether to enable auto configuration of the minio component. This is enabled by default.		Boolean
camel.component.minio.endpoint	Endpoint can be an URL, domain name, IPv4 address or IPv6 address.		String
camel.component.minio.include-body	If it is true, the exchange body will be set to a stream to the contents of the file. If false, the headers will be set with the Minio object metadata, but the body will be null. This option is strongly related to autocloseBody option. In case of setting includeBody to true and autocloseBody to false, it will be up to the caller to close the MinioObject stream. Setting autocloseBody to true, will close the MinioObject stream automatically.	true	Boolean
camel.component.minio.include-folders	The flag which is used in the ListObjectsRequest to set include folders.	false	Boolean
camel.component.minio.include-user-metadata	The flag which is used in the ListObjectsRequest to get objects with user meta data.	false	Boolean
camel.component.minio.include-versions	The flag which is used in the ListObjectsRequest to get objects with versioning.	false	Boolean
camel.component.minio.key-name	Setting the key name for an element in the bucket through endpoint parameter.		String
camel.component.minio.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.minio.length	Number of bytes of object data from offset.		Long
camel.component.minio.match-e-tag	Set match ETag parameter for get object(s).		String
camel.component.minio.max-connections	Set the maxConnections parameter in the minio client configuration.	60	Integer
camel.component.minio.max-messages-per-poll	Gets the maximum number of messages as a limit to poll at each polling. Gets the maximum number of messages as a limit to poll at each polling. The default value is 10. Use 0 or a negative number to set it as unlimited.	10	Integer
camel.component.minio.minio-client	Reference to a Minio Client object in the registry. The option is a io.minio.MinioClient type.		MinioClient
camel.component.minio.modified-since	Set modified since parameter for get object(s). The option is a java.time.ZonedDateTime type.		ZonedDateTime
camel.component.minio.move-after-read	Move objects from bucket to a different bucket after they have been retrieved. To accomplish the operation the destinationBucket option must be set. The copy bucket operation is only performed if the Exchange is committed. If a rollback occurs, the object is not moved.	false	Boolean
camel.component.minio.not-match-e-tag	Set not match ETag parameter for get object(s).		String
camel.component.minio.object-lock	Set when creating new bucket.	false	Boolean
camel.component.minio.object-name	To get the object from the bucket with the given object name.		String
camel.component.minio.offset	Start byte position of object data.		Long
camel.component.minio.operation	The operation to do in case the user don't want to do only an upload.		MinioOperations

Name	Description	Default	Type
camel.component.minio.pojo-request	If we want to use a POJO request as body or not.	false	Boolean
camel.component.minio.policy	The policy for this queue to set in the method.		String
camel.component.minio.prefix	Object name starts with prefix.		String
camel.component.minio.proxy-port	TCP/IP port number. 80 and 443 are used as defaults for HTTP and HTTPS.		Integer
camel.component.minio.recursive	List recursively than directory structure emulation.	false	Boolean
camel.component.minio.region	The region in which Minio client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1). You'll need to use the name Region.EU_WEST_1.id().		String
camel.component.minio.secret-key	Amazon AWS Access Key Id or Minio Secret Key. If not set camel will connect to service for anonymous access.		String
camel.component.minio.secure	Flag to indicate to use secure connection to minio service or not.	false	Boolean
camel.component.minio.server-side-encryption	Server-side encryption. The option is a io.minio.ServerSideEncryption type.		ServerSideEncryption
camel.component.minio.server-side-encryption-customer-key	Server-side encryption for source object while copy/move objects. The option is a io.minio.ServerSideEncryptionCustomerKey type.		ServerSideEncryptionCustomerKey
camel.component.minio.start-after	list objects in bucket after this object name.		String
camel.component.minio.storage-class	The storage class to set in the request.		String

Name	Description	Default	Type
camel.component.minio.un-modified-since	Set un modified since parameter for get object(s). The option is a java.time.ZonedDateTime type.		ZonedDateTime
camel.component.minio.use-version1	when true, version 1 of REST API is used.	false	Boolean
camel.component.minio.version-id	Set specific version_ID of a object when deleting the object.		String

CHAPTER 92. MLLP

Both producer and consumer are supported

The MLLP component is specifically designed to handle the nuances of the MLLP protocol and provide the functionality required by Healthcare providers to communicate with other systems using the MLLP protocol.

The MLLP component provides a simple configuration URI, automated HL7 acknowledgment generation and automatic acknowledgment interrogation.

The MLLP protocol does not typically use a large number of concurrent TCP connections - a single active TCP connection is the normal case. Therefore, the MLLP component uses a simple thread-per-connection model based on standard Java Sockets. This keeps the implementation simple and eliminates the dependencies on only Camel itself.

The component supports the following:

- A Camel consumer using a TCP Server
- A Camel producer using a TCP Client

The MLLP component use **byte[]** payloads, and relies on Camel type conversion to convert **byte[]** to other types.

92.1. DEPENDENCIES

When using **mllp** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-mllp-starter</artifactId>
</dependency>
```

92.2. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

92.2.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

92.2.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

92.3. COMPONENT OPTIONS

The MLLP component supports 30 options, which are listed below.

Name	Description	Default	Type
autoAck (common)	Enable/Disable the automatic generation of a MLLP Acknowledgement MLLP Consumers only.	true	boolean
charsetName (common)	Sets the default charset to use.		String
configuration (common)	Sets the default configuration to use when creating MLLP endpoints.		MllpConfiguration
hl7Headers (common)	Enable/Disable the automatic generation of message headers from the HL7 Message MLLP Consumers only.	true	boolean
requireEndOfData (common)	Enable/Disable strict compliance to the MLLP standard. The MLLP standard specifies START_OF_BLOCKhl7 payloadEND_OF_BLOCKEND_OF_DATA, however, some systems do not send the final END_OF_DATA byte. This setting controls whether or not the final END_OF_DATA byte is required or optional.	true	boolean

Name	Description	Default	Type
stringPayload (common)	Enable/Disable converting the payload to a String. If enabled, HL7 Payloads received from external systems will be validated converted to a String. If the charsetName property is set, that character set will be used for the conversion. If the charsetName property is not set, the value of MSH-18 will be used to determine th appropriate character set. If MSH-18 is not set, then the default ISO-8859-1 character set will be use.	true	boolean
validatePayload (common)	Enable/Disable the validation of HL7 Payloads If enabled, HL7 Payloads received from external systems will be validated (see Hl7Util.generateInvalidPayloadExceptionMessage for details on the validation). If and invalid payload is detected, a MllpInvalidMessageException (for consumers) or a MllpInvalidAcknowledgementException will be thrown.	false	boolean
acceptTimeout (consumer)	Timeout (in milliseconds) while waiting for a TCP connection TCP Server Only.	60000	int
backlog (consumer)	The maximum queue length for incoming connection indications (a request to connect) is set to the backlog parameter. If a connection indication arrives when the queue is full, the connection is refused.	5	Integer
bindRetryInterval (consumer)	TCP Server Only - The number of milliseconds to wait between bind attempts.	5000	int
bindTimeout (consumer)	TCP Server Only - The number of milliseconds to retry binding to a server port.	30000	int
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to receive incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. If disabled, the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions by logging them at WARN or ERROR level and ignored.	true	boolean
lenientBind (consumer)	TCP Server Only - Allow the endpoint to start before the TCP ServerSocket is bound. In some environments, it may be desirable to allow the endpoint to start before the TCP ServerSocket is bound.	false	boolean

Name	Description	Default	Type
maxConcurrentConsumers (consumer)	The maximum number of concurrent MLLP Consumer connections that will be allowed. If a new connection is received and the maximum is number are already established, the new connection will be reset immediately.	5	int
reuseAddress (consumer)	Enable/disable the SO_REUSEADDR socket option.	false	Boolean
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut	InOut	ExchangePattern
connectTimeout (producer)	Timeout (in milliseconds) for establishing for a TCP connection TCP Client only.	30000	int
idleTimeoutStrategy (producer)	decide what action to take when idle timeout occurs. Possible values are : RESET: set SO_LINGER to 0 and reset the socket CLOSE: close the socket gracefully default is RESET. Enum values: • RESET • CLOSE	RESET	MllpIdleTimeoutStrategy
keepAlive (producer)	Enable/disable the SO_KEEPALIVE socket option.	true	Boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
tcpNoDelay (producer)	Enable/disable the TCP_NODELAY socket option.	true	Boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
defaultCharset (advanced)	Set the default character set to use for byte to/from String conversions.	ISO-8859-1	String
logPhi (advanced)	Whether to log PHI.	true	Boolean
logPhiMaxBytes (advanced)	Set the maximum number of bytes of PHI that will be logged in a log entry.	5120	Integer
readTimeout (advanced)	The SO_TIMEOUT value (in milliseconds) used after the start of an MLLP frame has been received.	5000	int
receiveBufferSize (advanced)	Sets the SO_RCVBUF option to the specified value (in bytes).	8192	Integer
receiveTimeout (advanced)	The SO_TIMEOUT value (in milliseconds) used when waiting for the start of an MLLP frame.	15000	int
sendBufferSize (advanced)	Sets the SO_SNDBUF option to the specified value (in bytes).	8192	Integer
idleTimeout (tcp)	The approximate idle time allowed before the Client TCP Connection will be reset. A null value or a value less than or equal to zero will disable the idle timeout.		Integer

92.4. ENDPOINT OPTIONS

The MLLP endpoint is configured using URI syntax:

```
mllp:hostname:port
```

with the following path and query parameters:

92.4.1. Path Parameters (2 parameters)

Name	Description	Default	Type
hostname (common)	**Required** Hostname or IP for connection for the TCP connection. The default value is null, which means any local IP address.		String
port (common)	**Required** Port number for the TCP connection.		int

92.4.2. Query Parameters (26 parameters)

Name	Description	Default	Type
autoAck (common)	Enable/Disable the automatic generation of a MLLP Acknowledgement MLLP Consumers only.	true	boolean
charsetName (common)	Sets the default charset to use.		String
hl7Headers (common)	Enable/Disable the automatic generation of message headers from the HL7 Message MLLP Consumers only.	true	boolean
requireEndOfData (common)	Enable/Disable strict compliance to the MLLP standard. The MLLP standard specifies START_OF_BLOCKhl7 payloadEND_OF_BLOCKEND_OF_DATA, however, some systems do not send the final END_OF_DATA byte. This setting controls whether or not the final END_OF_DATA byte is required or optional.	true	boolean
stringPayload (common)	Enable/Disable converting the payload to a String. If enabled, HL7 Payloads received from external systems will be validated converted to a String. If the charsetName property is set, that character set will be used for the conversion. If the charsetName property is not set, the value of MSH-18 will be used to determine th appropriate character set. If MSH-18 is not set, then the default ISO-8859-1 character set will be use.	true	boolean

Name	Description	Default	Type
validatePayload (common)	Enable/Disable the validation of HL7 Payloads If enabled, HL7 Payloads received from external systems will be validated (see Hl7Util.generateInvalidPayloadExceptionMessage for details on the validation). If and invalid payload is detected, a MllpInvalidMessageException (for consumers) or a MllpInvalidAcknowledgementException will be thrown.	false	boolean
acceptTimeout (consumer)	Timeout (in milliseconds) while waiting for a TCP connection TCP Server Only.	60000	int
backlog (consumer)	The maximum queue length for incoming connection indications (a request to connect) is set to the backlog parameter. If a connection indication arrives when the queue is full, the connection is refused.	5	Integer
bindRetryInterval (consumer)	TCP Server Only - The number of milliseconds to wait between bind attempts.	5000	int
bindTimeout (consumer)	TCP Server Only - The number of milliseconds to retry binding to a server port.	30000	int
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to receive incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. If disabled, the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions by logging them at WARN or ERROR level and ignored.	true	boolean
lenientBind (consumer)	TCP Server Only - Allow the endpoint to start before the TCP ServerSocket is bound. In some environments, it may be desirable to allow the endpoint to start before the TCP ServerSocket is bound.	false	boolean
maxConcurrentConsumers (consumer)	The maximum number of concurrent MLLP Consumer connections that will be allowed. If a new connection is received and the maximum is number are already established, the new connection will be reset immediately.	5	int
reuseAddress (consumer)	Enable/disable the SO_REUSEADDR socket option.	false	Boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut	InOut	ExchangePattern
connectTimeout (producer)	Timeout (in milliseconds) for establishing for a TCP connection TCP Client only.	30000	int
idleTimeoutStrategy (producer)	decide what action to take when idle timeout occurs. Possible values are : RESET: set SO_LINGER to 0 and reset the socket CLOSE: close the socket gracefully default is RESET. Enum values: • RESET • CLOSE	RESET	MllpIdleTimeoutStrategy
keepAlive (producer)	Enable/disable the SO_KEEPALIVE socket option.	true	Boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
tcpNoDelay (producer)	Enable/disable the TCP_NODELAY socket option.	true	Boolean

Name	Description	Default	Type
readTimeout (advanced)	The SO_TIMEOUT value (in milliseconds) used after the start of an MLLP frame has been received.	5000	int
receiveBufferSize (advanced)	Sets the SO_RCVBUF option to the specified value (in bytes).	8192	Integer
receiveTimeout (advanced)	The SO_TIMEOUT value (in milliseconds) used when waiting for the start of an MLLP frame.	15000	int
sendBufferSize (advanced)	Sets the SO_SNDBUF option to the specified value (in bytes).	8192	Integer
idleTimeout (tcp)	The approximate idle time allowed before the Client TCP Connection will be reset. A null value or a value less than or equal to zero will disable the idle timeout.		Integer

92.5. MLLP CONSUMER

The MLLP Consumer supports receiving MLLP-framed messages and sending HL7 Acknowledgements. The MLLP Consumer can automatically generate the HL7 Acknowledgement (HL7 Application Acknowledgements only - AA, AE and AR), or the acknowledgement can be specified using the CamelMllpAcknowledgement exchange property. Additionally, the type of acknowledgement that will be generated can be controlled by setting the CamelMllpAcknowledgementType exchange property. The MLLP Consumer can read messages without sending any HL7 Acknowledgement if the automatic acknowledgement is disabled and exchange pattern is InOnly.

92.5.1. Message Headers

The MLLP Consumer adds these headers on the Camel message:

Key	Description
CamelMllpLocalAddress	The local TCP Address of the Socket
CamelMllpRemoteAddress	The local TCP Address of the Socket
CamelMllpSendingApplication	MSH-3 value
CamelMllpSendingFacility	MSH-4 value
CamelMllpReceivingApplication	MSH-5 value
CamelMllpReceivingFacility	MSH-6 value
CamelMllpTimestamp	MSH-7 value

CamelMllpSecurity	MSH-8 value
CamelMllpMessageType	MSH-9 value
CamelMllpEventType	MSH-9-1 value
CamelMllpTriggerEvent	MSH-9-2 value
CamelMllpMessageControlId	MSH-10 value
CamelMllpProcessingId	MSH-11 value
CamelMllpVersionId	MSH-12 value
CamelMllpCharset	MSH-18 value

All headers are String types. If a header value is missing, its value is null.

92.5.2. Exchange Properties

The type of acknowledgment the MLLP Consumer generates and state of the TCP Socket can be controlled by these properties on the Camel exchange:

Key	Type	Description
CamelMllpAcknowledgement	byte[]	If present, this property will we sent to client as the MLLP Acknowledgement
CamelMllpAcknowledgementString	String	If present and CamelMllpAcknowledgement is not present, this property will we sent to client as the MLLP Acknowledgement
CamelMllpAcknowledgementMsaText	String	If neither CamelMllpAcknowledgement or CamelMllpAcknowledgementString are present and autoAck is true, this property can be used to specify the contents of MSA-3 in the generated HL7 acknowledgement
CamelMllpAcknowledgementType	String	If neither CamelMllpAcknowledgement or CamelMllpAcknowledgementString are present and autoAck is true, this property can be used to specify the HL7 acknowledgement type (i.e. AA, AE, AR)
CamelMllpAutoAcknowledge	Boolean	Overrides the autoAck query parameter
CamelMllpCloseConnectionBeforeSend	Boolean	If true, the Socket will be closed before sending data

Key	Type	Description
CamelMllpResetConnectionBeforeSend	Boolean	If true, the Socket will be reset before sending data
CamelMllpCloseConnectionAfterSend	Boolean	If true, the Socket will be closed immediately after sending data
CamelMllpResetConnectionAfterSend	Boolean	If true, the Socket will be reset immediately after sending any data

92.6. MLLP PRODUCER

The MLLP Producer supports sending MLLP-framed messages and receiving HL7 Acknowledgements. The MLLP Producer interrogates the HL7 Acknowledgments and raises exceptions if a negative acknowledgement is received. The received acknowledgement is interrogated and an exception is raised in the event of a negative acknowledgement. The MLLP Producer can ignore acknowledgements when configured with InOnly exchange pattern.

92.6.1. Message Headers

The MLLP Producer adds these headers on the Camel message:

Key	Description
CamelMllpLocalAddress	The local TCP Address of the Socket
CamelMllpRemoteAddress	The remote TCP Address of the Socket
CamelMllpAcknowledgement	The HL7 Acknowledgment byte[] received
CamelMllpAcknowledgementString	The HL7 Acknowledgment received, converted to a String

92.6.2. Exchange Properties

The state of the TCP Socket can be controlled by these properties on the Camel exchange:

Key	Type	Description
CamelMllpCloseConnectionBeforeSend	Boolean	If true, the Socket will be closed before sending data
CamelMllpResetConnectionBeforeSend	Boolean	If true, the Socket will be reset before sending data

Key	Type	Description
CamelMllpCloseConnectionAfterSend	Boolean	If true, the Socket will be closed immediately after sending data
CamelMllpResetConnectionAfterSend	Boolean	If true, the Socket will be reset immediately after sending any data

92.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 31 options, which are listed below.

Name	Description	Default	Type
camel.component.mllp.accept-timeout	Timeout (in milliseconds) while waiting for a TCP connection TCP Server Only.	60000	Integer
camel.component.mllp.auto-ack	Enable/Disable the automatic generation of a MLLP Acknowledgement MLLP Consumers only.	true	Boolean
camel.component.mllp.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.mllp.backlog	The maximum queue length for incoming connection indications (a request to connect) is set to the backlog parameter. If a connection indication arrives when the queue is full, the connection is refused.	5	Integer
camel.component.mllp.bind-retry-interval	TCP Server Only - The number of milliseconds to wait between bind attempts.	5000	Integer
camel.component.mllp.bind-timeout	TCP Server Only - The number of milliseconds to retry binding to a server port.	30000	Integer

Name	Description	Default	Type
camel.component.mllp.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to receive incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. If disabled, the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions by logging them at WARN or ERROR level and ignored.	true	Boolean
camel.component.mllp.charset-name	Sets the default charset to use.		String
camel.component.mllp.configuration	Sets the default configuration to use when creating MLLP endpoints. The option is a org.apache.camel.component.mllp.MllpConfiguration type.		MllpConfiguration
camel.component.mllp.connect-timeout	Timeout (in milliseconds) for establishing for a TCP connection TCP Client only.	30000	Integer
camel.component.mllp.default-charset	Set the default character set to use for byte to/from String conversions.	ISO-8859-1	String
camel.component.mllp.enabled	Whether to enable auto configuration of the mllp component. This is enabled by default.		Boolean
camel.component.mllp.exchange-pattern	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
camel.component.mllp.hl7-headers	Enable/Disable the automatic generation of message headers from the HL7 Message MLLP Consumers only.	true	Boolean
camel.component.mllp.idle-timeout	The approximate idle time allowed before the Client TCP Connection will be reset. A null value or a value less than or equal to zero will disable the idle timeout.		Integer
camel.component.mllp.idle-timeout-strategy	decide what action to take when idle timeout occurs. Possible values are : RESET: set SO_LINGER to 0 and reset the socket CLOSE: close the socket gracefully default is RESET.		MllpIdleTimeoutStrategy

Name	Description	Default	Type
camel.component.mllp.keep-alive	Enable/disable the SO_KEEPALIVE socket option.	true	Boolean
camel.component.mllp.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.mllp.lenient-bind	TCP Server Only - Allow the endpoint to start before the TCP ServerSocket is bound. In some environments, it may be desirable to allow the endpoint to start before the TCP ServerSocket is bound.	false	Boolean
camel.component.mllp.log-phi	Whether to log PHI.	true	Boolean
camel.component.mllp.log-phi-max-bytes	Set the maximum number of bytes of PHI that will be logged in a log entry.	5120	Integer
camel.component.mllp.max-concurrent-consumers	The maximum number of concurrent MLLP Consumer connections that will be allowed. If a new connection is received and the maximum is number are already established, the new connection will be reset immediately.	5	Integer
camel.component.mllp.read-timeout	The SO_TIMEOUT value (in milliseconds) used after the start of an MLLP frame has been received.	5000	Integer
camel.component.mllp.receive-buffer-size	Sets the SO_RCVBUF option to the specified value (in bytes).	8192	Integer
camel.component.mllp.receive-timeout	The SO_TIMEOUT value (in milliseconds) used when waiting for the start of an MLLP frame.	15000	Integer

Name	Description	Default	Type
camel.component.mllp.require-end-of-data	Enable/Disable strict compliance to the MLLP standard. The MLLP standard specifies START_OF_BLOCKhl7 payloadEND_OF_BLOCKEND_OF_DATA, however, some systems do not send the final END_OF_DATA byte. This setting controls whether or not the final END_OF_DATA byte is required or optional.	true	Boolean
camel.component.mllp.reuse-address	Enable/disable the SO_REUSEADDR socket option.	false	Boolean
camel.component.mllp.send-buffer-size	Sets the SO_SNDBUF option to the specified value (in bytes).	8192	Integer
camel.component.mllp.string-payload	Enable/Disable converting the payload to a String. If enabled, HL7 Payloads received from external systems will be validated converted to a String. If the charsetName property is set, that character set will be used for the conversion. If the charsetName property is not set, the value of MSH-18 will be used to determine th appropriate character set. If MSH-18 is not set, then the default ISO-8859-1 character set will be use.	true	Boolean
camel.component.mllp.tcp-no-delay	Enable/disable the TCP_NODELAY socket option.	true	Boolean
camel.component.mllp.validate-payload	Enable/Disable the validation of HL7 Payloads If enabled, HL7 Payloads received from external systems will be validated (see Hl7Util.generateInvalidPayloadExceptionMessage for details on the validation). If and invalid payload is detected, a MllpInvalidMessageException (for consumers) or a MllpInvalidAcknowledgementException will be thrown.	false	Boolean

CHAPTER 93. MOCK

Only producer is supported

Testing of distributed and asynchronous processing is notoriously difficult. The Mock, Test and Dataset endpoints work great with the Camel Testing Framework to simplify your unit and integration testing using Enterprise Integration Patterns and Camel's large range of Components together with the powerful Bean Integration.

The Mock component provides a powerful declarative testing mechanism, which is similar to jMock in that it allows declarative expectations to be created on any Mock endpoint before a test begins. Then the test is run, which typically fires messages to one or more endpoints, and finally the expectations can be asserted in a test case to ensure the system worked as expected.

This allows you to test various things like:

- The correct number of messages are received on each endpoint,
- The correct payloads are received, in the right order,
- Messages arrive on an endpoint in order, using some Expression to create an order testing function,
- Messages arrive match some kind of Predicate such as that specific headers have certain values, or that messages match some predicate, such as by evaluating an XPath or XQuery Expression.

NOTE

There is also the Test endpoint which is a Mock endpoint, but which uses a second endpoint to provide the list of expected message bodies and automatically sets up the Mock endpoint assertions. In other words, it's a Mock endpoint that automatically sets up its assertions from some sample messages in a File or database, for example.

NOTE

Mock endpoints keep received Exchanges in memory indefinitely.
Remember that Mock is designed for testing. When you add Mock endpoints to a route, each Exchange sent to the endpoint will be stored (to allow for later validation) in memory until explicitly reset or the JVM is restarted. If you are sending high volume and/or large messages, this may cause excessive memory use. If your goal is to test deployable routes inline, consider using NotifyBuilder or AdviceWith in your tests instead of adding Mock endpoints to routes directly. There are two new options retainFirst, and retainLast that can be used to limit the number of messages the Mock endpoints keep in memory.

93.1. DEPENDENCIES

When using **mock** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-mock-starter</artifactId>
</dependency>
```

93.2. URI FORMAT

```
mock:someName[?options]
```

Where **someName** can be any string that uniquely identifies the endpoint.

93.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

93.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

93.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

93.4. COMPONENT OPTIONS

The Mock component supports 4 options, which are listed below.

Name	Description	Default	Type

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
log (producer)	To turn on logging when the mock receives an incoming message. This will log only one time at INFO level for the incoming message. For more detailed logging then set the logger to DEBUG level for the org.apache.camel.component.mock.MockEndpoint class.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
exchangeFormatter (advanced)	**Autowired** Sets a custom ExchangeFormatter to convert the Exchange to a String suitable for logging. If not specified, we default to DefaultExchangeFormatter.		ExchangeFormatter

93.5. ENDPOINT OPTIONS

The Mock endpoint is configured using URI syntax:

```
mock:name
```

with the following path and query parameters:

93.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (producer)	**Required** Name of mock endpoint.		String

93.5.2. Query Parameters (12 parameters)

Name	Description	Default	Type
assertPeriod (producer)	Sets a grace period after which the mock endpoint will re-assert to ensure the preliminary assertion is still valid. This is used for example to assert that exactly a number of messages arrives. For example if expectedMessageCount(int) was set to 5, then the assertion is satisfied when 5 or more message arrives. To ensure that exactly 5 messages arrives, then you would need to wait a little period to ensure no further message arrives. This is what you can use this method for. By default this period is disabled.		long
expectedCount (producer)	Specifies the expected number of message exchanges that should be received by this endpoint. Beware: If you want to expect that 0 messages, then take extra care, as 0 matches when the tests starts, so you need to set a assert period time to let the test run for a while to make sure there are still no messages arrived; for that use setAssertPeriod(long). An alternative is to use NotifyBuilder, and use the notifier to know when Camel is done routing some messages, before you call the assertIsSatisfied() method on the mocks. This allows you to not use a fixed assert period, to speedup testing times. If you want to assert that exactly n'th message arrives to this mock endpoint, then see also the setAssertPeriod(long) method for further details.	-1	int
failFast (producer)	Sets whether assertIsSatisfied() should fail fast at the first detected failed expectation while it may otherwise wait for all expected messages to arrive before performing expectations verifications. Is by default true. Set to false to use behavior as in Camel 2.x.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
log (producer)	To turn on logging when the mock receives an incoming message. This will log only one time at INFO level for the incoming message. For more detailed logging then set the logger to DEBUG level for the org.apache.camel.component.mock.MockEndpoint class.	false	boolean
reportGroup (producer)	A number that is used to turn on throughput logging based on groups of the size.		int
resultMinimumWaitTime (producer)	Sets the minimum expected amount of time (in millis) the assertIsSatisfied() will wait on a latch until it is satisfied.		long
resultWaitTime (producer)	Sets the maximum amount of time (in millis) the assertIsSatisfied() will wait on a latch until it is satisfied.		long
retainFirst (producer)	Specifies to only retain the first n'th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the getReceivedCounter() will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the first 10 Exchanges, then the getReceivedCounter() will still return 5000 but there is only the first 10 Exchanges in the getExchanges() and getReceivedExchanges() methods. When using this method, then some of the other expectation methods is not supported, for example the expectedBodiesReceived(Object...) sets a expectation on the first number of bodies received. You can configure both setRetainFirst(int) and setRetainLast(int) methods, to limit both the first and last received.	-1	int

Name	Description	Default	Type
retainLast (producer)	Specifies to only retain the last n'th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the getReceivedCounter() will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the last 20 Exchanges, then the getReceivedCounter() will still return 5000 but there is only the last 20 Exchanges in the getExchanges() and getReceivedExchanges() methods. When using this method, then some of the other expectation methods is not supported, for example the expectedBodiesReceived(Object...) sets a expectation on the first number of bodies received. You can configure both setRetainFirst(int) and setRetainLast(int) methods, to limit both the first and last received.	-1	int
sleepForEmptyTest (producer)	Allows a sleep to be specified to wait to check that this endpoint really is empty when expectedMessageCount(int) is called with zero.		long
copyOnExchange (producer (advanced))	Sets whether to make a deep copy of the incoming Exchange when received at this mock endpoint. Is by default true.	true	boolean

93.6. SIMPLE EXAMPLE

Here's a simple example of Mock endpoint in use. First, the endpoint is resolved on the context. Then we set an expectation, and then, after the test has run, we assert that our expectations have been met:

```
MockEndpoint resultEndpoint = context.getEndpoint("mock:foo", MockEndpoint.class);

// set expectations
resultEndpoint.expectedMessageCount(2);

// send some messages

// now lets assert that the mock:foo endpoint received 2 messages
resultEndpoint.assertIsSatisfied();
```

You typically always call the method to test that the expectations were met after running a test.

Camel will by default wait 10 seconds when the **assertIsSatisfied()** is invoked. This can be configured by setting the **setResultWaitTime(millis)** method.

93.7. USING ASSERTPERIOD

When the assertion is satisfied then Camel will stop waiting and continue from the **assertIsSatisfied** method. That means if a new message arrives on the mock endpoint, just a bit later, that arrival will not affect the outcome of the assertion. Suppose you do want to test that no new messages arrives after a period thereafter, then you can do that by setting the **setAssertPeriod** method, for example:

```
MockEndpoint resultEndpoint = context.getEndpoint("mock:foo", MockEndpoint.class);
resultEndpoint.setAssertPeriod(5000);
resultEndpoint.expectedMessageCount(2);

// send some messages

// now lets assert that the mock:foo endpoint received 2 messages
resultEndpoint.assertIsSatisfied();
```

93.8. SETTING EXPECTATIONS

You can see from the Javadoc of MockEndpoint the various helper methods you can use to set expectations. The main methods are as follows:

Method	Description
expectedMessageCount(int)	To define the expected message count on the endpoint.
expectedMinimumMessageCount(int)	To define the minimum number of expected messages on the endpoint.
expectedBodiesReceived(...)	To define the expected bodies that should be received (in order).
expectedHeaderReceived(...)	To define the expected header that should be received
expectsAscending(Expression)	To add an expectation that messages are received in order, using the given Expression to compare messages.
expectsDescending(Expression)	To add an expectation that messages are received in order, using the given Expression to compare messages.
expectsNoDuplicates(Expression)	To add an expectation that no duplicate messages are received; using an Expression to calculate a unique identifier for each message. This could be something like the **JMSMessageID** if using JMS, or some unique reference number within the message.

Here's another example:

```
resultEndpoint.expectedBodiesReceived("firstMessageBody", "secondMessageBody",
"thirdMessageBody");
```

93.9. ADDING EXPECTATIONS TO SPECIFIC MESSAGES

In addition, you can use the **message(int messageIndex)** method to add assertions about a specific message that is received.

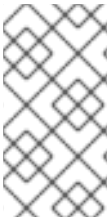
For example, to add expectations of the headers or body of the first message (using zero-based indexing like **java.util.List**), you can use the following code:

```
resultEndpoint.message(0).header("foo").isEqualTo("bar");
```

There are some examples of the Mock endpoint in use in the **camel-core** processor tests.

93.10. MOCKING EXISTING ENDPOINTS

Camel now allows you to automatically mock existing endpoints in your Camel routes.



NOTE

How it works
The endpoints are still in action. What happens differently is that a Mock endpoint is injected and receives the message first and then delegates the message to the target endpoint. You can view this as a kind of intercept and delegate or endpoint listener.

Suppose you have the given route below:

Route

```
@Override
protected RouteBuilder createRouteBuilder() throws Exception {
    return new RouteBuilder() {
        @Override
        public void configure() throws Exception {
            from("direct:start").routeId("start")
                    .to("direct:foo").to("log:foo").to("mock:result");

            from("direct:foo").routeId("foo")
                    .transform(constant("Bye World"));
        }
    };
}
```

You can then use the **adviceWith** feature in Camel to mock all the endpoints in a given route from your unit test, as shown below:

adviceWith mocking all endpoints

```
@Test
public void testAdvisedMockEndpoints() throws Exception {
    // advice the start route using the inlined AdviceWith lambda style route builder
    // which has extended capabilities than the regular route builder
    AdviceWith.adviceWith(context, "start", a ->
    // mock all endpoints
```

```
        a.mockEndpoints());

        getMockEndpoint("mock:direct:start").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:direct:foo").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:log:foo").expectedBodiesReceived("Bye World");
        getMockEndpoint("mock:result").expectedBodiesReceived("Bye World");

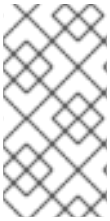
        template.sendBody("direct:start", "Hello World");

        assertMockEndpointsSatisfied();

        // additional test to ensure correct endpoints in registry
        assertNotNull(context.hasEndpoint("direct:start"));
        assertNotNull(context.hasEndpoint("direct:foo"));
        assertNotNull(context.hasEndpoint("log:foo"));
        assertNotNull(context.hasEndpoint("mock:result"));
        // all the endpoints was mocked
        assertNotNull(context.hasEndpoint("mock:direct:start"));
        assertNotNull(context.hasEndpoint("mock:direct:foo"));
        assertNotNull(context.hasEndpoint("mock:log:foo"));
    }
```

Notice that the mock endpoints is given the URI **mock:<endpoint>**, for example **mock:direct:foo**. Camel logs at **INFO** level the endpoints being mocked:

```
INFO  Adviced endpoint [direct://foo] with mock endpoint [mock:direct:foo]
```



NOTE

Mocked endpoints are without parameters
Endpoints which are mocked will have their parameters stripped off. For example the endpoint **log:foo?showAll=true** will be mocked to the following endpoint **mock:log:foo**. Notice the parameters have been removed.

Its also possible to only mock certain endpoints using a pattern. For example to mock all **log** endpoints you do as shown:

adviceWith mocking only log endpoints using a pattern

```
    @Test
    public void testAdvisedMockEndpointsWithPattern() throws Exception {
        // advice the start route using the inlined AdviceWith lambda style route builder
        // which has extended capabilities than the regular route builder
        AdviceWith.adviceWith(context, "start", a ->
        // mock only log endpoints
        a.mockEndpoints("log*"));

        // now we can refer to log:foo as a mock and set our expectations
        getMockEndpoint("mock:log:foo").expectedBodiesReceived("Bye World");

        getMockEndpoint("mock:result").expectedBodiesReceived("Bye World");

        template.sendBody("direct:start", "Hello World");
```

```
        assertMockEndpointsSatisfied();

        // additional test to ensure correct endpoints in registry
        assertNotNull(context.hasEndpoint("direct:start"));
        assertNotNull(context.hasEndpoint("direct:foo"));
        assertNotNull(context.hasEndpoint("log:foo"));
        assertNotNull(context.hasEndpoint("mock:result"));
        // only the log:foo endpoint was mocked
        assertNotNull(context.hasEndpoint("mock:log:foo"));
        assertNull(context.hasEndpoint("mock:direct:start"));
        assertNull(context.hasEndpoint("mock:direct:foo"));
    }
```

The pattern supported can be a wildcard or a regular expression. See more details about this at Intercept as its the same matching function used by Camel.

NOTE

Mind that mocking endpoints causes the messages to be copied when they arrive on the mock.
That means Camel will use more memory. This may not be suitable when you send in a lot of messages.

93.11. MOCKING EXISTING ENDPOINTS USING THE CAMEL-TEST COMPONENT

Instead of using the **adviceWith** to instruct Camel to mock endpoints, you can easily enable this behavior when using the **camel-test** Test Kit.

The same route can be tested as follows. Notice that we return **"*"** from the **isMockEndpoints** method, which tells Camel to mock all endpoints.

If you only want to mock all **log** endpoints you can return **"log*"** instead.

isMockEndpoints using camel-test kit

```
public class IsMockEndpointsJUnit4Test extends CamelTestSupport {

    @Override
    public String isMockEndpoints() {
        // override this method and return the pattern for which endpoints to mock.
        // use * to indicate all
        return "*";
    }

    @Test
    public void testMockAllEndpoints() throws Exception {
        // notice we have automatic mocked all endpoints and the name of the endpoints is "mock:uri"
        getMockEndpoint("mock:direct:start").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:direct:foo").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:log:foo").expectedBodiesReceived("Bye World");
        getMockEndpoint("mock:result").expectedBodiesReceived("Bye World");

        template.sendBody("direct:start", "Hello World");
```

```
        assertMockEndpointsSatisfied();

        // additional test to ensure correct endpoints in registry
        assertNotNull(context.hasEndpoint("direct:start"));
        assertNotNull(context.hasEndpoint("direct:foo"));
        assertNotNull(context.hasEndpoint("log:foo"));
        assertNotNull(context.hasEndpoint("mock:result"));
        // all the endpoints was mocked
        assertNotNull(context.hasEndpoint("mock:direct:start"));
        assertNotNull(context.hasEndpoint("mock:direct:foo"));
        assertNotNull(context.hasEndpoint("mock:log:foo"));
    }

    @Override
    protected RouteBuilder createRouteBuilder() throws Exception {
        return new RouteBuilder() {
            @Override
            public void configure() throws Exception {
                from("direct:start").to("direct:foo").to("log:foo").to("mock:result");

                from("direct:foo").transform(constant("Bye World"));
            }
        };
    }
}
```

93.12. MOCKING EXISTING ENDPOINTS WITH XML DSL

If you do not use the **camel-test** component for unit testing (as shown above) you can use a different approach when using XML files for routes.
The solution is to create a new XML file used by the unit test and then include the intended XML file which has the route you want to test.

Suppose we have the route in the **camel-route.xml** file:

camel-route.xml

```
<!-- this camel route is in the camel-route.xml file -->
<camelContext xmlns="http://camel.apache.org/schema/spring">

    <route>
        <from uri="direct:start"/>
        <to uri="direct:foo"/>
        <to uri="log:foo"/>
        <to uri="mock:result"/>
    </route>

    <route>
        <from uri="direct:foo"/>
        <transform>
            <constant>Bye World</constant>
        </transform>
    </route>

</camelContext>
```

Then we create a new XML file as follows, where we include the **camel-route.xml** file and define a spring bean with the class **org.apache.camel.impl.InterceptSendToMockEndpointStrategy** which tells Camel to mock all endpoints:

test-camel-route.xml

```
    <!-- the Camel route is defined in another XML file -->
    <import resource="camel-route.xml"/>

    <!-- bean which enables mocking all endpoints -->
    <bean id="mockAllEndpoints"
class="org.apache.camel.component.mock.InterceptSendToMockEndpointStrategy"/>
```

Then in your unit test you load the new XML file (**test-camel-route.xml**) instead of **camel-route.xml**.

To only mock all Log endpoints you can define the pattern in the constructor for the bean:

```
<bean id="mockAllEndpoints"
class="org.apache.camel.impl.InterceptSendToMockEndpointStrategy">
    <constructor-arg index="0" value="log*"/>
</bean>
```

93.13. MOCKING ENDPOINTS AND SKIP SENDING TO ORIGINAL ENDPOINT

Sometimes you want to easily mock and skip sending to a certain endpoints. So the message is detoured and send to the mock endpoint only. You can now use the **mockEndpointsAndSkip** method using AdviceWith. The example below will skip sending to the two endpoints **"direct:foo"**, and **"direct:bar"**.

adviceWith mock and skip sending to endpoints

```
    @Test
    public void testAdvisedMockEndpointsWithSkip() throws Exception {
        // advice the first route using the inlined AdviceWith route builder
        // which has extended capabilities than the regular route builder
        AdviceWith.adviceWith(context.getRouteDefinitions().get(0), context, new
AdviceWithRouteBuilder() {
            @Override
            public void configure() throws Exception {
                // mock sending to direct:foo and direct:bar and skip send to it
                mockEndpointsAndSkip("direct:foo", "direct:bar");
            }
        });

        getMockEndpoint("mock:result").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:direct:foo").expectedMessageCount(1);
        getMockEndpoint("mock:direct:bar").expectedMessageCount(1);

        template.sendBody("direct:start", "Hello World");

        assertMockEndpointsSatisfied();

        // the message was not send to the direct:foo route and thus not sent to
        // the seda endpoint
```

```
        SedaEndpoint seda = context.getEndpoint("seda:foo", SedaEndpoint.class);
        assertEquals(0, seda.getCurrentQueueSize());
    }
```

The same example using the Test Kit

isMockEndpointsAndSkip using camel-test kit

```
public class IsMockEndpointsAndSkipJUnit4Test extends CamelTestSupport {

    @Override
    public String isMockEndpointsAndSkip() {
        // override this method and return the pattern for which endpoints to mock,
        // and skip sending to the original endpoint.
        return "direct:foo";
    }

    @Test
    public void testMockEndpointAndSkip() throws Exception {
        // notice we have automatic mocked the direct:foo endpoints and the name of the endpoints is
"mock:uri"
        getMockEndpoint("mock:result").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:direct:foo").expectedMessageCount(1);

        template.sendBody("direct:start", "Hello World");

        assertMockEndpointsSatisfied();

        // the message was not send to the direct:foo route and thus not sent to the seda endpoint
        SedaEndpoint seda = context.getEndpoint("seda:foo", SedaEndpoint.class);
        assertEquals(0, seda.getCurrentQueueSize());
    }

    @Override
    protected RouteBuilder createRouteBuilder() throws Exception {
        return new RouteBuilder() {
            @Override
            public void configure() throws Exception {
                from("direct:start").to("direct:foo").to("mock:result");

                from("direct:foo").transform(constant("Bye World")).to("seda:foo");
            }
        };
    }
}
```

93.14. LIMITING THE NUMBER OF MESSAGES TO KEEP

The Mock endpoints will by default keep a copy of every Exchange that it received. So if you test with a lot of messages, then it will consume memory.
We have introduced two options **retainFirst** and **retainLast** that can be used to specify to only keep N'th of the first and/or last Exchanges.

For example in the code below, we only want to retain a copy of the first 5 and last 5 Exchanges the mock receives.

```
MockEndpoint mock = getMockEndpoint("mock:data");
mock.setRetainFirst(5);
mock.setRetainLast(5);
mock.expectedMessageCount(2000);

mock.assertIsSatisfied();
```

Using this has some limitations. The **getExchanges()** and **getReceivedExchanges()** methods on the **MockEndpoint** will return only the retained copies of the Exchanges. So in the example above, the list will contain 10 Exchanges; the first five, and the last five.
The **retainFirst** and **retainLast** options also have limitations on which expectation methods you can use. For example the **expectedXXX** methods that work on message bodies, headers, etc. will only operate on the retained messages. In the example above they can test only the expectations on the 10 retained messages.

93.15. TESTING WITH ARRIVAL TIMES

The Mock endpoint stores the arrival time of the message as a property on the Exchange

```
Date time = exchange.getProperty(Exchange.RECEIVED_TIMESTAMP, Date.class);
```

You can use this information to know when the message arrived on the mock. But it also provides foundation to know the time interval between the previous and next message arrived on the mock. You can use this to set expectations using the **arrives** DSL on the Mock endpoint.

For example to say that the first message should arrive between 0-2 seconds before the next you can do:

```
mock.message(0).arrives().noLaterThan(2).seconds().beforeNext();
```

You can also define this as that 2nd message (0 index based) should arrive no later than 0-2 seconds after the previous:

```
mock.message(1).arrives().noLaterThan(2).seconds().afterPrevious();
```

You can also use between to set a lower bound. For example suppose that it should be between 1-4 seconds:

```
mock.message(1).arrives().between(1, 4).seconds().afterPrevious();
```

You can also set the expectation on all messages, for example to say that the gap between them should be at most 1 second:

```
mock.allMessages().arrives().noLaterThan(1).seconds().beforeNext();
```

NOTE

Time units
In the example above we use **seconds** as the time unit, but Camel offers **milliseconds**, and **minutes** as well.

93.16. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.component.mock.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.mock.enabled	Whether to enable auto configuration of the mock component. This is enabled by default.		Boolean
camel.component.mock.exchange-formatter	Sets a custom ExchangeFormatter to convert the Exchange to a String suitable for logging. If not specified, we default to DefaultExchangeFormatter. The option is a org.apache.camel.spi.ExchangeFormatter type.		ExchangeFormatter
camel.component.mock.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.mock.log	To turn on logging when the mock receives an incoming message. This will log only one time at INFO level for the incoming message. For more detailed logging then set the logger to DEBUG level for the org.apache.camel.component.mock.MockEndpoint class.	false	Boolean

CHAPTER 94. MONGODB

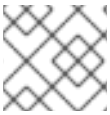
Both producer and consumer are supported

According to Wikipedia: "NoSQL is a movement promoting a loosely defined class of non-relational data stores that break with a long history of relational databases and ACID guarantees." NoSQL solutions have grown in popularity in the last few years, and major extremely-used sites and services such as Facebook, LinkedIn, Twitter, etc. are known to use them extensively to achieve scalability and agility.

Basically, NoSQL solutions differ from traditional RDBMS (Relational Database Management Systems) in that they don't use SQL as their query language and generally don't offer ACID-like transactional behaviour nor relational data. Instead, they are designed around the concept of flexible data structures and schemas (meaning that the traditional concept of a database table with a fixed schema is dropped), extreme scalability on commodity hardware and blazing-fast processing.

MongoDB is a very popular NoSQL solution and the camel-mongodb component integrates Camel with MongoDB allowing you to interact with MongoDB collections both as a producer (performing operations on the collection) and as a consumer (consuming documents from a MongoDB collection).

MongoDB revolves around the concepts of documents (not as is office documents, but rather hierarchical data defined in JSON/BSON) and collections. This component page will assume you are familiar with them. Otherwise, visit http://www.mongodb.org/.



NOTE

The MongoDB Camel component uses Mongo Java Driver 4.x.

94.1. DEPENDENCIES

When using **mongodb** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-mongodb-starter</artifactId>
</dependency>
```

94.2. URI FORMAT

```
mongodb:connectionBean?
database=databaseName&collection=collectionName&operation=operationName[&moreOptions...]
```

94.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

94.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

94.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

94.4. COMPONENT OPTIONS

The MongoDB component supports 4 options, which are listed below.

Name	Description	Default	Type
mongoConnection (common)	**Autowired** Shared client used for connection. All endpoints generated from the component will share this connection client.		MongoClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

94.5. ENDPOINT OPTIONS

The MongoDB endpoint is configured using URI syntax:

```
mongodb:connectionBean
```

with the following path and query parameters:

94.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
connectionBean (common)	**Required** Sets the connection bean reference used to lookup a client for connecting to a database.		String

94.5.2. Query Parameters (27 parameters)

Name	Description	Default	Type
collection (common)	Sets the name of the MongoDB collection to bind to this endpoint.		String
collectionIndex (common)	Sets the collection index (JSON FORMAT : \\{ field1 : order1, field2 : order2}).		String

Name	Description	Default	Type
createCollection (common)	Create collection during initialisation if it doesn't exist. Default is true.	true	boolean
database (common)	Sets the name of the MongoDB database to target.		String
hosts (common)	Host address of mongodb server in host:port format. It's possible also use more than one address, as comma separated list of hosts: host1:port1,host2:port2. If hosts parameter is specified, provided connectionBean is ignored.		String
mongoConnection (common)	Sets the connection bean used as a client for connecting to a database.		MongoClient
operation (common)	Sets the operation this endpoint will execute against MongoDB. Enum values: • findById • findOneByQuery • findAll • findDistinct • insert • save • update • remove • bulkWrite • aggregate • getDbStats • getColStats • count • command		MongoDbOperation

Name	Description	Default	Type
outputType (common)	Convert the output of the producer to the selected type : DocumentList Document or MongoIterable. DocumentList or MongoIterable applies to findAll and aggregate. Document applies to all other operations. Enum values: • DocumentList • Document • MongoIterable		MongoDbOutputType
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumerType (consumer)	Consumer type.		String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
cursorRegenerationDelay (advanced)	MongoDB tailable cursors will block until new data arrives. If no new data is inserted, after some time the cursor will be automatically freed and closed by the MongoDB server. The client is expected to regenerate the cursor if needed. This value specifies the time to wait before attempting to fetch a new cursor, and if the attempt fails, how long before the next attempt is made. Default value is 1000ms.	1000	long
dynamicity (advanced)	Sets whether this endpoint will attempt to dynamically resolve the target database and collection from the incoming Exchange properties. Can be used to override at runtime the database and collection specified on the otherwise static endpoint URI. It is disabled by default to boost performance. Enabling it will take a minimal performance hit.	false	boolean
readPreference (advanced)	Configure how MongoDB clients route read operations to the members of a replica set. Possible values are PRIMARY, PRIMARY_PREFERRED, SECONDARY, SECONDARY_PREFERRED or NEAREST. Enum values: • PRIMARY • PRIMARY_PREFERRED • SECONDARY • SECONDARY_PREFERRED • NEAREST	PRIMARY	String

Name	Description	Default	Type
writeConcern (advanced)	Configure the connection bean with the level of acknowledgment requested from MongoDB for write operations to a standalone mongod, replicaset or cluster. Possible values are ACKNOWLEDGED, W1, W2, W3, UNACKNOWLEDGED, JOURNALED or MAJORITY. Enum values: • ACKNOWLEDGED • W1 • W2 • W3 • UNACKNOWLEDGED • JOURNALED • MAJORITY	ACKNOWLEDGED	String
writeResultAsHeader (advanced)	In write operations, it determines whether instead of returning WriteResult as the body of the OUT message, we transfer the IN message to the OUT and attach the WriteResult as a header.	false	boolean
streamFilter (changeStream)	Filter condition for change streams consumer.		String
password (security)	User password for mongodb connection.		String
username (security)	Username for mongodb connection.		String
persistentId (tail)	One tail tracking collection can host many trackers for several tailable consumers. To keep them separate, each tracker should have its own unique persistentId.		String
persistentTailTracking (tail)	Enable persistent tail tracking, which is a mechanism to keep track of the last consumed message across system restarts. The next time the system is up, the endpoint will recover the cursor from the point where it last stopped slurping records.	false	boolean

Name	Description	Default	Type
tailTrackCollection (tail)	Collection where tail tracking information will be persisted. If not specified, MongoDbTailTrackingConfig#DEFAULT_COLLECTION will be used by default.		String
tailTrackDb (tail)	Indicates what database the tail tracking mechanism will persist to. If not specified, the current database will be picked by default. Dynamicity will not be taken into account even if enabled, i.e. the tail tracking database will not vary past endpoint initialisation.		String
tailTrackField (tail)	Field where the last tracked value will be placed. If not specified, MongoDbTailTrackingConfig#DEFAULT_FIELD will be used by default.		String
tailTrackIncreasingField (tail)	Correlation field in the incoming record which is of increasing nature and will be used to position the tailing cursor every time it is generated. The cursor will be (re)created with a query of type: tailTrackIncreasingField greater than lastValue (possibly recovered from persistent tail tracking). Can be of type Integer, Date, String, etc. NOTE: No support for dot notation at the current time, so the field should be at the top level of the document.		String

94.6. CONFIGURATION OF DATABASE IN SPRING XML

The following Spring XML creates a bean defining the connection to a MongoDB instance.

Since mongo java driver 3, the WriteConcern and readPreference options are not dynamically modifiable. They are defined in the mongoClient object

```
<beans xmlns="http://www.springframework.org/schema/beans"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:context="http://www.springframework.org/schema/context"
xmlns:mongo="http://www.springframework.org/schema/data/mongo"
xsi:schemaLocation="http://www.springframework.org/schema/context
      http://www.springframework.org/schema/context/spring-context.xsd
      http://www.springframework.org/schema/data/mongo
      http://www.springframework.org/schema/data/mongo/spring-mongo.xsd
      http://www.springframework.org/schema/beans
      http://www.springframework.org/schema/beans/spring-beans.xsd">

  <mongo:mongo-client id="mongoBean" host="${mongo.url}" port="${mongo.port}"
credentials="${mongo.user}:${mongo.pass}@${mongo.dbname}">
    <mongo:client-options write-concern="NORMAL" />
  </mongo:mongo-client>
</beans>
```

94.7. SAMPLE ROUTE

The following route defined in Spring XML executes the operation **getDbStats** on a collection.

Get DB stats for specified collection

```
<route>
  <from uri="direct:start" />
  <!-- using bean 'mongoBean' defined above -->
  <to uri="mongodb:mongoBean?
database=${mongodb.database}&amp;collection=${mongodb.collection}&amp;operation=getDbStats"
/>
  <to uri="direct:result" />
</route>
```

94.8. MONGODB OPERATIONS - PRODUCER ENDPOINTS

94.8.1. Query operations

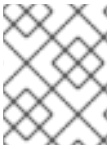
94.8.1.1. findById

This operation retrieves only one element from the collection whose _id field matches the content of the IN message body. The incoming object can be anything that has an equivalent to a **Bson** type. See http://bsonspec.org/spec.html and http://www.mongodb.org/display/DOCS/Java+Types.

```
from("direct:findById")
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findById")
    .to("mock:resultFindById");
```

Please, note that the default _id is treated by Mongo as and **ObjectId** type, so you may need to convert it properly.

```
from("direct:findById")
    .convertBodyTo(ObjectId.class)
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findById")
    .to("mock:resultFindById");
```



NOTE

Supports optional parameters
This operation supports projection operators. See Specifying a fields filter (projection) .

94.8.1.2. findOneByQuery

Retrieve the first element from a collection matching a MongoDB query selector. **If the CamelMongoDbCriteria header is set, then its value is used as the query selector**If the **CamelMongoDbCriteria** header is *null*, then the IN message body is used as the query selector. In both cases, the query selector should be of type **Bson** or convertible to **Bson** (for instance, a JSON string or **HashMap**). See Type conversions for more info.

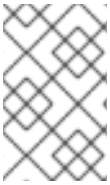
Create query selectors using the **Filters** provided by the MongoDB Driver.

94.8.1.3. Example without a query selector (returns the first document in a collection)

```
from("direct:findOneByQuery")
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findOneByQuery")
    .to("mock:resultFindOneByQuery");
```

94.8.1.4. Example with a query selector (returns the first matching document in a collection):

```
from("direct:findOneByQuery")
    .setHeader(MongoDbConstants.CRITERIA, constant(Filters.eq("name", "Raul Kripalani")))
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findOneByQuery")
    .to("mock:resultFindOneByQuery");
```



NOTE

Supports optional parameters
This operation supports projection operators and sort clauses. See Specifying a fields filter (projection), Specifying a sort clause.

94.8.1.5. findAll

The **findAll** operation returns all documents matching a query, or none at all, in which case all documents contained in the collection are returned. **The query object is extracted CamelMongoDbCriteria header**. if the CamelMongoDbCriteria header is null the query object is extracted message body, i.e. it should be of type **Bson** or convertible to **Bson**. It can be a JSON String or a Hashmap. See Type conversions for more info.

94.8.1.5.1. Example without a query selector (returns all documents in a collection)

```
from("direct:findAll")
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findAll")
    .to("mock:resultFindAll");
```

94.8.1.5.2. Example with a query selector (returns all matching documents in a collection)

```
from("direct:findAll")
    .setHeader(MongoDbConstants.CRITERIA, Filters.eq("name", "Raul Kripalani"))
    .to("mongodb:myDb?database=flights&collection=tickets&operation=findAll")
    .to("mock:resultFindAll");
```

Paging and efficient retrieval is supported via the following headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbNumToSkip	**MongoDbConstants.NUM_TO_SKIP**	Discards a given number of elements at the beginning of the cursor.	int/Integer

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbLimit	**MongoDbConstants.LIMIT**	Limits the number of elements returned.	int/Integer
CamelMongoDbBatchSize	**MongoDbConstants.BATCH_SIZE**	Limits the number of elements returned in one batch. A cursor typically fetches a batch of result objects and store them locally. If batchSize is positive, it represents the size of each batch of objects retrieved. It can be adjusted to optimize performance and limit data transfer. If batchSize is negative, it will limit of number objects returned, that fit within the max batch size limit (usually 4MB), and cursor will be closed. For example if batchSize is -10, then the server will return a maximum of 10 documents and as many as can fit in 4MB, then close the cursor. Note that this feature is different from limit() in that documents must fit within a maximum size, and it removes the need to send a request to close the cursor server-side. The batch size can be changed even after a cursor is iterated, in which case the setting will apply on the next batch retrieval.	int/Integer
CamelMongoDbAllowDiskUse	**MongoDbConstants.ALLOW_DISK_USE**	Sets allowDiskUse MongoDB flag. This is supported since MongoDB Server 4.3.1. Using this header with older MongoDB Server version can cause query to fail.	boolean/Boolean

94.8.1.5.3. Example with option *outputType=MongoIterable* and batch size

```
from("direct:findAll")
    .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
    .setHeader(MongoDbConstants.CRITERIA, constant(Filters.eq("name", "Raul Kripalani")))
    .to("mongodb:myDb?
database=flights&collection=tickets&operation=findAll&outputType=MongoIterable")
    .to("mock:resultFindAll");
```

The **findAll** operation will also return the following OUT headers to enable you to iterate through result pages if you are using paging:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Data type
CamelMongoDbResultTotalSize	**MongoDbConstants.RESULT_TOTAL_SIZE**	Number of objects matching the query. This does not take limit/skip into consideration.	int/Integer
CamelMongoDbResultPageSize	**MongoDbConstants.RESULT_PAGE_SIZE**	Number of objects matching the query. This does not take limit/skip into consideration.	int/Integer

NOTE

Supports optional parameters
This operation supports projection operators and sort clauses. See Specifying a fields filter (projection), Specifying a sort clause.

94.8.1.6. count

Returns the total number of objects in a collection, returning a Long as the OUT message body. The following example will count the number of records in the "dynamicCollectionName" collection. Notice how dynamicity is enabled, and as a result, the operation will not run against the "notableScientists" collection, but against the "dynamicCollectionName" collection.

```
// from("direct:count").to("mongodb:myDb?
database=tickets&collection=flights&operation=count&dynamicity=true");
Long result = template.requestBodyAndHeader("direct:count", "irrelevantBody",
MongoDbConstants.COLLECTION, "dynamicCollectionName");
assertTrue("Result is not of type Long", result instanceof Long);
```

You can provide a query **The query object is extracted CamelMongoDbCriteria header**. if the CamelMongoDbCriteria header is null the query object is extracted message body, i.e. it should be of type **Bson** or convertible to **Bson**., and operation will return the amount of documents matching this criteria.

```
Document query = ...
Long count = template.requestBodyAndHeader("direct:count", query,
MongoDbConstants.COLLECTION, "dynamicCollectionName");
```

94.8.1.7. Specifying a fields filter (projection)

Query operations will, by default, return the matching objects in their entirety (with all their fields). If your documents are large and you only require retrieving a subset of their fields, you can specify a field filter in all query operations, simply by setting the relevant **Bson** (or type convertible to **Bson**, such as a JSON String, Map, etc.) on the **CamelMongoDbFieldsProjection** header, constant shortcut: **MongoDbConstants.FIELDS_PROJECTION**.

Here is an example that uses MongoDB's **Projections** to simplify the creation of Bson. It retrieves all fields except **_id** and **boringField**:

```
// route: from("direct:findAll").to("mongodb:myDb?
database=flights&collection=tickets&operation=findAll")
Bson fieldProjection = Projection.exclude("_id", "boringField");
Object result = template.requestBodyAndHeader("direct:findAll", ObjectUtils.NULL,
MongoDbConstants.FIELDS_PROJECTION, fieldProjection);
```

Here is an example that uses MongoDB's **Projections** to simplify the creation of Bson. It retrieves all fields except **_id** and **boringField**:

```
// route: from("direct:findAll").to("mongodb:myDb?
database=flights&collection=tickets&operation=findAll")
Bson fieldProjection = Projection.exclude("_id", "boringField");
Object result = template.requestBodyAndHeader("direct:findAll", ObjectUtils.NULL,
MongoDbConstants.FIELDS_PROJECTION, fieldProjection);
```

94.8.1.8. Specifying a sort clause

There is a often a requirement to fetch the min/max record from a collection based on sorting by a particular field that uses MongoDB's **Sorts** to simplify the creation of Bson. It retrieves all fields except **_id** and **boringField**:

```
// route: from("direct:findAll").to("mongodb:myDb?
database=flights&collection=tickets&operation=findAll")
Bson sorts = Sorts.descending("_id");
Object result = template.requestBodyAndHeader("direct:findAll", ObjectUtils.NULL,
MongoDbConstants.SORT_BY, sorts);
```

In a Camel route the SORT_BY header can be used with the findOneByQuery operation to achieve the same result. If the FIELDS_PROJECTION header is also specified the operation will return a single field/value pair that can be passed directly to another component (for example, a parameterized MyBatis SELECT query). This example demonstrates fetching the temporally newest document from a collection and reducing the result to a single field, based on the **documentTimestamp** field:

```
.from("direct:someTriggeringEvent")
.setHeader(MongoDbConstants.SORT_BY).constant(Sorts.descending("documentTimestamp"))
.setHeader(MongoDbConstants.FIELDS_PROJECTION).constant(Projection.include("documentTime
stamp"))
.setBody().constant("{}")
.to("mongodb:myDb?database=local&collection=myDemoCollection&operation=findOneByQuery")
.to("direct:aMyBatisParameterizedSelect");
```

94.8.2. Create/update operations

94.8.2.1. insert

Inserts an new object into the MongoDB collection, taken from the IN message body. Type conversion is attempted to turn it into **Document** or a **List**.
Two modes are supported: single insert and multiple insert. For multiple insert, the endpoint will expect a List, Array or Collections of objects of any type, as long as they are - or can be converted to - **Document**. Example:

```
from("direct:insert")
    .to("mongodb:myDb?database=flights&collection=tickets&operation=insert");
```

The operation will return a WriteResult, and depending on the **WriteConcern** or the value of the **invokeGetLastError** option, **getLastError()** would have been called already or not. If you want to access the ultimate result of the write operation, you need to retrieve the **CommandResult** by calling **getLastError()** or **getCachedLastError()** on the **WriteResult**. Then you can verify the result by calling **CommandResult.ok()**, **CommandResult.getErrorMessage()** and/or **CommandResult.getException()**.

Note that the new object's **_id** must be unique in the collection. If you don't specify the value, MongoDB will automatically generate one for you. But if you do specify it and it is not unique, the insert operation will fail (and for Camel to notice, you will need to enable invokeGetLastError or set a WriteConcern that waits for the write result).

This is not a limitation of the component, but it is how things work in MongoDB for higher throughput. If you are using a custom **_id**, you are expected to ensure at the application level that is unique (and this is a good practice too).

OID(s) of the inserted record(s) is stored in the message header under **CamelMongoOid** key (**MongoDbConstants.OID** constant). The value stored is **org.bson.types.ObjectId** for single insert or **java.util.List<org.bson.types.ObjectId>** if multiple records have been inserted.

In MongoDB Java Driver 3.x the insertOne and insertMany operation return void. The Camel insert operation return the Document or List of Documents inserted. Note that each Documents are Updated by a new OID if need.

94.8.2.2. save

The save operation is equivalent to an *upsert* (UPdate, inSERT) operation, where the record will be updated, and if it doesn't exist, it will be inserted, all in one atomic operation. MongoDB will perform the matching based on the **_id** field.

Beware that in case of an update, the object is replaced entirely and the usage of MongoDB's $modifiers is not permitted. Therefore, if you want to manipulate the object if it already exists, you have two options:

1. perform a query to retrieve the entire object first along with all its fields (may not be efficient), alter it inside Camel and then save it.

2. use the update operation with $modifiers, which will execute the update at the server-side instead. You can enable the upsert flag, in which case if an insert is required, MongoDB will apply the $modifiers to the filter query object and insert the result.

If the document to be saved does not contain the **_id** attribute, the operation will be an insert, and the new **_id** created will be placed in the **CamelMongoOid** header.

For example:

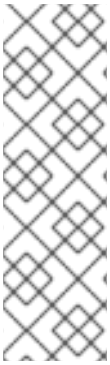
```
from("direct:insert")
    .to("mongodb:myDb?database=flights&collection=tickets&operation=save");
```

```
// route: from("direct:insert").to("mongodb:myDb?
database=flights&collection=tickets&operation=save");
org.bson.Document docForSave = new org.bson.Document();
docForSave.put("key", "value");
Object result = template.requestBody("direct:insert", docForSave);
```

94.8.2.3. update

Update one or multiple records on the collection. Requires a filter query and a update rules.

You can define the filter using MongoDBConstants.CRITERIA header as **Bson** and define the update rules as **Bson** in Body.

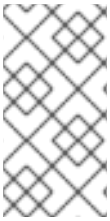


NOTE

Update after enrich
While defining the filter by using MongoDBConstants.CRITERIA header as **Bson** to query mongodb before you do update, you should notice you need to remove it from the resulting camel exchange during aggregation if you use enrich pattern with a aggregation strategy and then apply mongodb update. If you don't remove this header during aggregation and/or redefine MongoDBConstants.CRITERIA header before sending camel exchange to mongodb producer endpoint, you may end up with invalid camel exchange payload while updating mongodb.

The second way Require a List<Bson> as the IN message body containing exactly 2 elements:

- Element 1 (index 0) ⇒ filter query ⇒ determines what objects will be affected, same as a typical query object
- Element 2 (index 1) ⇒ update rules ⇒ how matched objects will be updated. All modifier operations from MongoDB are supported.



NOTE

Multiupdates
By default, MongoDB will only update 1 object even if multiple objects match the filter query. To instruct MongoDB to update **all** matching records, set the **CamelMongoDbMultiUpdate** IN message header to **true**.

A header with key **CamelMongoDbRecordsAffected** will be returned (**MongoDbConstants.RECORDS_AFFECTED** constant) with the number of records updated (copied from **WriteResult.getN()**).

Supports the following IN message headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbMultiUpdate	**MongoDbConstants.MULTIUPDATE**	If the update should be applied to all objects matching. See http://www.mongodb.org/display/DOCS/Atomic+Operations	boolean/Boolean
CamelMongoDbUpsert	**MongoDbConstants.UPSERT**	If the database should create the element if it does not exist	boolean/Boolean

For example, the following will update **all** records whose filterField field equals true by setting the value of the "scientist" field to "Darwin":

```
// route: from("direct:update").to("mongodb:myDb?database=science&collection=notableScientists&operation=update");
List<Bson> body = new ArrayList<>();
Bson filterField = Filters.eq("filterField", true);
body.add(filterField);
BsonDocument updateObj = new BsonDocument().append("$set", new BsonDocument("scientist", new BsonString("Darwin")));
body.add(updateObj);
Object result = template.requestBodyAndHeader("direct:update", body, MongoDbConstants.MULTIUPDATE, true);
```

```
// route: from("direct:update").to("mongodb:myDb?database=science&collection=notableScientists&operation=update");
Maps<String, Object> headers = new HashMap<>(2);
headers.add(MongoDbConstants.MULTIUPDATE, true);
headers.add(MongoDbConstants.FIELDS_FILTER, Filters.eq("filterField", true));
String updateObj = Updates.set("scientist", "Darwin");;
Object result = template.requestBodyAndHeaders("direct:update", updateObj, headers);
```

```
// route: from("direct:update").to("mongodb:myDb?database=science&collection=notableScientists&operation=update");
String updateObj = "[{\"filterField\": true}, {\"$set\", {\"scientist\", \"Darwin\"}}]";
Object result = template.requestBodyAndHeader("direct:update", updateObj, MongoDbConstants.MULTIUPDATE, true);
```

94.8.3. Delete operations

94.8.3.1. remove

Remove matching records from the collection. The IN message body will act as the removal filter query, and is expected to be of type **DBObject** or a type convertible to it.
The following example will remove all objects whose field 'conditionField' equals true, in the science database, notableScientists collection:

```
// route: from("direct:remove").to("mongodb:myDb?
database=science&collection=notableScientists&operation=remove");
Bson conditionField = Filters.eq("conditionField", true);
Object result = template.requestBody("direct:remove", conditionField);
```

A header with key **CamelMongoDbRecordsAffected** is returned (**MongoDbConstants.RECORDS_AFFECTED** constant) with type **int**, containing the number of records deleted (copied from **WriteResult.getN()**).

94.8.4. Bulk Write Operations

94.8.4.1. bulkWrite

Performs write operations in bulk with controls for order of execution. Requires a **List<WriteModel<Document>>** as the IN message body containing commands for insert, update, and delete operations.

The following example will insert a new scientist "Pierre Curie", update record with id "5" by setting the value of the "scientist" field to "Marie Curie" and delete record with id "3" :

```
// route: from("direct:bulkWrite").to("mongodb:myDb?
database=science&collection=notableScientists&operation=bulkWrite");
List<WriteModel<Document>> bulkOperations = Arrays.asList(
        new InsertOneModel<>(new Document("scientist", "Pierre Curie")),
        new UpdateOneModel<>(new Document("_id", "5"),
                        new Document("$set", new Document("scientist", "Marie Curie"))),
        new DeleteOneModel<>(new Document("_id", "3")));

BulkWriteResult result = template.requestBody("direct:bulkWrite", bulkOperations,
BulkWriteResult.class);
```

By default, operations are executed in order and interrupted on the first write error without processing any remaining write operations in the list. To instruct MongoDB to continue to process remaining write operations in the list, set the **CamelMongoDbBulkOrdered** IN message header to **false**. Unordered operations are executed in parallel and this behavior is not guaranteed.

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbBulkOrdered	**MongoDbConstants.BULK_ORDERED**	Perform an ordered or unordered operation execution. Defaults to true.	boolean/Boolean

94.8.5. Other operations

94.8.5.1. aggregate

Perform a aggregation with the given pipeline contained in the body. **Aggregations could be long and heavy operations. Use with care.**

```
// route: from("direct:aggregate").to("mongodb:myDb?
```

```
database=science&collection=notableScientists&operation=aggregate");
List<Bson> aggregate = Arrays.asList(match(or(eq("scientist", "Darwin"), eq("scientist",
        group("$scientist", sum("count", 1)));
from("direct:aggregate")
    .setBody().constant(aggregate)
    .to("mongodb:myDb?database=science&collection=notableScientists&operation=aggregate")
    .to("mock:resultAggregate");
```

Supports the following IN message headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbBatchSize	**MongoDbConstants.BATCH_SIZE**	Sets the number of documents to return per batch.	int/Integer
CamelMongoDbAllowDiskUse	**MongoDbConstants.ALLOW_DISK_USE**	Enable aggregation pipeline stages to write data to temporary files.	boolean/Boolean

By default a List of all results is returned. This can be heavy on memory depending on the size of the results. A safer alternative is to set your outputType=MongoIterable. The next Processor will see an iterable in the message body allowing it to step through the results one by one. Thus setting a batch size and returning an iterable allows for efficient retrieval and processing of the result.

An example would look like:

```
List<Bson> aggregate = Arrays.asList(match(or(eq("scientist", "Darwin"), eq("scientist",
        group("$scientist", sum("count", 1)));
from("direct:aggregate")
    .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
    .setBody().constant(aggregate)
    .to("mongodb:myDb?
database=science&collection=notableScientists&operation=aggregate&outputType=MongoIterable")
    .split(body())
    .streaming()
    .to("mock:resultAggregate");
```

Note that calling **.split(body())** is enough to send the entries down the route one-by-one, however it would still load all the entries into memory first. Calling **.streaming()** is thus required to load data into memory by batches.

94.8.5.2. getDbStats

Equivalent of running the **db.stats()** command in the MongoDB shell, which displays useful statistic figures about the database.
For example:

```
> db.stats();
{
    "db" : "test",
```

```
    "collections" : 7,
    "objects" : 719,
    "avgObjSize" : 59.73296244784423,
    "dataSize" : 42948,
    "storageSize" : 1000058880,
    "numExtents" : 9,
    "indexes" : 4,
    "indexSize" : 32704,
    "fileSize" : 1275068416,
    "nsSizeMB" : 16,
    "ok" : 1
}
```

Usage example:

```
// from("direct:getDbStats").to("mongodb:myDb?
database=flights&collection=tickets&operation=getDbStats");
Object result = template.requestBody("direct:getDbStats", "irrelevantBody");
assertTrue("Result is not of type Document", result instanceof Document);
```

The operation will return a data structure similar to the one displayed in the shell, in the form of a **Document** in the OUT message body.

94.8.5.3. getColStats

Equivalent of running the **db.collection.stats()** command in the MongoDB shell, which displays useful statistic figures about the collection.
For example:

```
> db.camelTest.stats();
{
    "ns" : "test.camelTest",
    "count" : 100,
    "size" : 5792,
    "avgObjSize" : 57.92,
    "storageSize" : 20480,
    "numExtents" : 2,
    "nindexes" : 1,
    "lastExtentSize" : 16384,
    "paddingFactor" : 1,
    "flags" : 1,
    "totalIndexSize" : 8176,
    "indexSizes" : {
        "_id_" : 8176
    },
    "ok" : 1
}
```

Usage example:

```
// from("direct:getColStats").to("mongodb:myDb?
database=flights&collection=tickets&operation=getColStats");
Object result = template.requestBody("direct:getColStats", "irrelevantBody");
assertTrue("Result is not of type Document", result instanceof Document);
```

The operation will return a data structure similar to the one displayed in the shell, in the form of a **Document** in the OUT message body.

94.8.5.4. command

Run the body as a command on database. Useful for admin operation as getting host information, replication or sharding status.

Collection parameter is not use for this operation.

```
// route: from("command").to("mongodb:myDb?database=science&operation=command");
DBObject commandBody = new BasicDBObject("hostInfo", "1");
Object result = template.requestBody("direct:command", commandBody);
```

94.8.6. Dynamic operations

An Exchange can override the endpoint's fixed operation by setting the **CamelMongoDbOperation** header, defined by the **MongoDbConstants.OPERATION_HEADER** constant.
The values supported are determined by the MongoDbOperation enumeration and match the accepted values for the **operation** parameter on the endpoint URI.

For example:

```
// from("direct:insert").to("mongodb:myDb?database=flights&collection=tickets&operation=insert");
Object result = template.requestBodyAndHeader("direct:insert", "irrelevantBody",
MongoDbConstants.OPERATION_HEADER, "count");
assertTrue("Result is not of type Long", result instanceof Long);
```

94.9. CONSUMERS

There are several types of consumers:

1. Tailable Cursor Consumer
2. Change Streams Consumer

94.9.1. Tailable Cursor Consumer

MongoDB offers a mechanism to instantaneously consume ongoing data from a collection, by keeping the cursor open just like the **tail -f** command of *nix systems. This mechanism is significantly more efficient than a scheduled poll, due to the fact that the server pushes new data to the client as it becomes available, rather than making the client ping back at scheduled intervals to fetch new data. It also reduces otherwise redundant network traffic.

There is only one requisite to use tailable cursors: the collection must be a "capped collection", meaning that it will only hold N objects, and when the limit is reached, MongoDB flushes old objects in the same order they were originally inserted. For more information, please refer to http://www.mongodb.org/display/DOCS/Tailable+Cursors.

The Camel MongoDB component implements a tailable cursor consumer, making this feature available for you to use in your Camel routes. As new objects are inserted, MongoDB will push them as **Document** in natural order to your tailable cursor consumer, who will transform them to an Exchange and will trigger your route logic.

94.10. HOW THE TAILABLE CURSOR CONSUMER WORKS

To turn a cursor into a tailable cursor, a few special flags are to be signalled to MongoDB when first generating the cursor. Once created, the cursor will then stay open and will block upon calling the **MongoCursor.next()** method until new data arrives. However, the MongoDB server reserves itself the right to kill your cursor if new data doesn't appear after an indeterminate period. If you are interested to continue consuming new data, you have to regenerate the cursor. And to do so, you will have to remember the position where you left off or else you will start consuming from the top again.

The Camel MongoDB tailable cursor consumer takes care of all these tasks for you. You will just need to provide the key to some field in your data of increasing nature, which will act as a marker to position your cursor every time it is regenerated, e.g. a timestamp, a sequential ID, etc. It can be of any datatype supported by MongoDB. Date, Strings and Integers are found to work well. We call this mechanism "tail tracking" in the context of this component.

The consumer will remember the last value of this field and whenever the cursor is to be regenerated, it will run the query with a filter like: **increasingField > lastValue**, so that only unread data is consumed.

Setting the increasing field: Set the key of the increasing field on the endpoint URI **tailTrackingIncreasingField** option. In Camel 2.10, it must be a top-level field in your data, as nested navigation for this field is not yet supported. That is, the "timestamp" field is okay, but "nested.timestamp" will not work. Please open a ticket in the Camel JIRA if you do require support for nested increasing fields.

Cursor regeneration delay: One thing to note is that if new data is not already available upon initialisation, MongoDB will kill the cursor instantly. Since we don't want to overwhelm the server in this case, a **cursorRegenerationDelay** option has been introduced (with a default value of 1000ms.), which you can modify to suit your needs.

An example:

```
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime")
    .id("tailableCursorConsumer1")
    .autoStartup(false)
    .to("mock:test");
```

The above route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms.

94.11. PERSISTENT TAIL TRACKING

Standard tail tracking is volatile and the last value is only kept in memory. However, in practice you will need to restart your Camel container every now and then, but your last value would then be lost and your tailable cursor consumer would start consuming from the top again, very likely sending duplicate records into your route.

To overcome this situation, you can enable the **persistent tail tracking** feature to keep track of the last consumed increasing value in a special collection inside your MongoDB database too. When the consumer initialises again, it will restore the last tracked value and continue as if nothing happened.

The last read value is persisted on two occasions: every time the cursor is regenerated and when the consumer shuts down. We may consider persisting at regular intervals too in the future (flush every 5 seconds) for added robustness if the demand is there. To request this feature, please open a ticket in the Camel JIRA.

94.12. ENABLING PERSISTENT TAIL TRACKING

To enable this function, set at least the following options on the endpoint URI:

- **persistentTailTracking** option to **true**
- **persistentId** option to a unique identifier for this consumer, so that the same collection can be reused across many consumers

Additionally, you can set the **tailTrackDb**, **tailTrackCollection** and **tailTrackField** options to customise where the runtime information will be stored. Refer to the endpoint options table at the top of this page for descriptions of each option.

For example, the following route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms, with persistent tail tracking turned on, and persisting under the "cancellationsTracker" id on the "flights.camelTailTracking", storing the last processed value under the "lastTrackingValue" field (**camelTailTracking** and **lastTrackingValue** are defaults).

```
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTrack
ng=true" +
    "&persistentId=cancellationsTracker")
   .id("tailableCursorConsumer2")
   .autoStartup(false)
   .to("mock:test");
```

Below is another example identical to the one above, but where the persistent tail tracking runtime information will be stored under the "trackers.camelTrackers" collection, in the "lastProcessedDepartureTime" field:

```
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTrack
ng=true" +
    "&persistentId=cancellationsTracker&tailTrackDb=trackers&tailTrackCollection=camelTrackers" +
    "&tailTrackField=lastProcessedDepartureTime")
   .id("tailableCursorConsumer3")
   .autoStartup(false)
   .to("mock:test");
```

94.12.1. Change Streams Consumer

Change Streams allow applications to access real-time data changes without the complexity and risk of tailing the MongoDB oplog. Applications can use change streams to subscribe to all data changes on a collection and immediately react to them. Because change streams use the aggregation framework, applications can also filter for specific changes or transform the notifications at will. The exchange body will contain the full document of any change.

To configure Change Streams Consumer you need to specify **consumerType**, **database**, **collection** and optional JSON property **streamFilter** to filter events. That JSON property is standard MongoDB **$match** aggregation. It could be easily specified using XML DSL configuration:

```
<route id="filterConsumer">
   <from uri="mongodb:myDb?
consumerType=changeStreams&amp;database=flights&amp;collection=tickets&amp;streamFilter={
```

```
'$match':{'$or':[{'fullDocument.stringValue': 'specificValue'}]} }"/>
    <to uri="mock:test"/>
</route>
```

Java configuration:

```
from("mongodb:myDb?
consumerType=changeStreams&database=flights&collection=tickets&streamFilter={ '$match':{'$or':
[{'fullDocument.stringValue': 'specificValue'}]} }")
    .to("mock:test");
```

NOTE

You can externalize the streamFilter value into a property placeholder which allows the endpoint URI parameters to be *cleaner* and easier to read.

The **changeStreams** consumer type will also return the following OUT headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Data type
CamelMongoDbStreamOperationType	**MongoDbConstants.STREAM_OPERATION_TYPE**	The type of operation that occurred. Can be any of the following values: insert, delete, replace, update, drop, rename, dropDatabase, invalidate.	String
_id	**MongoDbConstants.MONGO_ID**	A document that contains the _id of the document created or modified by the insert, replace, delete, update operations (i.e. CRUD operations). For sharded collections, also displays the full shard key for the document. The _id field is not repeated if it is already a part of the shard key.	ObjectId

94.13. TYPE CONVERSIONS

The **MongoDbBasicConverters** type converter included with the camel-mongodb component provides the following conversions:

Name	From type	To type	How?
fromMapToDocument	**Map**	**Document**	constructs a new **Document** via the **new Document(Map m)** constructor.
fromDocumentToMap	**Document**	**Map**	**Document** already implements **Map**.

Name	From type	To type	How?
fromStringToDocument	**String**	**Document**	uses **com.mongodb.Document.parse(String s)**.
fromStringToObjectId	**String**	**ObjectId**	constructs a new **ObjectId** via the **new ObjectId(s)**
fromFileToDocument	**File**	**Document**	uses **fromInputStreamToDocument** under the hood
fromInputStreamToDocument	**InputStream**	**Document**	converts the inputstream bytes to a **Document**
fromStringToList	**String**	**List<Bson>**	uses **org.bson.codecs.configuration.CodecRegistries** to convert to BsonArray then to List<Bson>.

This type converter is auto-discovered, so you don't need to configure anything manually.

94.14. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.component.mongodb.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.mongodb.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.mongodb.enabled	Whether to enable auto configuration of the mongodb component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.mongodb.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.mongodb.mongo-connection	Shared client used for connection. All endpoints generated from the component will share this connection client. The option is a com.mongodb.client.MongoClient type.		MongoClient

CHAPTER 95. MYBATIS

Since Camel 2.7

Both producer and consumer are supported

The MyBatis component allows you to query, poll, insert, update and delete data in a relational database using MyBatis.

95.1. DEPENDENCIES

When using **mybatis** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-mybatis-starter</artifactId>
</dependency>
```

95.2. URI FORMAT

```
mybatis:statementName[?options]
```

Where **statementName** is the statement name in the MyBatis XML mapping file which maps to the query, insert, update or delete operation you choose to evaluate.

You can append query options to the URI in the following format, **?option=value&option=value&…**

This component will by default load the MyBatis SqlMapConfig file from the root of the classpath with the expected name of **SqlMapConfig.xml**.
If the file is located in another location, you will need to configure the **configurationUri** option on the **MyBatisComponent** component.

95.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

95.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

95.3.2. Configuring Endpoint Options

Endpoints have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL and DataFormat DSL as a *type safe* way of configuring endpoints and data formats in Java.

Use Property Placeholders to configure options that allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

95.4. COMPONENT OPTIONS

The MyBatis component supports 5 options, which are listed below.

Name	Description	Default	Type
configurationUri (common)	Location of MyBatis xml configuration file. The default value is: SqlMapConfig.xml loaded from the classpath.	SqlMapConfig.xml	String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
sqlSessionFactory (advanced)	To use the SqlSessionFactory.		SqlSessionFactory

95.5. ENDPOINT OPTIONS

The MyBatis endpoint is configured using URI syntax:

```
mybatis:statement
```

-

Following are the path and query parameters.

95.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
statement (common)	**Required** The statement name in the MyBatis XML mapping file which maps to the query, insert, update or delete operation you wish to evaluate.		String

95.5.2. Query Parameters (30 parameters)

Name	Description	Default	Type
maxMessagesPerPoll (consumer)	This option is intended to split results returned by the database pool into the batches and deliver them in multiple exchanges. This integer defines the maximum messages to deliver in single exchange. By default, no maximum is set. Can be used to set a limit of e.g. 1000 to avoid when starting up the server that there are thousands of files. Set a value of 0 or negative to disable it.	0	int
onConsume (consumer)	Statement to run after data has been processed in the route.		String
routeEmptyResultSet (consumer)	Whether allow empty resultset to be routed to the next hop.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean

Name	Description	Default	Type
transacted (consumer)	Enables or disables transaction. If enabled then if processing an exchange failed then the consumer breaks out processing any further exchanges to cause a rollback eager.	false	boolean
useIterator (consumer)	Process resultset individually or as a list.	true	boolean
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: * InOnly * InOut * InOptionalOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
processingStrategy (consumer (advanced))	To use a custom MyBatisProcessingStrategy.		MyBatisProcessingStrategy
executorType (producer)	The executor type to be used while executing statements. simple - executor does nothing special. reuse - executor reuses prepared statements. batch - executor reuses statements and batches updates. Enum values: * SIMPLE * REUSE * BATCH	SIMPLE	ExecutorType

Name	Description	Default	Type
inputHeader (producer)	User the header value for input parameters instead of the message body. By default, inputHeader == null and the input parameters are taken from the message body. If outputHeader is set, the value is used and query parameters will be taken from the header instead of the body.		String
outputHeader (producer)	Store the query result in a header instead of the message body. By default, outputHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. Setting outputHeader will also omit populating the default CamelMyBatisResult header since it would be the same as outputHeader all the time.		String
statementType (producer)	Mandatory to specify for the producer to control which kind of operation to invoke. Enum values: * SelectOne * SelectList * Insert * InsertList * Update * UpdateList * Delete * DeleteList		StatementType

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: * TRACE * DEBUG * INFO * WARN * ERROR * OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: * NANOSECONDS * MICROSECONDS * MILLISECONDS * SECONDS * MINUTES * HOURS * DAYS	MILLISECONDS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

95.6. MESSAGE HEADERS

The MyBatis component supports 2 message headers that are listed below.

Name	Description	Default	Type
CamelMyBatisResult (producer) Constant: **MYBATIS_RESULT**	The response returned from MtBatis in any of the operations. For instance an INSERT could return the auto-generated key, or number of rows etc.		Object
CamelMyBatisStatementName (common) Constant: **MYBATIS_STATEMENT_NAME**	The statementName used (for example: insertAccount).		String

95.7. MESSAGE BODY

The response from MyBatis will only be set as the body if it is a **SELECT** statement. For example, for **INSERT** statements Camel will not replace the body. This allows you to continue routing and keep the original body. The response from MyBatis is always stored in the header with the key **CamelMyBatisResult**.

95.8. SAMPLES

For example if you wish to consume beans from a JMS queue and insert them into a database you could do the following:

```
from("activemq:queue:newAccount")
  .to("mybatis:insertAccount?statementType=Insert");
```

You must specify the **statementType** as you need to instruct Camel which kind of operation to invoke.

Where **insertAccount** is the MyBatis ID in the SQL mapping file:

```
<!-- Insert example, using the Account parameter class -->
<insert id="insertAccount" parameterType="Account">
  insert into ACCOUNT (
```

```
    ACC_ID,
    ACC_FIRST_NAME,
    ACC_LAST_NAME,
    ACC_EMAIL
  )
  values (
    #{id}, #{firstName}, #{lastName}, #{emailAddress}
  )
</insert>
```

95.9. USING STATEMENTTYPE FOR BETTER CONTROL OF MYBATIS

When routing to an MyBatis endpoint you will want more fine grained control so you can control whether the SQL statement to be executed is a **SELECT**, **UPDATE**, **DELETE** or **INSERT** etc. So for instance if we want to route to an MyBatis endpoint in which the IN body contains parameters to a **SELECT** statement we can do:

In the code above we can invoke the MyBatis statement **selectAccountById** and the IN body should contain the account id we want to retrieve, such as an **Integer** type.

You can do the same for some of the other operations, such as **SelectList**:

And the same for **UPDATE**, where you can send an **Account** object as the IN body to MyBatis:

95.9.1. Using InsertList StatementType

MyBatis allows you to insert multiple rows using its for-each batch driver. To use this, you need to use the <foreach> in the mapper XML file. For example as shown below:

Then you can insert multiple rows, by sending a Camel message to the **mybatis** endpoint which uses the **InsertList** statement type, as shown below:

95.9.2. Using UpdateList StatementType

MyBatis allows you to update multiple rows using its for-each batch driver. To use this, you need to use the <foreach> in the mapper XML file. For example as shown below:

```
<update id="batchUpdateAccount" parameterType="java.util.Map">
    update ACCOUNT set
    ACC_EMAIL = #{emailAddress}
    where
    ACC_ID in
    <foreach item="Account" collection="list" open="(" close=")" separator=",">
        #{Account.id}
    </foreach>
</update>
```

Then you can update multiple rows, by sending a Camel message to the mybatis endpoint which uses the UpdateList statement type, as shown below:

```
from("direct:start")
    .to("mybatis:batchUpdateAccount?statementType=UpdateList")
    .to("mock:result");
```

95.9.3. Using DeleteList StatementType

MyBatis allows you to delete multiple rows using its for-each batch driver. To use this, you need to use the <foreach> in the mapper XML file. For example as shown below:

```
<delete id="batchDeleteAccountById" parameterType="java.util.List">
    delete from ACCOUNT
    where
    ACC_ID in
    <foreach item="AccountID" collection="list" open="(" close=")" separator=",">
        #{AccountID}
    </foreach>
</delete>
```

Then you can delete multiple rows, by sending a Camel message to the mybatis endpoint which uses the DeleteList statement type, as shown below:

```
from("direct:start")
    .to("mybatis:batchDeleteAccount?statementType=DeleteList")
    .to("mock:result");
```

95.9.4. Notice on InsertList, UpdateList and DeleteList StatementTypes

Parameter of any type (List, Map, etc.) can be passed to mybatis and an end user is responsible for handling it as required
with the help of mybatis dynamic queries capabilities.

95.9.5. cheduled polling example

This component supports scheduled polling and can therefore be used as a Polling Consumer. For example to poll the database every minute:

```
from("mybatis:selectAllAccounts?delay=60000")
  .to("activemq:queue:allAccounts");
```

See "ScheduledPollConsumer Options" on Polling Consumer for more options.

Alternatively you can use another mechanism for triggering the scheduled polls, such as the Timer or Quartz components. In the sample below we poll the database, every 30 seconds using the Timer component and send the data to the JMS queue:

```
from("timer://pollTheDatabase?delay=30000")
  .to("mybatis:selectAllAccounts")
  .to("activemq:queue:allAccounts");
```

And the MyBatis SQL mapping file used:

```
<!-- Select with no parameters using the result map for Account class. -->
<select id="selectAllAccounts" resultMap="AccountResult">
  select * from ACCOUNT
</select>
```

95.9.6. Using onConsume

This component supports executing statements **after** data have been consumed and processed by Camel. This allows you to do post updates in the database. Notice all statements must be **UPDATE** statements. Camel supports executing multiple statements whose names should be separated by commas.

The route below illustrates we execute the **consumeAccount** statement data is processed. This allows us to change the status of the row in the database to processed, so we avoid consuming it twice or more.

And the statements in the sqlmap file:

95.9.7. Participating in transactions

Setting up a transaction manager under camel-mybatis can be a little bit fiddly, as it involves externalizing the database configuration outside the standard MyBatis **SqlMapConfig.xml** file.

The first part requires the setup of a **DataSource**. This is typically a pool (either DBCP, or c3p0), which needs to be wrapped in a Spring proxy. This proxy enables non-Spring use of the **DataSource** to participate in Spring transactions (the MyBatis **SqlSessionFactory** does just this).

```
<bean id="dataSource"
class="org.springframework.jdbc.datasource.TransactionAwareDataSourceProxy">
   <constructor-arg>
      <bean class="com.mchange.v2.c3p0.ComboPooledDataSource">
         <property name="driverClass" value="org.postgresql.Driver"/>
         <property name="jdbcUrl" value="jdbc:postgresql://localhost:5432/myDatabase"/>
         <property name="user" value="myUser"/>
         <property name="password" value="myPassword"/>
      </bean>
   </constructor-arg>
</bean>
```

This has the additional benefit of enabling the database configuration to be externalized using property placeholders.

A transaction manager is then configured to manage the outermost **DataSource**:

```
<bean id="txManager"
class="org.springframework.jdbc.datasource.DataSourceTransactionManager">
   <property name="dataSource" ref="dataSource"/>
</bean>
```

A mybatis-spring **SqlSessionFactoryBean** then wraps that same **DataSource**:

```
<bean id="sqlSessionFactory" class="org.mybatis.spring.SqlSessionFactoryBean">
   <property name="dataSource" ref="dataSource"/>
   <!-- standard mybatis config file -->
<property name="configLocation" value="/META-INF/SqlMapConfig.xml"/>
   <!-- externalised mappers -->
<property name="mapperLocations" value="classpath*:META-INF/mappers/**/*.xml"/>
</bean>
```

The camel-mybatis component is then configured with that factory:

```
<bean id="mybatis" class="org.apache.camel.component.mybatis.MyBatisComponent">
    <property name="sqlSessionFactory" ref="sqlSessionFactory"/>
</bean>
```

Finally, a transaction policy is defined over the top of the transaction manager, which can then be used as usual:

```
<bean id="PROPAGATION_REQUIRED"
class="org.apache.camel.spring.spi.SpringTransactionPolicy">
    <property name="transactionManager" ref="txManager"/>
    <property name="propagationBehaviorName" value="PROPAGATION_REQUIRED"/>
</bean>

<camelContext id="my-model-context" xmlns="http://camel.apache.org/schema/spring">
    <route id="insertModel">
        <from uri="direct:insert"/>
        <transacted ref="PROPAGATION_REQUIRED"/>
        <to uri="mybatis:myModel.insert?statementType=Insert"/>
    </route>
</camelContext>
```

95.10. MYBATIS SPRING BOOT STARTER INTEGRATION

Spring Boot users can use mybatis-spring-boot-starter artifact provided by the mybatis team

```
<dependency>
  <groupId>org.mybatis.spring.boot</groupId>
  <artifactId>mybatis-spring-boot-starter</artifactId>
  <version>2.3.0</version>
</dependency>
```

in particular AutoConfigured beans from mybatis-spring-boot-starter can be used as follow:

```
#application.properties
camel.component.mybatis.sql-session-factory=#sqlSessionFactory
```

95.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type

Name	Description	Default	Type
camel.component.mybatis-bean.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.mybatis-bean.configuration-uri	Location of MyBatis xml configuration file. The default value is: SqlMapConfig.xml loaded from the classpath.	SqlMapConfig.xml	String
camel.component.mybatis-bean.enabled	Whether to enable auto configuration of the mybatis-bean component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.mybatis-bean.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.mybatis-bean.sql-session-factory	To use the SqlSessionFactory. The option is a org.apache.ibatis.session.SqlSessionFactory type.		SqlSessionFactory
camel.component.mybatis.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.mybatis.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.mybatis.configuration-uri	Location of MyBatis xml configuration file. The default value is: SqlMapConfig.xml loaded from the classpath.	SqlMapConfig.xml	String
camel.component.mybatis.enabled	Whether to enable auto configuration of the mybatis component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.mybatis.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.mybatis.sql-session-factory	To use the SqlSessionFactory. The option is a org.apache.ibatis.session.SqlSessionFactory type.		SqlSessionFactory

CHAPTER 96. NETTY

Both producer and consumer are supported

The Netty component in Camel is a socket communication component, based on the Netty project version 4.
Netty is a NIO client server framework which enables quick and easy development of networkServerInitializerFactory applications such as protocol servers and clients.
Netty greatly simplifies and streamlines network programming such as TCP and UDP socket server.

This camel component supports both producer and consumer endpoints.

The Netty component has several options and allows fine-grained control of a number of TCP/UDP communication parameters (buffer sizes, keepAlives, tcpNoDelay, etc) and facilitates both In-Only and In-Out communication on a Camel route.

96.1. DEPENDENCIES

When using **netty** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-netty-starter</artifactId>
</dependency>
```

96.2. URI FORMAT

The URI scheme for a netty component is as follows

```
netty:tcp://0.0.0.0:99999[?options]
netty:udp://remotehost:99999/[?options]
```

This component supports producer and consumer endpoints for both TCP and UDP.

96.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

96.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

96.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

96.4. COMPONENT OPTIONS

The Netty component supports 73 options, which are listed below.

Name	Description	Default	Type
configuration (common)	To use the NettyConfiguration as configuration when creating endpoints.		NettyConfiguration
disconnect (common)	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	boolean
keepAlive (common)	Setting to ensure socket is not closed due to inactivity.	true	boolean
reuseAddress (common)	Setting to facilitate socket multiplexing.	true	boolean
reuseChannel (common)	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key NettyConstants#NETTY_CHANNEL which allows you to obtain the channel during routing and use it as well.	false	boolean

Name	Description	Default	Type
sync (common)	Setting to set endpoint as one-way or request-response.	true	boolean
tcpNoDelay (common)	Setting to improve TCP protocol performance.	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
broadcast (consumer)	Setting to choose Multicast over UDP.	false	boolean
clientMode (consumer)	If the clientMode is true, netty consumer will connect the address as a TCP client.	false	boolean
reconnect (consumer)	Used only in clientMode in consumer, the consumer will attempt to reconnect on disconnection if this is enabled.	true	boolean
reconnectInterval (consumer)	Used if reconnect and clientMode is enabled. The interval in milli seconds to attempt reconnection.	10000	int
backlog (consumer (advanced))	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be If this option is not configured, then the backlog depends on OS setting.		int
bossCount (consumer (advanced))	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this option to override the default bossCount from Netty.	1	int
bossGroup (consumer (advanced))	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint.		EventLoopGroup

Name	Description	Default	Type
disconnectOnNoReply (consumer (advanced))	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	boolean
executorService (consumer (advanced))	To use the given EventExecutorGroup.		EventExecutorGroup
maximumPoolSize (consumer (advanced))	Sets a maximum thread pool size for the netty consumer ordered thread pool. The default size is 2 x cpu_core plus 1. Setting this value to eg 10 will then use 10 threads unless 2 x cpu_core plus 1 is a higher value, which then will override and be used. For example if there are 8 cores, then the consumer thread pool will be 17. This thread pool is used to route messages received from Netty by Camel. We use a separate thread pool to ensure ordering of messages and also in case some messages will block, then nettys worker threads (event loop) wont be affected.		int
nettyServerBootstrapFactory (consumer (advanced))	To use a custom NettyServerBootstrapFactory.		NettyServerBootstrapFactory
networkInterface (consumer (advanced))	When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.		String
noReplyLogLevel (consumer (advanced))	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel

Name	Description	Default	Type
serverClosedChannelExceptionCaughtLogLevel (consumer (advanced))	If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	DEBUG	LoggingLevel
serverExceptionCaughtLogLevel (consumer (advanced))	If the server (NettyConsumer) catches an exception then its logged using this logging level. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel
serverInitializerFactory (consumer (advanced))	To use a custom ServerInitializerFactory.		ServerInitializerFactory
usingExecutorService (consumer (advanced))	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	boolean
connectTimeout (producer)	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	int

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
requestTimeout (producer)	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		long
clientInitializerFactory (producer (advanced))	To use a custom ClientInitializerFactory.		ClientInitializerFactory
correlationManager (producer (advanced))	To use a custom correlation manager to manage how request and reply messages are mapped when using request/reply with the netty producer. This should only be used if you have a way to map requests together with replies such as if there is correlation ids in both the request and reply messages. This can be used if you want to multiplex concurrent messages on the same channel (aka connection) in netty. When doing this you must have a way to correlate the request and reply messages so you can store the right reply on the inflight Camel Exchange before its continued routed. We recommend extending the TimeoutCorrelationManagerSupport when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well. See also the producerPoolEnabled option for more details.		NettyCamelStateCorrelationManager
lazyChannelCreation (producer (advanced))	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean

Name	Description	Default	Type
producerPoolEnabled (producer (advanced))	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement NettyCamelStateCorrelationManager as correlation manager and configure it via the correlationManager option. See also the correlationManager option for more details.	true	boolean
producerPoolMaxIdle (producer (advanced))	Sets the cap on the number of idle instances in the pool.	100	int
producerPoolMaxTotal (producer (advanced))	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	int
producerPoolMinEvictableIdle (producer (advanced))	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	300000	long
producerPoolMinIdle (producer (advanced))	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		int
udpConnectionlessSending (producer (advanced))	This option supports connection less udp sending which is a real fire and forget. A connected udp send receive the PortUnreachableException if no one is listen on the receiving port.	false	boolean
useByteBuf (producer (advanced))	If the useByteBuf is true, netty producer will turn the message body into ByteBuf before sending it out.	false	boolean
hostnameVerification (security)	To enable/disable hostname verification on SSLEngine.	false	boolean

Name	Description	Default	Type
allowSerializedHeaders (advanced)	Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
channelGroup (advanced)	To use a explicit ChannelGroup.		ChannelGroup
nativeTransport (advanced)	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: .	false	boolean
options (advanced)	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
receiveBufferSize (advanced)	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	int
receiveBufferSizePredictor (advanced)	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		int
sendBufferSize (advanced)	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	int
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean

Name	Description	Default	Type
udpByteArrayCodec (advanced)	For UDP only. If enabled the using byte array codec instead of Java serialization protocol.	false	boolean
workerCount (advanced)	When netty works on nio mode, it uses default workerCount parameter from Netty (which is cpu_core_threads x 2). User can use this option to override the default workerCount from Netty.		int
workerGroup (advanced)	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with 2 x cpu count core threads.		EventLoopGroup
allowDefaultCodec (codec)	The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.	true	boolean
autoAppendDelimiter (codec)	Whether or not to auto append missing end delimiter when sending using the textline codec.	true	boolean
decoderMaxLineLength (codec)	The max line length to use for the textline codec.	1024	int
decoders (codec)	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		List
delimiter (codec)	The delimiter to use for the textline codec. Possible values are LINE and NULL. Enum values: • LINE • NULL	LINE	TextLineDelimiter
encoders (codec)	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		List

Name	Description	Default	Type
encoding (codec)	The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.		String
textline (codec)	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP - however only Strings are allowed to be serialized by default.	false	boolean
enabledProtocols (security)	Which protocols to enable when using SSL.	TLSv1, TLSv1.1, TLSv1.2	String
keyStoreFile (security)	Client side certificate keystore to be used for encryption.		File
keyStoreFormat (security)	Keystore format to be used for payload encryption. Defaults to JKS if not set.		String
keyStoreResource (security)	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
needClientAuth (security)	Configures whether the server needs client authentication when using SSL.	false	boolean
passphrase (security)	Password setting to use in order to encrypt/decrypt payloads sent using SSH.		String
securityProvider (security)	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String
ssl (security)	Setting to specify whether SSL encryption is applied to this endpoint.	false	boolean
sslClientCertHeaders (security)	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters

Name	Description	Default	Type
sslHandler (security)	Reference to a class that could be used to return an SSL Handler.		SslHandler
trustStoreFile (security)	Server side certificate keystore to be used for encryption.		File
trustStoreResource (security)	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

96.5. ENDPOINT OPTIONS

The Netty endpoint is configured using URI syntax:

```
netty:protocol://host:port
```

with the following path and query parameters:

96.5.1. Path Parameters (3 parameters)

Name	Description	Default	Type
protocol (common)	**Required** The protocol to use which can be tcp or udp. Enum values: • tcp • udp		String
host (common)	**Required** The hostname. For the consumer the hostname is localhost or 0.0.0.0. For the producer the hostname is the remote host to connect to.		String
port (common)	**Required** The host port number.		int

96.5.2. Query Parameters (71 parameters)

Name	Description	Default	Type
disconnect (common)	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	boolean
keepAlive (common)	Setting to ensure socket is not closed due to inactivity.	true	boolean
reuseAddress (common)	Setting to facilitate socket multiplexing.	true	boolean
reuseChannel (common)	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key NettyConstants#NETTY_CHANNEL which allows you to obtain the channel during routing and use it as well.	false	boolean
sync (common)	Setting to set endpoint as one-way or request-response.	true	boolean
tcpNoDelay (common)	Setting to improve TCP protocol performance.	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
broadcast (consumer)	Setting to choose Multicast over UDP.	false	boolean
clientMode (consumer)	If the clientMode is true, netty consumer will connect the address as a TCP client.	false	boolean

Name	Description	Default	Type
reconnect (consumer)	Used only in clientMode in consumer, the consumer will attempt to reconnect on disconnection if this is enabled.	true	boolean
reconnectInterval (consumer)	Used if reconnect and clientMode is enabled. The interval in milli seconds to attempt reconnection.	10000	int
backlog (consumer (advanced))	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be If this option is not configured, then the backlog depends on OS setting.		int
bossCount (consumer (advanced))	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this option to override the default bossCount from Netty.	1	int
bossGroup (consumer (advanced))	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint.		EventLoopGroup
disconnectOnNoReply (consumer (advanced))	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
nettyServerBootstrapFactory (consumer (advanced))	To use a custom NettyServerBootstrapFactory.		NettyServerBootstrapFactory

Name	Description	Default	Type
networkInterface (consumer (advanced))	When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.		String
noReplyLogLevel (consumer (advanced))	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel
serverClosedChannelExceptionCaughtLogLevel (consumer (advanced))	If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	DEBUG	LoggingLevel

Name	Description	Default	Type
serverExceptionCaughtLogLevel (consumer (advanced))	If the server (NettyConsumer) catches an exception then its logged using this logging level. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel
serverInitializerFactory (consumer (advanced))	To use a custom ServerInitializerFactory.		ServerInitializerFactory
usingExecutorService (consumer (advanced))	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	boolean
connectTimeout (producer)	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	int
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
requestTimeout (producer)	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		long
clientInitializerFactory (producer (advanced))	To use a custom ClientInitializerFactory.		ClientInitializerFactory

Name	Description	Default	Type
correlationManager (producer (advanced))	To use a custom correlation manager to manage how request and reply messages are mapped when using request/reply with the netty producer. This should only be used if you have a way to map requests together with replies such as if there is correlation ids in both the request and reply messages. This can be used if you want to multiplex concurrent messages on the same channel (aka connection) in netty. When doing this you must have a way to correlate the request and reply messages so you can store the right reply on the inflight Camel Exchange before its continued routed. We recommend extending the TimeoutCorrelationManagerSupport when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well. See also the producerPoolEnabled option for more details.		NettyCamelStateCorrelationManager
lazyChannelCreation (producer (advanced))	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean
producerPoolEnabled (producer (advanced))	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement NettyCamelStateCorrelationManager as correlation manager and configure it via the correlationManager option. See also the correlationManager option for more details.	true	boolean
producerPoolMaxIdle (producer (advanced))	Sets the cap on the number of idle instances in the pool.	100	int
producerPoolMaxTotal (producer (advanced))	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	int
producerPoolMinEvictableIdle (producer (advanced))	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	300000	long

Name	Description	Default	Type
producerPoolMinIdle (producer (advanced))	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		int
udpConnectionlessSending (producer (advanced))	This option supports connection less udp sending which is a real fire and forget. A connected udp send receive the PortUnreachableException if no one is listen on the receiving port.	false	boolean
useByteBuf (producer (advanced))	If the useByteBuf is true, netty producer will turn the message body into ByteBuf before sending it out.	false	boolean
hostnameVerification (security)	To enable/disable hostname verification on SSLEngine.	false	boolean
allowSerializedHeaders (advanced)	Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
channelGroup (advanced)	To use a explicit ChannelGroup.		ChannelGroup
nativeTransport (advanced)	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: .	false	boolean
options (advanced)	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
receiveBufferSize (advanced)	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	int
receiveBufferSizePredictor (advanced)	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		int
sendBufferSize (advanced)	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	int

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
udpByteArrayCodec (advanced)	For UDP only. If enabled the using byte array codec instead of Java serialization protocol.	false	boolean
workerCount (advanced)	When netty works on nio mode, it uses default workerCount parameter from Netty (which is cpu_core_threads x 2). User can use this option to override the default workerCount from Netty.		int
workerGroup (advanced)	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with 2 x cpu count core threads.		EventLoopGroup
allowDefaultCodec (codec)	The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.	true	boolean
autoAppendDelimiter (codec)	Whether or not to auto append missing end delimiter when sending using the textline codec.	true	boolean
decoderMaxLineLength (codec)	The max line length to use for the textline codec.	1024	int
decoders (codec)	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		List

Name	Description	Default	Type
delimiter (codec)	The delimiter to use for the textline codec. Possible values are LINE and NULL. Enum values: • LINE • NULL	LINE	TextLineDelimiter
encoders (codec)	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		List
encoding (codec)	The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.		String
textline (codec)	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP - however only Strings are allowed to be serialized by default.	false	boolean
enabledProtocols (security)	Which protocols to enable when using SSL.	TLSv1, TLSv1.1, TLSv1.2	String
keyStoreFile (security)	Client side certificate keystore to be used for encryption.		File
keyStoreFormat (security)	Keystore format to be used for payload encryption. Defaults to JKS if not set.		String
keyStoreResource (security)	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
needClientAuth (security)	Configures whether the server needs client authentication when using SSL.	false	boolean
passphrase (security)	Password setting to use in order to encrypt/decrypt payloads sent using SSH.		String
securityProvider (security)	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String

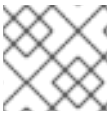
Name	Description	Default	Type
ssl (security)	Setting to specify whether SSL encryption is applied to this endpoint.	false	boolean
sslClientCertHeaders (security)	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters
sslHandler (security)	Reference to a class that could be used to return an SSL Handler.		SslHandler
trustStoreFile (security)	Server side certificate keystore to be used for encryption.		File
trustStoreResource (security)	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String

96.6. REGISTRY BASED OPTIONS

Codec Handlers and SSL Keystores can be enlisted in the Registry, such as in the Spring XML file. The values that could be passed in, are the following:

Name	Description
passphrase	password setting to use in order to encrypt/decrypt payloads sent using SSH
keyStoreFormat	keystore format to be used for payload encryption. Defaults to "JKS" if not set
securityProvider	Security provider to be used for payload encryption. Defaults to "SunX509" if not set.
keyStoreFile	**deprecated:** Client side certificate keystore to be used for encryption
trustStoreFile	**deprecated:** Server side certificate keystore to be used for encryption
keyStoreResource	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with **"classpath:"**, **"file:"**, or **"http:"** to load the resource from different systems.

Name	Description
trustStoreResource	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with **"classpath:"**, **"file:"**, or **"http:"** to load the resource from different systems.
sslHandler	Reference to a class that could be used to return an SSL Handler
encoder	A custom **ChannelHandler** class that can be used to perform special marshalling of outbound payloads. Must override io.netty.channel.ChannelInboundHandlerAdapter.
encoders	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.
decoder	A custom **ChannelHandler** class that can be used to perform special marshalling of inbound payloads. Must override io.netty.channel.ChannelOutboundHandlerAdapter.
decoders	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.



NOTE

Read below about using non shareable encoders/decoders.

96.6.1. Using non shareable encoders or decoders

If your encoders or decoders are not shareable (e.g. they don't have the @Shareable class annotation), then your encoder/decoder must implement the **org.apache.camel.component.netty.ChannelHandlerFactory** interface, and return a new instance in the **newChannelHandler** method. This is to ensure the encoder/decoder can safely be used. If this is not the case, then the Netty component will log a WARN when an endpoint is created.

The Netty component offers a **org.apache.camel.component.netty.ChannelHandlerFactories** factory class, that has a number of commonly used methods.

96.7. SENDING MESSAGES TO/FROM A NETTY ENDPOINT

96.7.1. Netty Producer

In Producer mode, the component provides the ability to send payloads to a socket endpoint using either TCP or UDP protocols (with optional SSL support).

The producer mode supports both one-way and request-response based operations.

96.7.2. Netty Consumer

In Consumer mode, the component provides the ability to:

- listen on a specified socket using either TCP or UDP protocols (with optional SSL support),
- receive requests on the socket using text/xml, binary and serialized object based payloads and
- send them along on a route as message exchanges.

The consumer mode supports both one-way and request-response based operations.

96.8. EXAMPLES

96.8.1. A UDP Netty endpoint using Request-Reply and serialized object payload

Note that Object serialization is not allowed by default, and so a decoder must be configured.

```
@BindToRegistry("decoder")
public ChannelHandler getDecoder() throws Exception {
    return new DefaultChannelHandlerFactory() {
        @Override
        public ChannelHandler newChannelHandler() {
            return new DatagramPacketObjectDecoder(ClassResolvers.weakCachingResolver(null));
        }
    };
}

RouteBuilder builder = new RouteBuilder() {
  public void configure() {
    from("netty:udp://0.0.0.0:5155?sync=true&decoders=#decoder")
      .process(new Processor() {
        public void process(Exchange exchange) throws Exception {
          Poetry poetry = (Poetry) exchange.getIn().getBody();
          // Process poetry in some way
          exchange.getOut().setBody("Message received);
        }
      }
    }
};
```

96.8.2. A TCP based Netty consumer endpoint using One-way communication

```
RouteBuilder builder = new RouteBuilder() {
  public void configure() {
      from("netty:tcp://0.0.0.0:5150")
          .to("mock:result");
  }
};
```

96.8.3. An SSL/TCP based Netty consumer endpoint using Request-Reply communication

Using the JSSE Configuration Utility

The Netty component supports SSL/TLS configuration through the Camel JSSE Configuration Utility. This utility greatly decreases the amount of component specific code you need to write and is

configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the Netty component.

Programmatic configuration of the component

```
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("keyPassword");

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

NettyComponent nettyComponent = getContext().getComponent("netty", NettyComponent.class);
nettyComponent.setSslContextParameters(scp);
```

Spring DSL based configuration of endpoint

```
...
  <camel:sslContextParameters
     id="sslContextParameters">
    <camel:keyManagers
       keyPassword="keyPassword">
      <camel:keyStore
         resource="/users/home/server/keystore.jks"
         password="keystorePassword"/>
    </camel:keyManagers>
  </camel:sslContextParameters>...
...
  <to uri="netty:tcp://0.0.0.0:5150?
sync=true&ssl=true&sslContextParameters=#sslContextParameters"/>
...
```

Using Basic SSL/TLS configuration on the Jetty Component

```
Registry registry = context.getRegistry();
registry.bind("password", "changeit");
registry.bind("ksf", new File("src/test/resources/keystore.jks"));
registry.bind("tsf", new File("src/test/resources/keystore.jks"));

context.addRoutes(new RouteBuilder() {
  public void configure() {
     String netty_ssl_endpoint =
       "netty:tcp://0.0.0.0:5150?sync=true&ssl=true&passphrase=#password"
       + "&keyStoreFile=#ksf&trustStoreFile=#tsf";
     String return_string =
       "When You Go Home, Tell Them Of Us And Say,"
       + "For Your Tomorrow, We Gave Our Today.";

     from(netty_ssl_endpoint)
      .process(new Processor() {
        public void process(Exchange exchange) throws Exception {
```

```
            exchange.getOut().setBody(return_string);
          }
        }
      }
    });
```

Getting access to SSLSession and the client certificate

You can get access to the **javax.net.ssl.SSLSession** if you eg need to get details about the client certificate. When **ssl=true** then the Netty component will store the **SSLSession** as a header on the Camel Message as shown below:

```
SSLSession session = exchange.getIn().getHeader(NettyConstants.NETTY_SSL_SESSION,
SSLSession.class);
// get the first certificate which is client certificate
javax.security.cert.X509Certificate cert = session.getPeerCertificateChain()[0];
Principal principal = cert.getSubjectDN();
```

Remember to set **needClientAuth=true** to authenticate the client, otherwise **SSLSession** cannot access information about the client certificate, and you may get an exception **javax.net.ssl.SSLPeerUnverifiedException: peer not authenticated**. You may also get this exception if the client certificate is expired or not valid etc.

NOTE

The option **sslClientCertHeaders** can be set to **true** which then enriches the Camel Message with headers having details about the client certificate. For example the subject name is readily available in the header **CamelNettySSLClientCertSubjectName**.

96.8.4. Using Multiple Codecs

In certain cases it may be necessary to add chains of encoders and decoders to the netty pipeline. To add multpile codecs to a camel netty endpoint the 'encoders' and 'decoders' uri parameters should be used. Like the 'encoder' and 'decoder' parameters they are used to supply references (lists of ChannelUpstreamHandlers and ChannelDownstreamHandlers) that should be added to the pipeline. Note that if encoders is specified then the encoder param will be ignored, similarly for decoders and the decoder param.

NOTE

Read further above about using non shareable encoders/decoders.

The lists of codecs need to be added to the Camel's registry so they can be resolved when the endpoint is created.

```
ChannelHandlerFactory lengthDecoder =
ChannelHandlerFactories.newLengthFieldBasedFrameDecoder(1048576, 0, 4, 0, 4);

StringDecoder stringDecoder = new StringDecoder();
registry.bind("length-decoder", lengthDecoder);
registry.bind("string-decoder", stringDecoder);

LengthFieldPrepender lengthEncoder = new LengthFieldPrepender(4);
StringEncoder stringEncoder = new StringEncoder();
```

```
registry.bind("length-encoder", lengthEncoder);
registry.bind("string-encoder", stringEncoder);

List<ChannelHandler> decoders = new ArrayList<ChannelHandler>();
decoders.add(lengthDecoder);
decoders.add(stringDecoder);

List<ChannelHandler> encoders = new ArrayList<ChannelHandler>();
encoders.add(lengthEncoder);
encoders.add(stringEncoder);

registry.bind("encoders", encoders);
registry.bind("decoders", decoders);
```

Spring's native collections support can be used to specify the codec lists in an application context

```
<util:list id="decoders" list-class="java.util.LinkedList">
        <bean class="org.apache.camel.component.netty.ChannelHandlerFactories" factory-
method="newLengthFieldBasedFrameDecoder">
            <constructor-arg value="1048576"/>
            <constructor-arg value="0"/>
            <constructor-arg value="4"/>
            <constructor-arg value="0"/>
            <constructor-arg value="4"/>
        </bean>
        <bean class="io.netty.handler.codec.string.StringDecoder"/>
    </util:list>

    <util:list id="encoders" list-class="java.util.LinkedList">
        <bean class="io.netty.handler.codec.LengthFieldPrepender">
            <constructor-arg value="4"/>
        </bean>
        <bean class="io.netty.handler.codec.string.StringEncoder"/>
    </util:list>

    <bean id="length-encoder" class="io.netty.handler.codec.LengthFieldPrepender">
        <constructor-arg value="4"/>
    </bean>
    <bean id="string-encoder" class="io.netty.handler.codec.string.StringEncoder"/>

    <bean id="length-decoder" class="org.apache.camel.component.netty.ChannelHandlerFactories"
factory-method="newLengthFieldBasedFrameDecoder">
        <constructor-arg value="1048576"/>
        <constructor-arg value="0"/>
        <constructor-arg value="4"/>
        <constructor-arg value="0"/>
        <constructor-arg value="4"/>
    </bean>
    <bean id="string-decoder" class="io.netty.handler.codec.string.StringDecoder"/>
```

The bean names can then be used in netty endpoint definitions either as a comma separated list or contained in a List e.g.

```
 from("direct:multiple-codec").to("netty:tcp://0.0.0.0:{{port}}?encoders=#encoders&sync=false");
```

```
 from("netty:tcp://0.0.0.0:{{port}}?decoders=#length-decoder,#string-
decoder&sync=false").to("mock:multiple-codec");
```

or via XML.

```
<camelContext id="multiple-netty-codecs-context" xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="direct:multiple-codec"/>
        <to uri="netty:tcp://0.0.0.0:5150?encoders=#encoders&amp;sync=false"/>
    </route>
    <route>
        <from uri="netty:tcp://0.0.0.0:5150?decoders=#length-decoder,#string-
decoder&amp;sync=false"/>
        <to uri="mock:multiple-codec"/>
    </route>
</camelContext>
```

96.9. CLOSING CHANNEL WHEN COMPLETE

When acting as a server you sometimes want to close the channel when, for example, a client conversion is finished.
You can do this by simply setting the endpoint option **disconnect=true**.

However you can also instruct Camel on a per message basis as follows.
To instruct Camel to close the channel, you should add a header with the key **CamelNettyCloseChannelWhenComplete** set to a boolean **true** value.
For instance, the example below will close the channel after it has written the bye message back to the client:

```
from("netty:tcp://0.0.0.0:8080").process(new Processor() {
    public void process(Exchange exchange) throws Exception {
        String body = exchange.getIn().getBody(String.class);
        exchange.getOut().setBody("Bye " + body);
        // some condition which determines if we should close
        if (close) {

exchange.getOut().setHeader(NettyConstants.NETTY_CLOSE_CHANNEL_WHEN_COMPLETE,
true);
        }
    }
});
```

Adding custom channel pipeline factories to gain complete control over a created pipeline.

96.10. CUSTOM PIPELINE

Custom channel pipelines provide complete control to the user over the handler/interceptor chain by inserting custom handler(s), encoder(s) & decoder(s) without having to specify them in the Netty Endpoint URL in a very simple way.

In order to add a custom pipeline, a custom channel pipeline factory must be created and registered with the context via the context registry (Registry, or the camel-spring ApplicationContextRegistry etc).

A custom pipeline factory must be constructed as follows

- A Producer linked channel pipeline factory must extend the abstract class **ClientPipelineFactory**.
- A Consumer linked channel pipeline factory must extend the abstract class **ServerInitializerFactory**.
- The classes should override the initChannel() method in order to insert custom handler(s), encoder(s) and decoder(s). Not overriding the **initChannel()** method creates a pipeline with no handlers, encoders or decoders wired to the pipeline.

The example below shows how ServerInitializerFactory factory may be created

96.10.1. Using custom pipeline factory

```
public class SampleServerInitializerFactory extends ServerInitializerFactory {
    private int maxLineSize = 1024;

    protected void initChannel(Channel ch) throws Exception {
        ChannelPipeline channelPipeline = ch.pipeline();

        channelPipeline.addLast("encoder-SD", new StringEncoder(CharsetUtil.UTF_8));
        channelPipeline.addLast("decoder-DELIM", new DelimiterBasedFrameDecoder(maxLineSize,
true, Delimiters.lineDelimiter()));
        channelPipeline.addLast("decoder-SD", new StringDecoder(CharsetUtil.UTF_8));
        // here we add the default Camel ServerChannelHandler for the consumer, to allow Camel to
route the message etc.
        channelPipeline.addLast("handler", new ServerChannelHandler(consumer));
    }
}
```

The custom channel pipeline factory can then be added to the registry and instantiated/utilized on a camel route in the following way

```
Registry registry = camelContext.getRegistry();
ServerInitializerFactory factory = new TestServerInitializerFactory();
registry.bind("spf", factory);
context.addRoutes(new RouteBuilder() {
  public void configure() {
      String netty_ssl_endpoint =
        "netty:tcp://0.0.0.0:5150?serverInitializerFactory=#spf"
      String return_string =
        "When You Go Home, Tell Them Of Us And Say,"
        + "For Your Tomorrow, We Gave Our Today.";

      from(netty_ssl_endpoint)
       .process(new Processor() {
          public void process(Exchange exchange) throws Exception {
            exchange.getOut().setBody(return_string);
          }
       }
  }
});
```

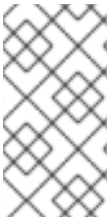
96.11. REUSING NETTY BOSS AND WORKER THREAD POOLS

Netty has two kind of thread pools: boss and worker. By default each Netty consumer and producer has their private thread pools. If you want to reuse these thread pools among multiple consumers or producers then the thread pools must be created and enlisted in the Registry.

For example using Spring XML we can create a shared worker thread pool using the **NettyWorkerPoolBuilder** with 2 worker threads as shown below:

```
<!-- use the worker pool builder to help create the shared thread pool -->
<bean id="poolBuilder" class="org.apache.camel.component.netty.NettyWorkerPoolBuilder">
  <property name="workerCount" value="2"/>
</bean>

<!-- the shared worker thread pool -->
<bean id="sharedPool" class="org.jboss.netty.channel.socket.nio.WorkerPool"
      factory-bean="poolBuilder" factory-method="build" destroy-method="shutdown">
</bean>
```



NOTE

For boss thread pool there is a **org.apache.camel.component.netty.NettyServerBossPoolBuilder** builder for Netty consumers, and a **org.apache.camel.component.netty.NettyClientBossPoolBuilder** for the Netty producers.

Then in the Camel routes we can refer to this worker pools by configuring the **workerPool** option in the URI as shown below:

```
<route>
  <from uri="netty:tcp://0.0.0.0:5021?
textline=true&amp;sync=true&amp;workerPool=#sharedPool&amp;usingExecutorService=false"/>
  <to uri="log:result"/>
  ...
</route>
```

And if we have another route we can refer to the shared worker pool:

```
<route>
  <from uri="netty:tcp://0.0.0.0:5022?
textline=true&amp;sync=true&amp;workerPool=#sharedPool&amp;usingExecutorService=false"/>
  <to uri="log:result"/>
  ...
</route>
```

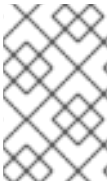
and so forth.

96.12. MULTIPLEXING CONCURRENT MESSAGES OVER A SINGLE CONNECTION WITH REQUEST/REPLY

When using Netty for request/reply messaging via the netty producer then by default each message is sent via a non-shared connection (pooled). This ensures that replies are automatic being able to map to the correct request thread for further routing in Camel. In other words correlation between request/reply messages happens out-of-the-box because the replies comes back on the same

connection that was used for sending the request; and this connection is not shared with others. When the response comes back, the connection is returned back to the connection pool, where it can be reused by others.

However if you want to multiplex concurrent request/responses on a single shared connection, then you need to turn off the connection pooling by setting **producerPoolEnabled=false**. Now this means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement **NettyCamelStateCorrelationManager** as correlation manager and configure it via the **correlationManager=#myManager** option.



NOTE

We recommend extending the **TimeoutCorrelationManagerSupport** when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well.

You can find an example with the Apache Camel source code in the examples directory under the **camel-example-netty-custom-correlation** directory.

96.13. SPRING BOOT AUTO-CONFIGURATION

The component supports 74 options, which are listed below.

Name	Description	Default	Type
camel.component.netty.allow-default-codec	The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.	true	Boolean
camel.component.netty.allow-serialized-headers	Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
camel.component.netty.auto-append-delimiter	Whether or not to auto append missing end delimiter when sending using the textline codec.	true	Boolean
camel.component.netty.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.netty.backlog	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be If this option is not configured, then the backlog depends on OS setting.		Integer
camel.component.netty.boss-count	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this option to override the default bossCount from Netty.	1	Integer
camel.component.netty.boss-group	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint. The option is a io.netty.channel.EventLoopGroup type.		EventLoopGroup
camel.component.netty.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.netty.broadcast	Setting to choose Multicast over UDP.	false	Boolean
camel.component.netty.channel-group	To use a explicit ChannelGroup. The option is a io.netty.channel.group.ChannelGroup type.		ChannelGroup
camel.component.netty.client-initializer-factory	To use a custom ClientInitializerFactory. The option is a org.apache.camel.component.netty.ClientInitializerFactory type.		ClientInitializerFactory
camel.component.netty.client-mode	If the clientMode is true, netty consumer will connect the address as a TCP client.	false	Boolean
camel.component.netty.configuration	To use the NettyConfiguration as configuration when creating endpoints. The option is a org.apache.camel.component.netty.NettyConfiguration type.		NettyConfiguration

Name	Description	Default	Type
camel.component.netty.connect-timeout	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	Integer
camel.component.netty.correlation-manager	To use a custom correlation manager to manage how request and reply messages are mapped when using request/reply with the netty producer. This should only be used if you have a way to map requests together with replies such as if there is correlation ids in both the request and reply messages. This can be used if you want to multiplex concurrent messages on the same channel (aka connection) in netty. When doing this you must have a way to correlate the request and reply messages so you can store the right reply on the inflight Camel Exchange before its continued routed. We recommend extending the TimeoutCorrelationManagerSupport when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well. See also the producerPoolEnabled option for more details. The option is a org.apache.camel.component.netty.NettyCamelStateCorrelationManager type.		NettyCamelStateCorrelationManager
camel.component.netty.decoder-max-line-length	The max line length to use for the textline codec.	1024	Integer
camel.component.netty.decoders	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
camel.component.netty.delimiter	The delimiter to use for the textline codec. Possible values are LINE and NULL.		TextLineDelimiter
camel.component.netty.disconnect	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	Boolean
camel.component.netty.disconnect-on-no-reply	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	Boolean

Name	Description	Default	Type
camel.component.netty.enabled	Whether to enable auto configuration of the netty component. This is enabled by default.		Boolean
camel.component.netty.enabled-protocols	Which protocols to enable when using SSL.	TLSv1, TLSv1.1, TLSv1.2	String
camel.component.netty.encoders	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
camel.component.netty.encoding	The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.		String
camel.component.netty.executor-service	To use the given EventExecutorGroup. The option is a io.netty.util.concurrent.EventExecutorGroup type.		EventExecutorGroup
camel.component.netty.hostname-verification	To enable/disable hostname verification on SSLEngine.	false	Boolean
camel.component.netty.keep-alive	Setting to ensure socket is not closed due to inactivity.	true	Boolean
camel.component.netty.key-store-file	Client side certificate keystore to be used for encryption.		File
camel.component.netty.key-store-format	Keystore format to be used for payload encryption. Defaults to JKS if not set.		String
camel.component.netty.key-store-resource	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
camel.component.netty.lazy-channel-creation	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	Boolean

Name	Description	Default	Type
camel.component.netty.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.netty.maximum-pool-size	Sets a maximum thread pool size for the netty consumer ordered thread pool. The default size is 2 x cpu_core plus 1. Setting this value to eg 10 will then use 10 threads unless 2 x cpu_core plus 1 is a higher value, which then will override and be used. For example if there are 8 cores, then the consumer thread pool will be 17. This thread pool is used to route messages received from Netty by Camel. We use a separate thread pool to ensure ordering of messages and also in case some messages will block, then nettys worker threads (event loop) wont be affected.		Integer
camel.component.netty.native-transport	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: .	false	Boolean
camel.component.netty.need-client-auth	Configures whether the server needs client authentication when using SSL.	false	Boolean
camel.component.netty.netty-server-bootstrap-factory	To use a custom NettyServerBootstrapFactory. The option is a org.apache.camel.component.netty.NettyServerBootstrapFactory type.		NettyServerBootstrapFactory
camel.component.netty.network-interface	When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.		String
camel.component.netty.no-reply-log-level	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back.		LoggingLevel

Name	Description	Default	Type
camel.component.netty.options	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
camel.component.netty.passphrase	Password setting to use in order to encrypt/decrypt payloads sent using SSH.		String
camel.component.netty.producer-pool-enabled	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement NettyCamelStateCorrelationManager as correlation manager and configure it via the correlationManager option. See also the correlationManager option for more details.	true	Boolean
camel.component.netty.producer-pool-max-idle	Sets the cap on the number of idle instances in the pool.	100	Integer
camel.component.netty.producer-pool-max-total	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	Integer
camel.component.netty.producer-pool-min-evictable-idle	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	300000	Long
camel.component.netty.producer-pool-min-idle	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		Integer
camel.component.netty.receive-buffer-size	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	Integer

Name	Description	Default	Type
camel.component.netty.receive-buffer-size-predictor	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		Integer
camel.component.netty.reconnect	Used only in clientMode in consumer, the consumer will attempt to reconnect on disconnection if this is enabled.	true	Boolean
camel.component.netty.reconnect-interval	Used if reconnect and clientMode is enabled. The interval in milli seconds to attempt reconnection.	10000	Integer
camel.component.netty.request-timeout	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		Long
camel.component.netty.reuse-address	Setting to facilitate socket multiplexing.	true	Boolean
camel.component.netty.reuse-channel	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key NettyConstants#NETTY_CHANNEL which allows you to obtain the channel during routing and use it as well.	false	Boolean
camel.component.netty.security-provider	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String
camel.component.netty.send-buffer-size	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	Integer

Name	Description	Default	Type
camel.component.netty.server-closed-channel-exception-caught-log-level	If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.		LoggingLevel
camel.component.netty.server-exception-caught-log-level	If the server (NettyConsumer) catches an exception then its logged using this logging level.		LoggingLevel
camel.component.netty.server-initializer-factory	To use a custom ServerInitializerFactory. The option is a org.apache.camel.component.netty.ServerInitializerFactory type.		ServerInitializerFactory
camel.component.netty.ssl	Setting to specify whether SSL encryption is applied to this endpoint.	false	Boolean
camel.component.netty.ssl-client-cert-headers	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	Boolean
camel.component.netty.ssl-context-parameters	To configure security using SSLContextParameters. The option is a org.apache.camel.support.jsse.SSLContextParameters type.		SSLContextParameters
camel.component.netty.ssl-handler	Reference to a class that could be used to return an SSL Handler. The option is a io.netty.handler.ssl.SslHandler type.		SslHandler
camel.component.netty.sync	Setting to set endpoint as one-way or request-response.	true	Boolean
camel.component.netty.tcp-no-delay	Setting to improve TCP protocol performance.	true	Boolean
camel.component.netty.textline	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP - however only Strings are allowed to be serialized by default.	false	Boolean

Name	Description	Default	Type
camel.component.netty.transfer-exchange	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
camel.component.netty.trust-store-file	Server side certificate keystore to be used for encryption.		File
camel.component.netty.trust-store-resource	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
camel.component.netty.udp-byte-array-codec	For UDP only. If enabled the using byte array codec instead of Java serialization protocol.	false	Boolean
camel.component.netty.udp-connectionless-sending	This option supports connection less udp sending which is a real fire and forget. A connected udp send receive the PortUnreachableException if no one is listen on the receiving port.	false	Boolean
camel.component.netty.use-byte-buf	If the useByteBuf is true, netty producer will turn the message body into ByteBuf before sending it out.	false	Boolean
camel.component.netty.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.netty.using-executor-service	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	Boolean
camel.component.netty.worker-count	When netty works on nio mode, it uses default workerCount parameter from Netty (which is cpu_core_threads x 2). User can use this option to override the default workerCount from Netty.		Integer

Name	Description	Default	Type
camel.component.netty.worker-group	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with 2 x cpu count core threads. The option is a io.netty.channel.EventLoopGroup type.		EventLoopGroup

CHAPTER 97. NETTY HTTP

Since Camel 2.14

Both producer and consumer are supported

The Netty HTTP component is an extension to Netty component to facilitiate HTTP transport with Netty.

NOTE

Stream

Netty is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream **once**. If you find a situation where the message body appears to be empty or you need to access the data multiple times (eg: doing multicasting, or redelivery error handling) you should use Stream caching or convert the message body to a **String** which is safe to be re-read multiple times. Notice Netty HTTP reads the entire stream into memory using **io.netty.handler.codec.http.HttpObjectAggregator** to build the entire full http message. But the resulting message is still a stream based message which is readable once.

97.1. DEPENDENCIES

When using **netty-http** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-netty-http-starter</artifactId>
</dependency>
```

97.2. URI FORMAT

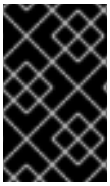
The URI scheme for a netty component is as follows

```
netty-http:http://0.0.0.0:8080[?options]
```

NOTE

Query parameters vs endpoint options

You may be wondering how Camel recognizes URI query parameters and endpoint options. For example you might create endpoint URI as follows: **netty-http:http//example.com?myParam=myValue&compression=true** . In this example **myParam** is the HTTP parameter, while **compression** is the Camel endpoint option. The strategy used by Camel in such situations is to resolve available endpoint options and remove them from the URI. It means that for the discussed example, the HTTP request sent by Netty HTTP producer to the endpoint will look as follows: **http//example.com?myParam=myValue**, because **compression** endpoint option will be resolved and removed from the target URL. Keep also in mind that you cannot specify endpoint options using dynamic headers (like **CamelHttpQuery**). Endpoint options can be specified only at the endpoint URI definition level (like **to** or **from** DSL elements).



IMPORTANT

This component inherits all the options from Netty. Notice that some options from Netty are not applicable when using this Netty HTTP component, such as options related to UDP transport.

97.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

97.3.1. Configuring component options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

97.3.2. Configuring endpoint options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL and DataFormat DSL as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

97.4. COMPONENT OPTIONS

The Netty HTTP component supports 80 options, which are listed below.

Name	Description	Default	Type
configuration (common)	To use the NettyConfiguration as configuration when creating endpoints.		NettyConfiguration

Name	Description	Default	Type
disconnect (common)	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	boolean
keepAlive (common)	Setting to ensure socket is not closed due to inactivity.	true	boolean
reuseAddress (common)	Setting to facilitate socket multiplexing.	true	boolean
reuseChannel (common)	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key NettyConstants#NETTY_CHANNEL which allows you to obtain the channel during routing and use it as well.	false	boolean
sync (common)	Setting to set endpoint as one-way or request-response.	true	boolean
tcpNoDelay (common)	Setting to improve TCP protocol performance.	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
broadcast (consumer)	Setting to choose Multicast over UDP.	false	boolean
clientMode (consumer)	If the clientMode is true, netty consumer will connect the address as a TCP client.	false	boolean

Name	Description	Default	Type
muteException (consumer)	If enabled and an Exchange failed processing on the consumer side the response's body won't contain the exception's stack trace.	false	boolean
reconnect (consumer)	Used only in clientMode in consumer, the consumer will attempt to reconnect on disconnection if this is enabled.	true	boolean
reconnectInterval (consumer)	Used if reconnect and clientMode is enabled. The interval in milli seconds to attempt reconnection.	10000	int
backlog (consumer (advanced))	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be If this option is not configured, then the backlog depends on OS setting.		int
bossCount (consumer (advanced))	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this option to override the default bossCount from Netty.	1	int
bossGroup (consumer (advanced))	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint.		EventLoopGroup
disconnectOnNoReply (consumer (advanced))	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	boolean
executorService (consumer (advanced))	To use the given EventExecutorGroup.		EventExecutorGroup
maximumPoolSize (consumer (advanced))	Sets a maximum thread pool size for the netty consumer ordered thread pool. The default size is 2 x cpu_core plus 1. Setting this value to eg 10 will then use 10 threads unless 2 x cpu_core plus 1 is a higher value, which then will override and be used. For example if there are 8 cores, then the consumer thread pool will be 17. This thread pool is used to route messages received from Netty by Camel. We use a separate thread pool to ensure ordering of messages and also in case some messages will block, then nettys worker threads (event loop) wont be affected.		int

Name	Description	Default	Type
nettyServerBootstrapFactory (consumer (advanced))	To use a custom NettyServerBootstrapFactory.		NettyServerBootstrapFactory
networkInterface (consumer (advanced))	When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.		String
noReplyLogLevel (consumer (advanced))	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel
serverClosedChannelExceptionCaughtLogLevel (consumer (advanced))	If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	DEBUG	LoggingLevel

Name	Description	Default	Type
serverExceptionCaughtLogLevel (consumer (advanced))	If the server (NettyConsumer) catches an exception then its logged using this logging level. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel
serverInitializerFactory (consumer (advanced))	To use a custom ServerInitializerFactory.		ServerInitializerFactory
usingExecutorService (consumer (advanced))	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	boolean
connectTimeout (producer)	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	int
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
requestTimeout (producer)	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		long
clientInitializerFactory (producer (advanced))	To use a custom ClientInitializerFactory.		ClientInitializerFactory

Name	Description	Default	Type
correlationManager (producer (advanced))	To use a custom correlation manager to manage how request and reply messages are mapped when using request/reply with the netty producer. This should only be used if you have a way to map requests together with replies such as if there is correlation ids in both the request and reply messages. This can be used if you want to multiplex concurrent messages on the same channel (aka connection) in netty. When doing this you must have a way to correlate the request and reply messages so you can store the right reply on the inflight Camel Exchange before its continued routed. We recommend extending the TimeoutCorrelationManagerSupport when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well. See also the producerPoolEnabled option for more details.		NettyCamelStateCorrelationManager
lazyChannelCreation (producer (advanced))	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean
producerPoolBlockWhenExhausted (producer (advanced))	Sets the value for the blockWhenExhausted configuration attribute. It determines whether to block when the borrowObject() method is invoked when the pool is exhausted (the maximum number of active objects has been reached).	true	boolean
producerPoolEnabled (producer (advanced))	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement NettyCamelStateCorrelationManager as correlation manager and configure it via the correlationManager option. See also the correlationManager option for more details.	true	boolean
producerPoolMaxIdle (producer (advanced))	Sets the cap on the number of idle instances in the pool.	100	int

Name	Description	Default	Type
producerPoolMaxTotal (producer (advanced))	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	int
producerPoolMaxWait (producer (advanced))	Sets the maximum duration (value in millis) the borrowObject() method should block before throwing an exception when the pool is exhausted and producerPoolBlockWhenExhausted is true. When less than 0, the borrowObject() method may block indefinitely.	-1	long
producerPoolMinEvictableIdle (producer (advanced))	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	300000	long
producerPoolMinIdle (producer (advanced))	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		int
udpConnectionlessSending (producer (advanced))	This option supports connection less udp sending which is a real fire and forget. A connected udp send receive the PortUnreachableException if no one is listen on the receiving port.	false	boolean
useByteBuf (producer (advanced))	If the useByteBuf is true, netty producer will turn the message body into ByteBuf before sending it out.	false	boolean
hostnameVerification (security)	To enable/disable hostname verification on SSLEngine.	false	boolean
allowSerializedHeaders (advanced)	Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
channelGroup (advanced)	To use a explicit ChannelGroup.		ChannelGroup
headerFilterStrategy (advanced)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers.		HeaderFilterStrategy
nativeTransport (advanced)	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: .	false	boolean
nettyHttpBinding (advanced)	To use a custom org.apache.camel.component.netty.http.NettyHttpBinding for binding to/from Netty and Camel Message API.		NettyHttpBinding
options (advanced)	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
receiveBufferSize (advanced)	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	int
receiveBufferSizePredictor (advanced)	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		int
sendBufferSize (advanced)	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	int
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
udpByteArrayCodec (advanced)	For UDP only. If enabled the using byte array codec instead of Java serialization protocol.	false	boolean

Name	Description	Default	Type
unixDomainSocketPath (advanced)	Path to unix domain socket to use instead of inet socket. Host and port parameters will not be used, however required. It is ok to set dummy values for them. Must be used with nativeTransport=true and clientMode=false.		String
workerCount (advanced)	When netty works on nio mode, it uses default workerCount parameter from Netty (which is cpu_core_threads x 2). User can use this option to override the default workerCount from Netty.		int
workerGroup (advanced)	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with 2 x cpu count core threads.		EventLoopGroup
allowDefaultCodec (codec)	The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.	true	boolean
autoAppendDelimiter (codec)	Whether or not to auto append missing end delimiter when sending using the textline codec.	true	boolean
decoderMaxLineLength (codec)	The max line length to use for the textline codec.	1024	int
decoders (codec)	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
delimiter (codec)	The delimiter to use for the textline codec. Possible values are LINE and NULL. Enum values: • LINE • NULL	LINE	TextLineDelimiter

Name	Description	Default	Type
encoders (codec)	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
encoding (codec)	The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.		String
textline (codec)	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP - however only Strings are allowed to be serialized by default.	false	boolean
enabledProtocols (security)	Which protocols to enable when using SSL.	TLSv1.2,TLSv1.3	String
keyStoreFile (security)	Client side certificate keystore to be used for encryption.		File
keyStoreFormat (security)	Keystore format to be used for payload encryption. Defaults to JKS if not set.		String
keyStoreResource (security)	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
needClientAuth (security)	Configures whether the server needs client authentication when using SSL.	false	boolean
passphrase (security)	Password setting to use in order to encrypt/decrypt payloads sent using SSH.		String
securityConfiguration (security)	Refers to a org.apache.camel.component.netty.http.NettyHttpSecurityConfiguration for configuring secure web resources.		NettyHttpSecurityConfiguration
securityProvider (security)	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String
ssl (security)	Setting to specify whether SSL encryption is applied to this endpoint.	false	boolean

Name	Description	Default	Type
sslClientCertHeaders (security)	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters
sslHandler (security)	Reference to a class that could be used to return an SSL Handler.		SslHandler
trustStoreFile (security)	Server side certificate keystore to be used for encryption.		File
trustStoreResource (security)	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

97.5. ENDPOINT OPTIONS

The Netty HTTP endpoint is configured using URI syntax:

```
netty-http:protocol://host:port/path
```

with the following path and query parameters:

97.5.1. Path Parameters (4 parameters)

Name	Description	Default	Type
protocol (common)	**Required** The protocol to use which is either http, https or proxy - a consumer only option. Enum values: • http • https		String

Name	Description	Default	Type
host (common)	**Required** The local hostname such as localhost, or 0.0.0.0 when being a consumer. The remote HTTP server hostname when using producer.		String
port (common)	The host port number.		int
path (common)	Resource path.		String

97.5.2. Query Parameters (85 parameters)

Name	Description	Default	Type
bridgeEndpoint (common)	If the option is true, the producer will ignore the NettyHttpConstants.HTTP_URI header, and use the endpoint's URI for request. You may also set the throwExceptionOnFailure to be false to let the producer send all the fault response back. The consumer working in the bridge mode will skip the gzip compression and WWW URL form encoding (by adding the Exchange.SKIP_GZIP_ENCODING and Exchange.SKIP_WWW_FORM_URLENCODED headers to the consumed exchange).	false	boolean
disconnect (common)	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	boolean
keepAlive (common)	Setting to ensure socket is not closed due to inactivity.	true	boolean
reuseAddress (common)	Setting to facilitate socket multiplexing.	true	boolean
reuseChannel (common)	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key NettyConstants#NETTY_CHANNEL which allows you to obtain the channel during routing and use it as well.	false	boolean

Name	Description	Default	Type
sync (common)	Setting to set endpoint as one-way or request-response.	true	boolean
tcpNoDelay (common)	Setting to improve TCP protocol performance.	true	boolean
matchOnUriPrefix (consumer)	Whether or not Camel should try to find a target consumer by matching the URI prefix if no exact match is found.	false	boolean
muteException (consumer)	If enabled and an Exchange failed processing on the consumer side the response's body won't contain the exception's stack trace.	false	boolean
send503whenSuspended (consumer)	Whether to send back HTTP status code 503 when the consumer has been suspended. If the option is false then the Netty Acceptor is unbound when the consumer is suspended, so clients cannot connect anymore.	true	boolean
backlog (consumer (advanced))	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be If this option is not configured, then the backlog depends on OS setting.		int
bossCount (consumer (advanced))	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this option to override the default bossCount from Netty.	1	int
bossGroup (consumer (advanced))	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint.		EventLoopGroup
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
chunkedMaxContentLength (consumer (advanced))	Value in bytes the max content length per chunked frame received on the Netty HTTP server.	1048576	int
compression (consumer (advanced))	Allow using gzip/deflate for compression on the Netty HTTP server if the client supports it from the HTTP headers.	false	boolean
disconnectOnNoReply (consumer (advanced))	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
httpMethodRestrict (consumer (advanced))	To disable HTTP methods on the Netty HTTP consumer. You can specify multiple separated by comma.		String
logWarnOnBadRequest (consumer (advanced))	Whether Netty HTTP server should log a WARN if decoding the HTTP request failed and a HTTP Status 400 (bad request) is returned.	true	boolean
mapHeaders (consumer (advanced))	If this option is enabled, then during binding from Netty to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the org.apache.camel.component.netty.http.NettyHttpMessage message with the method getHttpRequest() that returns the Netty HTTP request io.netty.handler.codec.http.HttpRequest instance.	true	boolean

Name	Description	Default	Type
maxChunkSize (consumer (advanced))	The maximum length of the content or each chunk. If the content length (or the length of each chunk) exceeds this value, the content or chunk will be split into multiple io.netty.handler.codec.http.HttpContents whose length is maxChunkSize at maximum. See io.netty.handler.codec.http.HttpObjectDecoder.	8192	int
maxHeaderSize (consumer (advanced))	The maximum length of all headers. If the sum of the length of each header exceeds this value, a io.netty.handler.codec.TooLongFrameException will be raised.	8192	int
maxInitialLineLength (consumer (advanced))	The maximum length of the initial line (e.g. \\{code GET / HTTP/1.0} or \\{code HTTP/1.0 200 OK}) If the length of the initial line exceeds this value, a TooLongFrameException will be raised. See io.netty.handler.codec.http.HttpObjectDecoder.	4096	int
nettyServerBootstrapFactory (consumer (advanced))	To use a custom NettyServerBootstrapFactory.		NettyServerBootstrapFactory
nettySharedHttpServer (consumer (advanced))	To use a shared Netty HTTP server. See Netty HTTP Server Example for more details.		NettySharedHttpServer
noReplyLogLevel (consumer (advanced))	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel

Name	Description	Default	Type
serverClosedChannelExceptionCaughtLogLevel (consumer (advanced))	If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	DEBUG	LoggingLevel
serverExceptionCaughtLogLevel (consumer (advanced))	If the server (NettyConsumer) catches an exception then its logged using this logging level. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel
serverInitializerFactory (consumer (advanced))	To use a custom ServerInitializerFactory.		ServerInitializerFactory
traceEnabled (consumer (advanced))	Specifies whether to enable HTTP TRACE for this Netty HTTP consumer. By default TRACE is turned off.	false	boolean

Name	Description	Default	Type
urlDecodeHeaders (consumer (advanced))	If this option is enabled, then during binding from Netty to Camel Message then the header values will be URL decoded (eg %20 will be a space character. Notice this option is used by the default org.apache.camel.component.netty.http.NettyHttpBinding and therefore if you implement a custom org.apache.camel.component.netty.http.NettyHttpBinding then you would need to decode the headers accordingly to this option.	false	boolean
usingExecutorService (consumer (advanced))	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	boolean
connectTimeout (producer)	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	int
cookieHandler (producer)	Configure a cookie handler to maintain a HTTP session.		CookieHandler
requestTimeout (producer)	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		long
throwExceptionOnFailure (producer)	Option to disable throwing the HttpOperationFailedException in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.	true	boolean
clientInitializerFactory (producer (advanced))	To use a custom ClientInitializerFactory.		ClientInitializerFactory
lazyChannelCreation (producer (advanced))	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
okStatusCodeRange (producer (advanced))	The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included. The default range is 200-299.	200-299	String
producerPoolBlockWhenExhausted (producer (advanced))	Sets the value for the blockWhenExhausted configuration attribute. It determines whether to block when the borrowObject() method is invoked when the pool is exhausted (the maximum number of active objects has been reached).	true	boolean
producerPoolEnabled (producer (advanced))	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement NettyCamelStateCorrelationManager as correlation manager and configure it via the correlationManager option. See also the correlationManager option for more details.	true	boolean
producerPoolMaxIdle (producer (advanced))	Sets the cap on the number of idle instances in the pool.	100	int
producerPoolMaxTotal (producer (advanced))	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	int

Name	Description	Default	Type
producerPoolMaxWait (producer (advanced))	Sets the maximum duration (value in millis) the borrowObject() method should block before throwing an exception when the pool is exhausted and producerPoolBlockWhenExhausted is true. When less than 0, the borrowObject() method may block indefinitely.	-1	long
producerPoolMinEvictableIdle (producer (advanced))	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	300000	long
producerPoolMinIdle (producer (advanced))	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		int
useRelativePath (producer (advanced))	Sets whether to use a relative path in HTTP requests.	true	boolean
hostnameVerification (security)	To enable/disable hostname verification on SSLEngine.	false	boolean
allowSerializedHeaders (advanced)	Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
channelGroup (advanced)	To use a explicit ChannelGroup.		ChannelGroup
configuration (advanced)	To use a custom configured NettyHttpConfiguration for configuring this endpoint.		NettyHttpConfiguration

Name	Description	Default	Type
disableStreamCache (advanced)	Determines whether or not the raw input stream from Netty HttpRequest#getContent() or HttpResponset#getContent() is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Netty raw stream. Also Netty will auto-close the Netty stream when the Netty HTTP server/HTTP client is done processing, which means that if the asynchronous routing engine is in use then any asynchronous thread that may continue routing the org.apache.camel.Exchange may not be able to read the Netty stream, because Netty has closed it.	false	boolean
headerFilterStrategy (advanced)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers.		HeaderFilterStrategy
nativeTransport (advanced)	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: .	false	boolean
nettyHttpBinding (advanced)	To use a custom org.apache.camel.component.netty.http.NettyHttpBinding for binding to/from Netty and Camel Message API.		NettyHttpBinding
options (advanced)	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
receiveBufferSize (advanced)	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	int

Name	Description	Default	Type
receiveBufferSizePredictor (advanced)	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		int
sendBufferSize (advanced)	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	int
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean
transferException (advanced)	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the HttpOperationFailedException. The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
unixDomainSocketPath (advanced)	Path to unix domain socket to use instead of inet socket. Host and port parameters will not be used, however required. It is ok to set dummy values for them. Must be used with nativeTransport=true and clientMode=false.		String
workerCount (advanced)	When netty works on nio mode, it uses default workerCount parameter from Netty (which is cpu_core_threads x 2). User can use this option to override the default workerCount from Netty.		int
workerGroup (advanced)	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with 2 x cpu count core threads.		EventLoopGroup

Name	Description	Default	Type
decoders (codec)	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
encoders (codec)	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
enabledProtocols (security)	Which protocols to enable when using SSL.	TLSv1.2,TLSv1.3	String
keyStoreFile (security)	Client side certificate keystore to be used for encryption.		File
keyStoreFormat (security)	Keystore format to be used for payload encryption. Defaults to JKS if not set.		String
keyStoreResource (security)	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
needClientAuth (security)	Configures whether the server needs client authentication when using SSL.	false	boolean
passphrase (security)	Password setting to use in order to encrypt/decrypt payloads sent using SSH.		String
securityConfiguration (security)	Refers to a org.apache.camel.component.netty.http.NettyHttpSecurityConfiguration for configuring secure web resources.		NettyHttpSecurityConfiguration
securityOptions (security)	To configure NettyHttpSecurityConfiguration using key/value pairs from the map.		Map
securityProvider (security)	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String
ssl (security)	Setting to specify whether SSL encryption is applied to this endpoint.	false	boolean

Name	Description	Default	Type
sslClientCertHeaders (security)	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters
sslHandler (security)	Reference to a class that could be used to return an SSL Handler.		SslHandler
trustStoreFile (security)	Server side certificate keystore to be used for encryption.		File
trustStoreResource (security)	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String

97.6. MESSAGE HEADERS

The Netty HTTP component supports 23 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelHttpAuthentication (common) Constant: HTTP_AUTHENTICATION	If the user was authenticated using HTTP Basic then this header is added with the value Basic.		String
Content-Type (common) Constant: CONTENT_TYPE	To set the content-type of the HTTP body. For example: text/plain; charset=UTF-8.		String
connection (common) Constant: CONNECTION	The value of the HTTP header connection to use.		String

Name	Description	Default	Type
CamelNettyCloseChannelWhenComplete (common) Constant: NETTY_CLOSE_CHANNEL_WHEN_COMPLETE	Indicates whether the channel should be closed after complete.		Boolean
CamelHttpResponseCode (common) Constant: HTTP_RESPONSE_CODE	Allows to set the HTTP Status code to use. By default 200 is used for success, and 500 for failure.		Integer
CamelHttpProtocolVersion (common) Constant: HTTP_PROTOCOL_VERSION	The version of the HTTP protocol.	HTTP/1.1	String
CamelHttpMethod (common) Constant: HTTP_METHOD	The HTTP method used, such as GET, POST, TRACE etc.	GET	String
CamelHttpQuery (common) Constant: HTTP_QUERY	Any query parameters, such as foo=bar&beer=yes.		String
CamelHttpPath (common) Constant: HTTP_PATH	Allows to provide URI context-path and query parameters as a String value that overrides the endpoint configuration. This allows to reuse the same producer for calling same remote http server, but using a dynamic context-path and query parameters.		String
CamelHttpRawQuery (common) Constant: HTTP_RAW_QUERY	Any query parameters, such as foo=bar&beer=yes. Stored in the raw form, as they arrived to the consumer (i.e. before URL decoding).		String

Name	Description	Default	Type
CamelHttpUrl (common) Constant: HTTP_URL	The URL including protocol, host and port, etc:http://0.0.0.0:8080/myapp .		String
CamelHttpCharacterEncoding (common) Constant: HTTP_CHARACTER_ENCODING	The charset from the content-type header.		String
CamelHttpUri (common) Constant: HTTP_URI	The URI without protocol, host and port, etc: /myapp.		String
CamelNettyChannelHandlerContext (common) Constant: NETTY_CHANNEL_HANDLER_CONTEXT	The channel handler context.		ChannelHandlerContext
CamelNettyRemoteAddress (common) Constant: NETTY_REMOTE_ADDRESS	The remote address.		SocketAddress
CamelNettyLocalAddress (common) Constant: NETTY_LOCAL_ADDRESS	The local address.		SocketAddress

Name	Description	Default	Type
CamelNettySSLSession (common) Constant: NETTY_SSL_SESSION	The SSL session.		SSLSession
CamelNettySSLClientCertSubjectName (common) Constant: NETTY_SSL_CLIENT_CERT_SUBJECT_NAME	The SSL client certificate subject name.		String
CamelNettySSLClientCertIssuerName (common) Constant: NETTY_SSL_CLIENT_CERT_ISSUER_NAME	The SSL client certificate issuer name.		String
CamelNettySSLClientCertSerialNumber (common) Constant: NETTY_SSL_CLIENT_CERT_SERIAL_NO	The SSL client certificate serial number.		String
CamelNettySSLClientCertNotBefore (common) Constant: NETTY_SSL_CLIENT_CERT_NOT_BEFORE	The SSL client certificate not before.		Date

Name	Description	Default	Type
CamelNettySSLClientCertNotAfter (common) Constant: NETTY_SSL_CLIENT_CERT_NOT_AFTER	The SSL client certificate not after.		Date
CamelNettyRequestTimeout (common) Constant: NETTY_REQUEST_TIMEOUT	The read timeout.		Long

97.7. ACCESS TO NETTY TYPES

This component uses the **org.apache.camel.component.netty.http.NettyHttpMessage** as the message implementation on the Exchange. This allows end users to get access to the original Netty request/response instances if needed, as shown below. Mind that the original response may not be accessible at all times.

```
io.netty.handler.codec.http.HttpRequest request =
exchange.getIn(NettyHttpMessage.class).getHttpRequest();
```

97.8. EXAMPLES

In the route below we use Netty HTTP as a HTTP server, which returns back a hardcoded "Bye World" message.

```
from("netty-http:http://0.0.0.0:8080/foo")
  .transform().constant("Bye World");
```

And we can call this HTTP server using Camel also, with the ProducerTemplate as shown below:

```
String out = template.requestBody("netty-http:http://0.0.0.0:8080/foo", "Hello World", String.class);
System.out.println(out);
```

And we get back "Bye World" as the output.

97.8.1. How do I let Netty match wildcards

By default Netty HTTP will only match on exact uri's. But you can instruct Netty to match prefixes. For example

```
from("netty-http:http://0.0.0.0:8123/foo").to("mock:foo");
```

In the route above Netty HTTP will only match if the uri is an exact match, so it will match if you enter **http://0.0.0.0:8123/foo** but not match if you do **http://0.0.0.0:8123/foo/bar**.

So if you want to enable wildcard matching you do as follows:

```
from("netty-http:http://0.0.0.0:8123/foo?matchOnUriPrefix=true").to("mock:foo");
```

So now Netty matches any endpoints with starts with **foo**.

To match **any** endpoint you can do:

```
from("netty-http:http://0.0.0.0:8123?matchOnUriPrefix=true").to("mock:foo");
```

97.8.2. Using multiple routes with same port

In the same CamelContext you can have multiple routes from Netty HTTP that shares the same port (eg a **io.netty.bootstrap.ServerBootstrap** instance). Doing this requires a number of bootstrap options to be identical in the routes, as the routes will share the same **io.netty.bootstrap.ServerBootstrap** instance. The instance will be configured with the options from the first route created.

The options the routes must be identical configured is all the options defined in the **org.apache.camel.component.netty.NettyServerBootstrapConfiguration** configuration class. If you have configured another route with different options, Camel will throw an exception on startup, indicating the options is not identical. To mitigate this ensure all options is identical.

Here is an example with two routes that share the same port.

Two routes sharing the same port

```
from("netty-http:http://0.0.0.0:{{port}}/foo")
  .to("mock:foo")
  .transform().constant("Bye World");

from("netty-http:http://0.0.0.0:{{port}}/bar")
  .to("mock:bar")
  .transform().constant("Bye Camel");
```

And here is an example of a misconfigured 2nd route that do not have identical **org.apache.camel.component.netty.NettyServerBootstrapConfiguration** option as the 1st route. This will cause Camel to fail on startup.

Two routes sharing the same port, but the 2nd route is misconfigured

and will fail on starting

```
from("netty-http:http://0.0.0.0:{{port}}/foo")
  .to("mock:foo")
  .transform().constant("Bye World");

// we cannot have a 2nd route on same port with SSL enabled, when the 1st route is NOT
from("netty-http:http://0.0.0.0:{{port}}/bar?ssl=true")
  .to("mock:bar")
  .transform().constant("Bye Camel");
```

97.8.3. Reusing same server bootstrap configuration with multiple routes

By configuring the common server bootstrap option in an single instance of a **org.apache.camel.component.netty.NettyServerBootstrapConfiguration** type, we can use the **bootstrapConfiguration** option on the Netty HTTP consumers to refer and reuse the same options across all consumers.

```
<bean id="nettyHttpBootstrapOptions"
class="org.apache.camel.component.netty.NettyServerBootstrapConfiguration">
  <property name="backlog" value="200"/>
  <property name="connectionTimeout" value="20000"/>
  <property name="workerCount" value="16"/>
</bean>
```

And in the routes you refer to this option as shown below

```
<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/foo?
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/bar?
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/beer?
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>
```

97.8.4. Reusing same server bootstrap configuration with multiple routes across multiple bundles in OSGi container

See the above Netty HTTP Server Example for more details and example how to do that.

97.8.5. Implementing a reverse proxy

Netty HTTP component can act as a reverse proxy, in that case **Exchange.HTTP_SCHEME**, **Exchange.HTTP_HOST** and **Exchange.HTTP_PORT** headers are populated from the absolute URL received on the request line of the HTTP request.

Here's an example of a HTTP proxy that simply transforms the response from the origin server to uppercase.

```
from("netty-http:proxy://0.0.0.0:8080")
    .toD("netty-http:"
        + "${headers." + Exchange.HTTP_SCHEME + "}://"
        + "${headers." + Exchange.HTTP_HOST + "}:"
        + "${headers." + Exchange.HTTP_PORT + "}")
    .process(this::processResponse);
```

```
void processResponse(final Exchange exchange) {
    final NettyHttpMessage message = exchange.getIn(NettyHttpMessage.class);
    final FullHttpResponse response = message.getHttpResponse();

    final ByteBuf buf = response.content();
    final String string = buf.toString(StandardCharsets.UTF_8);

    buf.resetWriterIndex();
    ByteBufUtil.writeUtf8(buf, string.toUpperCase(Locale.US));
}
```

97.9. USING HTTP BASIC AUTHENTICATION

The Netty HTTP consumer supports HTTP basic authentication by specifying the security realm name to use, as shown below

```
<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/foo?securityConfiguration.realm=karaf"/>
  ...
</route>
```

The realm name is mandatory to enable basic authentication. By default the JAAS based authenticator is used, which will use the realm name specified (karaf in the example above) and use the JAAS \\{{LoginModule}}s of this realm for authentication.

End user of Apache Karaf / ServiceMix has a karaf realm out of the box, and hence why the example above would work out of the box in these containers.

97.9.1. Specifying ACL on web resources

The **org.apache.camel.component.netty.http.SecurityConstraint** allows to define constrains on web resources. The **org.apache.camel.component.netty.http.SecurityConstraintMapping** is provided out of the box, allowing to easily define inclusions and exclusions with roles.

For example as shown below in the XML DSL, we define the constraint bean:

```
<bean id="constraint" class="org.apache.camel.component.netty.http.SecurityConstraintMapping">
  <!-- inclusions defines url -> roles restrictions -->
  <!-- a * should be used for any role accepted (or even no roles) -->
  <property name="inclusions">
    <map>
      <entry key="/*" value="*"/>
      <entry key="/admin/*" value="admin"/>
      <entry key="/guest/*" value="admin,guest"/>
    </map>
  </property>
  <!-- exclusions is used to define public urls, which requires no authentication -->
  <property name="exclusions">
    <set>
      <value>/public/*</value>
    </set>
  </property>
</bean>
```

The constraint above is define so that

- access to /* is restricted and any roles is accepted (also if user has no roles)
- access to /admin/* requires the admin role
- access to /guest/* requires the admin or guest role
- access to /public/* is an exclusion which means no authentication is needed, and is therefore public for everyone without logging in

To use this constraint we just need to refer to the bean id as shown below:

```
<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/foo?
matchOnUriPrefix=true&amp;securityConfiguration.realm=karaf&amp;securityConfiguration.securityCon
straint=#constraint"/>
  ...
</route>
```

97.10. SPRING BOOT AUTO-CONFIGURATION

The component supports 67 options, which are listed below.

Name	Description	Default	Type
camel.component.netty-http.allow-serialized-headers	Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
camel.component.netty-http.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.netty-http.backlog	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be If this option is not configured, then the backlog depends on OS setting.		Integer
camel.component.netty-http.boss-count	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this option to override the default bossCount from Netty.	1	Integer

Name	Description	Default	Type
camel.component.netty-http.boss-group	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint. The option is a io.netty.channel.EventLoopGroup type.		EventLoopGroup
camel.component.netty-http.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.netty-http.channel-group	To use a explicit ChannelGroup. The option is a io.netty.channel.group.ChannelGroup type.		ChannelGroup
camel.component.netty-http.client-initializer-factory	To use a custom ClientInitializerFactory. The option is a org.apache.camel.component.netty.ClientInitializerFactory type.		ClientInitializerFactory
camel.component.netty-http.configuration	To use the NettyConfiguration as configuration when creating endpoints. The option is a org.apache.camel.component.netty.NettyConfiguration type.		NettyConfiguration
camel.component.netty-http.connect-timeout	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	Integer

Name	Description	Default	Type
camel.component.netty-http.correlation-manager	To use a custom correlation manager to manage how request and reply messages are mapped when using request/reply with the netty producer. This should only be used if you have a way to map requests together with replies such as if there is correlation ids in both the request and reply messages. This can be used if you want to multiplex concurrent messages on the same channel (aka connection) in netty. When doing this you must have a way to correlate the request and reply messages so you can store the right reply on the inflight Camel Exchange before its continued routed. We recommend extending the TimeoutCorrelationManagerSupport when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well. See also the producerPoolEnabled option for more details. The option is a org.apache.camel.component.netty.NettyCamelStateCorrelationManager type.		NettyCamelStateCorrelationManager
camel.component.netty-http.decoders	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
camel.component.netty-http.disconnect	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	Boolean
camel.component.netty-http.disconnect-on-no-reply	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	Boolean
camel.component.netty-http.enabled	Whether to enable auto configuration of the netty-http component. This is enabled by default.		Boolean
camel.component.netty-http.enabled-protocols	Which protocols to enable when using SSL.	TLSv1.2,TLSv1.3	String

Name	Description	Default	Type
camel.component.netty-http.encoders	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
camel.component.netty-http.executor-service	To use the given EventExecutorGroup. The option is a io.netty.util.concurrent.EventExecutorGroup type.		EventExecutorGroup
camel.component.netty-http.header-filter-strategy	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		HeaderFilterStrategy
camel.component.netty-http.hostname-verification	To enable/disable hostname verification on SSLEngine.	false	Boolean
camel.component.netty-http.keep-alive	Setting to ensure socket is not closed due to inactivity.	true	Boolean
camel.component.netty-http.key-store-file	Client side certificate keystore to be used for encryption.		File
camel.component.netty-http.key-store-format	Keystore format to be used for payload encryption. Defaults to JKS if not set.		String
camel.component.netty-http.key-store-resource	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
camel.component.netty-http.lazy-channel-creation	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	Boolean

Name	Description	Default	Type
camel.component.netty-http.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.netty-http.maximum-pool-size	Sets a maximum thread pool size for the netty consumer ordered thread pool. The default size is 2 x cpu_core plus 1. Setting this value to eg 10 will then use 10 threads unless 2 x cpu_core plus 1 is a higher value, which then will override and be used. For example if there are 8 cores, then the consumer thread pool will be 17. This thread pool is used to route messages received from Netty by Camel. We use a separate thread pool to ensure ordering of messages and also in case some messages will block, then nettys worker threads (event loop) wont be affected.		Integer
camel.component.netty-http.mute-exception	If enabled and an Exchange failed processing on the consumer side the response's body won't contain the exception's stack trace.	false	Boolean
camel.component.netty-http.native-transport	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: .	false	Boolean
camel.component.netty-http.need-client-auth	Configures whether the server needs client authentication when using SSL.	false	Boolean
camel.component.netty-http.netty-http-binding	To use a custom org.apache.camel.component.netty.http.NettyHttpBinding for binding to/from Netty and Camel Message API. The option is a org.apache.camel.component.netty.http.NettyHttpBinding type.		NettyHttpBinding

Name	Description	Default	Type
camel.component.netty-http.netty-server-bootstrap-factory	To use a custom NettyServerBootstrapFactory. The option is a org.apache.camel.component.netty.NettyServerBootstrapFactory type.		NettyServerBootstrapFactory
camel.component.netty-http.no-reply-log-level	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back.		LoggingLevel
camel.component.netty-http.options	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
camel.component.netty-http.passphrase	Password setting to use in order to encrypt/decrypt payloads sent using SSH.		String
camel.component.netty-http.producer-pool-block-when-exhausted	Sets the value for the blockWhenExhausted configuration attribute. It determines whether to block when the borrowObject() method is invoked when the pool is exhausted (the maximum number of active objects has been reached).	true	Boolean
camel.component.netty-http.producer-pool-enabled	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement NettyCamelStateCorrelationManager as correlation manager and configure it via the correlationManager option. See also the correlationManager option for more details.	true	Boolean
camel.component.netty-http.producer-pool-max-idle	Sets the cap on the number of idle instances in the pool.	100	Integer

Name	Description	Default	Type
camel.component.netty-http.producer-pool-max-total	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	Integer
camel.component.netty-http.producer-pool-max-wait	Sets the maximum duration (value in millis) the borrowObject() method should block before throwing an exception when the pool is exhausted and producerPoolBlockWhenExhausted is true. When less than 0, the borrowObject() method may block indefinitely.	-1	Long
camel.component.netty-http.producer-pool-min-evictable-idle	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	300000	Long
camel.component.netty-http.producer-pool-min-idle	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		Integer
camel.component.netty-http.receive-buffer-size	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	Integer
camel.component.netty-http.receive-buffer-size-predictor	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		Integer
camel.component.netty-http.request-timeout	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		Long
camel.component.netty-http.reuse-address	Setting to facilitate socket multiplexing.	true	Boolean

Name	Description	Default	Type
camel.component.netty-http.reuse-channel	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key NettyConstants#NETTY_CHANNEL which allows you to obtain the channel during routing and use it as well.	false	Boolean
camel.component.netty-http.security-configuration	Refers to a org.apache.camel.component.netty.http.NettyHttpSecurityConfiguration for configuring secure web resources. The option is a org.apache.camel.component.netty.http.NettyHttpSecurityConfiguration type.		NettyHttpSecurityConfiguration
camel.component.netty-http.security-provider	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String
camel.component.netty-http.send-buffer-size	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	Integer
camel.component.netty-http.server-closed-channel-exception-caught-log-level	If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.		LoggingLevel
camel.component.netty-http.server-exception-caught-log-level	If the server (NettyConsumer) catches an exception then its logged using this logging level.		LoggingLevel
camel.component.netty-http.server-initializer-factory	To use a custom ServerInitializerFactory. The option is a org.apache.camel.component.netty.ServerInitializerFactory type.		ServerInitializerFactory

Name	Description	Default	Type
camel.component.netty-http.ssl	Setting to specify whether SSL encryption is applied to this endpoint.	false	Boolean
camel.component.netty-http.ssl-client-cert-headers	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	Boolean
camel.component.netty-http.ssl-context-parameters	To configure security using SSLContextParameters. The option is a org.apache.camel.support.jsse.SSLContextParameters type.		SSLContextParameters
camel.component.netty-http.ssl-handler	Reference to a class that could be used to return an SSL Handler. The option is a io.netty.handler.ssl.SslHandler type.		SslHandler
camel.component.netty-http.sync	Setting to set endpoint as one-way or request-response.	true	Boolean
camel.component.netty-http.tcp-no-delay	Setting to improve TCP protocol performance.	true	Boolean
camel.component.netty-http.transfer-exchange	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
camel.component.netty-http.trust-store-file	Server side certificate keystore to be used for encryption.		File
camel.component.netty-http.trust-store-resource	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String

Name	Description	Default	Type
camel.component.netty-http.unix-domain-socket-path	Path to unix domain socket to use instead of inet socket. Host and port parameters will not be used, however required. It is ok to set dummy values for them. Must be used with nativeTransport=true and clientMode=false.		String
camel.component.netty-http.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.netty-http.using-executor-service	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	Boolean
camel.component.netty-http.worker-count	When netty works on nio mode, it uses default workerCount parameter from Netty (which is cpu_core_threads x 2). User can use this option to override the default workerCount from Netty.		Integer
camel.component.netty-http.worker-group	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with 2 x cpu count core threads. The option is a io.netty.channel.EventLoopGroup type.		EventLoopGroup

CHAPTER 98. OLINGO4

Since Camel 2.19

Both producer and consumer are supported

The Olingo4 component uses Apache Olingo version 4.0 APIs to interact with OData 4.0 compliant service. Since version 4.0, OData is an OASIS standard and a number of popular open source and commercial vendors and products support this protocol. A sample list of supporting products can be found on the OData website.

The Olingo4 component supports reading entity sets, entities, simple and complex properties, counts, using custom and OData system query parameters. It supports updating entities and properties. It also supports submitting queries and change requests as a single OData batch operation.

The component supports configuring HTTP connection parameters and headers for OData service connection. This allows configuring use of SSL, OAuth2.0, etc. as required by the target OData service.

98.1. DEPENDENCIES

When using **camel-olingo4** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-olingo4-starter</artifactId>
</dependency>
```

98.2. URI FORMAT

```
olingo4://endpoint/<resource-path>?[options]
```

98.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

98.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

98.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

98.4. COMPONENT OPTIONS

The Olingo4 component supports 16 options, which are listed below.

Name	Description	Default	Type
configuration (common)	To use the shared configuration.		Olingo4Configuration
connectTimeout (common)	HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds).	30000	int
contentType (common)	Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8.	application/json;charset=utf-8	String
filterAlreadySeen (common)	Set this to true to filter out results that have already been communicated by this component.	false	boolean
httpHeaders (common)	Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.		Map
proxy (common)	HTTP proxy server configuration.		HttpHost
serviceUri (common)	Target OData service base URI, for example, http://services.odata.org/OData/OData.svc.		String
socketTimeout (common)	HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds).	30000	int

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
splitResult (consumer)	For endpoints that return an array or collection, a consumer endpoint will map every element to distinct messages, unless splitResult is set to false.	true	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
httpAsyncClientBuilder (advanced)	Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely.		HttpAsyncClientBuilder
httpClientBuilder (advanced)	Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely.		HttpClientBuilder

Name	Description	Default	Type
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

98.5. ENDPOINT OPTIONS

The Olingo4 endpoint is configured using URI syntax:

```
olingo4:apiName/methodName
```

With the following *path* and *query* parameters:

98.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
apiName (common)	**Required** What kind of operation to perform. Enum values: • DEFAULT		Olingo4ApiName
methodName (common)	**Required** What sub operation to use for the selected operation.		String

98.5.2. Query Parameters (32 parameters)

Name	Description	Default	Type
connectTimeout (common)	HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds).	30000	int
contentType (common)	Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8.	application/json;charset=utf-8	String
filterAlreadySeen (common)	Set this to true to filter out results that have already been communicated by this component.	false	boolean

Name	Description	Default	Type
httpHeaders (common)	Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.		Map
inBody (common)	Sets the name of a parameter to be passed in the exchange In Body.		String
proxy (common)	HTTP proxy server configuration.		HttpHost
serviceUri (common)	Target OData service base URI, for example, http://services.odata.org/OData/OData.svc.		String
socketTimeout (common)	HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds).	30000	int
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
splitResult (consumer)	For endpoints that return an array or collection, a consumer endpoint will map every element to distinct messages, unless splitResult is set to false.	true	boolean
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
httpAsyncClientBuilder (advanced)	Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely.		HttpAsyncClientBuilder
httpClientBuilder (advanced)	Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely.		HttpClientBuilder
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map

Name	Description	Default	Type
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters

98.6. API PARAMETERS (1 APIS)

The Olingo4 endpoint is an API-based component and has additional parameters based on which API name and API method is used. The API name and API method is located in the endpoint URI as the **apiName/methodName** path parameters:

```
olingo4:apiName/methodName
```

There are 1 API names as listed in the table below:

API Name	Type	Description
API:DEFAULT	Both	Olingo4 Client Api Interface

Each API is documented in the following sections to come.

98.6.1. API: DEFAULT

Both producer and consumer are supported

The DEFAULT API is defined in the syntax as follows:

```
olingo4:DEFAULT/methodName?[parameters]
```

The 9 method(s) is(are) listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand *alias* name which can be used in the syntax instead of the name)

Method	Alias	Description
action		Calls a OData action
batch		Executes a batch request
create		Creates a new OData resource
delete		Deletes an OData resource and invokes callback with org
merge		Patches/merges an OData resource using HTTP MERGE
patch		Patches/merges an OData resource using HTTP PATCH
read		Reads an OData resource and invokes callback with appropriate result
update		Updates an OData resource
uread		Reads an OData resource and invokes callback with the unparsed input stream

98.6.1.1. Method action

Signatures:

- void action(org.apache.olingo.commons.api.edm.Edm edm, String resourcePath, java.util.Map<String, String> endpointHttpHeaders, Object data, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler responseHandler);

The olingo4/action API method has the parameters listed in the table below:

Parameter	Description	Type
data	Action data	Object
edm	Service Edm	Edm
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map

Parameter	Description	Type
resourcePath	Resource path to action	String
responseHandler	Org.apache.olingo.client.api.domain.ClientEntity callback handler	Olingo4ResponseHandler

98.6.1.2. Method batch

Signatures:

- void batch(org.apache.olingo.commons.api.edm.Edm edm, java.util.Map<String, String> endpointHttpHeaders, Object data, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler<java.util.List<org.apache.came responseHandler);

The olingo4/batch API method has the parameters listed in the table below:

Parameter	Description	Type
data	Ordered org.apache.camel.component.olingo4.api.batch.Olingo4BatchRequest list	Object
edm	Service Edm	Edm
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map
responseHandler	Callback handler	Olingo4ResponseHandler

98.6.1.3. Method create

Signatures:

- void create(org.apache.olingo.commons.api.edm.Edm edm, String resourcePath, java.util.Map<String, String> endpointHttpHeaders, Object data, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler responseHandler);

The olingo4/create API method has the parameters listed in the table below:

Parameter	Description	Type
data	Request data	Object
edm	Service Edm	Edm

Parameter	Description	Type
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map
resourcePath	Resource path to create	String
responseHandler	Callback handler	Olingo4ResponseHandler

98.6.1.4. Method delete

Signatures:

- void delete(String resourcePath, java.util.Map<String, String> endpointHttpHeaders, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler<org.apache.olingo.commons.a responseHandler);

The olingo4/delete API method has the parameters listed in the table below:

Parameter	Description	Type
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map
resourcePath	Resource path for Entry	String
responseHandler	Org.apache.olingo.commons.api.http.HttpStatusCode callback handler	Olingo4ResponseHandler

98.6.1.5. Method merge

Signatures:

- void merge(org.apache.olingo.commons.api.edm.Edm edm, String resourcePath, java.util.Map<String, String> endpointHttpHeaders, Object data, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler responseHandler);

The olingo4/merge API method has the parameters listed in the table below:

Parameter	Description	Type
data	Patch/merge data	Object
edm	Service Edm	Edm
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map

Parameter	Description	Type
resourcePath	Resource path to update	String
responseHandler	Org.apache.olingo.client.api.domain.ClientEntity callback handler	Olingo4ResponseHandler

98.6.1.6. Method patch

Signatures:

- void patch(org.apache.olingo.commons.api.edm.Edm edm, String resourcePath, java.util.Map<String, String> endpointHttpHeaders, Object data, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler responseHandler);

The olingo4/patch API method has the parameters listed in the table below:

Parameter	Description	Type
data	Patch/merge data	Object
edm	Service Edm	Edm
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map
resourcePath	Resource path to update	String
responseHandler	Org.apache.olingo.client.api.domain.ClientEntity callback handler	Olingo4ResponseHandler

98.6.1.7. Method read

Signatures:

- void read(org.apache.olingo.commons.api.edm.Edm edm, String resourcePath, java.util.Map<String, String> queryParams, java.util.Map<String, String> endpointHttpHeaders, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler responseHandler);

The olingo4/read API method has the parameters listed in the table below:

Parameter	Description	Type
edm	Service Edm, read from calling read(null, $metdata, null, responseHandler)	Edm

Parameter	Description	Type
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map
queryParams	OData query params http://docs.oasis-open.org/odata/odata/v4.0/odata-v4.0-part1-protocol.html#_Toc453752288	Map
resourcePath	OData Resource path	String
responseHandler	Callback handler	Olingo4ResponseHandler

98.6.1.8. Method update

Signatures:

- void update(org.apache.olingo.commons.api.edm.Edm edm, String resourcePath, java.util.Map<String, String> endpointHttpHeaders, Object data, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler responseHandler);

The olingo4/update API method has the parameters listed in the table below:

Parameter	Description	Type
data	Updated data	Object
edm	Service Edm	Edm
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map
resourcePath	Resource path to update	String
responseHandler	Org.apache.olingo.client.api.domain.ClientEntity callback handler	Olingo4ResponseHandler

98.6.1.9. Method uread

Signatures:

- void uread(org.apache.olingo.commons.api.edm.Edm edm, String resourcePath, java.util.Map<String, String> queryParams, java.util.Map<String, String> endpointHttpHeaders, org.apache.camel.component.olingo4.api.Olingo4ResponseHandler<java.io.InputStream> responseHandler);

The olingo4/uread API method has the parameters listed in the table below:

Parameter	Description	Type
edm	Service Edm, read from calling read(null, $metdata, null, responseHandler)	Edm
endpointHttpHeaders	HTTP Headers to add/override the component versions	Map
queryParams	OData query params http://docs.oasis-open.org/odata/odata/v4.0/odata-v4.0-part1-protocol.html#_Toc453752288	Map
resourcePath	OData Resource path	String
responseHandler	Callback handler	Olingo4ResponseHandler

In addition to the parameters above, the olingo4 API can also use any of the Query Parameters listed above.

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelOlingo4.parameter**. The **inBody** parameter overrides message header, i.e., the endpoint parameter **inBody=myParameterNameHere** would override a **CamelOlingo4.myParameterNameHere** header.

98.7. MESSAGE HEADERS

The Olingo4 component supports 1 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelOlingo4.responseHttpHeaders (producer) Constant: FULL_RESPONSE_HTTP_HEADERS	The response Http headers.		Map

98.8. ENDPOINT HTTP HEADERS

The component level configuration property **httpHeaders** supplies static HTTP header information. However, some systems require dynamic header information to be passed to and received from the endpoint. A sample use case would be systems that require dynamic security tokens. The **endpointHttpHeaders** and **responseHttpHeaders** endpoint properties provide this capability. Set headers that need to be passed to the endpoint in the **CamelOlingo4.endpointHttpHeaders** property and the response headers will be returned in a **CamelOlingo4.responseHttpHeaders** property. Both properties are of the type **java.util.Map<String, String>**.

98.9. ODATA RESOURCE TYPE MAPPING

The result of **read** endpoint and data type of **data** option depends on the OData resource being queried, created or modified.

OData Resource Type	Resource URI from resourcePath and keyPredicate	In or Out Body Type
Entity data model	$metadata	**org.apache.olingo.commons.api.edm.Edm**
Service document	/	**org.apache.olingo.client.api.domain.ClientServiceDocument**
OData entity set	<entity-set>	**org.apache.olingo.client.api.domain.ClientEntitySet**
OData entity	<entity-set>(<key-predicate>)	**org.apache.olingo.client.api.domain.ClientEntity** for Out body (response)**java.util.Map<String, Object>** for In body (request)
Simple property	<entity-set>(<key-predicate>)/<simple-property>	**org.apache.olingo.client.api.domain.ClientPrimitiveValue**
Simple property value	<entity-set>(<key-predicate>)/<simple-property>/$value	**org.apache.olingo.client.api.domain.ClientPrimitiveValue**
Complex property	<entity-set>(<key-predicate>)/<complex-property>	**org.apache.olingo.client.api.domain.ClientComplexValue**
Count	<resource-uri>/$count	**java.lang.Long**

98.10. SAMPLES

The following route reads top 5 entries from the People entity ordered by ascending FirstName property.

```
from("direct:...")
    .setHeader("CamelOlingo4.$top", "5");
    .to("olingo4://read/People?orderBy=FirstName%20asc");
```

The following route reads Airports entity using the key property value in incoming **id** header.

```
from("direct:...")
    .setHeader("CamelOlingo4.keyPredicate", header("id"))
    .to("olingo4://read/Airports");
```

The following route creates People entity using the **ClientEntity** in body message.

```
from("direct:...")
    .to("olingo4://create/People");
```

The following route calls an odata action using the **ClientEntity** in the body message. The body message may be null for actions that do not expect an input.

```
from("direct:...")
    .to("olingo4://action/People");
```

98.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 17 options, which are listed below.

Name	Description	Default	Type
camel.component.olingo4.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.olingo4.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.olingo4.configuration	To use the shared configuration. The option is a org.apache.camel.component.olingo4.Olingo4Configuration type.		Olingo4Configuration
camel.component.olingo4.connect-timeout	HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds).	30000	Integer

Name	Description	Default	Type
camel.component.olingo4.content-type	Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8.	application/json;charset=utf-8	String
camel.component.olingo4.enabled	Whether to enable auto configuration of the olingo4 component. This is enabled by default.		Boolean
camel.component.olingo4.filter-already-seen	Set this to true to filter out results that have already been communicated by this component.	false	Boolean
camel.component.olingo4.http-async-client-builder	Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely. The option is a org.apache.http.impl.nio.client.HttpAsyncClientBuilder type.		HttpAsyncClientBuilder
camel.component.olingo4.http-client-builder	Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely. The option is a org.apache.http.impl.client.HttpClientBuilder type.		HttpClientBuilder
camel.component.olingo4.http-headers	Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.		Map
camel.component.olingo4.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.olingo4.proxy	HTTP proxy server configuration. The option is a org.apache.http.HttpHost type.		HttpHost

Name	Description	Default	Type
camel.component.olingo4.service-uri	Target OData service base URI, e.g. .		String
camel.component.olingo4.socket-timeout	HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds).	30000	Integer
camel.component.olingo4.split-result	For endpoints that return an array or collection, a consumer endpoint will map every element to distinct messages, unless splitResult is set to false.	true	Boolean
camel.component.olingo4.ssl-context-parameters	To configure security using SSLContextParameters. The option is a org.apache.camel.support.jsse.SSLContextParameters type.		SSLContextParameters
camel.component.olingo4.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean

CHAPTER 99. OPENAPI JAVA

The Rest DSL can be integrated with the **camel-openapi-java** module which is used for exposing the REST services and their APIs using OpenApi.

The camel-openapi-java module can be used from the REST components (without the need for servlet).

99.1. DEPENDENCIES

When using **openapi-java** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-openapi-java-starter</artifactId>
</dependency>
```

99.2. USING OPENAPI IN REST-DSL

You can enable the OpenApi api from the rest-dsl by configuring the **apiContextPath** dsl as shown below:

```
public class UserRouteBuilder extends RouteBuilder {
    @Override
    public void configure() throws Exception {
        // configure we want to use servlet as the component for the rest DSL
        // and we enable json binding mode
        restConfiguration().component("netty-http").bindingMode(RestBindingMode.json)
            // and output using pretty print
            .dataFormatProperty("prettyPrint", "true")
            // setup context path and port number that netty will use
            .contextPath("/").port(8080)
            // add OpenApi api-doc out of the box
            .apiContextPath("/api-doc")
                .apiProperty("api.title", "User API").apiProperty("api.version", "1.2.3")
                // and enable CORS
                .apiProperty("cors", "true");

        // this user REST service is json only
        rest("/user").description("User rest service")
            .consumes("application/json").produces("application/json")
            .get("/{id}").description("Find user by id").outType(User.class)
                .param().name("id").type(path).description("The id of the user to
get").dataType("int").endParam()
                .to("bean:userService?method=getUser(${header.id})")
            .put().description("Updates or create a user").type(User.class)
                .param().name("body").type(body).description("The user to update or create").endParam()
                .to("bean:userService?method=updateUser")
            .get("/findAll").description("Find all users").outType(User[].class)
                .to("bean:userService?method=listUsers");
    }
}
```

99.3. OPTIONS

The OpenApi module can be configured using the following options. To configure using a servlet you use the init-param as shown above. When configuring directly in the rest-dsl, you use the appropriate method, such as **enableCORS**, **host,contextPath**, dsl. The options with **api.xxx** is configured using **apiProperty** dsl.

Option	Type	Description
cors	Boolean	Whether to enable CORS. Notice this only enables CORS for the api browser, and not the actual access to the REST services. Is default false.
openapi.version	String	OpenApi spec version. Is default 3.0.
host	String	To setup the hostname. If not configured camel-openapi-java will calculate the name as localhost based.
schemes	String	The protocol schemes to use. Multiple values can be separated by comma such as "http,https". The default value is "http".
base.path	String	**Required**: To setup the base path where the REST services is available. The path is relative (eg do not start with http/https) and camel-openapi-java will calculate the absolute base path at runtime, which will be **protocol://host:port/context-path/base.path**
api.path	String	To setup the path where the API is available (eg /api-docs). The path is relative (eg do not start with http/https) and camel-openapi-java will calculate the absolute base path at runtime, which will be **protocol://host:port/context-path/api.path** So using relative paths is much easier. See above for an example.
api.version	String	The version of the api. Is default 0.0.0.
api.title	String	The title of the application.
api.description	String	A short description of the application.
api.termsOfService	String	A URL to the Terms of Service of the API.
api.contact.name	String	Name of person or organization to contact
api.contact.email	String	An email to be used for API-related correspondence.
api.contact.url	String	A URL to a website for more contact information.
api.license.name	String	The license name used for the API.
api.license.url	String	A URL to the license used for the API.

99.4. ADDING SECURITY DEFINITIONS IN API DOC

The Rest DSL now supports declaring OpenApi **securityDefinitions** in the generated API document. For example as shown below:

```
rest("/user").tag("dude").description("User rest service")
    // setup security definitions
    .securityDefinitions()
        .oauth2("petstore_auth").authorizationUrl("http://petstore.swagger.io/oauth/dialog").end()
        .apiKey("api_key").withHeader("myHeader").end()
    .end()
    .consumes("application/json").produces("application/json")
```

Here we have setup two security definitions

- OAuth2 - with implicit authorization with the provided url
- Api Key - using an api key that comes from HTTP header named *myHeader*

Then you need to specify on the rest operations which security to use by referring to their key (petstore_auth or api_key).

```
.get("/{id}/{date}").description("Find user by id and date").outType(User.class)
    .security("api_key")

...

.put().description("Updates or create a user").type(User.class)
    .security("petstore_auth", "write:pets,read:pets")
```

Here the get operation is using the Api Key security and the put operation is using OAuth security with permitted scopes of read and write pets.

99.5. JSON OR YAML

The camel-openapi-java module supports both JSon and Yaml out of the box. You can specify in the request url what you want returned by using /openapi.json or /openapi.yaml for either one. If none is specified then the HTTP Accept header is used to detect if json or yaml can be accepted. If either both is accepted or none was set as accepted then json is returned as the default format.

99.6. USEXFORWARDHEADERS AND API URL RESOLUTION

The OpenApi specification allows you to specify the host, port & path that is serving the API. In OpenApi V2 this is done via the **host** field and in OpenAPI V3 it is part of the **servers** field.

By default, the value for these fields is determined by **X-Forwarded** headers, **X-Forwarded-Host** & **X-Forwarded-Proto**.

This can be overridden by disabling the lookup of **X-Forwarded** headers and by specifying your own host, port & scheme on the REST configuration.

```
restConfiguration().component("netty-http")
    .useXForwardHeaders(false)
    .apiProperty("schemes", "https");
```

```
    .host("localhost")
    .port(8080);
```

99.7. EXAMPLES

In the Apache Camel distribution we ship the **camel-example-openapi-cdi** and **camel-example-spring-boot-rest-openapi-simple** which demonstrates using this OpenApi component.

99.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 1 options, which are listed below.

Name	Description	Default	Type
camel.openapi.enabled	Enables Camel Rest DSL to automatic register its OpenAPI (eg swagger doc) in Spring Boot which allows tooling such as SpringDoc to integrate with Camel.	true	Boolean

CHAPTER 100. OPENTELEMETRY

Since Camel 3.5

The OpenTelemetry component is used for tracing and timing the incoming and outgoing Camel messages using OpenTelemetry.

Events (spans) are captured for incoming and outgoing messages that are sent to/from Camel.

100.1. DEPENDENCIES

Add the following dependency to your **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-opentelemetry-starter</artifactId>
</dependency>
```

100.2. CONFIGURATION

The configuration properties for the OpenTelemetry tracer are:

Option	Default	Description
excludePatterns		Sets exclude pattern(s) that will disable tracing for Camel messages that matches the pattern. The content is a Set<String> where the key is a pattern. The pattern uses the rules from Intercept.
encoding	false	Sets whether the header keys need to be encoded (connector specific) or not. The value is a boolean. Dashes need for instances to be encoded for JMS property keys.

100.2.1. Configuration

Add the **camel-opentelemetry** component in your POM, in addition to any specific dependencies associated with the chosen OpenTelemetry compliant Tracer.

To explicitly configure OpenTelemetry support, instantiate the **OpenTelemetryTracer** and initialize the camel context. You can optionally specify a **Tracer**, or alternatively it can be implicitly discovered using the **Registry**

```
OpenTelemetryTracer otelTracer = new OpenTelemetryTracer();
// By default it uses the DefaultTracer, but you can override it with a specific OpenTelemetry Tracer implementation.
otelTracer.setTracer(...);
// And then initialize the context
otelTracer.init(camelContext);
```

100.3. SPRING BOOT

Add the **camel-opentelemetry-starter** dependency, and then turn on the OpenTracing by annotating the main class with **@CamelOpenTelemetry**.

The **OpenTelemetryTracer** is implicitly obtained from the camel context's **Registry**, unless a **OpenTelemetryTracer** bean has been defined by the application.

100.4. JAVA AGENT

Download the Java agent.

This package includes the instrumentation agent as well as instrumentations for all supported libraries and all available data exporters. The package provides a completely automatic, out-of-the-box experience.

Enable the instrumentation agent using the **-javaagent** flag to the JVM.

```
java -javaagent:path/to/opentelemetry-javaagent.jar \
     -jar myapp.jar
```

By default, the OpenTelemetry Java agent uses OTLP exporter configured to send data to OpenTelemetry collector at http://localhost:4317.

Configuration parameters are passed as Java system properties (**-D** flags) or as environment variables. See Configuring the agent and OpenTelemetry auto-configuration for the full list of configuration items. For example:

```
java -javaagent:path/to/opentelemetry-javaagent.jar \
     -Dotel.service.name=your-service-name \
     -Dotel.traces.exporter=jaeger \
     -jar myapp.jar
```

100.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.opentelemetry.encoding	Activate or deactivate the dash encoding in headers (required by JMS) for messaging.		Boolean
camel.opentelemetry.exclude-patterns	Sets exclude pattern(s) that will disable the tracing for the Camel messages that matches the pattern.		Set

100.6. MDC LOGGING

When MDC Logging is enabled for the active Camel context, the Trace ID and Span ID are added and removed from the MDC for each route, where the keys are **trace_id** and **span_id**, respectively.

CHAPTER 101. PAHO

Both producer and consumer are supported

Paho component provides connector for the MQTT messaging protocol using the Eclipse Paho library. Paho is one of the most popular MQTT libraries, so if you would like to integrate it with your Java project - Camel Paho connector is a way to go.

101.1. DEPENDENCIES

When using **paho** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-paho-starter</artifactId>
</dependency>
```

101.2. URI FORMAT

```
paho:topic[?options]
```

Where **topic** is the name of the topic.

101.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

101.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

101.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

101.4. COMPONENT OPTIONS

The Paho component supports 31 options, which are listed below.

Name	Description	Default	Type
automaticReconnect (common)	Sets whether the client will automatically attempt to reconnect to the server if the connection is lost. If set to false, the client will not attempt to automatically reconnect to the server in the event that the connection is lost. If set to true, in the event that the connection is lost, the client will attempt to reconnect to the server. It will initially wait 1 second before it attempts to reconnect, for every failed reconnect attempt, the delay will double until it is at 2 minutes at which point the delay will stay at 2 minutes.	true	boolean
brokerUrl (common)	The URL of the MQTT broker.	tcp://localhost:1883	String
cleanSession (common)	Sets whether the client and server should remember state across restarts and reconnects. If set to false both the client and server will maintain state across restarts of the client, the server and the connection. As state is maintained: Message delivery will be reliable meeting the specified QOS even if the client, server or connection are restarted. The server will treat a subscription as durable. If set to true the client and server will not maintain state across restarts of the client, the server or the connection. This means Message delivery to the specified QOS cannot be maintained if the client, server or connection are restarted The server will treat a subscription as non-durable.	true	boolean
clientId (common)	MQTT client identifier. The identifier must be unique.		String
configuration (common)	To use the shared Paho configuration.		PahoConfiguration

Name	Description	Default	Type
connectionTimeout (common)	Sets the connection timeout value. This value, measured in seconds, defines the maximum time interval the client will wait for the network connection to the MQTT server to be established. The default timeout is 30 seconds. A value of 0 disables timeout processing meaning the client will wait until the network connection is made successfully or fails.	30	int
filePersistenceDirectory (common)	Base directory used by file persistence. Will by default use user directory.		String
keepAliveInterval (common)	Sets the keep alive interval. This value, measured in seconds, defines the maximum time interval between messages sent or received. It enables the client to detect if the server is no longer available, without having to wait for the TCP/IP timeout. The client will ensure that at least one message travels across the network within each keep alive period. In the absence of a data-related message during the time period, the client sends a very small ping message, which the server will acknowledge. A value of 0 disables keepalive processing in the client. The default value is 60 seconds.	60	int
maxInflight (common)	Sets the max inflight. please increase this value in a high traffic environment. The default value is 10.	10	int
maxReconnectDelay (common)	Get the maximum time (in millis) to wait between reconnects.	128000	int
mqttVersion (common)	Sets the MQTT version. The default action is to connect with version 3.1.1, and to fall back to 3.1 if that fails. Version 3.1.1 or 3.1 can be selected specifically, with no fall back, by using the MQTT_VERSION_3_1_1 or MQTT_VERSION_3_1 options respectively.		int
persistence (common)	Client persistence to be used - memory or file. Enum values: • FILE • MEMORY	MEMORY	PahoPersistence
qos (common)	Client quality of service level (0-2).	2	int
retained (common)	Retain option.	false	boolean

Name	Description	Default	Type
serverURIs (common)	Set a list of one or more serverURIs the client may connect to. Multiple servers can be separated by comma. Each serverURI specifies the address of a server that the client may connect to. Two types of connection are supported tcp:// for a TCP connection and ssl:// for a TCP connection secured by SSL/TLS. For example: tcp://localhost:1883 ssl://localhost:8883 If the port is not specified, it will default to 1883 for tcp:// URIs, and 8883 for ssl:// URIs. If serverURIs is set then it overrides the serverURI parameter passed in on the constructor of the MQTT client. When an attempt to connect is initiated the client will start with the first serverURI in the list and work through the list until a connection is established with a server. If a connection cannot be made to any of the servers then the connect attempt fails. Specifying a list of servers that a client may connect to has several uses: High Availability and reliable message delivery Some MQTT servers support a high availability feature where two or more equal MQTT servers share state. An MQTT client can connect to any of the equal servers and be assured that messages are reliably delivered and durable subscriptions are maintained no matter which server the client connects to. The cleansession flag must be set to false if durable subscriptions and/or reliable message delivery is required. Hunt List A set of servers may be specified that are not equal (as in the high availability option). As no state is shared across the servers reliable message delivery and durable subscriptions are not valid. The cleansession flag must be set to true if the hunt list mode is used.		String
willPayload (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		String
willQos (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		int

Name	Description	Default	Type
willRetained (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.	false	boolean
willTopic (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
client (advanced)	To use a shared Paho client.		MqttClient

Name	Description	Default	Type
customWebSocketHeaders (advanced)	Sets the Custom WebSocket Headers for the WebSocket Connection.		Properties
executorServiceTimeout (advanced)	Set the time in seconds that the executor service should wait when terminating before forcefully terminating. It is not recommended to change this value unless you are absolutely sure that you need to.	1	int
httpsHostnameVerificationEnabled (security)	Whether SSL HostnameVerifier is enabled or not. The default value is true.	true	boolean
password (security)	Password to be used for authentication against the MQTT broker.		String
socketFactory (security)	Sets the SocketFactory to use. This allows an application to apply its own policies around the creation of network sockets. If using an SSL connection, an SSLSocketFactory can be used to supply application-specific security settings.		SocketFactory
sslClientProps (security)	Sets the SSL properties for the connection. Note that these properties are only valid if an implementation of the Java Secure Socket Extensions (JSSE) is available. These properties are not used if a custom SocketFactory has been set. The following properties can be used: com.ibm.ssl.protocol One of: SSL, SSLv3, TLS, TLSv1, SSL_TLS. com.ibm.ssl.contextProvider Underlying JSSE provider. For example IBMJSSE2 or SunJSSE com.ibm.ssl.keyStore The name of the file that contains the KeyStore object that you want the KeyManager to use. For example /mydir/etc/key.p12 com.ibm.ssl.keyStorePassword The password for the KeyStore object that you want the KeyManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.keyStoreType Type of key store, for example PKCS12, JKS, or JCEKS. com.ibm.ssl.keyStoreProvider Key store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.trustStore The name of the file that contains the KeyStore object that you want the TrustManager to use.		Properties

Name	Description	Default	Type
	com.ibm.ssl.trustStorePassword The password for the TrustStore object that you want the TrustManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.trustStoreType The type of KeyStore object that you want the default TrustManager to use. Same possible values as keyStoreType. com.ibm.ssl.trustStoreProvider Trust store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.enabledCipherSuites A list of which ciphers are enabled. Values are dependent on the provider, for example: SSL_RSA_WITH_AES_128_CBC_SHA;SSL_RSA_WITH_3DES_EDE_CBC_SHA. com.ibm.ssl.keyManager Sets the algorithm that will be used to instantiate a KeyManagerFactory object instead of using the default algorithm available in the platform. Example values: IbmX509 or IBMJ9X509. com.ibm.ssl.trustManager Sets the algorithm that will be used to instantiate a TrustManagerFactory object instead of using the default algorithm available in the platform. Example values: PKIX or IBMJ9X509.		
sslHostnameVerifier (security)	Sets the HostnameVerifier for the SSL connection. Note that it will be used after handshake on a connection and you should do actions by yourself when hostname is verified error. There is no default HostnameVerifier.		HostnameVerifier
userName (security)	Username to be used for authentication against the MQTT broker.		String

101.5. ENDPOINT OPTIONS

The Paho endpoint is configured using URI syntax:

```
paho:topic
```

with the following path and query parameters:

101.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
topic (common)	**Required** Name of the topic.		String

101.5.2. Query Parameters (31 parameters)

Name	Description	Default	Type
automaticReconnect (common)	Sets whether the client will automatically attempt to reconnect to the server if the connection is lost. If set to false, the client will not attempt to automatically reconnect to the server in the event that the connection is lost. If set to true, in the event that the connection is lost, the client will attempt to reconnect to the server. It will initially wait 1 second before it attempts to reconnect, for every failed reconnect attempt, the delay will double until it is at 2 minutes at which point the delay will stay at 2 minutes.	true	boolean
brokerUrl (common)	The URL of the MQTT broker.	tcp://localhost:1883	String
cleanSession (common)	Sets whether the client and server should remember state across restarts and reconnects. If set to false both the client and server will maintain state across restarts of the client, the server and the connection. As state is maintained: Message delivery will be reliable meeting the specified QOS even if the client, server or connection are restarted. The server will treat a subscription as durable. If set to true the client and server will not maintain state across restarts of the client, the server or the connection. This means Message delivery to the specified QOS cannot be maintained if the client, server or connection are restarted The server will treat a subscription as non-durable.	true	boolean
clientId (common)	MQTT client identifier. The identifier must be unique.		String
connectionTimeout (common)	Sets the connection timeout value. This value, measured in seconds, defines the maximum time interval the client will wait for the network connection to the MQTT server to be established. The default timeout is 30 seconds. A value of 0 disables timeout processing meaning the client will wait until the network connection is made successfully or fails.	30	int
filePersistenceDirectory (common)	Base directory used by file persistence. Will by default use user directory.		String

Name	Description	Default	Type
keepAliveInterval (common)	Sets the keep alive interval. This value, measured in seconds, defines the maximum time interval between messages sent or received. It enables the client to detect if the server is no longer available, without having to wait for the TCP/IP timeout. The client will ensure that at least one message travels across the network within each keep alive period. In the absence of a data-related message during the time period, the client sends a very small ping message, which the server will acknowledge. A value of 0 disables keepalive processing in the client. The default value is 60 seconds.	60	int
maxInflight (common)	Sets the max inflight. please increase this value in a high traffic environment. The default value is 10.	10	int
maxReconnectDelay (common)	Get the maximum time (in millis) to wait between reconnects.	128000	int
mqttVersion (common)	Sets the MQTT version. The default action is to connect with version 3.1.1, and to fall back to 3.1 if that fails. Version 3.1.1 or 3.1 can be selected specifically, with no fall back, by using the MQTT_VERSION_3_1_1 or MQTT_VERSION_3_1 options respectively.		int
persistence (common)	Client persistence to be used - memory or file. Enum values: • FILE • MEMORY	MEMORY	PahoPersistence
qos (common)	Client quality of service level (0-2).	2	int
retained (common)	Retain option.	false	boolean

Name	Description	Default	Type
serverURIs (common)	Set a list of one or more serverURIs the client may connect to. Multiple servers can be separated by comma. Each serverURI specifies the address of a server that the client may connect to. Two types of connection are supported tcp:// for a TCP connection and ssl:// for a TCP connection secured by SSL/TLS. For example: tcp://localhost:1883 ssl://localhost:8883 If the port is not specified, it will default to 1883 for tcp:// URIs, and 8883 for ssl:// URIs. If serverURIs is set then it overrides the serverURI parameter passed in on the constructor of the MQTT client. When an attempt to connect is initiated the client will start with the first serverURI in the list and work through the list until a connection is established with a server. If a connection cannot be made to any of the servers then the connect attempt fails. Specifying a list of servers that a client may connect to has several uses: High Availability and reliable message delivery Some MQTT servers support a high availability feature where two or more equal MQTT servers share state. An MQTT client can connect to any of the equal servers and be assured that messages are reliably delivered and durable subscriptions are maintained no matter which server the client connects to. The cleansession flag must be set to false if durable subscriptions and/or reliable message delivery is required. Hunt List A set of servers may be specified that are not equal (as in the high availability option). As no state is shared across the servers reliable message delivery and durable subscriptions are not valid. The cleansession flag must be set to true if the hunt list mode is used.		String
willPayload (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		String
willQos (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		int

Name	Description	Default	Type
willRetained (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.	false	boolean
willTopic (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
client (advanced)	To use an existing mqtt client.		MqttClient
customWebSocketHeaders (advanced)	Sets the Custom WebSocket Headers for the WebSocket Connection.		Properties
executorServiceTimeout (advanced)	Set the time in seconds that the executor service should wait when terminating before forcefully terminating. It is not recommended to change this value unless you are absolutely sure that you need to.	1	int
httpsHostnameVerificationEnabled (security)	Whether SSL HostnameVerifier is enabled or not. The default value is true.	true	boolean
password (security)	Password to be used for authentication against the MQTT broker.		String
socketFactory (security)	Sets the SocketFactory to use. This allows an application to apply its own policies around the creation of network sockets. If using an SSL connection, an SSLSocketFactory can be used to supply application-specific security settings.		SocketFactory
sslClientProps (security)	Sets the SSL properties for the connection. Note that these properties are only valid if an implementation of the Java Secure Socket Extensions (JSSE) is available. These properties are not used if a custom SocketFactory has been set. The following properties can be used: com.ibm.ssl.protocol One of: SSL, SSLv3, TLS, TLSv1, SSL_TLS. com.ibm.ssl.contextProvider Underlying JSSE provider. For example IBMJSSE2 or SunJSSE com.ibm.ssl.keyStore The name of the file that contains the KeyStore object that you want the KeyManager to use. For example /mydir/etc/key.p12 com.ibm.ssl.keyStorePassword The password for the KeyStore object that you want the KeyManager to		Properties

Name	Description	Default	Type
	use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.keyStoreType Type of key store, for example PKCS12, JKS, or JCEKS. com.ibm.ssl.keyStoreProvider Key store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.trustStore The name of the file that contains the KeyStore object that you want the TrustManager to use. com.ibm.ssl.trustStorePassword The password for the TrustStore object that you want the TrustManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.trustStoreType The type of KeyStore object that you want the default TrustManager to use. Same possible values as keyStoreType. com.ibm.ssl.trustStoreProvider Trust store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.enabledCipherSuites A list of which ciphers are enabled. Values are dependent on the provider, for example: SSL_RSA_WITH_AES_128_CBC_SHA;SSL_RSA_WITH_3DES_EDE_CBC_SHA. com.ibm.ssl.keyManager Sets the algorithm that will be used to instantiate a KeyManagerFactory object instead of using the default algorithm available in the platform. Example values: IbmX509 or IBMJ9X509. com.ibm.ssl.trustManager Sets the algorithm that will be used to instantiate a TrustManagerFactory object instead of using the default algorithm available in the platform. Example values: PKIX or IBMJ9X509.		
sslHostnameVerifier (security)	Sets the HostnameVerifier for the SSL connection. Note that it will be used after handshake on a connection and you should do actions by yourself when hostname is verified error. There is no default HostnameVerifier.		HostnameVerifier
userName (security)	Username to be used for authentication against the MQTT broker.		String

101.6. HEADERS

The following headers are recognized by the Paho component:

Header	Java constant	Endpoint type	Value type	Description
CamelMqttTopic	PahoConstants.MQTT_TOPIC	Consumer	String	The name of the topic
CamelMqttQoS	PahoConstants.MQTT_QOS	Consumer	Integer	QualityOfService of the incoming message
CamelPahoOverrideTopic	PahoConstants.CAMEL_PAHO_OVERRIDE_TOPIC	Producer	String	Name of topic to override and send to instead of topic specified on endpoint

101.7. DEFAULT PAYLOAD TYPE

By default Camel Paho component operates on the binary payloads extracted out of (or put into) the MQTT message:

```
// Receive payload
byte[] payload = (byte[]) consumerTemplate.receiveBody("paho:topic");

// Send payload
byte[] payload = "message".getBytes();
producerTemplate.sendBody("paho:topic", payload);
```

But of course Camel build-in type conversion API can perform the automatic data type transformations for you. In the example below Camel automatically converts binary payload into **String** (and conversely):

```
// Receive payload
String payload = consumerTemplate.receiveBody("paho:topic", String.class);

// Send payload
String payload = "message";
producerTemplate.sendBody("paho:topic", payload);
```

101.8. SAMPLES

For example the following snippet reads messages from the MQTT broker installed on the same host as the Camel router:

```
from("paho:some/queue")
    .to("mock:test");
```

While the snippet below sends message to the MQTT broker:

```
from("direct:test")
    .to("paho:some/target/queue");
```

For example this is how to read messages from the remote MQTT broker:

```
from("paho:some/queue?brokerUrl=tcp://iot.eclipse.org:1883")
    .to("mock:test");
```

And here we override the default topic and set to a dynamic topic

```
from("direct:test")
    .setHeader(PahoConstants.CAMEL_PAHO_OVERRIDE_TOPIC, simple("${header.customerId}"))
    .to("paho:some/target/queue");
```

101.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 32 options, which are listed below.

Name	Description	Default	Type
camel.component.paho.automatic-reconnect	Sets whether the client will automatically attempt to reconnect to the server if the connection is lost. If set to false, the client will not attempt to automatically reconnect to the server in the event that the connection is lost. If set to true, in the event that the connection is lost, the client will attempt to reconnect to the server. It will initially wait 1 second before it attempts to reconnect, for every failed reconnect attempt, the delay will double until it is at 2 minutes at which point the delay will stay at 2 minutes.	true	Boolean
camel.component.paho.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.paho.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.paho.broker-url	The URL of the MQTT broker.	tcp://localhost:1883	String

Name	Description	Default	Type
camel.component.paho.clean-session	Sets whether the client and server should remember state across restarts and reconnects. If set to false both the client and server will maintain state across restarts of the client, the server and the connection. As state is maintained: Message delivery will be reliable meeting the specified QOS even if the client, server or connection are restarted. The server will treat a subscription as durable. If set to true the client and server will not maintain state across restarts of the client, the server or the connection. This means Message delivery to the specified QOS cannot be maintained if the client, server or connection are restarted The server will treat a subscription as non-durable.	true	Boolean
camel.component.paho.client	To use a shared Paho client. The option is a org.eclipse.paho.client.mqttv3.MqttClient type.		MqttClient
camel.component.paho.client-id	MQTT client identifier. The identifier must be unique.		String
camel.component.paho.configuration	To use the shared Paho configuration. The option is a org.apache.camel.component.paho.PahoConfiguration type.		PahoConfiguration
camel.component.paho.connection-timeout	Sets the connection timeout value. This value, measured in seconds, defines the maximum time interval the client will wait for the network connection to the MQTT server to be established. The default timeout is 30 seconds. A value of 0 disables timeout processing meaning the client will wait until the network connection is made successfully or fails.	30	Integer
camel.component.paho.custom-web-socket-headers	Sets the Custom WebSocket Headers for the WebSocket Connection. The option is a java.util.Properties type.		Properties
camel.component.paho.enabled	Whether to enable auto configuration of the paho component. This is enabled by default.		Boolean
camel.component.paho.executor-service-timeout	Set the time in seconds that the executor service should wait when terminating before forcefully terminating. It is not recommended to change this value unless you are absolutely sure that you need to.	1	Integer

Name	Description	Default	Type
camel.component.paho.file-persistence-directory	Base directory used by file persistence. Will by default use user directory.		String
camel.component.paho.https-hostname-verification-enabled	Whether SSL HostnameVerifier is enabled or not. The default value is true.	true	Boolean
camel.component.paho.keep-alive-interval	Sets the keep alive interval. This value, measured in seconds, defines the maximum time interval between messages sent or received. It enables the client to detect if the server is no longer available, without having to wait for the TCP/IP timeout. The client will ensure that at least one message travels across the network within each keep alive period. In the absence of a data-related message during the time period, the client sends a very small ping message, which the server will acknowledge. A value of 0 disables keepalive processing in the client. The default value is 60 seconds.	60	Integer
camel.component.paho.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.paho.max-inflight	Sets the max inflight. please increase this value in a high traffic environment. The default value is 10.	10	Integer
camel.component.paho.max-reconnect-delay	Get the maximum time (in millis) to wait between reconnects.	128000	Integer
camel.component.paho.mqtt-version	Sets the MQTT version. The default action is to connect with version 3.1.1, and to fall back to 3.1 if that fails. Version 3.1.1 or 3.1 can be selected specifically, with no fall back, by using the MQTT_VERSION_3_1_1 or MQTT_VERSION_3_1 options respectively.		Integer

Name	Description	Default	Type
camel.component.paho.password	Password to be used for authentication against the MQTT broker.		String
camel.component.paho.persistence	Client persistence to be used - memory or file.		PahoPersistence
camel.component.paho.qos	Client quality of service level (0-2).	2	Integer
camel.component.paho.retained	Retain option.	false	Boolean
camel.component.paho.server-u-r-is	Set a list of one or more serverURIs the client may connect to. Multiple servers can be separated by comma. Each serverURI specifies the address of a server that the client may connect to. Two types of connection are supported tcp:// for a TCP connection and ssl:// for a TCP connection secured by SSL/TLS. For example: tcp://localhost:1883 ssl://localhost:8883 If the port is not specified, it will default to 1883 for tcp:// URIs, and 8883 for ssl:// URIs. If serverURIs is set then it overrides the serverURI parameter passed in on the constructor of the MQTT client. When an attempt to connect is initiated the client will start with the first serverURI in the list and work through the list until a connection is established with a server. If a connection cannot be made to any of the servers then the connect attempt fails. Specifying a list of servers that a client may connect to has several uses: High Availability and reliable message delivery Some MQTT servers support a high availability feature where two or more equal MQTT servers share state. An MQTT client can connect to any of the equal servers and be assured that messages are reliably delivered and durable subscriptions are maintained no matter which server the client connects to. The cleansession flag must be set to false if durable subscriptions and/or reliable message delivery is required. Hunt List A set of servers may be specified that are not equal (as in the high availability option). As no state is shared across the servers reliable message delivery and durable subscriptions are not valid. The cleansession flag must be set to true if the hunt list mode is used.		String

Name	Description	Default	Type
camel.component.paho.socket-factory	Sets the SocketFactory to use. This allows an application to apply its own policies around the creation of network sockets. If using an SSL connection, an SSLSocketFactory can be used to supply application-specific security settings. The option is a javax.net.SocketFactory type.		SocketFactory
camel.component.paho.ssl-client-props	Sets the SSL properties for the connection. Note that these properties are only valid if an implementation of the Java Secure Socket Extensions (JSSE) is available. These properties are not used if a custom SocketFactory has been set. The following properties can be used: com.ibm.ssl.protocol One of: SSL, SSLv3, TLS, TLSv1, SSL_TLS. com.ibm.ssl.contextProvider Underlying JSSE provider. For example IBMJSSE2 or SunJSSE com.ibm.ssl.keyStore The name of the file that contains the KeyStore object that you want the KeyManager to use. For example /mydir/etc/key.p12 com.ibm.ssl.keyStorePassword The password for the KeyStore object that you want the KeyManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.keyStoreType Type of key store, for example PKCS12, JKS, or JCEKS. com.ibm.ssl.keyStoreProvider Key store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.trustStore The name of the file that contains the KeyStore object that you want the TrustManager to use. com.ibm.ssl.trustStorePassword The password for the TrustStore object that you want the TrustManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.trustStoreType The type of KeyStore object that you want the default TrustManager to use. Same possible values as keyStoreType. com.ibm.ssl.trustStoreProvider Trust store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.enabledCipherSuites A list of which ciphers are enabled. Values are dependent on the		Properties

Name	Description	Default	Type
	provider, for example: SSL_RSA_WITH_AES_128_CBC_SHA;SSL_RSA_WITH_3DES_EDE_CBC_SHA. com.ibm.ssl.keyManager Sets the algorithm that will be used to instantiate a KeyManagerFactory object instead of using the default algorithm available in the platform. Example values: IbmX509 or IBMJ9X509. com.ibm.ssl.trustManager Sets the algorithm that will be used to instantiate a TrustManagerFactory object instead of using the default algorithm available in the platform. Example values: PKIX or IBMJ9X509. The option is a java.util.Properties type.		
camel.component.paho.ssl-hostname-verifier	Sets the HostnameVerifier for the SSL connection. Note that it will be used after handshake on a connection and you should do actions by yourself when hostname is verified error. There is no default HostnameVerifier. The option is a javax.net.ssl.HostnameVerifier type.		HostnameVerifier
camel.component.paho.user-name	Username to be used for authentication against the MQTT broker.		String
camel.component.paho.will-payload	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		String
camel.component.paho.will-qos	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		Integer
camel.component.paho.will-retained	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.	false	Boolean

Name	Description	Default	Type
camel.component.paho.will-topic	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to The byte payload for the message. The quality of service to publish the message at (0, 1 or 2). Whether or not the message should be retained.		String

CHAPTER 102. PAHO MQTT 5

Both producer and consumer are supported

Paho MQTT5 component provides connector for the MQTT messaging protocol using the Eclipse Paho library with MQTT v5. Paho is one of the most popular MQTT libraries, so if you would like to integrate it with your Java project - Camel Paho connector is a way to go.

102.1. DEPENDENCIES

When using **paho-mqtt5** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-paho-mqtt5-starter</artifactId>
</dependency>
```

102.2. URI FORMAT

```
paho-mqtt5:topic[?options]
```

Where **topic** is the name of the topic.

102.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

102.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

102.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

102.4. COMPONENT OPTIONS

The Paho MQTT 5 component supports 32 options, which are listed below.

Name	Description	Default	Type
automaticReconnect (common)	Sets whether the client will automatically attempt to reconnect to the server if the connection is lost. If set to false, the client will not attempt to automatically reconnect to the server in the event that the connection is lost. If set to true, in the event that the connection is lost, the client will attempt to reconnect to the server. It will initially wait 1 second before it attempts to reconnect, for every failed reconnect attempt, the delay will double until it is at 2 minutes at which point the delay will stay at 2 minutes.	true	boolean
brokerUrl (common)	The URL of the MQTT broker.	tcp://localhost:1883	String
cleanStart (common)	Sets whether the client and server should remember state across restarts and reconnects. If set to false both the client and server will maintain state across restarts of the client, the server and the connection. As state is maintained: Message delivery will be reliable meeting the specified QOS even if the client, server or connection are restarted. The server will treat a subscription as durable. If set to true the client and server will not maintain state across restarts of the client, the server or the connection. This means Message delivery to the specified QOS cannot be maintained if the client, server or connection are restarted The server will treat a subscription as non-durable.	true	boolean
clientId (common)	MQTT client identifier. The identifier must be unique.		String
configuration (common)	To use the shared Paho configuration.		PahoMqtt5Configuration

Name	Description	Default	Type
connectionTimeout (common)	Sets the connection timeout value. This value, measured in seconds, defines the maximum time interval the client will wait for the network connection to the MQTT server to be established. The default timeout is 30 seconds. A value of 0 disables timeout processing meaning the client will wait until the network connection is made successfully or fails.	30	int
filePersistenceDirectory (common)	Base directory used by file persistence. Will by default use user directory.		String
keepAliveInterval (common)	Sets the keep alive interval. This value, measured in seconds, defines the maximum time interval between messages sent or received. It enables the client to detect if the server is no longer available, without having to wait for the TCP/IP timeout. The client will ensure that at least one message travels across the network within each keep alive period. In the absence of a data-related message during the time period, the client sends a very small ping message, which the server will acknowledge. A value of 0 disables keepalive processing in the client. The default value is 60 seconds.	60	int
maxReconnectDelay (common)	Get the maximum time (in millis) to wait between reconnects.	128000	int
persistence (common)	Client persistence to be used - memory or file. Enum values: • FILE • MEMORY	MEMORY	PahoMqtt5Persistence
qos (common)	Client quality of service level (0-2).	2	int
receiveMaximum (common)	Sets the Receive Maximum. This value represents the limit of QoS 1 and QoS 2 publications that the client is willing to process concurrently. There is no mechanism to limit the number of QoS 0 publications that the Server might try to send. The default value is 65535.	65535	int
retained (common)	Retain option.	false	boolean

Name	Description	Default	Type
serverURIs (common)	Set a list of one or more serverURIs the client may connect to. Multiple servers can be separated by comma. Each serverURI specifies the address of a server that the client may connect to. Two types of connection are supported tcp:// for a TCP connection and ssl:// for a TCP connection secured by SSL/TLS. For example: tcp://localhost:1883 ssl://localhost:8883 If the port is not specified, it will default to 1883 for tcp:// URIs, and 8883 for ssl:// URIs. If serverURIs is set then it overrides the serverURI parameter passed in on the constructor of the MQTT client. When an attempt to connect is initiated the client will start with the first serverURI in the list and work through the list until a connection is established with a server. If a connection cannot be made to any of the servers then the connect attempt fails. Specifying a list of servers that a client may connect to has several uses: High Availability and reliable message delivery Some MQTT servers support a high availability feature where two or more equal MQTT servers share state. An MQTT client can connect to any of the equal servers and be assured that messages are reliably delivered and durable subscriptions are maintained no matter which server the client connects to. The cleansession flag must be set to false if durable subscriptions and/or reliable message delivery is required. Hunt List A set of servers may be specified that are not equal (as in the high availability option). As no state is shared across the servers reliable message delivery and durable subscriptions are not valid. The cleansession flag must be set to true if the hunt list mode is used.		String
sessionExpiryInterval (common)	Sets the Session Expiry Interval. This value, measured in seconds, defines the maximum time that the broker will maintain the session for once the client disconnects. Clients should only connect with a long Session Expiry interval if they intend to connect to the server at some later point in time. By default this value is -1 and so will not be sent, in this case, the session will not expire. If a 0 is sent, the session will end immediately once the Network Connection is closed. When the client has determined that it has no longer any use for the session, it should disconnect with a Session Expiry Interval set to 0.	-1	long

Name	Description	Default	Type
willMqttProperties (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The MQTT properties set for the message.		MqttProperties
willPayload (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The byte payload for the message.		String
willQos (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The quality of service to publish the message at (0, 1 or 2).	1	int
willRetained (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. Whether or not the message should be retained.	false	boolean
willTopic (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
client (advanced)	To use a shared Paho client.		MqttClient
customWebSocketHeaders (advanced)	Sets the Custom WebSocket Headers for the WebSocket Connection.		Map
executorServiceTimeout (advanced)	Set the time in seconds that the executor service should wait when terminating before forcefully terminating. It is not recommended to change this value unless you are absolutely sure that you need to.	1	int
httpsHostnameVerificationEnabled (security)	Whether SSL HostnameVerifier is enabled or not. The default value is true.	true	boolean
password (security)	Password to be used for authentication against the MQTT broker.		String
socketFactory (security)	Sets the SocketFactory to use. This allows an application to apply its own policies around the creation of network sockets. If using an SSL connection, an SSLSocketFactory can be used to supply application-specific security settings.		SocketFactory
sslClientProps (security)	Sets the SSL properties for the connection. Note that these properties are only valid if an implementation of the Java Secure Socket Extensions (JSSE) is		Properties

Name	Description	Default	Type
	available. These properties are not used if a custom SocketFactory has been set. The following properties can be used: com.ibm.ssl.protocol One of: SSL, SSLv3, TLS, TLSv1, SSL_TLS. com.ibm.ssl.contextProvider Underlying JSSE provider. For example IBMJSSE2 or SunJSSE com.ibm.ssl.keyStore The name of the file that contains the KeyStore object that you want the KeyManager to use. For example /mydir/etc/key.p12 com.ibm.ssl.keyStorePassword The password for the KeyStore object that you want the KeyManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.keyStoreType Type of key store, for example PKCS12, JKS, or JCEKS. com.ibm.ssl.keyStoreProvider Key store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.trustStore The name of the file that contains the KeyStore object that you want the TrustManager to use. com.ibm.ssl.trustStorePassword The password for the TrustStore object that you want the TrustManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.trustStoreType The type of KeyStore object that you want the default TrustManager to use. Same possible values as keyStoreType. com.ibm.ssl.trustStoreProvider Trust store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.enabledCipherSuites A list of which ciphers are enabled. Values are dependent on the provider, for example: SSL_RSA_WITH_AES_128_CBC_SHA;SSL_RSA_WITH_3DES_EDE_CBC_SHA. com.ibm.ssl.keyManager Sets the algorithm that will be used to instantiate a KeyManagerFactory object instead of using the default algorithm available in the platform. Example values: IbmX509 or IBMJ9X509. com.ibm.ssl.trustManager Sets the algorithm that will be used to instantiate a TrustManagerFactory object instead of using the default algorithm available in the platform. Example values: PKIX or IBMJ9X509.		

Name	Description	Default	Type
sslHostnameVerifier (security)	Sets the HostnameVerifier for the SSL connection. Note that it will be used after handshake on a connection and you should do actions by yourself when hostname is verified error. There is no default HostnameVerifier.		HostnameVerifier
userName (security)	Username to be used for authentication against the MQTT broker.		String

102.5. ENDPOINT OPTIONS

The Paho MQTT 5 endpoint is configured using URI syntax:

```
paho-mqtt5:topic
```

with the following path and query parameters:

102.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
topic (common)	**Required** Name of the topic.		String

102.5.2. Query Parameters (32 parameters)

Name	Description	Default	Type
automaticReconnect (common)	Sets whether the client will automatically attempt to reconnect to the server if the connection is lost. If set to false, the client will not attempt to automatically reconnect to the server in the event that the connection is lost. If set to true, in the event that the connection is lost, the client will attempt to reconnect to the server. It will initially wait 1 second before it attempts to reconnect, for every failed reconnect attempt, the delay will double until it is at 2 minutes at which point the delay will stay at 2 minutes.	true	boolean
brokerUrl (common)	The URL of the MQTT broker.	tcp://localhost:1883	String

Name	Description	Default	Type
cleanStart (common)	Sets whether the client and server should remember state across restarts and reconnects. If set to false both the client and server will maintain state across restarts of the client, the server and the connection. As state is maintained: Message delivery will be reliable meeting the specified QOS even if the client, server or connection are restarted. The server will treat a subscription as durable. If set to true the client and server will not maintain state across restarts of the client, the server or the connection. This means Message delivery to the specified QOS cannot be maintained if the client, server or connection are restarted The server will treat a subscription as non-durable.	true	boolean
clientId (common)	MQTT client identifier. The identifier must be unique.		String
connectionTimeout (common)	Sets the connection timeout value. This value, measured in seconds, defines the maximum time interval the client will wait for the network connection to the MQTT server to be established. The default timeout is 30 seconds. A value of 0 disables timeout processing meaning the client will wait until the network connection is made successfully or fails.	30	int
filePersistenceDirectory (common)	Base directory used by file persistence. Will by default use user directory.		String
keepAliveInterval (common)	Sets the keep alive interval. This value, measured in seconds, defines the maximum time interval between messages sent or received. It enables the client to detect if the server is no longer available, without having to wait for the TCP/IP timeout. The client will ensure that at least one message travels across the network within each keep alive period. In the absence of a data-related message during the time period, the client sends a very small ping message, which the server will acknowledge. A value of 0 disables keepalive processing in the client. The default value is 60 seconds.	60	int
maxReconnectDelay (common)	Get the maximum time (in millis) to wait between reconnects.	128000	int

Name	Description	Default	Type
persistence (common)	Client persistence to be used - memory or file. Enum values: • FILE • MEMORY	MEMORY	PahoMqtt5Persistence
qos (common)	Client quality of service level (0-2).	2	int
receiveMaximum (common)	Sets the Receive Maximum. This value represents the limit of QoS 1 and QoS 2 publications that the client is willing to process concurrently. There is no mechanism to limit the number of QoS 0 publications that the Server might try to send. The default value is 65535.	65535	int
retained (common)	Retain option.	false	boolean

Name	Description	Default	Type
serverURIs (common)	Set a list of one or more serverURIs the client may connect to. Multiple servers can be separated by comma. Each serverURI specifies the address of a server that the client may connect to. Two types of connection are supported tcp:// for a TCP connection and ssl:// for a TCP connection secured by SSL/TLS. For example: tcp://localhost:1883 ssl://localhost:8883 If the port is not specified, it will default to 1883 for tcp:// URIs, and 8883 for ssl:// URIs. If serverURIs is set then it overrides the serverURI parameter passed in on the constructor of the MQTT client. When an attempt to connect is initiated the client will start with the first serverURI in the list and work through the list until a connection is established with a server. If a connection cannot be made to any of the servers then the connect attempt fails. Specifying a list of servers that a client may connect to has several uses: High Availability and reliable message delivery Some MQTT servers support a high availability feature where two or more equal MQTT servers share state. An MQTT client can connect to any of the equal servers and be assured that messages are reliably delivered and durable subscriptions are maintained no matter which server the client connects to. The cleansession flag must be set to false if durable subscriptions and/or reliable message delivery is required. Hunt List A set of servers may be specified that are not equal (as in the high availability option). As no state is shared across the servers reliable message delivery and durable subscriptions are not valid. The cleansession flag must be set to true if the hunt list mode is used.		String
sessionExpiryInterval (common)	Sets the Session Expiry Interval. This value, measured in seconds, defines the maximum time that the broker will maintain the session for once the client disconnects. Clients should only connect with a long Session Expiry interval if they intend to connect to the server at some later point in time. By default this value is -1 and so will not be sent, in this case, the session will not expire. If a 0 is sent, the session will end immediately once the Network Connection is closed. When the client has determined that it has no longer any use for the session, it should disconnect with a Session Expiry Interval set to 0.	-1	long

Name	Description	Default	Type
willMqttProperties (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The MQTT properties set for the message.		MqttProperties
willPayload (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The byte payload for the message.		String
willQos (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The quality of service to publish the message at (0, 1 or 2).	1	int
willRetained (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. Whether or not the message should be retained.	false	boolean
willTopic (common)	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
client (advanced)	To use an existing mqtt client.		MqttClient
customWebSocketHeaders (advanced)	Sets the Custom WebSocket Headers for the WebSocket Connection.		Map
executorServiceTimeout (advanced)	Set the time in seconds that the executor service should wait when terminating before forcefully terminating. It is not recommended to change this value unless you are absolutely sure that you need to.	1	int
httpsHostnameVerificationEnabled (security)	Whether SSL HostnameVerifier is enabled or not. The default value is true.	true	boolean
password (security)	Password to be used for authentication against the MQTT broker.		String
socketFactory (security)	Sets the SocketFactory to use. This allows an application to apply its own policies around the creation of network sockets. If using an SSL connection, an SSLSocketFactory can be used to supply application-specific security settings.		SocketFactory
sslClientProps (security)	Sets the SSL properties for the connection. Note that these properties are only valid if an implementation of the Java Secure Socket Extensions (JSSE) is		Properties

Name	Description	Default	Type
	available. These properties are not used if a custom SocketFactory has been set. The following properties can be used: com.ibm.ssl.protocol One of: SSL, SSLv3, TLS, TLSv1, SSL_TLS. com.ibm.ssl.contextProvider Underlying JSSE provider. For example IBMJSSE2 or SunJSSE com.ibm.ssl.keyStore The name of the file that contains the KeyStore object that you want the KeyManager to use. For example /mydir/etc/key.p12 com.ibm.ssl.keyStorePassword The password for the KeyStore object that you want the KeyManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.keyStoreType Type of key store, for example PKCS12, JKS, or JCEKS. com.ibm.ssl.keyStoreProvider Key store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.trustStore The name of the file that contains the KeyStore object that you want the TrustManager to use. com.ibm.ssl.trustStorePassword The password for the TrustStore object that you want the TrustManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.trustStoreType The type of KeyStore object that you want the default TrustManager to use. Same possible values as keyStoreType. com.ibm.ssl.trustStoreProvider Trust store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.enabledCipherSuites A list of which ciphers are enabled. Values are dependent on the provider, for example: SSL_RSA_WITH_AES_128_CBC_SHA;SSL_RSA_WITH_3DES_EDE_CBC_SHA. com.ibm.ssl.keyManager Sets the algorithm that will be used to instantiate a KeyManagerFactory object instead of using the default algorithm available in the platform. Example values: IbmX509 or IBMJ9X509. com.ibm.ssl.trustManager Sets the algorithm that will be used to instantiate a TrustManagerFactory object instead of using the default algorithm available in the platform. Example values: PKIX or IBMJ9X509.		

Name	Description	Default	Type
sslHostnameVerifier (security)	Sets the HostnameVerifier for the SSL connection. Note that it will be used after handshake on a connection and you should do actions by yourself when hostname is verified error. There is no default HostnameVerifier.		HostnameVerifier
userName (security)	Username to be used for authentication against the MQTT broker.		String

102.6. HEADERS

The following headers are recognized by the Paho component:

Header	Java constant	Endpoint type	Value type	Description
CamelMqttTopic	PahoConstants.MQTT_TOPIC	Consumer	String	The name of the topic
CamelMqttQoS	PahoConstants.MQTT_QOS	Consumer	Integer	QualityOfService of the incoming message
CamelPahoOverrideTopic	PahoConstants.CAMEL_PAHO_OVERRIDE_TOPIC	Producer	String	Name of topic to override and send to instead of topic specified on endpoint

102.7. DEFAULT PAYLOAD TYPE

By default Camel Paho component operates on the binary payloads extracted out of (or put into) the MQTT message:

```
// Receive payload
byte[] payload = (byte[]) consumerTemplate.receiveBody("paho:topic");

// Send payload
byte[] payload = "message".getBytes();
producerTemplate.sendBody("paho:topic", payload);
```

But of course Camel build-in type conversion API can perform the automatic data type transformations for you. In the example below Camel automatically converts binary payload into **String** (and conversely):

```
// Receive payload
String payload = consumerTemplate.receiveBody("paho:topic", String.class);

// Send payload
String payload = "message";
producerTemplate.sendBody("paho:topic", payload);
```

-

102.8. SAMPLES

For example the following snippet reads messages from the MQTT broker installed on the same host as the Camel router:

```
from("paho:some/queue")
    .to("mock:test");
```

While the snippet below sends message to the MQTT broker:

```
from("direct:test")
    .to("paho:some/target/queue");
```

For example this is how to read messages from the remote MQTT broker:

```
from("paho:some/queue?brokerUrl=tcp://iot.eclipse.org:1883")
    .to("mock:test");
```

And here we override the default topic and set to a dynamic topic

```
from("direct:test")
    .setHeader(PahoConstants.CAMEL_PAHO_OVERRIDE_TOPIC, simple("${header.customerId}"))
    .to("paho:some/target/queue");
```

102.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 33 options, which are listed below.

Name	Description	Default	Type
camel.component.paho-mqtt5.automatic-reconnect	Sets whether the client will automatically attempt to reconnect to the server if the connection is lost. If set to false, the client will not attempt to automatically reconnect to the server in the event that the connection is lost. If set to true, in the event that the connection is lost, the client will attempt to reconnect to the server. It will initially wait 1 second before it attempts to reconnect, for every failed reconnect attempt, the delay will double until it is at 2 minutes at which point the delay will stay at 2 minutes.	true	Boolean
camel.component.paho-mqtt5.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.paho-mqtt5.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.paho-mqtt5.broker-url	The URL of the MQTT broker.	tcp://localhost:1883	String
camel.component.paho-mqtt5.clean-start	Sets whether the client and server should remember state across restarts and reconnects. If set to false both the client and server will maintain state across restarts of the client, the server and the connection. As state is maintained: Message delivery will be reliable meeting the specified QOS even if the client, server or connection are restarted. The server will treat a subscription as durable. If set to true the client and server will not maintain state across restarts of the client, the server or the connection. This means Message delivery to the specified QOS cannot be maintained if the client, server or connection are restarted The server will treat a subscription as non-durable.	true	Boolean
camel.component.paho-mqtt5.client	To use a shared Paho client. The option is a org.eclipse.paho.mqttv5.client.MqttClient type.		MqttClient
camel.component.paho-mqtt5.client-id	MQTT client identifier. The identifier must be unique.		String
camel.component.paho-mqtt5.configuration	To use the shared Paho configuration. The option is a org.apache.camel.component.paho.mqtt5.PahoMqtt5Configuration type.		PahoMqtt5Configuration
camel.component.paho-mqtt5.connection-timeout	Sets the connection timeout value. This value, measured in seconds, defines the maximum time interval the client will wait for the network connection to the MQTT server to be established. The default timeout is 30 seconds. A value of 0 disables timeout processing meaning the client will wait until the network connection is made successfully or fails.	30	Integer

Name	Description	Default	Type
camel.component.paho-mqtt5.custom-web-socket-headers	Sets the Custom WebSocket Headers for the WebSocket Connection.		Map
camel.component.paho-mqtt5.enabled	Whether to enable auto configuration of the paho-mqtt5 component. This is enabled by default.		Boolean
camel.component.paho-mqtt5.executor-service-timeout	Set the time in seconds that the executor service should wait when terminating before forcefully terminating. It is not recommended to change this value unless you are absolutely sure that you need to.	1	Integer
camel.component.paho-mqtt5.file-persistence-directory	Base directory used by file persistence. Will by default use user directory.		String
camel.component.paho-mqtt5.https-hostname-verification-enabled	Whether SSL HostnameVerifier is enabled or not. The default value is true.	true	Boolean
camel.component.paho-mqtt5.keep-alive-interval	Sets the keep alive interval. This value, measured in seconds, defines the maximum time interval between messages sent or received. It enables the client to detect if the server is no longer available, without having to wait for the TCP/IP timeout. The client will ensure that at least one message travels across the network within each keep alive period. In the absence of a data-related message during the time period, the client sends a very small ping message, which the server will acknowledge. A value of 0 disables keepalive processing in the client. The default value is 60 seconds.	60	Integer

Name	Description	Default	Type
camel.component.paho-mqtt5.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.paho-mqtt5.max-reconnect-delay	Get the maximum time (in millis) to wait between reconnects.	128000	Integer
camel.component.paho-mqtt5.password	Password to be used for authentication against the MQTT broker.		String
camel.component.paho-mqtt5.persistence	Client persistence to be used - memory or file.		PahoMqtt5Persistence
camel.component.paho-mqtt5.qos	Client quality of service level (0-2).	2	Integer
camel.component.paho-mqtt5.receive-maximum	Sets the Receive Maximum. This value represents the limit of QoS 1 and QoS 2 publications that the client is willing to process concurrently. There is no mechanism to limit the number of QoS 0 publications that the Server might try to send. The default value is 65535.	65535	Integer
camel.component.paho-mqtt5.retained	Retain option.	false	Boolean

Name	Description	Default	Type
camel.component.paho-mqtt5.server-u-r-is	Set a list of one or more serverURIs the client may connect to. Multiple servers can be separated by comma. Each serverURI specifies the address of a server that the client may connect to. Two types of connection are supported tcp:// for a TCP connection and ssl:// for a TCP connection secured by SSL/TLS. For example: tcp://localhost:1883 ssl://localhost:8883 If the port is not specified, it will default to 1883 for tcp:// URIs, and 8883 for ssl:// URIs. If serverURIs is set then it overrides the serverURI parameter passed in on the constructor of the MQTT client. When an attempt to connect is initiated the client will start with the first serverURI in the list and work through the list until a connection is established with a server. If a connection cannot be made to any of the servers then the connect attempt fails. Specifying a list of servers that a client may connect to has several uses: High Availability and reliable message delivery Some MQTT servers support a high availability feature where two or more equal MQTT servers share state. An MQTT client can connect to any of the equal servers and be assured that messages are reliably delivered and durable subscriptions are maintained no matter which server the client connects to. The cleansession flag must be set to false if durable subscriptions and/or reliable message delivery is required. Hunt List A set of servers may be specified that are not equal (as in the high availability option). As no state is shared across the servers reliable message delivery and durable subscriptions are not valid. The cleansession flag must be set to true if the hunt list mode is used.		String
camel.component.paho-mqtt5.session-expiry-interval	Sets the Session Expiry Interval. This value, measured in seconds, defines the maximum time that the broker will maintain the session for once the client disconnects. Clients should only connect with a long Session Expiry interval if they intend to connect to the server at some later point in time. By default this value is -1 and so will not be sent, in this case, the session will not expire. If a 0 is sent, the session will end immediately once the Network Connection is closed. When the client has determined that it has no longer any use for the session, it should disconnect with a Session Expiry Interval set to 0.	-1	Long

Name	Description	Default	Type
camel.component.paho-mqtt5.socket-factory	Sets the SocketFactory to use. This allows an application to apply its own policies around the creation of network sockets. If using an SSL connection, an SSLSocketFactory can be used to supply application-specific security settings. The option is a javax.net.SocketFactory type.		SocketFactory
camel.component.paho-mqtt5.ssl-client-props	Sets the SSL properties for the connection. Note that these properties are only valid if an implementation of the Java Secure Socket Extensions (JSSE) is available. These properties are not used if a custom SocketFactory has been set. The following properties can be used: com.ibm.ssl.protocol One of: SSL, SSLv3, TLS, TLSv1, SSL_TLS. com.ibm.ssl.contextProvider Underlying JSSE provider. For example IBMJSSE2 or SunJSSE com.ibm.ssl.keyStore The name of the file that contains the KeyStore object that you want the KeyManager to use. For example /mydir/etc/key.p12 com.ibm.ssl.keyStorePassword The password for the KeyStore object that you want the KeyManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.keyStoreType Type of key store, for example PKCS12, JKS, or JCEKS. com.ibm.ssl.keyStoreProvider Key store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.trustStore The name of the file that contains the KeyStore object that you want the TrustManager to use. com.ibm.ssl.trustStorePassword The password for the TrustStore object that you want the TrustManager to use. The password can either be in plain-text, or may be obfuscated using the static method: com.ibm.micro.security.Password.obfuscate(char password). This obfuscates the password using a simple and insecure XOR and Base64 encoding mechanism. Note that this is only a simple scrambler to obfuscate clear-text passwords. com.ibm.ssl.trustStoreType The type of KeyStore object that you want the default TrustManager to use. Same possible values as keyStoreType. com.ibm.ssl.trustStoreProvider Trust store provider, for example IBMJCE or IBMJCEFIPS. com.ibm.ssl.enabledCipherSuites A list of which ciphers are enabled. Values are dependent on the		Properties

Name	Description	Default	Type
	provider, for example: SSL_RSA_WITH_AES_128_CBC_SHA;SSL_RSA_WITH_3DES_EDE_CBC_SHA. com.ibm.ssl.keyManager Sets the algorithm that will be used to instantiate a KeyManagerFactory object instead of using the default algorithm available in the platform. Example values: IbmX509 or IBMJ9X509. com.ibm.ssl.trustManager Sets the algorithm that will be used to instantiate a TrustManagerFactory object instead of using the default algorithm available in the platform. Example values: PKIX or IBMJ9X509. The option is a java.util.Properties type.		
camel.component.paho-mqtt5.ssl-hostname-verifier	Sets the HostnameVerifier for the SSL connection. Note that it will be used after handshake on a connection and you should do actions by yourself when hostname is verified error. There is no default HostnameVerifier. The option is a javax.net.ssl.HostnameVerifier type.		HostnameVerifier
camel.component.paho-mqtt5.user-name	Username to be used for authentication against the MQTT broker.		String
camel.component.paho-mqtt5.will-mqtt-properties	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The MQTT properties set for the message. The option is a org.eclipse.paho.mqttv5.common.packet.MqttProperties type.		MqttProperties
camel.component.paho-mqtt5.will-payload	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The byte payload for the message.		String
camel.component.paho-mqtt5.will-qos	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The quality of service to publish the message at (0, 1 or 2).	1	Integer
camel.component.paho-mqtt5.will-retained	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. Whether or not the message should be retained.	false	Boolean

Name	Description	Default	Type
camel.component.paho-mqtt5.will-topic	Sets the Last Will and Testament (LWT) for the connection. In the event that this client unexpectedly loses its connection to the server, the server will publish a message to itself using the supplied details. The topic to publish to.		String

CHAPTER 103. PLATFORM HTTP

Since Camel 3.0

Only consumer is supported

The Platform HTTP is used to allow Camel to use the existing HTTP server from the runtime, for example when running Camel on Spring Boot, Quarkus, or other runtimes.

103.1. DEPENDENCIES

When using **platform-http** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-platform-http-starter</artifactId>
</dependency>
```

103.2. PLATFORM HTTP PROVIDER

To use Platform HTTP a provider (engine) is required to be available on the classpath. The purpose is to have drivers for different runtimes such as Quarkus, VertX, or Spring Boot.

At this moment there is only support for Quarkus and VertX by **camel-platform-http-vertx**. This JAR must be on the classpath otherwise the Platform HTTP component cannot be used and an exception will be thrown on startup.

```
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-platform-http-vertx</artifactId>
    <version>4.4.0.redhat-00019</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

103.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

103.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

103.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

103.4. COMPONENT OPTIONS

The Platform HTTP component supports 3 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
engine (advanced)	An HTTP Server engine implementation to serve the requests.		PlatformHttpEngine

103.4.1. Endpoint Options

The Platform HTTP endpoint is configured using URI syntax:

```
platform-http:path
```

with the following path and query parameters:

103.4.1.1. Path Parameters (1 parameters)

Name	Description	Default	Type
path (consumer)	**Required** The path under which this endpoint serves the HTTP requests, for proxy use 'proxy'.		String

103.4.1.2. Query Parameters (11 parameters)

Name	Description	Default	Type
consumes (consumer)	The content type this endpoint accepts as an input, such as application/xml or application/json. null or / mean no restriction.		String
httpMethodRestrict (consumer)	A comma separated list of HTTP methods to serve, e.g. GET,POST . If no methods are specified, all methods will be served.		String
matchOnUriPrefix (consumer)	Whether or not the consumer should try to find a target consumer by matching the URI prefix if no exact match is found.	false	boolean
muteException (consumer)	If enabled and an Exchange failed processing on the consumer side the response's body won't contain the exception's stack trace.	true	boolean
produces (consumer)	The content type this endpoint produces, such as application/xml or application/json.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
fileNameExtWhitelist (consumer (advanced))	A comma or whitespace separated list of file extensions. Uploads having these extensions will be stored locally. Null value or asterisk () will allow all files.		String
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter headers to and from Camel message.		HeaderFilterStrategy
platformHttpEngine (advanced)	An HTTP Server engine implementation to serve the requests of this endpoint.		PlatformHttpEngine

103.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.platform-http.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.platform-http.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.platform-http.enabled	Whether to enable auto configuration of the platform-http component. This is enabled by default.		Boolean
camel.component.platform-http.engine	An HTTP Server engine implementation to serve the requests. The option is a org.apache.camel.component.platform.http.spi.PlatformHttpEngine type.		PlatformHttpEngine

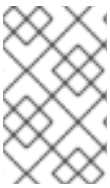
103.5.1. Implementing a reverse proxy

Platform HTTP component can act as a reverse proxy, in that case some headers are populated from the absolute URL received on the request line of the HTTP request. Those headers are specific to the underlining platform.

At this moment, this feature is only supported for Vert.x in **camel-platform-http-vertx** component.

CHAPTER 104. PROTOBUF JACKSON

Jackson Protobuf is a Data Format which uses the Jackson library with the Protobuf extension to unmarshal a Protobuf payload into Java objects or to marshal Java objects into a Protobuf payload.



NOTE

If you are familiar with Jackson, this Protobuf data format behaves in the same way as its JSON counterpart, and thus can be used with classes annotated for JSON serialization/deserialization.

```
from("kafka:topic").
  unmarshal().protobuf(ProtobufLibrary.Jackson, JsonNode.class).
  to("log:info");
```

104.1. DEPENDENCIES

When using **protobuf-jackson** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jackson-protobuf-starter</artifactId>
</dependency>
```

104.2. CONFIGURING THE SCHEMARESOLVER

Since Protobuf serialization is schema-based, this data format requires that you provide a SchemaResolver object that is able to lookup the schema for each exchange that is going to be marshalled/unmarshalled.

You can add a single SchemaResolver to the registry and it will be looked up automatically. Or you can explicitly specify the reference to a custom SchemaResolver.

104.3. PROTOBUF JACKSON OPTIONS

The Protobuf Jackson dataformat supports 18 options, which are listed below.

Name	Default	Java Type	Description
contentTypeHeader		**Boolean**	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.
objectMapper		**String**	Lookup and use the existing ObjectMapper with the given id when using Jackson.

Name	Default	Java Type	Description
useDefaultObjectMapper		Boolean	Whether to lookup and use default Jackson ObjectMapper from the registry.
unmarshalType		String	Class name of the java type to use when unmarshalling.
jsonView		String	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations.
include		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL.
allowJmsType		Boolean	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
collectionType		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.
useList		Boolean	To unmarshal to a List of Map or a List of Pojo.
moduleClassNames		String	To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.
moduleRefs		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
enableFeatures		String	Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma.

Name	Default	Java Type	Description
disableFeatures		String	Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma.
allowUnmarshallType		Boolean	If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.
timezone		String	If set then Jackson will use the Timezone when marshalling/unmarshalling.
autoDiscoverObjectMapper		Boolean	If set to true then Jackson will lookup for an objectMapper into the registry.
schemaResolver		String	Optional schema resolver used to lookup schemas for the data in transit.
autoDiscoverSchemaResolver		Boolean	When not disabled, the SchemaResolver will be looked up into the registry.

104.4. USING CUSTOM PROTOBUFMAPPER

You can configure **JacksonProtobufDataFormat** to use a custom **ProtobufMapper** in case you need more control of the mapping configuration.

If you setup a single **ProtobufMapper** in the registry, then Camel will automatic lookup and use this **ProtobufMapper**.

104.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 19 options, which are listed below.

Name	Description	Default	Type
camel.dataformat.protobuf-jackson.allow-jms-type	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean

Name	Description	Default	Type
camel.dataformat.protobuf-jackson.allow-unmarshall-type	If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean
camel.dataformat.protobuf-jackson.auto-discover-object-mapper	If set to true then Jackson will lookup for an objectMapper into the registry.	false	Boolean
camel.dataformat.protobuf-jackson.auto-discover-schema-resolver	When not disabled, the SchemaResolver will be looked up into the registry.	true	Boolean
camel.dataformat.protobuf-jackson.collection-type	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.		String
camel.dataformat.protobuf-jackson.content-type-header	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.	true	Boolean
camel.dataformat.protobuf-jackson.disable-features	Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma.		String
camel.dataformat.protobuf-jackson.enable-features	Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma.		String
camel.dataformat.protobuf-jackson.enabled	Whether to enable auto configuration of the protobuf-jackson data format. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.dataformat.protobuf-jackson.include	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL.		String
camel.dataformat.protobuf-jackson.json-view	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations.		String
camel.dataformat.protobuf-jackson.module-class-names	To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.		String
camel.dataformat.protobuf-jackson.module-refs	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
camel.dataformat.protobuf-jackson.object-mapper	Lookup and use the existing ObjectMapper with the given id when using Jackson.		String
camel.dataformat.protobuf-jackson.schema-resolver	Optional schema resolver used to lookup schemas for the data in transit.		String
camel.dataformat.protobuf-jackson.timezone	If set then Jackson will use the Timezone when marshalling/unmarshalling.		String
camel.dataformat.protobuf-jackson.unmarshal-type	Class name of the java type to use when unmarshalling.		String
camel.dataformat.protobuf-jackson.use-default-object-mapper	Whether to lookup and use default Jackson ObjectMapper from the registry.	true	Boolean

Name	Description	Default	Type
camel.dataformat.protobuf-jackson.use-list	To unmarshal to a List of Map or a List of Pojo.	false	Boolean

CHAPTER 105. QUARTZ

Only consumer is supported

The Quartz component provides a scheduled delivery of messages using the Quartz Scheduler 2.x. Each endpoint represents a different timer (in Quartz terms, a Trigger and JobDetail).

105.1. DEPENDENCIES

When using **quartz** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-quartz-starter</artifactId>
</dependency>
```

105.2. URI FORMAT

```
quartz://timerName?options
quartz://groupName/timerName?options
quartz://groupName/timerName?cron=expression
quartz://timerName?cron=expression
```

The component uses either a **CronTrigger** or a **SimpleTrigger**. If no cron expression is provided, the component uses a simple trigger. If no **groupName** is provided, the quartz component uses the **Camel** group name.

105.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

105.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

105.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

105.4. COMPONENT OPTIONS

The Quartz component supports 13 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
enableJmx (consumer)	Whether to enable Quartz JMX which allows to manage the Quartz scheduler from JMX. This options is default true.	true	boolean
prefixInstanceName (consumer)	Whether to prefix the Quartz Scheduler instance name with the CamelContext name. This is enabled by default, to let each CamelContext use its own Quartz scheduler instance by default. You can set this option to false to reuse Quartz scheduler instances between multiple CamelContext's.	true	boolean
prefixJobNameWithEndpointId (consumer)	Whether to prefix the quartz job with the endpoint id. This option is default false.	false	boolean
properties (consumer)	Properties to configure the Quartz scheduler.		Map
propertiesFile (consumer)	File name of the properties to load from the classpath.		String
propertiesRef (consumer)	References to an existing Properties or Map to lookup in the registry to use for configuring quartz.		String

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
scheduler (advanced)	To use the custom configured Quartz scheduler, instead of creating a new Scheduler.		Scheduler
schedulerFactory (advanced)	To use the custom SchedulerFactory which is used to create the Scheduler.		SchedulerFactory
autoStartScheduler (scheduler)	Whether or not the scheduler should be auto started. This options is default true.	true	boolean
interruptJobsOnShutdown (scheduler)	Whether to interrupt jobs on shutdown which forces the scheduler to shutdown quicker and attempt to interrupt any running jobs. If this is enabled then any running jobs can fail due to being interrupted. When a job is interrupted then Camel will mark the exchange to stop continue routing and set java.util.concurrent.RejectedExecutionException as caused exception. Therefore use this with care, as its often better to allow Camel jobs to complete and shutdown gracefully.	false	boolean
startDelayedSeconds (scheduler)	Seconds to wait before starting the quartz scheduler.		int

105.5. ENDPOINT OPTIONS

The Quartz endpoint is configured using URI syntax:

```
quartz:groupName/triggerName
```

with the following path and query parameters:

105.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
groupName (consumer)	The quartz group name to use. The combination of group name and trigger name should be unique.	Camel	String
triggerName (consumer)	**Required** The quartz trigger name to use. The combination of group name and trigger name should be unique.		String

105.5.2. Query Parameters (17 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
cron (consumer)	Specifies a cron expression to define when to trigger.		String
deleteJob (consumer)	If set to true, then the trigger automatically delete when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both deleteJob and pauseJob set to true.	true	boolean
durableJob (consumer)	Whether or not the job should remain stored after it is orphaned (no triggers point to it).	false	boolean
pauseJob (consumer)	If set to true, then the trigger automatically pauses when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both deleteJob and pauseJob set to true.	false	boolean
recoverableJob (consumer)	Instructs the scheduler whether or not the job should be re-executed if a 'recovery' or 'fail-over' situation is encountered.	false	boolean

Name	Description	Default	Type
stateful (consumer)	Uses a Quartz PersistJobDataAfterExecution and DisallowConcurrentExecution instead of the default job.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
customCalendar (advanced)	Specifies a custom calendar to avoid specific range of date.		Calendar
jobParameters (advanced)	To configure additional options on the job.		Map
prefixJobNameWithEndpointId (advanced)	Whether the job name should be prefixed with endpoint id.	false	boolean
triggerParameters (advanced)	To configure additional options on the trigger.		Map
usingFixedCamelContextName (advanced)	If it is true, JobDataMap uses the CamelContext name directly to reference the CamelContext, if it is false, JobDataMap uses use the CamelContext management name which could be changed during the deploy time.	false	boolean
autoStartScheduler (scheduler)	Whether or not the scheduler should be auto started.	true	boolean
startDelayedSeconds (scheduler)	Seconds to wait before starting the quartz scheduler.		int

Name	Description	Default	Type
triggerStartDelay (scheduler)	In case of scheduler has already started, we want the trigger start slightly after current time to ensure endpoint is fully started before the job kicks in. Negative value shifts trigger start time in the past.	500	long

105.5.3. Configuring quartz.properties file

By default Quartz will look for a **quartz.properties** file in the **org/quartz** directory of the classpath. If you are using WAR deployments this means just drop the quartz.properties in **WEB-INF/classes/org/quartz**.

However the Camel Quartz component also allows you to configure properties:

Parameter	Default	Type	Description
properties	**null**	**Properties**	You can configure a **java.util.Properties** instance.
propertiesFile	**null**	**String**	File name of the properties to load from the classpath

To do this you can configure this in Spring XML as follows

```
<bean id="quartz" class="org.apache.camel.component.quartz.QuartzComponent">
    <property name="propertiesFile" value="com/mycompany/myquartz.properties"/>
</bean>
```

105.6. ENABLING QUARTZ SCHEDULER IN JMX

You need to configure the quartz scheduler properties to enable JMX.
That is typically setting the option **"org.quartz.scheduler.jmx.export"** to a **true** value in the configuration file.

This option is set to true by default, unless explicitly disabled.

105.7. STARTING THE QUARTZ SCHEDULER

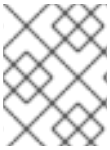
The Quartz component offers an option to let the Quartz scheduler be started delayed, or not auto started at all.

This is an example:

```
<bean id="quartz" class="org.apache.camel.component.quartz.QuartzComponent">
    <property name="startDelayedSeconds" value="5"/>
</bean>
```

105.8. CLUSTERING

If you use Quartz in clustered mode, e.g. the **JobStore** is clustered. Then the Quartz component will not pause/remove triggers when a node is being stopped/shutdown. This allows the trigger to keep running on the other nodes in the cluster.



NOTE

When running in clustered node no checking is done to ensure unique job name/group for endpoints.

105.9. MESSAGE HEADERS

Camel adds the getters from the Quartz Execution Context as header values. The following headers are added:
calendar, **fireTime**, **jobDetail**, **jobInstance**, **jobRuntTime**, **mergedJobDataMap**, **nextFireTime**, **previousFireTime**, **refireCount**, **result**, **scheduledFireTime**, **scheduler**, **trigger**, **triggerName**, **triggerGroup**.

The **fireTime** header contains the **java.util.Date** of when the exchange was fired.

105.10. USING CRON TRIGGERS

Quartz supports Cron-like expressions for specifying timers in a handy format. You can use these expressions in the **cron** URI parameter; though to preserve valid URI encoding we allow **+** to be used instead of spaces.

For example, the following will fire a message every five minutes starting at 12pm (noon) to 6pm on weekdays:

```
from("quartz://myGroup/myTimerName?cron=0+0/5+12-18+?+*+MON-FRI")
    .to("activemq:Totally.Rocks");
```

which is equivalent to using the cron expression

```
0 0/5 12-18 ? * MON-FRI
```

The following table shows the URI character encodings we use to preserve valid URI syntax:

URI Character	Cron character
+	*Space*

105.11. SPECIFYING TIME ZONE

The Quartz Scheduler allows you to configure time zone per trigger. For example to use a timezone of your country, then you can do as follows:

```
quartz://groupName/timerName?cron=0+0/5+12-18+?+*+MON-
FRI&trigger.timeZone=Europe/Stockholm
```

The timeZone value is the values accepted by **java.util.TimeZone**.

105.12. CONFIGURING MISFIRE INSTRUCTIONS

The quartz scheduler can be configured with a misfire instruction to handle misfire situations for the trigger. The concrete trigger type that you are using will have defined a set of additional **MISFIRE_INSTRUCTION_XXX** constants that may be set as this property's value.

For example to configure the simple trigger to use misfire instruction 4:

```
quartz://myGroup/myTimerName?trigger.repeatInterval=2000&trigger.misfireInstruction=4
```

And likewise you can configure the cron trigger with one of its misfire instructions as well:

```
quartz://myGroup/myTimerName?cron=0/2+*+*+*+*+?&trigger.misfireInstruction=2
```

The simple and cron triggers has the following misfire instructions representative:

105.12.1. SimpleTrigger.MISFIRE_INSTRUCTION_FIRE_NOW = 1 (default)

Instructs the Scheduler that upon a mis-fire situation, the SimpleTrigger wants to be fired now by Scheduler.

This instruction should typically only be used for 'one-shot' (non-repeating) Triggers. If it is used on a trigger with a repeat count > 0 then it is equivalent to the instruction MISFIRE_INSTRUCTION_RESCHEDULE_NOW_WITH_REMAINING_REPEAT_COUNT.

105.12.2. SimpleTrigger.MISFIRE_INSTRUCTION_RESCHEDULE_NOW_WITH_EXISTIN = 2

Instructs the Scheduler that upon a mis-fire situation, the SimpleTrigger wants to be re-scheduled to 'now' (even if the associated Calendar excludes 'now') with the repeat count left as-is. This does obey the Trigger end-time however, so if 'now' is after the end-time the Trigger will not fire again.

Use of this instruction causes the trigger to 'forget' the start-time and repeat-count that it was originally setup with (this is only an issue if you for some reason wanted to be able to tell what the original values were at some later time).

105.12.3. SimpleTrigger.MISFIRE_INSTRUCTION_RESCHEDULE_NOW_WITH_REMAIN = 3

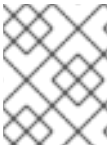
Instructs the Scheduler that upon a mis-fire situation, the SimpleTrigger wants to be re-scheduled to 'now' (even if the associated Calendar excludes 'now') with the repeat count set to what it would be, if it had not missed any firings. This does obey the Trigger end-time however, so if 'now' is after the end-time the Trigger will not fire again.

Use of this instruction causes the trigger to 'forget' the start-time and repeat-count that it was originally setup with. Instead, the repeat count on the trigger will be changed to whatever the remaining repeat count is (this is only an issue if you for some reason wanted to be able to tell what the original values were at some later time).

This instruction could cause the Trigger to go to the 'COMPLETE' state after firing 'now', if all the repeat-fire-times where missed.

105.12.4. SimpleTrigger.MISFIRE_INSTRUCTION_RESCHEDULE_NEXT_WITH_REMAIN = 4

Instructs the Scheduler that upon a mis-fire situation, the SimpleTrigger wants to be re-scheduled to the next scheduled time after 'now' - taking into account any associated Calendar and with the repeat count set to what it would be, if it had not missed any firings.

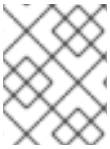


NOTE

This instruction could cause the Trigger to go directly to the 'COMPLETE' state if all fire-times where missed.

105.12.5. SimpleTrigger.MISFIRE_INSTRUCTION_RESCHEDULE_NEXT_WITH_EXISTIN = 5

Instructs the Scheduler that upon a mis-fire situation, the SimpleTrigger wants to be re-scheduled to the next scheduled time after 'now' - taking into account any associated Calendar, and with the repeat count left unchanged.



NOTE

This instruction could cause the Trigger to go directly to the 'COMPLETE' state if the end-time of the trigger has arrived.

105.12.6. CronTrigger.MISFIRE_INSTRUCTION_FIRE_ONCE_NOW = 1 (default)

Instructs the Scheduler that upon a mis-fire situation, the CronTrigger wants to be fired now by Scheduler.

105.12.7. CronTrigger.MISFIRE_INSTRUCTION_DO_NOTHING = 2

Instructs the Scheduler that upon a mis-fire situation, the CronTrigger wants to have it's next-fire-time updated to the next time in the schedule after the current time (taking into account any associated Calendar but it does not want to be fired now.

105.13. USING QUARTZSCHEDULEDPOLLCONSUMERSCHEDULER

The Quartz component provides a Polling Consumer scheduler which allows to use cron based scheduling for Polling Consumer such as the File and FTP consumers.

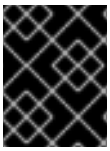
For example to use a cron based expression to poll for files every 2nd second, then a Camel route can be define simply as:

```
from("file:inbox?scheduler=quartz&scheduler.cron=0/2+*+*+*+*+?")
  .to("bean:process");
```

Notice we define the **scheduler=quartz** to instruct Camel to use the Quartz based scheduler. Then we use **scheduler.xxx** options to configure the scheduler. The Quartz scheduler requires the cron option to be set.

The following options is supported:

Parameter	Default	Type	Description
quartzScheduler	**null**	**org.quartz.Scheduler**	To use a custom Quartz scheduler. If none configure then the shared scheduler from the component is used.
cron	**null**	**String**	**Mandatory**: To define the cron expression for triggering the polls.
triggerId	**null**	**String**	To specify the trigger id. If none provided then an UUID is generated and used.
triggerGroup	**QuartzScheduledPollConsumerScheduler**	**String**	To specify the trigger group.
timeZone	**Default**	**TimeZone**	The time zone to use for the CRON trigger.



IMPORTANT

Remember configuring these options from the endpoint URIs must be prefixed with **scheduler**.

For example to configure the trigger id and group:

```
    from("file:inbox?scheduler=quartz&scheduler.cron=0/2+*+*+*+*+?
&scheduler.triggerId=myId&scheduler.triggerGroup=myGroup")
        .to("bean:process");
```

There is also a CRON scheduler in Spring, so you can use the following as well:

```
    from("file:inbox?scheduler=spring&scheduler.cron=0/2+*+*+*+*+?")
        .to("bean:process");
```

105.14. CRON COMPONENT SUPPORT

The Quartz component can be used as implementation of the Camel Cron component.

Maven users will need to add the following additional dependency to their **pom.xml**:

```
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-cron</artifactId>
```

```
    <version>{CamelSBVersion}</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

Users can then use the cron component instead of the quartz component, as in the following route:

```
from("cron://name?schedule=0+0/5+12-18+?+*+MON-FRI")
.to("activemq:Totally.Rocks");
```

105.15. SPRING BOOT AUTO-CONFIGURATION

The component supports 14 options, which are listed below.

Name	Description	Default	Type
camel.component.quartz.auto-start-scheduler	Whether or not the scheduler should be auto started. This options is default true.	true	Boolean
camel.component.quartz.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.quartz.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.quartz.enable-jmx	Whether to enable Quartz JMX which allows to manage the Quartz scheduler from JMX. This options is default true.	true	Boolean
camel.component.quartz.enabled	Whether to enable auto configuration of the quartz component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.quartz.interrupt-jobs-on-shutdown	Whether to interrupt jobs on shutdown which forces the scheduler to shutdown quicker and attempt to interrupt any running jobs. If this is enabled then any running jobs can fail due to being interrupted. When a job is interrupted then Camel will mark the exchange to stop continue routing and set java.util.concurrent.RejectedExecutionException as caused exception. Therefore use this with care, as its often better to allow Camel jobs to complete and shutdown gracefully.	false	Boolean
camel.component.quartz.prefix-instance-name	Whether to prefix the Quartz Scheduler instance name with the CamelContext name. This is enabled by default, to let each CamelContext use its own Quartz scheduler instance by default. You can set this option to false to reuse Quartz scheduler instances between multiple CamelContext's.	true	Boolean
camel.component.quartz.prefix-job-name-with-endpoint-id	Whether to prefix the quartz job with the endpoint id. This option is default false.	false	Boolean
camel.component.quartz.properties	Properties to configure the Quartz scheduler.		Map
camel.component.quartz.properties-file	File name of the properties to load from the classpath.		String
camel.component.quartz.properties-ref	References to an existing Properties or Map to lookup in the registry to use for configuring quartz.		String
camel.component.quartz.scheduler	To use the custom configured Quartz scheduler, instead of creating a new Scheduler. The option is a org.quartz.Scheduler type.		Scheduler
camel.component.quartz.scheduler-factory	To use the custom SchedulerFactory which is used to create the Scheduler. The option is a org.quartz.SchedulerFactory type.		SchedulerFactory
camel.component.quartz.start-delayed-seconds	Seconds to wait before starting the quartz scheduler.		Integer

CHAPTER 106. REF

Both producer and consumer are supported

The Ref component is used for lookup of existing endpoints bound in the Registry.

106.1. DEPENDENCIES

When using **ref** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-ref-starter</artifactId>
</dependency>
```

106.2. URI FORMAT

```
ref:someName[?options]
```

Where **someName** is the name of an endpoint in the Registry (usually, but not always, the Spring registry). If you are using the Spring registry, **someName** would be the bean ID of an endpoint in the Spring registry.

106.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

106.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

106.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

106.4. COMPONENT OPTIONS

The Ref component supports 3 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

106.5. ENDPOINT OPTIONS

The Ref endpoint is configured using URI syntax:

```
ref:name
```

with the following path and query parameters:

106.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (common)	**Required** Name of endpoint to lookup in the registry.		String

106.5.2. Query Parameters (4 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

106.6. RUNTIME LOOKUP

This component can be used when you need dynamic discovery of endpoints in the Registry where you can compute the URI at runtime. Then you can look up the endpoint using the following code:

```
// lookup the endpoint
String myEndpointRef = "bigspenderOrder";
Endpoint endpoint = context.getEndpoint("ref:" + myEndpointRef);

Producer producer = endpoint.createProducer();
Exchange exchange = producer.createExchange();
exchange.getIn().setBody(payloadToSend);
// send the exchange
producer.process(exchange);
```

And you could have a list of endpoints defined in the Registry such as:

```
<camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring">
    <endpoint id="normalOrder" uri="activemq:order.slow"/>
    <endpoint id="bigspenderOrder" uri="activemq:order.high"/>
</camelContext>
```

106.7. SAMPLE

In the sample below we use the **ref:** in the URI to reference the endpoint with the spring ID, **endpoint2**:

You could, of course, have used the **ref** attribute instead:

```
<to uri="ref:endpoint2"/>
```

Which is the more common way to write it.

106.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.ref.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.ref.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.ref.enabled	Whether to enable auto configuration of the ref component. This is enabled by default.		Boolean
camel.component.ref.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 107. REF

The Ref Expression Language is really just a way to lookup a custom **Expression** or **Predicate** from the Registry.

This is particular usable in XML DSLs.

107.1. DEPENDENCIES

The Ref language is part of **camel-core**. When using **ref** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-core-starter</artifactId>
</dependency>
```

107.2. REF LANGUAGE OPTIONS

The Ref language supports 1 options, which are listed below.

Name	Default	Java Type	Description
trim		**Boolean**	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

107.3. EXAMPLE USAGE

The Splitter EIP in XML DSL can utilize a custom expression using **<ref>** like:

```
<bean id="myExpression" class="com.mycompany.MyCustomExpression"/>

<route>
  <from uri="seda:a"/>
  <split>
    <ref>myExpression</ref>
    <to uri="mock:b"/>
  </split>
</route>
```

in this case, the message coming from the seda:a endpoint will be splitted using a custom **Expression** which has the id **myExpression** in the Registry.

And the same example using Java DSL:

```
from("seda:a").split().ref("myExpression").to("seda:b");
```

107.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 147 options, which are listed below.

Name	Description	Default	Type
camel.cloud.consul.service-discovery.acl-token	Sets the ACL token to be used with Consul.		String
camel.cloud.consul.service-discovery.block-seconds	The seconds to wait for a watch event, default 10 seconds.	10	Integer
camel.cloud.consul.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.consul.service-discovery.connect-timeout-millis	Connect timeout for OkHttpClient.		Long
camel.cloud.consul.service-discovery.datacenter	The data center.		String
camel.cloud.consul.service-discovery.enabled	Enable the component.	true	Boolean
camel.cloud.consul.service-discovery.password	Sets the password to be used for basic authentication.		String
camel.cloud.consul.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.consul.service-discovery.read-timeout-millis	Read timeout for OkHttpClient.		Long

Name	Description	Default	Type
camel.cloud.consul.service-discovery.url	The Consul agent URL.		String
camel.cloud.consul.service-discovery.user-name	Sets the username to be used for basic authentication.		String
camel.cloud.consul.service-discovery.write-timeout-millis	Write timeout for OkHttpClient.		Long
camel.cloud.dns.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.dns.service-discovery.domain	The domain name;.		String
camel.cloud.dns.service-discovery.enabled	Enable the component.	true	Boolean
camel.cloud.dns.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.dns.service-discovery.proto	The transport protocol of the desired service.	_tcp	String
camel.cloud.etcd.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.etcd.service-discovery.enabled	Enable the component.	true	Boolean

Name	Description	Default	Type
camel.cloud.etcd.service-discovery.password	The password to use for basic authentication.		String
camel.cloud.etcd.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.etcd.service-discovery.service-path	The path to look for for service discovery.	/services/	String
camel.cloud.etcd.service-discovery.timeout	To set the maximum time an action could take to complete.		Long
camel.cloud.etcd.service-discovery.type	To set the discovery type, valid values are on-demand and watch.	on-demand	String
camel.cloud.etcd.service-discovery.uris	The URIs the client can connect to.		String
camel.cloud.etcd.service-discovery.user-name	The user name to use for basic authentication.		String
camel.cloud.kubernetes.service-discovery.api-version	Sets the API version when using client lookup.		String
camel.cloud.kubernetes.service-discovery.ca-cert-data	Sets the Certificate Authority data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.ca-cert-file	Sets the Certificate Authority data that are loaded from the file when using client lookup.		String

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.client-cert-data	Sets the Client Certificate data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-cert-file	Sets the Client Certificate data that are loaded from the file when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-algo	Sets the Client Keystore algorithm, such as RSA when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-data	Sets the Client Keystore data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-file	Sets the Client Keystore data that are loaded from the file when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-passphrase	Sets the Client Keystore passphrase when using client lookup.		String
camel.cloud.kubernetes.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.kubernetes.service-discovery.dns-domain	Sets the DNS domain to use for DNS lookup.		String
camel.cloud.kubernetes.service-discovery.enabled	Enable the component.	true	Boolean

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.lookup	How to perform service lookup. Possible values: client, dns, environment. When using client, then the client queries the kubernetes master to obtain a list of active pods that provides the service, and then random (or round robin) select a pod. When using dns the service name is resolved as name.namespace.svc.dnsDomain. When using dnssrv the service name is resolved with SRV query for .... svc... When using environment then environment variables are used to lookup the service. By default environment is used.	environment	String
camel.cloud.kubernetes.service-discovery.master-url	Sets the URL to the master when using client lookup.		String
camel.cloud.kubernetes.service-discovery.namespace	Sets the namespace to use. Will by default use namespace from the ENV variable KUBERNETES_MASTER.		String
camel.cloud.kubernetes.service-discovery.oauth-token	Sets the OAUTH token for authentication (instead of username/password) when using client lookup.		String
camel.cloud.kubernetes.service-discovery.password	Sets the password for authentication when using client lookup.		String
camel.cloud.kubernetes.service-discovery.port-name	Sets the Port Name to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.port-protocol	Sets the Port Protocol to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.trust-certs	Sets whether to turn on trust certificate check when using client lookup.	false	Boolean
camel.cloud.kubernetes.service-discovery.username	Sets the username for authentication when using client lookup.		String
camel.cloud.ribbon.load-balancer.client-name	Sets the Ribbon client name.		String
camel.cloud.ribbon.load-balancer.configurations	Define additional configuration definitions.		Map
camel.cloud.ribbon.load-balancer.enabled	Enable the component.	true	Boolean
camel.cloud.ribbon.load-balancer.namespace	The namespace.		String
camel.cloud.ribbon.load-balancer.password	The password.		String
camel.cloud.ribbon.load-balancer.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.ribbon.load-balancer.username	The username.		String

Name	Description	Default	Type
camel.hystrix.allow-maximum-size-to-diverge-from-core-size	Allows the configuration for maximumSize to take effect. That value can then be equal to, or higher, than coreSize.	false	Boolean
camel.hystrix.circuit-breaker-enabled	Whether to use a HystrixCircuitBreaker or not. If false no circuit-breaker logic will be used and all requests permitted. This is similar in effect to circuitBreakerForceClosed() except that continues tracking metrics and knowing whether it should be open/closed, this property results in not even instantiating a circuit-breaker.	true	Boolean
camel.hystrix.circuit-breaker-error-threshold-percentage	Error percentage threshold (as whole number such as 50) at which point the circuit breaker will trip open and reject requests. It will stay tripped for the duration defined in circuitBreakerSleepWindowInMilliseconds; The error percentage this is compared against comes from HystrixCommandMetrics.getHealthCounts().	50	Integer
camel.hystrix.circuit-breaker-force-closed	If true the HystrixCircuitBreaker#allowRequest() will always return true to allow requests regardless of the error percentage from HystrixCommandMetrics.getHealthCounts(). The circuitBreakerForceOpen() property takes precedence so if it set to true this property does nothing.	false	Boolean
camel.hystrix.circuit-breaker-force-open	If true the HystrixCircuitBreaker.allowRequest() will always return false, causing the circuit to be open (tripped) and reject all requests. This property takes precedence over circuitBreakerForceClosed();.	false	Boolean
camel.hystrix.circuit-breaker-request-volume-threshold	Minimum number of requests in the metricsRollingStatisticalWindowInMilliseconds() that must exist before the HystrixCircuitBreaker will trip. If below this number the circuit will not trip regardless of error percentage.	20	Integer
camel.hystrix.circuit-breaker-sleep-window-in-milliseconds	The time in milliseconds after a HystrixCircuitBreaker trips open that it should wait before trying requests again.	5000	Integer
camel.hystrix.configurations	Define additional configuration definitions.		Map

Name	Description	Default	Type
camel.hystrix.core-pool-size	Core thread-pool size that gets passed to java.util.concurrent.ThreadPoolExecutor#setCorePoolSize(int).	10	Integer
camel.hystrix.enabled	Enable the component.	true	Boolean
camel.hystrix.execution-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to HystrixCommand.run(). Requests beyond the concurrent limit will be rejected. Applicable only when executionIsolationStrategy == SEMAPHORE.	20	Integer
camel.hystrix.execution-isolation-strategy	What isolation strategy HystrixCommand.run() will be executed with. If THREAD then it will be executed on a separate thread and concurrent requests limited by the number of threads in the thread-pool. If SEMAPHORE then it will be executed on the calling thread and concurrent requests limited by the semaphore count.	THREAD	String
camel.hystrix.execution-isolation-thread-interrupt-on-timeout	Whether the execution thread should attempt an interrupt (using Future#cancel) when a thread times out. Applicable only when executionIsolationStrategy() == THREAD.	true	Boolean
camel.hystrix.execution-timeout-enabled	Whether the timeout mechanism is enabled for this command.	true	Boolean
camel.hystrix.execution-timeout-in-milliseconds	Time in milliseconds at which point the command will timeout and halt execution. If executionIsolationThreadInterruptOnTimeout == true and the command is thread-isolated, the executing thread will be interrupted. If the command is semaphore-isolated and a HystrixObservableCommand, that command will get unsubscribed.	1000	Integer
camel.hystrix.fallback-enabled	Whether HystrixCommand.getFallback() should be attempted when failure occurs.	true	Boolean
camel.hystrix.fallback-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to HystrixCommand.getFallback(). Requests beyond the concurrent limit will fail-fast and not attempt retrieving a fallback.	10	Integer

Name	Description	Default	Type
camel.hystrix.group-key	Sets the group key to use. The default value is CamelHystrix.	Camel Hystrix	String
camel.hystrix.keep-alive-time	Keep-alive time in minutes that gets passed to ThreadPoolExecutor#setKeepAliveTime(long,TimeUnit).	1	Integer
camel.hystrix.max-queue-size	Max queue size that gets passed to BlockingQueue in HystrixConcurrencyStrategy.getBlockingQueue(int) This should only affect the instantiation of a threadpool - it is not eliglible to change a queue size on the fly. For that, use queueSizeRejectionThreshold().	-1	Integer
camel.hystrix.maximum-size	Maximum thread-pool size that gets passed to ThreadPoolExecutor#setMaximumPoolSize(int) . This is the maximum amount of concurrency that can be supported without starting to reject HystrixCommands. Please note that this setting only takes effect if you also set allowMaximumSizeToDivergeFromCoreSize.	10	Integer
camel.hystrix.metrics-health-snapshot-interval-in-milliseconds	Time in milliseconds to wait between allowing health snapshots to be taken that calculate success and error percentages and affect HystrixCircuitBreaker.isOpen() status. On high-volume circuits the continual calculation of error percentage can become CPU intensive thus this controls how often it is calculated.	500	Integer
camel.hystrix.metrics-rolling-percentile-bucket-size	Maximum number of values stored in each bucket of the rolling percentile. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-percentile-enabled	Whether percentile metrics should be captured using HystrixRollingPercentile inside HystrixCommandMetrics.	true	Boolean
camel.hystrix.metrics-rolling-percentile-window-buckets	Number of buckets the rolling percentile window is broken into. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	6	Integer

Name	Description	Default	Type
camel.hystrix.metrics-rolling-percentile-window-in-milliseconds	Duration of percentile rolling window in milliseconds. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10000	Integer
camel.hystrix.metrics-rolling-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-statistical-window-in-milliseconds	This property sets the duration of the statistical rolling window, in milliseconds. This is how long metrics are kept for the thread pool. The window is divided into buckets and rolls by those increments.	10000	Integer
camel.hystrix.queue-size-rejection-threshold	Queue size rejection threshold is an artificial max size at which rejections will occur even if maxQueueSize has not been reached. This is done because the maxQueueSize of a BlockingQueue can not be dynamically changed and we want to support dynamically changing the queue size that affects rejections. This is used by HystrixCommand when queuing a thread for execution.	5	Integer
camel.hystrix.request-log-enabled	Whether HystrixCommand execution and events should be logged to HystrixRequestLog.	true	Boolean
camel.hystrix.thread-pool-key	Sets the thread pool key to use. Will by default use the same value as groupKey has been configured to use.	Camel Hystrix	String
camel.hystrix.thread-pool-rolling-number-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10	Integer
camel.hystrix.thread-pool-rolling-number-statistical-window-in-milliseconds	Duration of statistical rolling window in milliseconds. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10000	Integer
camel.language.constant.enabled	Whether to enable auto configuration of the constant language. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.language.constant.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.csimple.enabled	Whether to enable auto configuration of the csimple language. This is enabled by default.		Boolean
camel.language.csimple.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.exchangeproperty.enabled	Whether to enable auto configuration of the exchangeProperty language. This is enabled by default.		Boolean
camel.language.exchangeproperty.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.file.enabled	Whether to enable auto configuration of the file language. This is enabled by default.		Boolean
camel.language.file.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.header.enabled	Whether to enable auto configuration of the header language. This is enabled by default.		Boolean
camel.language.header.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.ref.enabled	Whether to enable auto configuration of the ref language. This is enabled by default.		Boolean
camel.language.ref.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.simple.enabled	Whether to enable auto configuration of the simple language. This is enabled by default.		Boolean
camel.language.simple.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.tokenize.enabled	Whether to enable auto configuration of the tokenize language. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.language.tokenize.group-delimiter	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.		String
camel.language.tokenize.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.resilience4j.automatic-transition-from-open-to-half-open-enabled	Enables automatic transition from OPEN to HALF_OPEN state once the waitDurationInOpenState has passed.	false	Boolean
camel.resilience4j.circuit-breaker-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreaker instance to lookup and use from the registry. When using this, then any other circuit breaker options are not in use.		String
camel.resilience4j.config-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreakerConfig instance to lookup and use from the registry.		String
camel.resilience4j.configurations	Define additional configuration definitions.		Map
camel.resilience4j.enabled	Enable the component.	true	Boolean
camel.resilience4j.failure-rate-threshold	Configures the failure rate threshold in percentage. If the failure rate is equal or greater than the threshold the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 50 percentage.		Float
camel.resilience4j.minimum-number-of-calls	Configures the minimum number of calls which are required (per sliding window period) before the CircuitBreaker can calculate the error rate. For example, if minimumNumberOfCalls is 10, then at least 10 calls must be recorded, before the failure rate can be calculated. If only 9 calls have been recorded the CircuitBreaker will not transition to open even if all 9 calls have failed. Default minimumNumberOfCalls is 100.	100	Integer

Name	Description	Default	Type
camel.resilience4j.permitted-number-of-calls-in-half-open-state	Configures the number of permitted calls when the CircuitBreaker is half open. The size must be greater than 0. Default size is 10.	10	Integer
camel.resilience4j.sliding-window-size	Configures the size of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. slidingWindowSize configures the size of the sliding window. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. The slidingWindowSize must be greater than 0. The minimumNumberOfCalls must be greater than 0. If the slidingWindowType is COUNT_BASED, the minimumNumberOfCalls cannot be greater than slidingWindowSize . If the slidingWindowType is TIME_BASED, you can pick whatever you want. Default slidingWindowSize is 100.	100	Integer
camel.resilience4j.sliding-window-type	Configures the type of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. Default slidingWindowType is COUNT_BASED.	COUNT_BASED	String
camel.resilience4j.slow-call-duration-threshold	Configures the duration threshold (seconds) above which calls are considered as slow and increase the slow calls percentage. Default value is 60 seconds.	60	Integer
camel.resilience4j.slow-call-rate-threshold	Configures a threshold in percentage. The CircuitBreaker considers a call as slow when the call duration is greater than slowCallDurationThreshold Duration. When the percentage of slow calls is equal or greater the threshold, the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 100 percentage which means that all recorded calls must be slower than slowCallDurationThreshold.		Float

Name	Description	Default	Type
camel.resilience4j.wait-duration-in-open-state	Configures the wait duration (in seconds) which specifies how long the CircuitBreaker should stay open, before it switches to half open. Default value is 60 seconds.	60	Integer
camel.resilience4j.writable-stack-trace-enabled	Enables writable stack traces. When set to false, Exception.getStackTrace returns a zero length array. This may be used to reduce log spam when the circuit breaker is open as the cause of the exceptions is already known (the circuit breaker is short-circuiting calls).	true	Boolean
camel.rest.api-component	The name of the Camel component to use as the REST API (such as swagger) If no API Component has been explicit configured, then Camel will lookup if there is a Camel component responsible for servicing and generating the REST API documentation, or if a org.apache.camel.spi.RestApiProcessorFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.api-context-path	Sets a leading API context-path the REST API services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path.		String
camel.rest.api-context-route-id	Sets the route id to use for the route that services the REST API. The route will by default use an auto assigned route id.		String
camel.rest.api-host	To use an specific hostname for the API documentation (eg swagger) This can be used to override the generated host with this configured hostname.		String
camel.rest.api-property	Allows to configure as many additional properties for the api documentation (swagger). For example set property api.title to my cool stuff.		Map
camel.rest.api-vendor-extension	Whether vendor extension is enabled in the Rest APIs. If enabled then Camel will include additional information as vendor extension (eg keys starting with x-) such as route ids, class names etc. Not all 3rd party API gateways and tools supports vendor-extensions when importing your API docs.	false	Boolean

Name	Description	Default	Type
camel.rest.binding-mode	Sets the binding mode to use. The default value is off.		RestBindingMode
camel.rest.client-request-validation	Whether to enable validation of the client request to check whether the Content-Type and Accept headers from the client is supported by the Rest-DSL configuration of its consumes/produces settings. This can be turned on, to enable this check. In case of validation error, then HTTP Status codes 415 or 406 is returned. The default value is false.	false	Boolean
camel.rest.component	The Camel Rest component to use for the REST transport (consumer), such as netty-http, jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.component-property	Allows to configure as many additional properties for the rest component in use.		Map
camel.rest.consumer-property	Allows to configure as many additional properties for the rest consumer in use.		Map
camel.rest.context-path	Sets a leading context-path the REST services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path. Or for components such as camel-jetty or camel-netty-http that includes a HTTP server.		String
camel.rest.cors-headers	Allows to configure custom CORS headers.		Map
camel.rest.data-format-property	Allows to configure as many additional properties for the data formats in use. For example set property prettyPrint to true to have json outputted in pretty mode. The properties can be prefixed to denote the option is only for either JSON or XML and for either the IN or the OUT. The prefixes are: json.in. json.out. xml.in. xml.out. For example a key with value xml.out.mustBeJAXBElement is only for the XML data format for the outgoing. A key without a prefix is a common key for all situations.		Map

Name	Description	Default	Type
camel.rest.enable-cors	Whether to enable CORS headers in the HTTP response. The default value is false.	false	Boolean
camel.rest.endpoint-property	Allows to configure as many additional properties for the rest endpoint in use.		Map
camel.rest.host	The hostname to use for exposing the REST service.		String
camel.rest.host-name-resolver	If no hostname has been explicit configured, then this resolver is used to compute the hostname the REST service will be using.		RestHostNameResolver
camel.rest.json-data-format	Name of specific json data format to use. By default json-jackson will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.port	The port number to use for exposing the REST service. Notice if you use servlet component then the port number configured here does not apply, as the port number in use is the actual port number the servlet component is using. eg if using Apache Tomcat its the tomcat http port, if using Apache Karaf its the HTTP service in Karaf that uses port 8181 by default etc. Though in those situations setting the port number here, allows tooling and JMX to know the port number, so its recommended to set the port number to the number that the servlet engine uses.		String
camel.rest.producer-api-doc	Sets the location of the api document (swagger api) the REST producer will use to validate the REST uri and query parameters are valid accordingly to the api document. This requires adding camel-swagger-java to the classpath, and any miss configuration will let Camel fail on startup and report the error(s). The location of the api document is loaded from classpath by default, but you can use file: or http: to refer to resources to load from file or http url.		String
camel.rest.producer-component	Sets the name of the Camel component to use as the REST producer.		String
camel.rest.scheme	The scheme to use for exposing the REST service. Usually http or https is supported. The default value is http.		String

Name	Description	Default	Type
camel.rest.skip-binding-on-error-code	Whether to skip binding on output if there is a custom HTTP error code header. This allows to build custom error messages that do not bind to json / xml etc, as success messages otherwise will do.	false	Boolean
camel.rest.use-x-forward-headers	Whether to use X-Forward headers for Host and related setting. The default value is true.	true	Boolean
camel.rest.xml-data-format	Name of specific XML data format to use. By default jaxb will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.api-context-id-pattern	**Deprecated** Sets an CamelContext id pattern to only allow Rest APIs from rest services within CamelContext's which name matches the pattern. The pattern name refers to the CamelContext name, to match on the current CamelContext only. For any other value, the pattern uses the rules from PatternHelper#matchPattern(String,String).		String
camel.rest.api-context-listing	**Deprecated** Sets whether listing of all available CamelContext's with REST services in the JVM is enabled. If enabled it allows to discover these contexts, if false then only the current CamelContext is in use.	false	Boolean

CHAPTER 108. REST

Both producer and consumer are supported

The REST component allows to define REST endpoints (consumer) using the Rest DSL and plugin to other Camel components as the REST transport.

The rest component can also be used as a client (producer) to call REST services.

108.1. DEPENDENCIES

When using **rest** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-rest-starter</artifactId>
</dependency>
```

108.2. URI FORMAT

```
rest://method:path[:uriTemplate]?[options]
```

108.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

108.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

108.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

108.4. COMPONENT OPTIONS

The REST component supports 8 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumerComponentName (consumer)	The Camel Rest component to use for (consumer) the REST transport, such as jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
apiDoc (producer)	The swagger api doc resource to use. The resource is loaded from classpath by default and must be in JSON format.		String
componentName (producer)	**Deprecated** The Camel Rest component to use for (producer) the REST transport, such as http, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestProducerFactory is registered in the registry. If either one is found, then that is being used.		String
host (producer)	Host and port of HTTP service to use (override host in swagger schema).		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
producerComponentName (producer)	The Camel Rest component to use for (producer) the REST transport, such as http, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestProducerFactory is registered in the registry. If either one is found, then that is being used.		String
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

108.5. ENDPOINT OPTIONS

The REST endpoint is configured using URI syntax:

```
rest:method:path:uriTemplate
```

with the following path and query parameters:

108.5.1. Path Parameters (3 parameters)

Name	Description	Default	Type

Name	Description	Default	Type
method (common)	**Required** HTTP method to use. Enum values: • get • post • put • delete • patch • head • trace • connect • options		String
path (common)	**Required** The base path.		String
uriTemplate (common)	The uri template.		String

108.5.2. Query Parameters (16 parameters)

Name	Description	Default	Type
consumes (common)	Media type such as: 'text/xml', or 'application/json' this REST service accepts. By default we accept all kinds of types.		String
inType (common)	To declare the incoming POJO binding type as a FQN class name.		String
outType (common)	To declare the outgoing POJO binding type as a FQN class name.		String
produces (common)	Media type such as: 'text/xml', or 'application/json' this REST service returns.		String
routeId (common)	Name of the route this REST services creates.		String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumerComponentName (consumer)	The Camel Rest component to use for (consumer) the REST transport, such as jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
description (consumer)	Human description to document this REST service.		String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
apiDoc (producer)	The openapi api doc resource to use. The resource is loaded from classpath by default and must be in JSON format.		String

Name	Description	Default	Type
bindingMode (producer)	Configures the binding mode for the producer. If set to anything other than 'off' the producer will try to convert the body of the incoming message from inType to the json or xml, and the response from json or xml to outType. Enum values: • auto • off • json • xml • json_xml		RestBindingMode
host (producer)	Host and port of HTTP service to use (override host in openapi schema).		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
producerComponentName (producer)	The Camel Rest component to use for (producer) the REST transport, such as http, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestProducerFactory is registered in the registry. If either one is found, then that is being used.		String
queryParameters (producer)	Query parameters for the HTTP service to call. The query parameters can contain multiple parameters separated by ampersand such such as foo=123&bar=456.		String

108.6. SUPPORTED REST COMPONENTS

The following components support rest consumer (Rest DSL):

- camel-servlet
- camel-platform-http

The following components support rest producer:

- camel-http

108.7. PATH AND URITEMPLATE SYNTAX

The path and uriTemplate option is defined using a REST syntax where you define the REST context path using support for parameters.

NOTE

If no uriTemplate is configured then path option works the same way. It does not matter if you configure only path or if you configure both options. Though configuring both a path and uriTemplate is a more common practice with REST.

The following is a Camel route using a path only

```
from("rest:get:hello")
  .transform().constant("Bye World");
```

And the following route uses a parameter which is mapped to a Camel header with the key "me".

```
from("rest:get:hello/{me}")
  .transform().simple("Bye ${header.me}");
```

The following examples have configured a base path as "hello" and then have two REST services configured using uriTemplates.

```
from("rest:get:hello:/{me}")
  .transform().simple("Hi ${header.me}");

from("rest:get:hello:/french/{me}")
  .transform().simple("Bonjour ${header.me}");
```

NOTE

The Rest endpoint path does not accept escaped characters, for example, the **plus** sign. This is default behavior of Apache Camel 3.

108.8. REST PRODUCER EXAMPLES

You can use the rest component to call REST services like any other Camel component.

For example to call a REST service on using **hello/{me}** you can do

```
from("direct:start")
  .to("rest:get:hello/{me}");
```

And then the dynamic value **{me}** is mapped to Camel message with the same name. So to call this REST service you can send an empty message body and a header as shown:

```
template.sendBodyAndHeader("direct:start", null, "me", "Donald Duck");
```

The Rest producer needs to know the hostname and port of the REST service, which you can configure using the host option as shown:

```
from("direct:start")
  .to("rest:get:hello/{me}?host=myserver:8080/foo");
```

Instead of using the host option, you can configure the host on the **restConfiguration** as shown:

```
restConfiguration().host("myserver:8080/foo");

from("direct:start")
  .to("rest:get:hello/{me}");
```

You can use the **producerComponent** to select which Camel component to use as the HTTP client, for example to use http you can do:

```
restConfiguration().host("myserver:8080/foo").producerComponent("http");

from("direct:start")
  .to("rest:get:hello/{me}");
```

108.9. REST PRODUCER BINDING

The REST producer supports binding using JSon or XML like the rest-dsl does.

For example to use jetty with json binding mode turned on you can configure this in the rest configuration:

```
restConfiguration().component("jetty").host("localhost").port(8080).bindingMode(RestBindingMode.json)
;

from("direct:start")
  .to("rest:post:user");
```

Then when calling the REST service using rest producer it will automatic bind any POJOs to json before calling the REST service:

```
  UserPojo user = new UserPojo();
  user.setId(123);
  user.setName("Donald Duck");

  template.sendBody("direct:start", user);
```

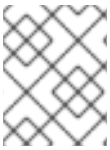
In the example above we send a POJO instance **UserPojo** as the message body. And because we have turned on JSon binding in the rest configuration, then the POJO will be marshalled from POJO to JSon before calling the REST service.

However if you want to also perform binding for the response message (eg what the REST service send back as response) you would need to configure the **outType** option to specify what is the classname of the POJO to unmarshal from JSon to POJO.

For example if the REST service returns a JSon payload that binds to **com.foo.MyResponsePojo** you can configure this as shown:

```
restConfiguration().component("jetty").host("localhost").port(8080).bindingMode(RestBindingMode.json)
;

  from("direct:start")
    .to("rest:post:user?outType=com.foo.MyResponsePojo");
```



NOTE

You must configure **outType** option if you want POJO binding to happen for the response messages received from calling the REST service.

108.10. MORE EXAMPLES

See Rest DSL which offers more examples and how you can use the Rest DSL to define those in a nicer RESTful way.

There is a **camel-example-servlet-rest-tomcat** example in the Apache Camel distribution, that demonstrates how to use the Rest DSL with SERVLET as transport that can be deployed on Apache Tomcat, or similar web containers.

108.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 12 options, which are listed below.

Name	Description	Default	Type
camel.component.rest-api.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.rest-api.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.rest-api.enabled	Whether to enable auto configuration of the rest-api component. This is enabled by default.		Boolean
camel.component.rest.api-doc	The swagger api doc resource to use. The resource is loaded from classpath by default and must be in JSON format.		String
camel.component.rest.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.rest.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.rest.consumer-component-name	The Camel Rest component to use for (consumer) the REST transport, such as jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.component.rest.enabled	Whether to enable auto configuration of the rest component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.rest.host	Host and port of HTTP service to use (override host in swagger schema).		String
camel.component.rest.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.rest.producer-component-name	The Camel Rest component to use for (producer) the REST transport, such as http, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestProducerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.component.rest.component-name	**Deprecated** The Camel Rest component to use for (producer) the REST transport, such as http, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestProducerFactory is registered in the registry. If either one is found, then that is being used.		String

CHAPTER 109. SAGA

Only producer is supported

The Saga component provides a bridge to execute custom actions within a route using the Saga EIP.

The component should be used for advanced tasks, such as deciding to complete or compensate a Saga with completionMode set to **MANUAL**.

Refer to the Saga EIP documentation for help on using sagas in common scenarios.

109.1. DEPENDENCIES

When using **saga** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-saga-starter</artifactId>
</dependency>
```

109.2. URI FORMAT

```
saga:action
```

109.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

109.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

109.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

109.4. COMPONENT OPTIONS

The Saga component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

109.5. ENDPOINT OPTIONS

The Saga endpoint is configured using URI syntax:

```
saga:action
```

with the following path and query parameters:

109.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type

Name	Description	Default	Type
action (producer)	**Required** Action to execute (complete or compensate). Enum values: • COMPLETE • COMPENSATE		SagaEndpointAction

109.5.2. Query Parameters (1 parameters)

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

109.6. USING CAMEL-SAGA WITH SPRING BOOT AND LRA COORDINATOR

This example shows how to work with Apache Camel Saga using Spring Boot and Narayana LRA Coordinator to manage long running actions. See Saga example for more information.

109.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.saga.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.saga.enabled	Whether to enable auto configuration of the saga component. This is enabled by default.		Boolean
camel.component.saga.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 110. SALESFORCE

Both producer and consumer are supported

This component supports producer and consumer endpoints to communicate with Salesforce using Java DTOs.
There is a companion maven plugin Camel Salesforce Plugin that generates these DTOs (see further below).

110.1. DEPENDENCIES

When using **salesforce** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-salesforce-starter</artifactId>
</dependency>
```

By default, **camel-salesforce-maven-plugin** uses TLSv1.3 to interact with salesforce. TLS version is configurable on the plugin. FIPS users can configure the property **sslContextParameters.secureSocketProtocol.** To use the **maven-plugin** you must add the following dependency to the **pom.xml** file.

```
<plugin>
  <groupId>org.apache.camel.maven</groupId>
  <artifactId>camel-salesforce-maven-plugin</artifactId>
  <version>${camel-community.version}</version>
  <executions>
    <execution>
      <goals>
        <goal>generate</goal>
      </goals>
      <configuration>
        <clientId>${camelSalesforce.clientId}</clientId>
        <clientSecret>${camelSalesforce.clientSecret}</clientSecret>
        <userName>${camelSalesforce.userName}</userName>
        <password>${camelSalesforce.password}</password>
        <sslContextParameters>
          <secureSocketProtocol>TLSv1.2</secureSocketProtocol>
        </sslContextParameters>
 <includes>
   <include>Contact</include>
 </includes>
      </configuration>
    </execution>
  </executions>
</plugin>
```

Where **camel-community.version** refers to the corresponding Camel community version that you use when working with **camel-salesforce-maven-plugin**. For example, for Red Hat build of Camel Spring Boot version 4.4.0 you can use '4.4.0' version of Apache Camel.

110.2. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

110.2.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

110.2.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

110.3. COMPONENT OPTIONS

The Salesforce component supports 90 options, which are listed below.

Name	Description	Default	Type
apexMethod (common)	APEX method name.		String
apexQueryParams (common)	Query params for APEX method.		Map
apiVersion (common)	Salesforce API version.	53.0	String
backoffIncrement (common)	Backoff interval increment for Streaming connection restart attempts for failures beyond CometD auto-reconnect.	1000	long

Name	Description	Default	Type
batchId (common)	Bulk API Batch ID.		String
contentType (common)	Bulk API content type, one of XML, CSV, ZIP_XML, ZIP_CSV. Enum values: • XML • CSV • JSON • ZIP_XML • ZIP_CSV • ZIP_JSON		ContentType
defaultReplayId (common)	Default replayId setting if no value is found in initialReplayIdMap.	-1	Long
fallBackReplayId (common)	ReplayId to fall back to after an Invalid Replay Id response.	-1	Long
format (common)	Payload format to use for Salesforce API calls, either JSON or XML, defaults to JSON. As of Camel 3.12, this option only applies to the Raw operation. Enum values: • JSON • XML		PayloadFormat
httpClient (common)	Custom Jetty Http Client to use to connect to Salesforce.		SalesforceHttpClient
httpClientConnectionTimeout (common)	Connection timeout used by the HttpClient when connecting to the Salesforce server.	60000	long
httpClientIdleTimeout (common)	Timeout used by the HttpClient when waiting for response from the Salesforce server.	10000	long
httpMaxContentLength (common)	Max content length of an HTTP response.		Integer

Name	Description	Default	Type
httpRequestBufferSize (common)	HTTP request buffer size. May need to be increased for large SOQL queries.	8192	Integer
includeDetails (common)	Include details in Salesforce1 Analytics report, defaults to false.		Boolean
initialReplayIdMap (common)	Replay IDs to start from per channel name.		Map
instanceId (common)	Salesforce1 Analytics report execution instance ID.		String
jobId (common)	Bulk API Job ID.		String
limit (common)	Limit on number of returned records. Applicable to some of the API, check the Salesforce documentation.		Integer
locator (common)	Locator provided by salesforce Bulk 2.0 API for use in getting results for a Query job.		String
maxBackoff (common)	Maximum backoff interval for Streaming connection restart attempts for failures beyond CometD auto-reconnect.	30000	long
maxRecords (common)	The maximum number of records to retrieve per set of results for a Bulk 2.0 Query. The request is still subject to the size limits. If you are working with a very large number of query results, you may experience a timeout before receiving all the data from Salesforce. To prevent a timeout, specify the maximum number of records your client is expecting to receive in the maxRecords parameter. This splits the results into smaller sets with this value as the maximum size.		Integer
notFoundBehaviour (common)	Sets the behaviour of 404 not found status received from Salesforce API. Should the body be set to NULL NotFoundBehaviour#NULL or should a exception be signaled on the exchange NotFoundBehaviour#EXCEPTION - the default. Enum values: • EXCEPTION • NULL	EXCEPTION	NotFoundBehaviour

Name	Description	Default	Type
notifyForFields (common)	Notify for fields, options are ALL, REFERENCED, SELECT, WHERE. Enum values: • ALL • REFERENCED • SELECT • WHERE		NotifyForFieldsEnum
notifyForOperationCreate (common)	Notify for create operation, defaults to false (API version = 29.0).		Boolean
notifyForOperationDelete (common)	Notify for delete operation, defaults to false (API version = 29.0).		Boolean
notifyForOperations (common)	Notify for operations, options are ALL, CREATE, EXTENDED, UPDATE (API version 29.0). Enum values: • ALL • CREATE • EXTENDED • UPDATE		NotifyForOperationsEnum
notifyForOperationUndelete (common)	Notify for un-delete operation, defaults to false (API version = 29.0).		Boolean
notifyForOperationUpdate (common)	Notify for update operation, defaults to false (API version = 29.0).		Boolean
objectMapper (common)	Custom Jackson ObjectMapper to use when serializing/deserializing Salesforce objects.		ObjectMapper

Name	Description	Default	Type
packages (common)	In what packages are the generated DTO classes. Typically the classes would be generated using camel-salesforce-maven-plugin. Set it if using the generated DTOs to gain the benefit of using short SObject names in parameters/header values. Multiple packages can be separated by comma.		String
pkChunking (common)	Use PK Chunking. Only for use in original Bulk API. Bulk 2.0 API performs PK chunking automatically, if necessary.		Boolean
pkChunkingChunkSize (common)	Chunk size for use with PK Chunking. If unspecified, salesforce default is 100,000. Maximum size is 250,000.		Integer
pkChunkingParent (common)	Specifies the parent object when you're enabling PK chunking for queries on sharing objects. The chunks are based on the parent object's records rather than the sharing object's records. For example, when querying on AccountShare, specify Account as the parent object. PK chunking is supported for sharing objects as long as the parent object is supported.		String
pkChunkingStartRow (common)	Specifies the 15-character or 18-character record ID to be used as the lower boundary for the first chunk. Use this parameter to specify a starting ID when restarting a job that failed between batches.		String
queryLocator (common)	Query Locator provided by salesforce for use when a query results in more records than can be retrieved in a single call. Use this value in a subsequent call to retrieve additional records.		String
rawPayload (common)	Use raw payload String for request and response (either JSON or XML depending on format), instead of DTOs, false by default.	false	boolean
reportId (common)	Salesforce1 Analytics report Id.		String
reportMetadata (common)	Salesforce1 Analytics report metadata for filtering.		ReportMetadata
resultId (common)	Bulk API Result ID.		String
sObjectBlobFieldName (common)	SObject blob field name.		String

Name	Description	Default	Type
sObjectClass (common)	Fully qualified SObject class name, usually generated using camel-salesforce-maven-plugin.		String
sObjectFields (common)	SObject fields to retrieve.		String
sObjectId (common)	SObject ID if required by API.		String
sObjectIdName (common)	SObject external ID field name.		String
sObjectIdValue (common)	SObject external ID field value.		String
sObjectName (common)	SObject name if required or supported by API.		String
sObjectQuery (common)	Salesforce SOQL query string.		String
sObjectSearch (common)	Salesforce SOSL search string.		String
updateTopic (common)	Whether to update an existing Push Topic when using the Streaming API, defaults to false.	false	boolean
config (common (advanced))	Global endpoint configuration - use to set values that are common to all endpoints.		SalesforceEndpointConfig
httpClientProperties (common (advanced))	Used to set any properties that can be configured on the underlying HTTP client. Have a look at properties of SalesforceHttpClient and the Jetty HttpClient for all available options.		Map
longPollingTransportProperties (common (advanced))	Used to set any properties that can be configured on the LongPollingTransport used by the BayeuxClient (CometD) used by the streaming api.		Map
workerPoolMaxSize (common (advanced))	Maximum size of the thread pool used to handle HTTP responses.	20	int
workerPoolSize (common (advanced))	Size of the thread pool used to handle HTTP responses.	10	int

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
allOrNone (producer)	Composite API option to indicate to rollback all records if any are not successful.	false	boolean
apexUrl (producer)	APEX method URL.		String
compositeMethod (producer)	Composite (raw) method.		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
rawHttpHeaders (producer)	Comma separated list of message headers to include as HTTP parameters for Raw operation.		String
rawMethod (producer)	HTTP method to use for the Raw operation.		String
rawPath (producer)	The portion of the endpoint URL after the domain name. E.g., '/services/data/v52.0/sobjects/Account/'.		String
rawQueryParameters (producer)	Comma separated list of message headers to include as query parameters for Raw operation. Do not url-encode values as this will be done automatically.		String

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
httpProxyExcludedAddresses (proxy)	A list of addresses for which HTTP proxy server should not be used.		Set
httpProxyHost (proxy)	Hostname of the HTTP proxy server to use.		String
httpProxyIncludedAddresses (proxy)	A list of addresses for which HTTP proxy server should be used.		Set
httpProxyPort (proxy)	Port number of the HTTP proxy server to use.		Integer
httpProxySocks4 (proxy)	If set to true the configures the HTTP proxy to use as a SOCKS4 proxy.	false	boolean
authenticationType (security)	Explicit authentication method to be used, one of USERNAME_PASSWORD, REFRESH_TOKEN or JWT. Salesforce component can auto-determine the authentication method to use from the properties set, set this property to eliminate any ambiguity. Enum values: • USERNAME_PASSWORD • REFRESH_TOKEN • JWT		AuthenticationType
clientId (security)	**Required** OAuth Consumer Key of the connected app configured in the Salesforce instance setup. Typically a connected app needs to be configured but one can be provided by installing a package.		String
clientSecret (security)	OAuth Consumer Secret of the connected app configured in the Salesforce instance setup.		String

Name	Description	Default	Type
httpProxyAuthUri (security)	Used in authentication against the HTTP proxy server, needs to match the URI of the proxy server in order for the httpProxyUsername and httpProxyPassword to be used for authentication.		String
httpProxyPassword (security)	Password to use to authenticate against the HTTP proxy server.		String
httpProxyRealm (security)	Realm of the proxy server, used in preemptive Basic/Digest authentication methods against the HTTP proxy server.		String
httpProxySecure (security)	If set to false disables the use of TLS when accessing the HTTP proxy.	true	boolean
httpProxyUseDigestAuth (security)	If set to true Digest authentication will be used when authenticating to the HTTP proxy, otherwise Basic authorization method will be used.	false	boolean
httpProxyUsername (security)	Username to use to authenticate against the HTTP proxy server.		String
instanceUrl (security)	URL of the Salesforce instance used after authentication, by default received from Salesforce on successful authentication.		String
jwtAudience (security)	Value to use for the Audience claim (aud) when using OAuth JWT flow. If not set, the login URL will be used, which is appropriate in most cases.		String
keystore (security)	KeyStore parameters to use in OAuth JWT flow. The KeyStore should contain only one entry with private key and certificate. Salesforce does not verify the certificate chain, so this can easily be a selfsigned certificate. Make sure that you upload the certificate to the corresponding connected app.		KeyStoreParameters
lazyLogin (security)	If set to true prevents the component from authenticating to Salesforce with the start of the component. You would generally set this to the (default) false and authenticate early and be immediately aware of any authentication issues.	false	boolean
loginConfig (security)	All authentication configuration in one nested bean, all properties set there can be set directly on the component as well.		SalesforceLoginConfig

Name	Description	Default	Type
loginUrl (security)	**Required** URL of the Salesforce instance used for authentication, by default set to https://login.salesforce.com.	https://login.salesforce.com	String
password (security)	Password used in OAuth flow to gain access to access token. It's easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows. Make sure that you append security token to the end of the password if using one.		String
refreshToken (security)	Refresh token already obtained in the refresh token OAuth flow. One needs to setup a web application and configure a callback URL to receive the refresh token, or configure using the builtin callback at https://login.salesforce.com/services/oauth2/success or https://test.salesforce.com/services/oauth2/success and then retrive the refresh_token from the URL at the end of the flow. Note that in development organizations Salesforce allows hosting the callback web application at localhost.		String
sslContextParameters (security)	SSL parameters to use, see SSLContextParameters class for all available options.		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
userName (security)	Username used in OAuth flow to gain access to access token. It's easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows.		String

110.4. ENDPOINT OPTIONS

The Salesforce endpoint is configured using URI syntax:

```
salesforce:operationName:topicName
```

with the following path and query parameters:

110.4.1. Path Parameters (2 parameters)

Name	Description	Default	Type
operationName (producer)	The operation to use. Enum values: • getVersions • getResources • getGlobalObjects • getBasicInfo • getDescription • getSObject • createSObject • updateSObject • deleteSObject • getSObjectWithId • upsertSObject • deleteSObjectWithId • getBlobField • query • queryMore • queryAll • search • apexCall • recent • createJob • getJob • closeJob • abortJob • createBatch • getBatch • getAllBatches • getRequest • getResults • createBatchQuery		OperationName

Name	Description	Default	Type
	• getQueryResultIds • getQueryResult • getRecentReports • getReportDescription • executeSyncReport • executeAsyncReport • getReportInstances • getReportResults • limits • approval • approvals • composite-tree • composite-batch • composite • compositeRetrieveSObjectCollections • compositeCreateSObjectCollections • compositeUpdateSObjectCollections • compositeUpsertSObjectCollections • compositeDeleteSObjectCollections • bulk2GetAllJobs • bulk2CreateJob • bulk2GetJob • bulk2CreateBatch • bulk2CloseJob • bulk2AbortJob • bulk2DeleteJob • bulk2GetSuccessfulResults • bulk2GetFailedResults • bulk2GetUnprocessedRecords • bulk2CreateQueryJob • bulk2GetQueryJob • bulk2GetAllQueryJobs • bulk2GetQueryJobResults		

Name	Description	Default	Type
	• bulk2AbortQueryJob • bulk2DeleteQueryJob • raw		
topicName (consumer)	The name of the topic/channel to use.		String

110.4.2. Query Parameters (57 parameters)

Name	Description	Default	Type
apexMethod (common)	APEX method name.		String
apexQueryParams (common)	Query params for APEX method.		Map
apiVersion (common)	Salesforce API version.	53.0	String
backoffIncrement (common)	Backoff interval increment for Streaming connection restart attempts for failures beyond CometD auto-reconnect.	1000	long
batchId (common)	Bulk API Batch ID.		String
contentType (common)	Bulk API content type, one of XML, CSV, ZIP_XML, ZIP_CSV. Enum values: • XML • CSV • JSON • ZIP_XML • ZIP_CSV • ZIP_JSON		ContentType
defaultReplayId (common)	Default replayId setting if no value is found in initialReplayIdMap.	-1	Long
fallBackReplayId (common)	ReplayId to fall back to after an Invalid Replay Id response.	-1	Long

Name	Description	Default	Type
format (common)	Payload format to use for Salesforce API calls, either JSON or XML, defaults to JSON. As of Camel 3.12, this option only applies to the Raw operation. Enum values: • JSON • XML		PayloadFormat
httpClient (common)	Custom Jetty Http Client to use to connect to Salesforce.		SalesforceHttpClient
includeDetails (common)	Include details in Salesforce1 Analytics report, defaults to false.		Boolean
initialReplayIdMap (common)	Replay IDs to start from per channel name.		Map
instanceId (common)	Salesforce1 Analytics report execution instance ID.		String
jobId (common)	Bulk API Job ID.		String
limit (common)	Limit on number of returned records. Applicable to some of the API, check the Salesforce documentation.		Integer
locator (common)	Locator provided by salesforce Bulk 2.0 API for use in getting results for a Query job.		String
maxBackoff (common)	Maximum backoff interval for Streaming connection restart attempts for failures beyond CometD auto-reconnect.	30000	long
maxRecords (common)	The maximum number of records to retrieve per set of results for a Bulk 2.0 Query. The request is still subject to the size limits. If you are working with a very large number of query results, you may experience a timeout before receiving all the data from Salesforce. To prevent a timeout, specify the maximum number of records your client is expecting to receive in the maxRecords parameter. This splits the results into smaller sets with this value as the maximum size.		Integer

Name	Description	Default	Type
notFoundBehaviour (common)	Sets the behaviour of 404 not found status received from Salesforce API. Should the body be set to NULL NotFoundBehaviour#NULL or should a exception be signaled on the exchange NotFoundBehaviour#EXCEPTION - the default. Enum values: • EXCEPTION • NULL	EXCEPTION	NotFoundBehaviour
notifyForFields (common)	Notify for fields, options are ALL, REFERENCED, SELECT, WHERE. Enum values: • ALL • REFERENCED • SELECT • WHERE		NotifyForFieldsEnum
notifyForOperationCreate (common)	Notify for create operation, defaults to false (API version = 29.0).		Boolean
notifyForOperationDelete (common)	Notify for delete operation, defaults to false (API version = 29.0).		Boolean
notifyForOperations (common)	Notify for operations, options are ALL, CREATE, EXTENDED, UPDATE (API version 29.0). Enum values: • ALL • CREATE • EXTENDED • UPDATE		NotifyForOperationsEnum
notifyForOperationUndelete (common)	Notify for un-delete operation, defaults to false (API version = 29.0).		Boolean

Name	Description	Default	Type
notifyForOperationUpdate (common)	Notify for update operation, defaults to false (API version = 29.0).		Boolean
objectMapper (common)	Custom Jackson ObjectMapper to use when serializing/deserializing Salesforce objects.		ObjectMapper
pkChunking (common)	Use PK Chunking. Only for use in original Bulk API. Bulk 2.0 API performs PK chunking automatically, if necessary.		Boolean
pkChunkingChunkSize (common)	Chunk size for use with PK Chunking. If unspecified, salesforce default is 100,000. Maximum size is 250,000.		Integer
pkChunkingParent (common)	Specifies the parent object when you're enabling PK chunking for queries on sharing objects. The chunks are based on the parent object's records rather than the sharing object's records. For example, when querying on AccountShare, specify Account as the parent object. PK chunking is supported for sharing objects as long as the parent object is supported.		String
pkChunkingStartRow (common)	Specifies the 15-character or 18-character record ID to be used as the lower boundary for the first chunk. Use this parameter to specify a starting ID when restarting a job that failed between batches.		String
queryLocator (common)	Query Locator provided by salesforce for use when a query results in more records than can be retrieved in a single call. Use this value in a subsequent call to retrieve additional records.		String
rawPayload (common)	Use raw payload String for request and response (either JSON or XML depending on format), instead of DTOs, false by default.	false	boolean
reportId (common)	Salesforce1 Analytics report Id.		String
reportMetadata (common)	Salesforce1 Analytics report metadata for filtering.		ReportMetadata
resultId (common)	Bulk API Result ID.		String
sObjectBlobFieldName (common)	SObject blob field name.		String

Name	Description	Default	Type
sObjectClass (common)	Fully qualified SObject class name, usually generated using camel-salesforce-maven-plugin.		String
sObjectFields (common)	SObject fields to retrieve.		String
sObjectId (common)	SObject ID if required by API.		String
sObjectIdName (common)	SObject external ID field name.		String
sObjectIdValue (common)	SObject external ID field value.		String
sObjectName (common)	SObject name if required or supported by API.		String
sObjectQuery (common)	Salesforce SOQL query string.		String
sObjectSearch (common)	Salesforce SOSL search string.		String
updateTopic (common)	Whether to update an existing Push Topic when using the Streaming API, defaults to false.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
replayId (consumer)	The replayId value to use when subscribing.		Long
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
allOrNone (producer)	Composite API option to indicate to rollback all records if any are not successful.	false	boolean
apexUrl (producer)	APEX method URL.		String
compositeMethod (producer)	Composite (raw) method.		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
rawHttpHeaders (producer)	Comma separated list of message headers to include as HTTP parameters for Raw operation.		String
rawMethod (producer)	HTTP method to use for the Raw operation.		String
rawPath (producer)	The portion of the endpoint URL after the domain name. E.g., '/services/data/v52.0/sobjects/Account/'.		String
rawQueryParameters (producer)	Comma separated list of message headers to include as query parameters for Raw operation. Do not url-encode values as this will be done automatically.		String

110.5. AUTHENTICATING TO SALESFORCE

The component supports three OAuth authentication flows:

- OAuth 2.0 Username-Password Flow
- OAuth 2.0 Refresh Token Flow
- OAuth 2.0 JWT Bearer Token Flow

For each of the flow different set of properties needs to be set:

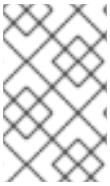
Table 110.1. Table 1. Properties to set for each authentication flow

Property	Where to find it on Salesforce	Flow
clientId	Connected App, Consumer Key	All flows
clientSecret	Connected App, Consumer Secret	Username-Password, Refresh Token
userName	Salesforce user username	Username-Password, JWT Bearer Token
password	Salesforce user password	Username-Password
refreshToken	From OAuth flow callback	Refresh Token
keystore	Connected App, Digital Certificate	JWT Bearer Token

The component auto determines what flow you're trying to configure, to be remove ambiguity set the **authenticationType** property.

NOTE

Using Username-Password Flow in production is not encouraged.



NOTE

The certificate used in JWT Bearer Token Flow can be a selfsigned certificate. The KeyStore holding the certificate and the private key must contain only single certificate-private key entry.

110.6. URI FORMAT

When used as a consumer, receiving streaming events, the URI scheme is:

```
salesforce:topic?options
```

When used as a producer, invoking the Salesforce REST APIs, the URI scheme is:

```
salesforce:operationName?options
```

110.7. PASSING IN SALESFORCE HEADERS AND FETCHING SALESFORCE RESPONSE HEADERS

There is support to pass Salesforce headers via inbound message headers, header names that start with **Sforce** or **x-sfdc** on the Camel message will be passed on in the request, and response headers that start with **Sforce** will be present in the outbound message headers.

For example to fetch API limits you can specify:

```
// in your Camel route set the header before Salesforce endpoint
//...
  .setHeader("Sforce-Limit-Info", constant("api-usage"))
  .to("salesforce:getGlobalObjects")
  .to(myProcessor);

// myProcessor will receive `Sforce-Limit-Info` header on the outbound
// message
class MyProcessor implements Processor {
    public void process(Exchange exchange) throws Exception {
        Message in = exchange.getIn();
        String apiLimits = in.getHeader("Sforce-Limit-Info", String.class);
    }
}
```

In addition, HTTP response status code and text are available as headers **Exchange.HTTP_RESPONSE_CODE** and **Exchange.HTTP_RESPONSE_TEXT**.

110.8. SUPPORTED SALESFORCE APIS

The component supports the following Salesforce APIs

Producer endpoints can use the following APIs. Most of the APIs process one record at a time, the Query API can retrieve multiple Records.

110.8.1. Rest API

You can use the following for **operationName**:

- getVersions - Gets supported Salesforce REST API versions
- getResources - Gets available Salesforce REST Resource endpoints
- getGlobalObjects - Gets metadata for all available SObject types
- getBasicInfo - Gets basic metadata for a specific SObject type
- getDescription - Gets comprehensive metadata for a specific SObject type
- getSObject - Gets an SObject using its Salesforce Id
- createSObject - Creates an SObject

- updateSObject - Updates an SObject using Id
- deleteSObject - Deletes an SObject using Id
- getSObjectWithId - Gets an SObject using an external (user defined) id field
- upsertSObject - Updates or inserts an SObject using an external id
- deleteSObjectWithId - Deletes an SObject using an external id
- query - Runs a Salesforce SOQL query
- queryMore - Retrieves more results (in case of large number of results) using result link returned from the 'query' API
- search - Runs a Salesforce SOSL query
- limits - fetching organization API usage limits
- recent - fetching recent items
- approval - submit a record or records (batch) for approval process
- approvals - fetch a list of all approval processes
- composite - submit up to 25 possibly related REST requests and receive individual responses. It's also possible to use "raw" composite without limitation.
- composite-tree - create up to 200 records with parent-child relationships (up to 5 levels) in one go
- composite-batch - submit a composition of requests in batch
- compositeRetrieveSObjectCollections - Retrieve one or more records of the same object type.
- compositeCreateSObjectCollections - Add up to 200 records, returning a list of SaveSObjectResult objects.
- compositeUpdateSObjectCollections - Update up to 200 records, returning a list of SaveSObjectResult objects.
- compositeUpsertSObjectCollections - Create or update (upsert) up to 200 records based on an external ID field. Returns a list of UpsertSObjectResult objects.
- compositeDeleteSObjectCollections - Delete up to 200 records, returning a list of SaveSObjectResult objects.
- queryAll - Runs a SOQL query. It returns the results that are deleted because of a merge (merges up to three records into one of the records, deletes the others, and reparents any related records) or delete. Also returns the information about archived Task and Event records.
- getBlobField - Retrieves the specified blob field from an individual record.
- apexCall - Executes a user defined APEX REST API call.
- raw - Send requests to salesforce and have full, raw control over endpoint, parameters, body, etc.

For example, the following producer endpoint uses the upsertSObject API, with the sObjectIdName parameter specifying 'Name' as the external id field. The request message body should be an SObject DTO generated using the maven plugin. The response message will either be **null** if an existing record was updated, or **CreateSObjectResult** with an id of the new record, or a list of errors while creating the new object.

```
...to("salesforce:upsertSObject?sObjectIdName=Name")...
```

110.8.2. Bulk 2.0 API

The Bulk 2.0 API has a simplified model over the original Bulk API. Use it to quickly load a large amount of data into salesforce, or query a large amount of data out of salesforce. Data must be provided in CSV format. The minimum API version for Bulk 2.0 is v41.0. The minimum API version for Bulk Queries is v47.0. DTO classes mentioned below are from the **org.apache.camel.component.salesforce.api.dto.bulkv2** package. The following operations are supported:

- **bulk2CreateJob** - Create a bulk job. Supply an instance of **Job** in the message body.
- **bulk2GetJob** - Get an existing Job. **jobId** parameter is required.
- **bulk2CreateBatch** - Add a Batch of CSV records to a job. Supply CSV data in the message body. The first row must contain headers. **jobId** parameter is required.
- **bulk2CloseJob** - Close a job. You must close the job in order for it to be processed or aborted/deleted. **jobId** parameter is required.
- **bulk2AbortJob** - Abort a job. **jobId** parameter is required.
- **bulk2DeleteJob** - Delete a job. **jobId** parameter is required.
- **bulk2GetSuccessfulResults** - Get successful results for a job. Returned message body will contain an InputStream of CSV data. **jobId** parameter is required.
- **bulk2GetFailedResults** - Get failed results for a job. Returned message body will contain an InputStream of CSV data. **jobId** parameter is required.
- **bulk2GetUnprocessedRecords** - Get unprocessed records for a job. Returned message body will contain an InputStream of CSV data. **jobId** parameter is required.
- **bulk2GetAllJobs** - Get all jobs. Response body is an instance of **Jobs**. If the **done** property is false, there are additional pages to fetch, and the **nextRecordsUrl** property contains the value to be set in the **queryLocator** parameter on subsequent calls.
- **bulk2CreateQueryJob** - Create a bulk query job. Supply an instance of **QueryJob** in the message body.
- **bulk2GetQueryJob** - Get a bulk query job. **jobId** parameter is required.
- **bulk2GetQueryJobResults** - Get bulk query job results. **jobId** parameter is required. Accepts **maxRecords** and **locator** parameters. Response message headers include **Sforce-NumberOfRecords** and **Sforce-Locator** headers. The value of **Sforce-Locator** can be passed into subsequent calls via the **locator** parameter.
- **bulk2AbortQueryJob** - Abort a bulk query job. **jobId** parameter is required.

- **bulk2DeleteQueryJob** - Delete a bulk query job. **jobId** parameter is required.
- **bulk2GetAllQueryJobs** - Get all jobs. Response body is an instance of **QueryJobs**. If the **done** property is false, there are additional pages to fetch, and the **nextRecordsUrl** property contains the value to be set in the **queryLocator** parameter on subsequent calls.

110.8.3. Rest Bulk (original) API

Producer endpoints can use the following APIs. All Job data formats, i.e. xml, csv, zip/xml, and zip/csv are supported.
The request and response have to be marshalled/unmarshalled by the route. Usually the request will be some stream source like a CSV file,
and the response may also be saved to a file to be correlated with the request.

You can use the following for **operationName**:

- **createJob** - Creates a Salesforce Bulk Job. Must supply a **JobInfo** instance in body. PK Chunking is supported via the pkChunking* options. See an explanation here.
- **getJob** - Gets a Job using its Salesforce Id
- **closeJob** - Closes a Job
- **abortJob** - Aborts a Job
- **createBatch** - Submits a Batch within a Bulk Job
- **getBatch** - Gets a Batch using Id
- **getAllBatches** - Gets all Batches for a Bulk Job Id
- **getRequest** - Gets Request data (XML/CSV) for a Batch
- **getResults** - Gets the results of the Batch when its complete
- **createBatchQuery** - Creates a Batch from an SOQL query
- **getQueryResultIds** - Gets a list of Result Ids for a Batch Query
- **getQueryResult** - Gets results for a Result Id
- **getRecentReports** - Gets up to 200 of the reports you most recently viewed by sending a GET request to the Report List resource.
- **getReportDescription** - Retrieves the report, report type, and related metadata for a report, either in a tabular or summary or matrix format.
- **executeSyncReport** - Runs a report synchronously with or without changing filters and returns the latest summary data.
- **executeAsyncReport** - Runs an instance of a report asynchronously with or without filters and returns the summary data with or without details.
- **getReportInstances** - Returns a list of instances for a report that you requested to be run asynchronously. Each item in the list is treated as a separate instance of the report.
- **getReportResults**: Contains the results of running a report.

For example, the following producer endpoint uses the createBatch API to create a Job Batch. The in message must contain a body that can be converted into an **InputStream** (usually UTF-8 CSV or XML content from a file, etc.) and header fields 'jobId' for the Job and 'contentType' for the Job content type, which can be XML, CSV, ZIP_XML or ZIP_CSV. The put message body will contain **BatchInfo** on success, or throw a **SalesforceException** on error.

```
...to("salesforce:createBatch")..
```

110.8.4. Rest Streaming API

Consumer endpoints can use the following syntax for streaming endpoints to receive Salesforce notifications on create/update.

To create and subscribe to a topic

```
from("salesforce:CamelTestTopic?
notifyForFields=ALL&notifyForOperations=ALL&sObjectName=Merchandise__c&updateTopic=true&sO
bjectQuery=SELECT Id, Name FROM Merchandise__c")...
```

To subscribe to an existing topic

```
from("salesforce:CamelTestTopic&sObjectName=Merchandise__c")...
```

110.8.5. Platform events

To emit a platform event use **createSObject** operation. And set the message body can be JSON string or InputStream with key-value data – in that case **sObjectName** needs to be set to the API name of the event, or a class that extends from AbstractDTOBase with the appropriate class name for the event.

For example using a DTO:

```
class Order_Event__e extends AbstractDTOBase {
  @JsonProperty("OrderNumber")
  private String orderNumber;
  // ... other properties and getters/setters
}

from("timer:tick")
    .process(exchange -> {
        final Message in = exchange.getIn();
        String orderNumber = "ORD" + exchange.getProperty(Exchange.TIMER_COUNTER);
        Order_Event__e event = new Order_Event__e();
        event.setOrderNumber(orderNumber);
        in.setBody(event);
    })
    .to("salesforce:createSObject");
```

Or using JSON event data:

```
from("timer:tick")
    .process(exchange -> {
        final Message in = exchange.getIn();
        String orderNumber = "ORD" + exchange.getProperty(Exchange.TIMER_COUNTER);
```

```
        in.setBody("{\"OrderNumber\":\"" + orderNumber + "\"}");
    })
    .to("salesforce:createSObject?sObjectName=Order_Event__e");
```

To receive platform events use the consumer endpoint with the API name of the platform event prefixed with **event/** (or **/event/**), e.g.: **salesforce:events/Order_Event__e**. Processor consuming from that endpoint will receive either **org.apache.camel.component.salesforce.api.dto.PlatformEvent** object or **org.cometd.bayeux.Message** in the body depending on the **rawPayload** being **false** or **true** respectively.

For example, in the simplest form to consume one event:

```
PlatformEvent event = consumer.receiveBody("salesforce:event/Order_Event__e",
PlatformEvent.class);
```

110.8.6. Change data capture events

On the one hand, Salesforce could be configured to emit notifications for record changes of select objects. On the other hand, the Camel Salesforce component could react to such notifications, allowing for instance to synchronize those changes into an external system .

The notifications of interest could be specified in the **from("salesforce:XXX")** clause of a Camel route via the subscription channel, e.g:

```
from("salesforce:data/ChangeEvents?replayId=-1").log("being notified of all change events")
from("salesforce:data/AccountChangeEvent?replayId=-1").log("being notified of change events for
Account records")
from("salesforce:data/Employee__ChangeEvent?replayId=-1").log("being notified of change events
for Employee__c custom object")
```

The received message contains either **java.util.Map<String,Object>** or **org.cometd.bayeux.Message** in the body depending on the **rawPayload** being **false** or **true** respectively. The **CamelSalesforceChangeType** header could be valued to one of **CREATE**, **UPDATE**, **DELETE** or **UNDELETE**.

More details about how to use the Camel Salesforce component change data capture capabilities could be found in the ChangeEventsConsumerIntegrationTest.

The Salesforce developer guide is a good fit to better know the subtleties of implementing a change data capture integration application. The dynamic nature of change event body fields, high level replication steps as well as security considerations could be of interest.

110.9. EXAMPLES

110.9.1. Uploading a document to a ContentWorkspace

Create the ContentVersion in Java, using a Processor instance:

```
public class ContentProcessor implements Processor {
    public void process(Exchange exchange) throws Exception {
        Message message = exchange.getIn();

        ContentVersion cv = new ContentVersion();
```

```
        ContentWorkspace cw = getWorkspace(exchange);
        cv.setFirstPublishLocationId(cw.getId());
        cv.setTitle("test document");
        cv.setPathOnClient("test_doc.html");
        byte[] document = message.getBody(byte[].class);
        ObjectMapper mapper = new ObjectMapper();
        String enc = mapper.convertValue(document, String.class);
        cv.setVersionDataUrl(enc);
        message.setBody(cv);
    }

    protected ContentWorkspace getWorkSpace(Exchange exchange) {
        // Look up the content workspace somehow, maybe use enrich() to add it to a
        // header that can be extracted here
        ----
    }
}
```

Give the output from the processor to the Salesforce component:

```
from("file:///home/camel/library")
    .to(new ContentProcessor())     // convert bytes from the file into a ContentVersion SObject
                                    // for the salesforce component
    .to("salesforce:createSObject");
```

110.10. USING SALESFORCE LIMITS API

With **salesforce:limits** operation you can fetch of API limits from Salesforce and then act upon that data received. The result of **salesforce:limits** operation is mapped to **org.apache.camel.component.salesforce.api.dto.Limits** class and can be used in a custom processors or expressions.

For instance, consider that you need to limit the API usage of Salesforce so that 10% of daily API requests is left for other routes. The body of output message contains an instance of **org.apache.camel.component.salesforce.api.dto.Limits** object that can be used in conjunction with Content Based Router and Content Based Router and Spring Expression Language (SpEL) to choose when to perform queries.

Notice how multiplying **1.0** with the integer value held in **body.dailyApiRequests.remaining** makes the expression evaluate as with floating point arithmetic, without it - it would end up making integral division which would result with either **0** (some API limits consumed) or **1** (no API limits consumed).

```
from("direct:querySalesforce")
    .to("salesforce:limits")
    .choice()
    .when(spel("#{1.0 * body.dailyApiRequests.remaining / body.dailyApiRequests.max < 0.1}"))
        .to("salesforce:query?...")
    .otherwise()
        .setBody(constant("Used up Salesforce API limits, leaving 10% for critical routes"))
    .endChoice()
```

110.11. WORKING WITH APPROVALS

All the properties are named exactly the same as in the Salesforce REST API prefixed with **approval.**.

You can set approval properties by setting **approval.PropertyName** of the Endpoint these will be used as template – meaning that any property not present in either body or header will be taken from the Endpoint configuration. Or you can set the approval template on the Endpoint by assigning **approval** property to a reference onto a bean in the Registry.

You can also provide header values using the same **approval.PropertyName** in the incoming message headers.

And finally body can contain one **AprovalRequest** or an **Iterable** of **ApprovalRequest** objects to process as a batch.

The important thing to remember is the priority of the values specified in these three mechanisms:

1. value in body takes precedence before any other
2. value in message header takes precedence before template value
3. value in template is set if no other value in header or body was given

For example to send one record for approval using values in headers use:

Given a route:

```
from("direct:example1")//
        .setHeader("approval.ContextId", simple("${body['contextId']}"))
        .setHeader("approval.NextApproverIds", simple("${body['nextApproverIds']}"))
        .to("salesforce:approval?"//
           + "approval.actionType=Submit"//
           + "&approval.comments=this is a test"//
           + "&approval.processDefinitionNameOrId=Test_Account_Process"//
           + "&approval.skipEntryCriteria=true");
```

You could send a record for approval using:

```
final Map<String, String> body = new HashMap<>();
body.put("contextId", accountIds.iterator().next());
body.put("nextApproverIds", userId);

final ApprovalResult result = template.requestBody("direct:example1", body, ApprovalResult.class);
```

110.12. USING SALESFORCE RECENT ITEMS API

To fetch the recent items use **salesforce:recent** operation. This operation returns an **java.util.List** of **org.apache.camel.component.salesforce.api.dto.RecentItem** objects (**List<RecentItem>**) that in turn contain the **Id**, **Name** and **Attributes** (with **type** and **url** properties). You can limit the number of returned items by specifying **limit** parameter set to maximum number of records to return. For example:

```
from("direct:fetchRecentItems")
    to("salesforce:recent")
        .split().body()
            .log("${body.name} at ${body.attributes.url}");
```

110.13. USING SALESFORCE COMPOSITE API TO SUBMIT SOBJECT TREE

To create up to 200 records including parent-child relationships use **salesforce:composite-tree** operation. This requires an instance of **org.apache.camel.component.salesforce.api.dto.composite.SObjectTree** in the input message and returns the same tree of objects in the output message. The **org.apache.camel.component.salesforce.api.dto.AbstractSObjectBase** instances within the tree get updated with the identifier values (**Id** property) or their corresponding **org.apache.camel.component.salesforce.api.dto.composite.SObjectNode** is populated with **errors** on failure.

Note that for some records operation can succeed and for some it can fail – so you need to manually check for errors.

Easiest way to use this functionality is to use the DTOs generated by the **camel-salesforce-maven-plugin**, but you also have the option of customizing the references that identify the each object in the tree, for instance primary keys from your database.

Lets look at an example:

```
Account account = ...
Contact president = ...
Contact marketing = ...

Account anotherAccount = ...
Contact sales = ...
Asset someAsset = ...

// build the tree
SObjectTree request = new SObjectTree();
request.addObject(account).addChildren(president, marketing);
request.addObject(anotherAccount).addChild(sales).addChild(someAsset);

final SObjectTree response = template.requestBody("salesforce:composite-tree", tree,
SObjectTree.class);
final Map<Boolean, List<SObjectNode>> result = response.allNodes()
                                        .collect(Collectors.groupingBy(SObjectNode::hasErrors));

final List<SObjectNode> withErrors = result.get(true);
final List<SObjectNode> succeeded = result.get(false);

final String firstId = succeeded.get(0).getId();
```

110.14. USING SALESFORCE COMPOSITE API TO SUBMIT MULTIPLE REQUESTS IN A BATCH

The Composite API batch operation (**composite-batch**) allows you to accumulate multiple requests in a batch and then submit them in one go, saving the round trip cost of multiple individual requests. Each response is then received in a list of responses with the order preserved, so that the n-th requests response is in the n-th place of the response.

NOTE

The results can vary from API to API so the result of the request is given as a **java.lang.Object**. In most cases the result will be a **java.util.Map** with string keys and values or other **java.util.Map** as value. Requests are made in JSON format and hold some type information (i.e. it is known what values are strings and what values are numbers).

Lets look at an example:

```
final String acountId = ...
final SObjectBatch batch = new SObjectBatch("38.0");

final Account updates = new Account();
updates.setName("NewName");
batch.addUpdate("Account", accountId, updates);

final Account newAccount = new Account();
newAccount.setName("Account created from Composite batch API");
batch.addCreate(newAccount);

batch.addGet("Account", accountId, "Name", "BillingPostalCode");

batch.addDelete("Account", accountId);

final SObjectBatchResponse response = template.requestBody("salesforce:composite-batch", batch,
SObjectBatchResponse.class);

boolean hasErrors = response.hasErrors(); // if any of the requests has resulted in either 4xx or 5xx
HTTP status
final List<SObjectBatchResult> results = response.getResults(); // results of three operations sent in
batch

final SObjectBatchResult updateResult = results.get(0); // update result
final int updateStatus = updateResult.getStatusCode(); // probably 204
final Object updateResultData = updateResult.getResult(); // probably null

final SObjectBatchResult createResult = results.get(1); // create result
@SuppressWarnings("unchecked")
final Map<String, Object> createData = (Map<String, Object>) createResult.getResult();
final String newAccountId = createData.get("id"); // id of the new account, this is for JSON, for XML it
would be createData.get("Result").get("id")

final SObjectBatchResult retrieveResult = results.get(2); // retrieve result
@SuppressWarnings("unchecked")
final Map<String, Object> retrieveData = (Map<String, Object>) retrieveResult.getResult();
final String accountName = retrieveData.get("Name"); // Name of the retrieved account, this is for
JSON, for XML it would be createData.get("Account").get("Name")
final String accountBillingPostalCode = retrieveData.get("BillingPostalCode"); // Name of the retrieved
account, this is for JSON, for XML it would be createData.get("Account").get("BillingPostalCode")

final SObjectBatchResult deleteResult = results.get(3); // delete result
final int updateStatus = deleteResult.getStatusCode(); // probably 204
final Object updateResultData = deleteResult.getResult(); // probably null
```

110.15. USING SALESFORCE COMPOSITE API TO SUBMIT MULTIPLE CHAINED REQUESTS

The **composite** operation allows submitting up to 25 requests that can be chained together, for instance identifier generated in previous request can be used in subsequent request. Individual requests and responses are linked with the provided *reference*.

NOTE

Composite API supports only JSON payloads.

NOTE

As with the batch API the results can vary from API to API so the result of the request is given as a **java.lang.Object**. In most cases the result will be a **java.util.Map** with string keys and values or other **java.util.Map** as value. Requests are made in JSON format hold some type information (i.e. it is known what values are strings and what values are numbers).

Lets look at an example:

```
SObjectComposite composite = new SObjectComposite("38.0", true);

// first insert operation via an external id
final Account updateAccount = new TestAccount();
updateAccount.setName("Salesforce");
updateAccount.setBillingStreet("Landmark @ 1 Market Street");
updateAccount.setBillingCity("San Francisco");
updateAccount.setBillingState("California");
updateAccount.setIndustry(Account_IndustryEnum.TECHNOLOGY);
composite.addUpdate("Account", "001xx000003DIpcAAG", updateAccount, "UpdatedAccount");

final Contact newContact = new TestContact();
newContact.setLastName("John Doe");
newContact.setPhone("1234567890");
composite.addCreate(newContact, "NewContact");

final AccountContactJunction__c junction = new AccountContactJunction__c();
junction.setAccount__c("001xx000003DIpcAAG");
junction.setContactId__c("@{NewContact.id}");
composite.addCreate(junction, "JunctionRecord");

final SObjectCompositeResponse response = template.requestBody("salesforce:composite",
composite, SObjectCompositeResponse.class);
final List<SObjectCompositeResult> results = response.getCompositeResponse();

final SObjectCompositeResult accountUpdateResult = results.stream().filter(r ->
"UpdatedAccount".equals(r.getReferenceId())).findFirst().get()
final int statusCode = accountUpdateResult.getHttpStatusCode(); // should be 200
final Map<String, ?> accountUpdateBody = accountUpdateResult.getBody();

final SObjectCompositeResult contactCreationResult = results.stream().filter(r ->
"JunctionRecord".equals(r.getReferenceId())).findFirst().get()
```

110.16. USING "RAW" SALESFORCE COMPOSITE

It's possible to directly call Salesforce composite by preparing the Salesforce JSON request in the route thanks to the **rawPayload** option.

For instance, you can have the following route:

```
from("timer:fire?period=2000").setBody(constant("{\n" +
    " \"allOrNone\" : true,\n" +
    " \"records\" : [ { \n" +
    "   \"attributes\" : {\"type\" : \"FOO\"},\n" +
    "   \"Name\" : \"123456789\",\n" +
    "   \"FOO\" : \"XXXX\",\n" +
    "   \"ACCOUNT\" : 2100.0\n" +
    "   \"ExternalID\" : \"EXTERNAL\"\n"
    " }]\n" +
    "}")
  .to("salesforce:composite?rawPayload=true")
  .log("${body}");
```

The route directly creates the body as JSON and directly submit to salesforce endpoint using **rawPayload=true** option.

With this approach, you have the complete control on the Salesforce request.

POST is the default HTTP method used to send raw Composite requests to salesforce. Use the **compositeMethod** option to override to the other supported value, **GET**, which returns a list of other available composite resources.

110.17. USING RAW OPERATION

Send HTTP requests to salesforce with full, raw control of all aspects of the call. Any serialization or deserialization of request and response bodies must be performed in the route. The **Content-Type** HTTP header will be automatically set based on the **format** option, but this can be overridden with the **rawHttpHeaders** option.

Parameter	Type	Description	Default	Required
request body	**String** or **InputStream**	Body of the HTTP request		
rawPath	**String**	The portion of the endpoint URL after the domain name, e.g., '/services/data/v51.0/sobjects/Account/'		x
rawMethod	**String**	The HTTP method		x

Parameter	Type	Description	Default	Required
rawQueryParameters	**String**	Comma separated list of message headers to include as query parameters. Do not url-encode values as this will be done automatically.		
rawHttpHeaders	**String**	Comma separated list of message headers to include as HTTP headers		

110.17.1. Query example

In this example we'll send a query to the REST API. The query must be passed in a URL parameter called "q", so we'll create a message header called q and tell the raw operation to include that message header as a URL parameter:

```
from("direct:queryExample")
  .setHeader("q", "SELECT Id, LastName FROM Contact")
  .to("salesforce:raw?
format=JSON&rawMethod=GET&rawQueryParameters=q&rawPath=/services/data/v51.0/query")
  // deserialize JSON results or handle in some other way
```

110.17.2. SObject example

In this example, we'll pass a Contact the REST API in a **create** operation. Since the **raw** operation does not perform any serialization, we make sure to pass XML in the message body

```
from("direct:createAContact")
  .setBody(constant("<Contact><LastName>TestLast</LastName></Contact>"))
  .to("salesforce:raw?
format=XML&rawMethod=POST&rawPath=/services/data/v51.0/sobjects/Contact")
```

The response is:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<Result>
    <id>0034x00000RnV6zAAF</id>
    <success>true</success>
</Result>
```

110.18. USING COMPOSITE SOBJECT COLLECTIONS

The SObject Collections API executes actions on multiple records in one request. Use sObject Collections to reduce the number of round-trips between the client and server. The entire request counts as a single call toward your API limits. This resource is available in API version 42.0 and later.

SObject records (aka DTOs) supplied to these operations must be instances of subclasses of **AbstractDescribedSObjectBase**. See the Maven Plugin section for information on generating these DTO classes. These operations serialize supplied DTOs to JSON.

110.18.1. compositeRetrieveSObjectCollections

Retrieve one or more records of the same object type.

Parameter	Type	Description	Default	Required
ids	List of String or comma-separated string	A list of one or more IDs of the objects to return. All IDs must belong to the same object type.		x
fields	List of String or comma-separated string	A list of fields to include in the response. The field names you specify must be valid, and you must have read-level permissions to each field.		x
sObjectName	String	Type of SObject, e.g. **Account**		x
sObjectClass	String	Fully-qualified class name of DTO class to use for deserializing the response.		Required if **sObjectName** parameter does not resolve to a class that exists in the package specified by the **package** option.

110.18.2. compositeCreateSObjectCollections

Add up to 200 records, returning a list of SaveSObjectResult objects. Mixed SObject types is supported.

Parameter	Type	Description	Default	Required
request body	List of **SObject**	A list of SObjects to create		x
allOrNone	boolean	Indicates whether to roll back the entire request when the creation of any object fails (true) or to continue with the independent creation of other objects in the request.	false	

110.18.3. compositeUpdateSObjectCollections

Update up to 200 records, returning a list of SaveSObjectResult objects. Mixed SObject types is supported.

Parameter	Type	Description	Default	Required
request body	List of **SObject**	A list of SObjects to update		x
allOrNone	boolean	Indicates whether to roll back the entire request when the update of any object fails (true) or to continue with the independent update of other objects in the request.	false	

110.18.4. compositeUpsertSObjectCollections

Create or update (upsert) up to 200 records based on an external ID field, returning a list of UpsertSObjectResult objects. Mixed SObject types is not supported.

Parameter	Type	Description	Default	Required
request body	List of **SObject**	A list of SObjects to upsert		x
allOrNone	boolean	Indicates whether to roll back the entire request when the upsert of any object fails (true) or to continue with the independent upsert of other objects in the request.	false	
sObjectName	String	Type of SObject, e.g. **Account**		x
sObjectIdName	String	Name of External ID field		x

110.18.5. compositeDeleteSObjectCollections

Delete up to 200 records, returning a list of DeleteSObjectResult objects. Mixed SObject types is supported.

Parameter	Type	Description	Default	Required
sObjectIds or request body	List of String or comma-separated string	A list of up to 200 IDs of objects to be deleted.		x
allOrNone	boolean	Indicates whether to roll back the entire request when the deletion of any object fails (true) or to continue with the independent deletion of other objects in the request.	false	

110.19. SENDING NULL VALUES TO SALESFORCE

By default, SObject fields with null values are not sent to salesforce. In order to send null values to salesforce, use the **fieldsToNull** property, as follows:

```
accountSObject.getFieldsToNull().add("Site");
```

110.20. GENERATING SOQL QUERY STRINGS

org.apache.camel.component.salesforce.api.utils.QueryHelper contains helper methods to generate SOQL queries. For instance to fetch all custom fields from *Account* SObject you can simply generate the SOQL SELECT by invoking:

```
String allCustomFieldsQuery = QueryHelper.queryToFetchFilteredFieldsOf(new Account(),
SObjectField::isCustom);
```

110.21. CAMEL SALESFORCE MAVEN PLUGIN

This Maven plugin generates DTOs for the Camel.

For obvious security reasons it is recommended that the clientId, clientSecret, userName and password fields be not set in the pom.xml. The plugin should be configured for the rest of the properties, and can be executed using the following command:

```
mvn camel-salesforce:generate -DcamelSalesforce.clientId=<clientid> -
DcamelSalesforce.clientSecret=<clientsecret> \
    -DcamelSalesforce.userName=<username> -DcamelSalesforce.password=<password>
```

The generated DTOs use Jackson annotations. All Salesforce field types are supported. Date and time fields are mapped to **java.time.ZonedDateTime** by default, and picklist fields are mapped to generated Java Enumerations.

Please refer to README.md for details on how to generate the DTO.

110.22. SPRING BOOT AUTO-CONFIGURATION

The component supports 91 options, which are listed below.

Name	Description	Default	Type
camel.component.salesforce.all-or-none	Composite API option to indicate to rollback all records if any are not successful.	false	Boolean
camel.component.salesforce.apex-method	APEX method name.		String
camel.component.salesforce.apex-query-params	Query params for APEX method.		Map
camel.component.salesforce.apex-url	APEX method URL.		String
camel.component.salesforce.api-version	Salesforce API version.	53.0	String
camel.component.salesforce.authentication-type	Explicit authentication method to be used, one of USERNAME_PASSWORD, REFRESH_TOKEN or JWT. Salesforce component can auto-determine the authentication method to use from the properties set, set this property to eliminate any ambiguity.		AuthenticationType
camel.component.salesforce.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.salesforce.backoff-increment	Backoff interval increment for Streaming connection restart attempts for failures beyond CometD auto-reconnect. The option is a long type.	1000	Long
camel.component.salesforce.batch-id	Bulk API Batch ID.		String

Name	Description	Default	Type
camel.component.salesforce.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.salesforce.client-id	OAuth Consumer Key of the connected app configured in the Salesforce instance setup. Typically a connected app needs to be configured but one can be provided by installing a package.		String
camel.component.salesforce.client-secret	OAuth Consumer Secret of the connected app configured in the Salesforce instance setup.		String
camel.component.salesforce.composite-method	Composite (raw) method.		String
camel.component.salesforce.config	Global endpoint configuration - use to set values that are common to all endpoints. The option is a org.apache.camel.component.salesforce.SalesforceEndpointConfig type.		SalesforceEndpointConfig
camel.component.salesforce.content-type	Bulk API content type, one of XML, CSV, ZIP_XML, ZIP_CSV.		ContentType
camel.component.salesforce.default-replay-id	Default replayId setting if no value is found in initialReplayIdMap.	-1	Long
camel.component.salesforce.enabled	Whether to enable auto configuration of the salesforce component. This is enabled by default.		Boolean
camel.component.salesforce.fall-back-replay-id	ReplayId to fall back to after an Invalid Replay Id response.	-1	Long
camel.component.salesforce.format	Payload format to use for Salesforce API calls, either JSON or XML, defaults to JSON. As of Camel 3.12, this option only applies to the Raw operation.		PayloadFormat

Name	Description	Default	Type
camel.component.salesforce.http-client	Custom Jetty Http Client to use to connect to Salesforce. The option is a org.apache.camel.component.salesforce.SalesforceHttpClient type.		SalesforceHttpClient
camel.component.salesforce.http-client-connection-timeout	Connection timeout used by the HttpClient when connecting to the Salesforce server.	60000	Long
camel.component.salesforce.http-client-idle-timeout	Timeout used by the HttpClient when waiting for response from the Salesforce server.	10000	Long
camel.component.salesforce.http-client-properties	Used to set any properties that can be configured on the underlying HTTP client. Have a look at properties of SalesforceHttpClient and the Jetty HttpClient for all available options.		Map
camel.component.salesforce.http-max-content-length	Max content length of an HTTP response.		Integer
camel.component.salesforce.http-proxy-auth-uri	Used in authentication against the HTTP proxy server, needs to match the URI of the proxy server in order for the httpProxyUsername and httpProxyPassword to be used for authentication.		String
camel.component.salesforce.http-proxy-excluded-addresses	A list of addresses for which HTTP proxy server should not be used.		Set
camel.component.salesforce.http-proxy-host	Hostname of the HTTP proxy server to use.		String
camel.component.salesforce.http-proxy-included-addresses	A list of addresses for which HTTP proxy server should be used.		Set
camel.component.salesforce.http-proxy-password	Password to use to authenticate against the HTTP proxy server.		String

Name	Description	Default	Type
camel.component.salesforce.http-proxy-port	Port number of the HTTP proxy server to use.		Integer
camel.component.salesforce.http-proxy-realm	Realm of the proxy server, used in preemptive Basic/Digest authentication methods against the HTTP proxy server.		String
camel.component.salesforce.http-proxy-secure	If set to false disables the use of TLS when accessing the HTTP proxy.	true	Boolean
camel.component.salesforce.http-proxy-socks4	If set to true the configures the HTTP proxy to use as a SOCKS4 proxy.	false	Boolean
camel.component.salesforce.http-proxy-use-digest-auth	If set to true Digest authentication will be used when authenticating to the HTTP proxy, otherwise Basic authorization method will be used.	false	Boolean
camel.component.salesforce.http-proxy-username	Username to use to authenticate against the HTTP proxy server.		String
camel.component.salesforce.http-request-buffer-size	HTTP request buffer size. May need to be increased for large SOQL queries.	8192	Integer
camel.component.salesforce.include-details	Include details in Salesforce1 Analytics report, defaults to false.		Boolean
camel.component.salesforce.initial-replay-id-map	Replay IDs to start from per channel name.		Map
camel.component.salesforce.instance-id	Salesforce1 Analytics report execution instance ID.		String
camel.component.salesforce.instance-url	URL of the Salesforce instance used after authentication, by default received from Salesforce on successful authentication.		String
camel.component.salesforce.job-id	Bulk API Job ID.		String

Name	Description	Default	Type
camel.component.salesforce.jwt-audience	Value to use for the Audience claim (aud) when using OAuth JWT flow. If not set, the login URL will be used, which is appropriate in most cases.		String
camel.component.salesforce.keystore	KeyStore parameters to use in OAuth JWT flow. The KeyStore should contain only one entry with private key and certificate. Salesforce does not verify the certificate chain, so this can easily be a selfsigned certificate. Make sure that you upload the certificate to the corresponding connected app. The option is a org.apache.camel.support.jsse.KeyStoreParameters type.		KeyStoreParameters
camel.component.salesforce.lazy-login	If set to true prevents the component from authenticating to Salesforce with the start of the component. You would generally set this to the (default) false and authenticate early and be immediately aware of any authentication issues.	false	Boolean
camel.component.salesforce.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.salesforce.limit	Limit on number of returned records. Applicable to some of the API, check the Salesforce documentation.		Integer
camel.component.salesforce.locator	Locator provided by salesforce Bulk 2.0 API for use in getting results for a Query job.		String
camel.component.salesforce.login-config	All authentication configuration in one nested bean, all properties set there can be set directly on the component as well. The option is a org.apache.camel.component.salesforce.SalesforceLoginConfig type.		SalesforceLoginConfig

Name	Description	Default	Type
camel.component.salesforce.login-url	URL of the Salesforce instance used for authentication, by default set to .		String
camel.component.salesforce.long-polling-transport-properties	Used to set any properties that can be configured on the LongPollingTransport used by the BayeuxClient (CometD) used by the streaming api.		Map
camel.component.salesforce.max-backoff	Maximum backoff interval for Streaming connection restart attempts for failures beyond CometD auto-reconnect. The option is a long type.	30000	Long
camel.component.salesforce.max-records	The maximum number of records to retrieve per set of results for a Bulk 2.0 Query. The request is still subject to the size limits. If you are working with a very large number of query results, you may experience a timeout before receiving all the data from Salesforce. To prevent a timeout, specify the maximum number of records your client is expecting to receive in the maxRecords parameter. This splits the results into smaller sets with this value as the maximum size.		Integer
camel.component.salesforce.not-found-behaviour	Sets the behaviour of 404 not found status received from Salesforce API. Should the body be set to NULL NotFoundBehaviour#NULL or should a exception be signaled on the exchange NotFoundBehaviour#EXCEPTION - the default.		NotFoundBehaviour
camel.component.salesforce.notify-for-fields	Notify for fields, options are ALL, REFERENCED, SELECT, WHERE.		NotifyForFieldsEnum
camel.component.salesforce.notify-for-operation-create	Notify for create operation, defaults to false (API version = 29.0).		Boolean
camel.component.salesforce.notify-for-operation-delete	Notify for delete operation, defaults to false (API version = 29.0).		Boolean
camel.component.salesforce.notify-for-operation-undelete	Notify for un-delete operation, defaults to false (API version = 29.0).		Boolean

Name	Description	Default	Type
camel.component.salesforce.notify-for-operation-update	Notify for update operation, defaults to false (API version = 29.0).		Boolean
camel.component.salesforce.notify-for-operations	Notify for operations, options are ALL, CREATE, EXTENDED, UPDATE (API version 29.0).		NotifyForOperationsEnum
camel.component.salesforce.object-mapper	Custom Jackson ObjectMapper to use when serializing/deserializing Salesforce objects. The option is a com.fasterxml.jackson.databind.ObjectMapper type.		ObjectMapper
camel.component.salesforce.packages	In what packages are the generated DTO classes. Typically the classes would be generated using camel-salesforce-maven-plugin. Set it if using the generated DTOs to gain the benefit of using short SObject names in parameters/header values. Multiple packages can be separated by comma.		String
camel.component.salesforce.password	Password used in OAuth flow to gain access to access token. It's easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows. Make sure that you append security token to the end of the password if using one.		String
camel.component.salesforce.pk-chunking	Use PK Chunking. Only for use in original Bulk API. Bulk 2.0 API performs PK chunking automatically, if necessary.		Boolean
camel.component.salesforce.pk-chunking-chunk-size	Chunk size for use with PK Chunking. If unspecified, salesforce default is 100,000. Maximum size is 250,000.		Integer
camel.component.salesforce.pk-chunking-parent	Specifies the parent object when you're enabling PK chunking for queries on sharing objects. The chunks are based on the parent object's records rather than the sharing object's records. For example, when querying on AccountShare, specify Account as the parent object. PK chunking is supported for sharing objects as long as the parent object is supported.		String
camel.component.salesforce.pk-chunking-start-row	Specifies the 15-character or 18-character record ID to be used as the lower boundary for the first chunk. Use this parameter to specify a starting ID when restarting a job that failed between batches.		String

Name	Description	Default	Type
camel.component.salesforce.query-locator	Query Locator provided by salesforce for use when a query results in more records than can be retrieved in a single call. Use this value in a subsequent call to retrieve additional records.		String
camel.component.salesforce.raw-http-headers	Comma separated list of message headers to include as HTTP parameters for Raw operation.		String
camel.component.salesforce.raw-method	HTTP method to use for the Raw operation.		String
camel.component.salesforce.raw-path	The portion of the endpoint URL after the domain name. E.g., '/services/data/v52.0/sobjects/Account/'.		String
camel.component.salesforce.raw-payload	Use raw payload String for request and response (either JSON or XML depending on format), instead of DTOs, false by default.	false	Boolean
camel.component.salesforce.raw-query-parameters	Comma separated list of message headers to include as query parameters for Raw operation. Do not url-encode values as this will be done automatically.		String
camel.component.salesforce.refresh-token	Refresh token already obtained in the refresh token OAuth flow. One needs to setup a web application and configure a callback URL to receive the refresh token, or configure using the builtin callback at and then retrive the refresh_token from the URL at the end of the flow. Note that in development organizations Salesforce allows hosting the callback web application at localhost.		String
camel.component.salesforce.report-id	Salesforce1 Analytics report Id.		String
camel.component.salesforce.report-metadata	Salesforce1 Analytics report metadata for filtering. The option is a org.apache.camel.component.salesforce.api.dto.analytics.reports.ReportMetadata type.		ReportMetadata
camel.component.salesforce.result-id	Bulk API Result ID.		String

Name	Description	Default	Type
camel.component.salesforce.s-object-blob-field-name	SObject blob field name.		String
camel.component.salesforce.s-object-class	Fully qualified SObject class name, usually generated using camel-salesforce-maven-plugin.		String
camel.component.salesforce.s-object-fields	SObject fields to retrieve.		String
camel.component.salesforce.s-object-id	SObject ID if required by API.		String
camel.component.salesforce.s-object-id-name	SObject external ID field name.		String
camel.component.salesforce.s-object-id-value	SObject external ID field value.		String
camel.component.salesforce.s-object-name	SObject name if required or supported by API.		String
camel.component.salesforce.s-object-query	Salesforce SOQL query string.		String
camel.component.salesforce.s-object-search	Salesforce SOSL search string.		String
camel.component.salesforce.ssl-context-parameters	SSL parameters to use, see SSLContextParameters class for all available options. The option is a org.apache.camel.support.jsse.SSLContextParameters type.		SSLContextParameters
camel.component.salesforce.update-topic	Whether to update an existing Push Topic when using the Streaming API, defaults to false.	false	Boolean

Name	Description	Default	Type
camel.component.salesforce.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.salesforce.user-name	Username used in OAuth flow to gain access to access token. It's easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows.		String
camel.component.salesforce.worker-pool-max-size	Maximum size of the thread pool used to handle HTTP responses.	20	Integer
camel.component.salesforce.worker-pool-size	Size of the thread pool used to handle HTTP responses.	10	Integer

CHAPTER 111. SAP COMPONENT

The SAP component is a package consisting of ten different SAP components. There are remote function call (RFC) components that support the sRFC, tRFC, and qRFC protocols and there are IDoc components that facilitate communication using messages in IDoc format. The component uses the SAP Java Connector (SAP JCo) library to facilitate bidirectional communication with SAP and the SAP IDoc library to transmit the documents in the Intermediate Document (IDoc) format.

111.1. DEPENDENCIES

Add the following dependency to your **pom.xml** for this component:

```
<dependency>
  <groupId>org.fusesource</groupId>
  <artifactId>camel-sap-starter</artifactId>
  <version>4.4.0.redhat-00019</version>
</dependency>
```

111.1.1. Additional platform restrictions for the SAP component

Because the SAP component depends on the third-party JCo 3 and IDoc 3 libraries, it can only be installed on the platforms that these libraries support.

111.1.2. SAP JCo and SAP IDoc libraries

A prerequisite for using the SAP component is that the SAP Java Connector (SAP JCo) libraries and the SAP IDoc library are installed into the **lib**/ directory of the Java runtime. You must make sure that you download the appropriate set of SAP libraries for your target operating system from the SAP Service Marketplace.

The names of the library files vary depending on the target operating system, as shown below.

Table 111.1. Required SAP Libraries

SAP Component	Linux and UNIX	Windows
SAP JCo 3	**sapjco3.jar** **libsapjco3.so**	**sapjco3.jar** **sapjco3.dll**
SAP IDoc	**sapidoc3.jar**	**sapidoc3.jar**

111.2. URI FORMAT

There are two different kinds of endpoint provided by the SAP component: the Remote Function Call (RFC) endpoints, and the Intermediate Document (IDoc) endpoints.

The URI formats for the RFC endpoints are as follows:

```
sap-srfc-destination:destinationName:rfcName
sap-trfc-destination:destinationName:rfcName
sap-qrfc-destination:destinationName:queueName:rfcName
```

```
sap-srfc-server:serverName:rfcName[?options]
sap-trfc-server:serverName:rfcName[?options]
```

The URI formats for the IDoc endpoints are as follows:

```
sap-idoc-
destination:destinationName:idocType[:idocTypeExtension[:systemRelease[:applicationRelease]]]
sap-idoclist-
destination:destinationName:idocType[:idocTypeExtension[:systemRelease[:applicationRelease]]]
sap-qidoc-
destination:destinationName:queueName:idocType[:idocTypeExtension[:systemRelease[:applicationR
elease]]]
sap-qidoclist-
destination:destinationName:queueName:idocType[:idocTypeExtension[:systemRelease[:applicationR
elease]]]
sap-idoclist-server:serverName:idocType[:idocTypeExtension[:systemRelease[:applicationRelease]]]
[?options]
```

The URI formats prefixed by sap-*endpointKind*-destination are used to define destination endpoints (in other words, Camel producer endpoints) and *destinationName* is the name of a specific outbound connection to an SAP instance. Outbound connections are named and configured at the component level.

The URI formats prefixed by sap-*endpointKind*-server are used to define server endpoints (in other words, Camel consumer endpoints) and *serverName* is the name of a specific inbound connection from an SAP instance. Inbound connections are named and configured at the component level.

The other components of an RFC endpoint URI are as follows:

rfcName

(Required) In a destination endpoint URI, is the name of the RFC invoked by the endpoint in the connected SAP instance. In a server endpoint URI, is the name of the RFC handled by the endpoint when invoked from the connected SAP instance.

queueName

Specifies the queue this endpoint sends an SAP request to.

The other components of an IDoc endpoint URI are as follows:

idocType

(Required) Specifies the Basic IDoc Type of an IDoc produced by this endpoint.

idocTypeExtension

Specifies the IDoc Type Extension, if any, of an IDoc produced by this endpoint.

systemRelease

Specifies the associated SAP Basis Release, if any, of an IDoc produced by this endpoint.

applicationRelease

Specifies the associated Application Release, if any, of an IDoc produced by this endpoint.

queueName

Specifies the queue this endpoint sends an SAP request to.

111.2.1. Options for RFC destination endpoints

The RFC destination endpoints (**sap-srfc-destination**, **sap-trfc-destination**, and **sap-qrfc-destination**) support the following URI options:

Name	Default	Description
stateful	**false**	If **true**, specifies that this endpoint initiates an SAP stateful session
transacted	**false**	If **true**, specifies that this endpoint initiates an SAP transaction

111.2.2. Options for RFC server endpoints

The SAP RFC server endpoints (**sap-srfc-server** and **sap-trfc-server**) support the following URI options:

Name	Default	Description
stateful	**false**	If **true**, specifies that this endpoint initiates an SAP stateful session.
propagateExceptions	**false**	**(sap-trfc-server endpoint only)** If **true**, specifies that this endpoint propagates exceptions back to the caller in SAP, instead of the exchange's exception handler.

111.2.3. Options for the IDoc List Server endpoint

The SAP IDoc List Server endpoint (**sap-idoclist-server**) supports the following URI options:

Name	Default	Description
stateful	**false**	If **true**, specifies that this endpoint initiates an SAP stateful session.
propagateExceptions	**false**	If **true**, specifies that this endpoint propagates exceptions back to the caller in SAP, instead of the exchange's exception handler.

111.2.4. Summary of the RFC and IDoc endpoints

The SAP component package provides the following RFC and IDoc endpoints:

sap-srfc-destination

Camel SAP Synchronous Remote Function Call Destination Camel component. This endpoint should be used in cases where Camel routes require synchronous delivery of requests to and responses from an SAP system.

NOTE

The sRFC protocol used by this component delivers requests and responses to and from an SAP system with **best effort**. In case of a communication error while sending a request, the completion status of a remote function call in the receiving SAP system remains **in doubt**.

sap-trfc-destination

Camel SAP Transactional Remote Function Call Destination Camel component. This endpoint should be used in cases where requests must be delivered to the receiving SAP system **at most once**. To accomplish this, the component generates a transaction ID, **tid**, which accompanies every request sent through the component in a route's exchange. The receiving SAP system records the **tid** accompanying a request before delivering the request; if the SAP system receives the request again with the same **tid** it will not deliver the request. Thus if a route encounters a communication error when sending a request through an endpoint of this component, it can retry sending the request within the same exchange knowing it will be delivered and executed only once.

NOTE

The tRFC protocol used by this component is asynchronous and does not return a response. Thus the endpoints of this component do not return a response message.

NOTE

This component does not guarantee the order of a series of requests through its endpoints, and the delivery and execution order of these requests may differ on the receiving SAP system due to communication errors and resends of a request. For guaranteed delivery order, please see the Camel SAP Queued Remote Function Call Destination Camel component.

sap-qrfc-destination

Camel SAP Queued Remote Function Call Destination Camel component. This component extends the capabilities of the Transactional Remote Function Call Destination camel component by adding **in order** delivery guarantees to the delivery of requests through its endpoints. This endpoint should be used in cases where a series of requests depend on each other and must be delivered to the receiving SAP system **at most once** and **in order**. The component accomplishes the **at most once** delivery guarantees using the same mechanisms as the Camel SAP Transactional Remote Function Call Destination Camel component. The ordering guarantee is accomplished by serializing the requests in the order they are received by the SAP system to an *inbound queue*. Inbound queues are processed by the *QIN scheduler* within SAP. When the inbound queue is **activated**, the QIN Scheduler will execute the queue requests in order.

NOTE

The qRFC protocol used by this component is asynchronous and does not return a response. Thus the endpoints of this component do not return a response message.

sap-srfc-server

Camel SAP Synchronous Remote Function Call Server Camel component. This component and its endpoints should be used in cases where a Camel route is required to synchronously handle requests from and responses to an SAP system.

sap-trfc-server

Camel SAP Transactional Remote Function Call Server Camel component. This endpoint should be used in cases where the sending SAP system requires **at most once** delivery of its requests to a Camel route. To accomplish this, the sending SAP system generates a transaction ID, **tid**, which accompanies every request it sends to the component's endpoints. The sending SAP system will first check with the component whether a given **tid** has been received by it before sending a series of requests associated with the **tid**. The component will check the list of received **tid**s it maintains, record the sent **tid** if it is not in that list, and then respond to the sending SAP system, indicating whether or not the **tid** has already been recorded. The sending SAP system will only then send the series of requests, if the **tid** has not been previously recorded. This enables a sending SAP system to reliably send a series of requests once to a camel route.

sap-idoc-destination

Camel SAP IDoc Destination Camel component. This endpoint should be used in cases where a Camel route sends a list of Intermediate Documents (IDocs) to an SAP system.

sap-idoclist-destination

Camel SAP IDoc List Destination Camel component. This endpoint should be used in cases where a Camel route sends a list of Intermediate documents (IDocs) list to an SAP system.

sap-qidoc-destination

Camel SAP Queued IDoc Destination Camel component. This component and its endpoints should be used in cases where a Camel route is required to send a list of Intermediate documents (IDocs) to an SAP system in order.

sap-qidoclist-destination

Camel SAP Queued IDoc List Destination Camel component. This component and its endpoints are used in cases where a camel route sends the Intermediate documents (IDocs) list to an SAP system in order.

sap-idoclist-server

Camel SAP IDoc List Server Camel component. This endpoint should be used in cases where a sending SAP system requires delivery of Intermediate Document lists to a Camel route. This component uses the tRFC protocol to communicate with SAP as described in the **sap-trfc-server-standalone** quick start.

111.2.5. SAP RFC destination endpoint

An RFC destination endpoint supports outbound communication to SAP, which enable these endpoints to make RFC calls out to ABAP function modules in SAP. An RFC destination endpoint is configured to make an RFC call to a specific ABAP function over a specific connection to an SAP instance. An RFC destination is a logical designation for an outbound connection and has a unique name. An RFC destination is specified by a set of connection parameters called *destination data*.

An RFC destination endpoint will extract an RFC request from the input message of the IN-OUT exchanges it receives and dispatch that request in a function call to SAP. The response from the function call will be returned in the output message of the exchange. Since SAP RFC destination endpoints only

support outbound communication, an RFC destination endpoint only supports the creation of producers.

111.2.6. SAP RFC server endpoint

An RFC server endpoint supports inbound communication from SAP, which enables ABAP applications in SAP to make RFC calls into server endpoints. An ABAP application interacts with an RFC server endpoint as if it were a remote function module. An RFC server endpoint is configured to receive an RFC call to a specific RFC function over a specific connection from an SAP instance. An RFC server is a logical designation for an inbound connection and has a unique name. An RFC server is specified by a set of connection parameters called *server data*.

An RFC server endpoint will handle an incoming RFC request and dispatch it as the input message of an IN-OUT exchange. The output message of the exchange will be returned as the response of the RFC call. Since SAP RFC server endpoints only support inbound communication, an RFC server endpoint only supports the creation of consumers.

111.2.7. SAP IDoc and IDoc list destination endpoints

An IDoc destination endpoint supports outbound communication to SAP, which can then perform further processing on the IDoc message. An IDoc document represents a business transaction, which can easily be exchanged with non-SAP systems. An IDoc destination is specified by a set of connection parameters called *destination data*.

An IDoc list destination endpoint is similar to an IDoc destination endpoint, except that the messages it handles consist of a **list** of IDoc documents.

111.2.8. SAP IDoc list server endpoint

An IDoc list server endpoint supports inbound communication from SAP, enabling a Camel route to receive a list of IDoc documents from an SAP system. An IDoc list server is specified by a set of connection parameters called *server data*.

111.2.9. Metadata repositories

A metadata repository is used to store the following kinds of metadata:

Interface descriptions of function modules

This metadata is used by the JCo and ABAP runtimes to check RFC calls to ensure the type-safe transfer of data between communication partners before dispatching those calls. A repository is populated with repository data. Repository data is a map of named function templates. A function template contains the metadata describing all the parameters and their typing information passed to and from a function module and has the unique name of the function module it describes.

IDoc type descriptions

This metadata is used by the IDoc runtime to ensure that the IDoc documents are correctly formatted before being sent to a communication partner. A basic IDoc type consists of a name, a list of permitted segments, and a description of the hierarchical relationship between the segments. Some additional constraints can be imposed on the segments: a segment can be mandatory or optional; and it is possible to specify a minimum/maximum range for each segment (defining the number of allowed repetitions of that segment).

SAP destination and server endpoints thus require access to a repository, in order to send and receive RFC calls and in order to send and receive IDoc documents. For RFC calls, the metadata for all function modules invoked and handled by the endpoints must reside within the repository; and for IDoc

endpoints, the metadata for all IDoc types and IDoc type extensions handled by the endpoints must reside within the repository. The location of the repository used by a destination and server endpoint is specified in the destination data and the server data of their respective connections.

In the case of an SAP destination endpoint, the repository it uses typically resides in an SAP system and it defaults to the SAP system it is connected to. This default requires no explicit configuration in the destination data. Furthermore, the metadata for the remote function call that a destination endpoint makes will already exist in a repository for any existing function module that it calls. The metadata for calls made by destination endpoints thus require no configuration in the SAP component.

On the other hand, the metadata for function calls handled by server endpoints do not typically reside in the repository of an SAP system and must instead be provided by a repository residing in the SAP component. The SAP component maintains a map of named metadata repositories. The name of a repository corresponds to the name of the server to which it provides metadata.

111.3. CONFIGURATION

The SAP component maintains three maps to store destination data, server data, and repository data. The *destination data store* and the *server data store* are configured on a special configuration object, **SapConnectionConfiguration**, which automatically gets injected into the SAP component (in the context of Blueprint XML configuration or Spring XML configuration files). The *repository data store* must be configured directly on the relevant SAP component.

111.3.1. Configuration Overview

The SAP component maintains three maps to store destination data, server data, and repository data. The component's property, **destinationDataStore**, stores destination data keyed by destination name, the property, **serverDataStore**, stores server data keyed by server name and the property, **repositoryDataStore**, stores repository data keyed by repository name. These configurations must be passed to the component during its initialization.

Example

The following example shows how to configure a sample destination data store and a sample server data store in a Blueprint XML file. The **sap-configuration** bean (of type **SapConnectionConfiguration**) will automatically be injected into any SAP component that is used in this XML file.

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
    ...
    <!-- Configures the Inbound and Outbound SAP Connections -->
    <bean id="sap-configuration"
        class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
        <property name="destinationDataStore">
            <map>
                <entry key="quickstartDest" value-ref="quickstartDestinationData" />
            </map>
        </property>
        <property name="serverDataStore">
            <map>
                <entry key="quickstartServer" value-ref="quickstartServerData" />
            </map>
        </property>
    </bean>
```

```
    <!-- Configures an Outbound SAP Connection -->
    <!-- *** Please enter the connection property values for your environment *** -->
    <bean id="quickstartDestinationData"
        class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
        <property name="ashost" value="example.com" />
        <property name="sysnr" value="00" />
        <property name="client" value="000" />
        <property name="user" value="username" />
        <property name="passwd" value="passowrd" />
        <property name="lang" value="en" />
    </bean>

    <!-- Configures an Inbound SAP Connection -->
    <!-- *** Please enter the connection property values for your environment ** -->
    <bean id="quickstartServerData"
        class="org.fusesource.camel.component.sap.model.rfc.impl.ServerDataImpl">
        <property name="gwhost" value="example.com" />
        <property name="gwserv" value="3300" />
        <!-- The following property values should not be changed -->
        <property name="progid" value="QUICKSTART" />
        <property name="repositoryDestination" value="quickstartDest" />
        <property name="connectionCount" value="2" />
    </bean>
</blueprint>
```

111.3.2. Destination Configuration

The configurations for destinations are maintained in the **destinationDataStore** property of the SAP component. Each entry in this map configures a distinct outbound connection to an SAP instance. The key for each entry is the name of the outbound connection and is used in the *destinationName* component of a destination endpoint URI as described in the URI format section.

The value for each entry is a destination data configuration object - **org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl** - that specifies the configuration of an outbound SAP connection.

Sample destination configuration

The following Blueprint XML code shows how to configure a sample destination with the name, **quickstartDest**.

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
    ...
    <!-- Create interceptor to support tRFC processing -->
    <bean id="currentProcessorDefinitionInterceptor"
          class="org.fusesource.camel.component.sap.CurrentProcessorDefinitionInterceptStrategy" />

    <!-- Configures the Inbound and Outbound SAP Connections -->
    <bean id="sap-configuration"
        class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
        <property name="destinationDataStore">
            <map>
                <entry key="quickstartDest" value-ref="quickstartDestinationData" />
            </map>
        </property>
```

```
    </bean>

    <!-- Configures an Outbound SAP Connection -->
    <!-- *** Please enter the connection property values for your environment *** -->
    <bean id="quickstartDestinationData"
        class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
        <property name="ashost" value="example.com" />
        <property name="sysnr" value="00" />
        <property name="client" value="000" />
        <property name="user" value="username" />
        <property name="passwd" value="password" />
        <property name="lang" value="en" />
    </bean>

</blueprint>
```

For example, after configuring the destination as shown in the preceding Blueprint XML file, you could invoke the **BAPI_FLCUST_GETLIST** remote function call on the **quickstartDest** destination using the following URI:

```
sap-srfc-destination:quickstartDest:BAPI_FLCUST_GETLIST
```

111.3.2.1. Interceptor for tRFC and qRFC destinations

The preceding sample destination configuration shows the instantiation of a **CurrentProcessorDefinitionInterceptStrategy** object. This object installs an interceptor in the Camel runtime, which enables the Camel SAP component to keep track of its position within a Camel route while it is handling RFC transactions.

IMPORTANT

This interceptor is critically important for transactional RFC destination endpoints (such as **sap-trfc-destination** and **sap-qrfc-destination**) and must be installed in the Camel runtime for outbound transactional RFC communication to be properly managed. The Destination RFC Transaction Handlers issues warnings into the Camel log if the strategy is not found at runtime. In this situation the Camel runtime will need to be re-provisioned and restarted to properly manage outbound transactional RFC communication.

111.3.2.2. Log on and authentication options

The following table lists the **log on and authentication** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
client		SAP client, mandatory log on parameter.
user		log on user, log on parameter for password based authentication.

aliasUser		log on user alias, can be used instead of log on user.
userId		User identity used for log on to the ABAP AS. Used by the JCo runtime, if the destination configuration uses SSO/assertion ticket, certificate, current user ,or SNC environment for authentication. The user ID is mandatory, if neither user nor user alias is set. This ID will never be sent to the SAP backend, it will be used by the JCo runtime locally.
passwd		log on password, log on parameter for password based authentication.
lang		log on language, if not defined, the default user language is used.
mysapsso2		Use the specified SAP Cookie Version 2 as a log on ticket for SSO based authentication.
x509cert		Use the specified X509 certificate for certificate based authentication.
lcheck		Postpone the authentication until the first call - 1 (enable). Used in special cases only.
useSapGui		Use a visible, hidden, or do not use SAP GUI
codePage		Additional log on parameter to define the codepage used to convert the log on parameters. Used in special cases only.
getsso2		Order an SSO ticket after log on, the obtained ticket is available in the destination attributes.
denyInitialPassword		If set to **1**, using initial passwords will lead to an exception (default is **0**).

111.3.2.3. Connection options

The following table lists the **connection** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
saprouter		SAP Router string for connection to systems behind a SAP Router. SAP Router string contains the chain of SAP Routers and theirs port numbers and has the form: **(/H/<host>[/S/<port>])+**.
sysnr		System number of the SAP ABAP application server, mandatory for a direct connection.
ashost		SAP ABAP application server, mandatory for a direct connection.
mshost		SAP message server, mandatory property for a load balancing connection.
msserv		SAP message server port, optional property for a load balancing connection. In order to resolve the service names sapmsXXX a lookup in **etc/services** is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no lookups are performed and no additional entries are needed.
gwhost		Allows specifying a concrete gateway, which should be used for establishing the connection to an application server. If not specified, the gateway on the application server is used.

gwserv		Should be set, when using gwhost. Allows specifying the port used on that gateway. If not specified, the port of the gateway on the application server is used. In order to resolve the service names sapgwXXX a lookup in etc/services is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no lookups are performed and no additional entries are needed.
r3name		System ID of the SAP system, mandatory property for a load balancing connection.
group		Group of SAP application servers, mandatory property for a load balancing connection.
network	**LAN**	Set this value depending on the network quality between JCo and your target system to optimize performance. The valid values are **LAN** or **WAN** (which is relevant for fast serialization only). If you set the **network** configuration option to **WAN**, a slower but more efficient compression algorithm is used and the data is analyzed for further compression options. If you set the **network** configuration to **LAN** a very fast compression algorithm is used and data analysis is performed only at a very basic level. When you set the **LAN** option, the compression ratio is not as efficient but the network transfer time is considered to be less significant. The default setting is **LAN**.
serializationFormat	**rowBased**	The valid values are **rowBased** or **columnBased**. For fast serialization **columnBased** must be set. The default serialization setting is **rowBased**.

111.3.2.4. Connection pool options

The following table lists the **connection pool** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
peakLimit	**0**	Maximum number of active outbound connections that can be created for a destination simultaneously. A value of **0** allows an unlimited number of active connections. Otherwise, if the value is less than the value of **jpoolCapacity**, it will be automatically increased to this value. Default setting is the value of **poolCapacity**, or in case of **poolCapacity** not being specified as well, the default is **0** (unlimited).
poolCapacity	**1**	Maximum number of idle outbound connections kept open by the destination. A value of **0** has the effect that there is no connection pooling (default is **1**).
expirationTime		Time in milliseconds after which a free connection held internally by the destination can be closed.
expirationPeriod		Period in milliseconds after which the destination checks the released connections for expiration.
maxGetTime		Maximum time in milliseconds to wait for a connection, if the maximum allowed number of connections has already been allocated by the application.

111.3.2.5. Secure network connection options

The following table lists the **secure network** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description

sncMode		Secure network connection (SNC) mode, **0** (off) or **1** (on).
sncPartnername		SNC partner, for example: **p:CN=R3, O=XYZ-INC, C=EN**.
sncQop		SNC level of security: **1** to **9**.
sncMyname		Own SNC name. Overrides the environment settings.
sncLibrary		Path to the library that provides the SNC service.

111.3.2.6. Repository options

The following table lists the **repository** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
repositoryDest		Specifies the destination which is used as a repository.
repositoryUser		If a repository destination is not set, and this property is set, it is used as user for repository calls. This enables you to use a different user for repository lookups.
repositoryPasswd		The password for a repository user. Mandatory, if a repository user is used.
repositorySnc		**(Optional)** If SNC is used for this destination, it is possible to turn it off for repository connections, if this property is set to **0**. Default setting is the value of **jco.client.snc**_mode. For special cases only.

repositoryRoundtripOptimization		Enable the **RFC_METADATA_GET** API, which provides the repository data in one single round trip. **1** Activates use of **RFC_METADATA_GET** in ABAP System. **0** Deactivates **RFC_METADATA_GET** in ABAP System. If the property is not set, the destination initially does a remote call to check whether **RFC_METADATA_GET** is available. If it is available, the destination will use it. **Note:** If the repository is already initialized (for example, because it is used by some other destination), this property does not have any effect. Generally, this property is related to the ABAP System, and should have the same value on all destinations pointing to the same ABAP System. See note 1456826 for backend prerequisites.

111.3.2.7. Trace configuration options

The following table lists the **trace configuration** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
trace		Enable/disable RFC trace (**0** or **1**).
cpicTrace		Enable/disable CPIC trace **[0..3]**.

111.3.3. Server Configuration

The configurations for servers are maintained in the **serverDataStore** property of the SAP component. Each entry in this map configures a distinct inbound connection from an SAP instance. The key for each entry is the name of the outbound connection and is used in the **serverName** component of a server

endpoint URI as described in the URI format section.

The value for each entry is a *server data configuration object*, **org.fusesource.camel.component.sap.model.rfc.impl.ServerDataImpl**, which defines the configuration of an inbound SAP connection.

Sample server configuration

The following Blueprint XML code shows how to create a sample server configuration with the name, **quickstartServer**.

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
    ...
    <!-- Configures the Inbound and Outbound SAP Connections -->
    <bean id="sap-configuration"
        class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
        <property name="destinationDataStore">
            <map>
                <entry key="quickstartDest" value-ref="quickstartDestinationData" />
            </map>
        </property>
        <property name="serverDataStore">
            <map>
                <entry key="quickstartServer" value-ref="quickstartServerData" />
            </map>
        </property>
    </bean>

    <!-- Configures an Outbound SAP Connection -->
    <!-- *** Please enter the connection property values for your environment *** -->
    <bean id="quickstartDestinationData"
        class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
        <property name="ashost" value="example.com" />
        <property name="sysnr" value="00" />
        <property name="client" value="000" />
        <property name="user" value="username" />
        <property name="passwd" value="passowrd" />
        <property name="lang" value="en" />
    </bean>

    <!-- Configures an Inbound SAP Connection -->
    <!-- *** Please enter the connection property values for your environment ** -->
    <bean id="quickstartServerData"
        class="org.fusesource.camel.component.sap.model.rfc.impl.ServerDataImpl">
        <property name="gwhost" value="example.com" />
        <property name="gwserv" value="3300" />
        <!-- The following property values should not be changed -->
        <property name="progid" value="QUICKSTART" />
        <property name="repositoryDestination" value="quickstartDest" />
        <property name="connectionCount" value="2" />
    </bean>
</blueprint>
```

Notice how this example also configures a destination connection, **quickstartDest**, which the server uses to retrieve metadata from a remote SAP instance. This destination is configured in the server data

through the **repositoryDestination** option. If you do not configure this option, you must create a local metadata repository instead.

For example, after configuring the destination as shown in the preceding Blueprint XML file, you could handle the **BAPI_FLCUST_GETLIST** remote function call from an invoking client, using the following URI:

```
sap-srfc-server:quickstartServer:BAPI_FLCUST_GETLIST
```

111.3.3.1. Required options

The required options for the server data configuration object are, as follows:

Name	Default Value	Description
gwhost		Gateway host on which the server connection should be registered.
gwserv		Gateway service, which is the port on which a registration can be done. In order to resolve the service names **sapgwXXX**, a lookup in **etc/services** is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no lookups are performed and no additional entries are needed.
progid		The program ID with which the registration is done. Serves as an identifier on the gateway and in the destination in the ABAP system.
repositoryDestination		Specifies a destination name that the server can use in order to retrieve metadata from a metadata repository hosted in a remote SAP server.
connectionCount		The number of connections that should be registered at the gateway.

111.3.3.2. Secure network connection options

The secure network connection options for the server data configuration object are as follows:

Name	Default Value	Description

sncMode		Secure network connection (SNC) mode, **0** (off) or **1** (on).
sncQop		SNC level of security, **1** to **9**.
sncMyname		SNC name of your server. Overrides the default SNC name. Typically something like **p:CN=JCoServer, O=ACompany, C=EN**.
sncLib		Path to library which provides SNC service. If this property is not provided, the value of the **jco.middleware.snc_lib** property is used instead.

111.3.3.3. Other options

The other options for the server data configuration object are, as follows:

Name	Default Value	Description
saprouter		SAP router string to use for a system protected by a firewall, which can therefore only be reached through a SAProuter, when registering the server at the gateway of that ABAP System. A typical router string is **/H/firewall.hostname/H/**.
maxStartupDelay		The maximum time (in seconds) between two start-up attempts in case of failures. The waiting time is doubled from initially 1 second after each start-up failure until either the maximum value is reached or the server could be started successfully.
trace		Enable/disable RFC trace (**0** or **1**)
workerThreadCount		The maximum number of threads used by the server connection. If not set, the value for the **connectionCount** is used as the **workerThreadCount**. The maximum number of threads can not exceed 99.

workerThreadMinCount		The minimum number of threads used by server connection. If not set, the value for **connectionCount** is used as the **workerThreadMinCount**.

111.3.4. Repository Configuration

The configurations for repositories are maintained in the **repositoryDataStore** property of the SAP Component. Each entry in this map configures a distinct repository. The key for each entry is the name of the repository and this key also corresponds to the name of the server to which this repository is attached.

The value of each entry is a repository data configuration object, **org.fusesource.camel.component.sap.model.rfc.impl.RepositoryDataImpl**, that defines the contents of a metadata repository. A repository data object is a map of function template configuration objects, **org.fuesource.camel.component.sap.model.rfc.impl.FunctionTemplateImpl**. Each entry in this map specifies the interface of a function module and the key for each entry is the name of the function module specified.

Repository data example

The following code shows a simple example of configuring a metadata repository:

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
    ...
    <!-- Configures the sap-srfc-server component -->
    <bean id="sap-configuration"
        class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
        <property name="repositoryDataStore">
            <map>
                <entry key="nplServer" value-ref="nplRepositoryData" />
            </map>
        </property>
    </bean>

    <!-- Configures a Metadata Repository -->
    <bean id="nplRepositoryData"
        class="org.fusesource.camel.component.sap.model.rfc.impl.RepositoryDataImpl">
        <property name="functionTemplates">
            <map>
                <entry key="BOOK_FLIGHT" value-ref="bookFlightFunctionTemplate" />
            </map>
        </property>
    </bean>
    ...
</blueprint>
```

111.3.4.1. Function template properties

The interface of a function module consists of four parameter lists by which data is transferred back and forth to the function module in an RFC call. Each parameter list consists of one or more fields, each of

which is a named parameter transferred in an RFC call. The following parameter lists and exception list are supported:

- The *import parameter list* contains parameter values sent to a function module in an RFC call;
- The *export parameter list* contains parameter values that are returned by a function module in an RFC call;
- The *changing parameter list* contains parameter values sent to and returned by a function module in an RFC call;
- The *table parameter list* contains internal table values sent to and returned by a function module in an RFC call.
- The interface of a function module also consists of an *exception list* of ABAP exceptions that may be raised when the module is invoked in an RFC call.

A function template describes the name and type of parameters in each parameter list of a function interface and the ABAP exceptions thrown by the function. A function template object maintains five property lists of metadata objects, as described in the following table.

Property	Description
importParameterList	A list of list field metadata objects, **org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl**. Specifies the parameters sent in an RFC call to a function module.
changingParameterList	A list of list field metadata objects, **org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl**. Specifies the parameters sent and returned in an RFC call to and from a function module.
exportParameterList	A list of list field metadata objects, **org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl**. Specifies the parameters returned in an RFC call from a function module.
tableParameterList	A list of list field metadata objects, **org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl**. Specifies the table parameters that are sent and returned in an RFC call to and from a function module.
exceptionList	A list of ABAP exception metadata objects, **org.fusesource.camel.component.sap.model.rfc.impl.AbapExceptionImpl**. Specifies the ABAP exceptions potentially raised in an RFC call of the function module.

Function template example

The following example shows an outline of how to configure a function template:

```
<bean id="bookFlightFunctionTemplate"
    class="org.fusesource.camel.component.sap.model.rfc.impl.FunctionTemplateImpl">
    <property name="importParameterList">
        <list>
            ...
        </list>
    </property>
    <property name="changingParameterList">
        <list>
            ...
        </list>
    </property>
    <property name="exportParameterList">
        <list>
            ...
        </list>
    </property>
    <property name="tableParameterList">
        <list>
            ...
        </list>
    </property>
    <property name="exceptionList">
        <list>
            ...
        </list>
    </property>
</bean>
```

111.3.4.2. List field metadata properties

A list field metadata object, **org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl**, specifies the name and type of a field in a parameter list. For an elementary parameter field (**CHAR**, **DATE**, **BCD**, **TIME**, **BYTE**, **NUM**, **FLOAT**, **INT**, **INT1**, **INT2**, **DECF16**, **DECF34**, **STRING**, **XSTRING**), the following table lists the configuration properties that may be set on a list field metadata object:

Name	Default Value	Description
name	-	The name of the parameter field.
type	-	The parameter type of the field.
byteLength	-	The field length in bytes for a non-Unicode layout. This value depends on the parameter type.
unicodeByteLength	-	The field length in bytes for a Unicode layout. This value depends on the parameter type.

decimals	**0**	The number of decimals in field value. Required for parameter types BCD and FLOAT.
optional	**false**	If **true**, the field is optional and need not be set in an RFC call.

Note that all elementary parameter fields require that the **name**, **type**, **byteLength**, and **unicodeByteLength** properties be specified in the field metadata object. In addition, the **BCD**, **FLOAT**, **DECF16**, and **DECF34** fields require the decimal property to be specified in the field metadata object.

For a complex parameter field of type **TABLE** or **STRUCTURE**, the following table lists the configuration properties that may be set on a list field metadata object:

Name	Default Value	Description
name	-	The name of the parameter field.
type	-	The parameter type of the field.
recordMetaData	-	The metadata for the structure or table. A record metadata object, **org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl**, is passed to specify the fields in the structure or table rows.
optional	**false**	If **true**, the field is optional and need not be set in a RFC call.

NOTE

All complex parameter fields require that the **name**, **type**, and **recordMetaData** properties be specified in the field metadata object. The value of the **recordMetaData** property is a record field metadata object, **org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl**, which specifies the structure of a nested structure or the structure of a table row.

Elementary list field metadata example

The following metadata configuration specifies an optional, 24-digit packed BCD number parameter with two decimal places named **TICKET_PRICE**:

```
<bean    class="org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl">
   <property name="name" value="TICKET_PRICE" />
   <property name="type" value="BCD" />
   <property name="byteLength" value="12" />
   <property name="unicodeByteLength" value="24" />
```

```
    <property name="decimals" value="2" />
    <property name="optional" value="true" />
</bean>
```

Complex list field metadata example

The following metadata configuration specifies a required **TABLE** parameter named **CONNINFO** with a row structure specified by the **connectionInfo** record metadata object:

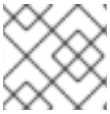
```
<bean    class="org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl">
    <property name="name" value="CONNINFO" />
    <property name="type" value="TABLE" />
    <property name="recordMetaData" ref="connectionInfo" />
</bean>
```

111.3.4.3. Record metadata properties

A record metadata object, **org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl**, specifies the name and contents of a nested **STRUCTURE** or the row of a **TABLE** parameter. A record metadata object maintains a list of record field metadata objects, **org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl**, which specifies the parameters that reside in the nested structure or table row.

The following table lists configuration properties that may be set on a record metadata object:

Name	Default Value	Description
name	-	The name of the record.
recordFieldMetaData	-	The list of record field metadata objects, **org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl**. Specifies the fields contained within the structure.



NOTE

All properties of the record metadata object are required.

Record metadata example

The following example shows how to configure a record metadata object:

```
<bean    id="connectionInfo"
        class="org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl">
    <property name="name" value="CONNECTION_INFO" />
    <property name="recordFieldMetaData">
        <list>
            ...
```

```
        </list>
      </property>
    </bean>
```

111.3.4.4. Record field metadata properties

A record field metadata object, **org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl**, specifies the name and type of a parameter field within a structure.

A record field metadata object is similar to a parameter field metadata object, except that the offsets of the individual field locations within the nested structure or table row must be additionally specified. The non-Unicode and Unicode offsets of an individual field must be calculated and specified from the sum of non-Unicode and Unicode byte lengths of the preceding fields in the structure or row.

NOTE

The failure to properly specify the offsets of fields in nested structures and table rows will cause the field storage of parameters in the underlying JCo and ABAP runtimes to overlap and prevent the proper transfer of values in RFC calls.

For an elementary parameter field (**CHAR**, **DATE**, **BCD**, **TIME**, **BYTE**, **NUM**, **FLOAT**, **INT**, **INT1**, **INT2**, **DECF16**, **DECF34**, **STRING**, **XSTRING**), the following table lists the configuration properties that may be set on a record field metadata object:

Name	Default Value	Description
name	-	The name of the parameter field.
type	-	The parameter type of the field.
byteLength	-	The field length in bytes for a non-Unicode layout. This value depends on the parameter type.
unicodeByteLength	-	The field length in bytes for a Unicode layout. This value depends on the parameter type.
byteOffset	-	The field offset in bytes for non-Unicode layout. This offset is the byte location of the field within the enclosing structure.
unicodeByteOffset	-	The field offset in bytes for Unicode layout. This offset is the byte location of the field within the enclosing structure.

decimals	**0**	The number of decimals in field value; only required for parameter types **BCD** and **FLOAT**.

For a complex parameter field of type **TABLE** or **STRUCTURE**, the following table lists the configuration properties that may be set on a record field metadata object:

Name	Default Value	Description
name	-	The name of the parameter field.
type	-	The parameter type of the field.
byteOffset	-	The field offset in bytes for non-Unicode layout. This offset is the byte location of the field within the enclosing structure.
unicodeByteOffset	-	The field offset in bytes for Unicode layout. This offset is the byte location of the field within the enclosing structure.
recordMetaData	-	The metadata for the structure or table. A record metadata object, **org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl**, is passed to specify the fields in the structure or table rows.

Elementary record field metadata example

The following metadata configuration specifies a **DATE** field parameter named **ARRDATE** located 85 bytes into the enclosing structure in the case of a non-Unicode layout and located 170 bytes into the enclosing structure in the case of a Unicode layout.

```
<bean    class="org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl">
   <property name="name" value="ARRDATE" />
   <property name="type" value="DATE" />
   <property name="byteLength" value="8" />
   <property name="unicodeByteLength" value="16" />
   <property name="byteOffset" value="85" />
   <property name="unicodeByteOffset" value="170" />
</bean>
```

Complex record field metadata example

The following metadata configuration specifies a **STRUCTURE** field parameter named **FLTINFO** with a structure specified by the **flightInfo** record metadata object. The parameter is located at the beginning of the enclosing structure in both the case of a non-Unicode and Unicode layout.

```
<bean    class="org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl">
   <property name="name" value="FLTINFO" />
   <property name="type" value="STRUCTURE" />
   <property name="byteOffset" value="0" />
   <property name="unicodeByteOffset" value="0" />
   <property name="recordMetaData" ref="flightInfo" />
</bean>
```

111.4. MESSAGE HEADERS

The SAP component supports the following message headers:

Header	Description
CamelSap.scheme	The URI scheme of the last endpoint to process the message. Use one of the following values: **sap-srfc-destination** **sap-trfc-destination** **sap-qrfc-destination** **sap-srfc-server** **sap-trfc-server** **sap-idoc-destination** **sap-idoclist-destination** **sap-qidoc-destination** **sap-qidoclist-destination** **sap-idoclist-server**
CamelSap.destinationName	The destination name of the last destination endpoint to process the message.
CamelSap.serverName	The server name of the last server endpoint to process the message.
CamelSap.queueName	The queue name of the last queuing endpoint to process the message.
CamelSap.rfcName	The RFC name of the last RFC endpoint to process the message.
CamelSap.idocType	The IDoc type of the last IDoc endpoint to process the message.

CamelSap.idocTypeExtension	The IDoc type extension, if any, of the last IDoc endpoint to process the message.
CamelSap.systemRelease	The system release, if any, of the last IDoc endpoint to process the message.
CamelSap.applicationRelease	The application release, if any, of the last IDoc endpoint to process the message.

111.5. EXCHANGE PROPERTIES

The SAP component adds the following exchange properties:

Property	Description
CamelSap.destinationPropertiesMap	A map containing the properties of each SAP destination encountered by the exchange. The map is keyed by destination name and each entry is a **java.util.Properties** object containing the configuration properties of that destination.
CamelSap.serverPropertiesMap	A map containing the properties of each SAP server encountered by the exchange. The map is keyed by server name and each entry is a **java.util.Properties** object containing the configuration properties of that server.

111.6. MESSAGE BODY FOR RFC

111.6.1. Request and response objects

An SAP endpoint expects to receive a message with a message body containing an SAP request object and will return a message with a message body containing an SAP response object. SAP requests and responses are fixed map data structures containing named fields with each field having a predefined data type.

Note that the named fields in an SAP request and response are specific to an SAP endpoint, with each endpoint defining the parameters in the SAP request and response it will accept. An SAP endpoint provides factory methods to create the request and response objects that are specific to it.

```
public class SAPEndpoint ... {
    ...
    public Structure getRequest() throws Exception;

    public Structure getResponse() throws Exception;
    ...
}
```

111.6.2. Structure objects

Both SAP request and response objects are represented in Java as a structure object which supports the **org.fusesource.camel.component.sap.model.rfc.Structure** interface. This interface extends both the **java.util.Map** and **org.eclipse.emf.ecore.EObject** interfaces.

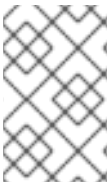
```
public interface Structure extends org.eclipse.emf.ecore.EObject,
                                   java.util.Map<String, Object> {

    <T> T get(Object key, Class<T> type);

}
```

The field values in a structure object are accessed through the field's getter methods in the map interface. In addition, the structure interface provides a type-restricted method to retrieve field values.

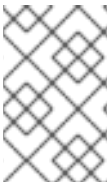
Structure objects are implemented in the component runtime using the Eclipse Modeling Framework (EMF) and support that framework's **EObject** interface. Instances of a structure object have attached metadata which define and restrict the structure and contents of the map of fields it provides. This metadata can be accessed and introspected using the standard methods provided by EMF. Please refer to the EMF documentation for further details.



NOTE

Attempts to get a parameter not defined on a structure object will return null. Attempts to set a parameter not defined on a structure will throw an exception as well as attempts to set the value of a parameter with an incorrect type.

As discussed in the following sections, structure objects can contain fields that contain values of the complex field types, **STRUCTURE**, and **TABLE**.



NOTE

It is unnecessary to create instances of these types and add them to the structure. Instances of these field values are created on demand if necessary when accessed in the enclosing structure.

111.6.3. Field types

The fields that reside within the structure object of an SAP request or response may be either *elementary* or *complex*. An elementary field contains a single scalar value, whereas a complex field will contain one or more fields of either an elementary or complex type.

111.6.3.1. Elementary field types

An elementary field may be a character, numeric, hexadecimal or string field type. The following table summarizes the types of elementary fields that may reside in a structure object:

Field Type	Corresponding Java Type	Byte Length	Unicode Byte Length	Number Decimals Digits	Description

CHAR	**java.lang.String**	1 to 65535	1 to 65535	-	ABAP Type 'C': Fixed sized character string
DATE	**java.util.Date**	8	16	-	ABAP Type 'D': Date (format: YYYYMMDD)
BCD	**java.math.BigDecimal**	1 to 16	1 to 16	0 to 14	ABAP Type 'P': Packed BCD number. A BCD number contains two digits per byte.
TIME	**java.util.Date**	6	12	-	ABAP Type 'T': Time (format: HHMMSS)
BYTE	**byte[]**	1 to 65535	1 to 65535	-	ABAP Type 'X':Fixed sized byte array
NUM	**java.lang.String**	1 to 65535	1 to 65535	-	ABAP Type 'N': Fixed sized numeric character string
FLOAT	**java.lang.Double**	8	8	0 to 15	ABAP Type 'F': Floating point number
INT	**java.lang.Integer**	4	4	-	ABAP Type 'I': 4-byte Integer
INT2	**java.lang.Integer**	2	2	-	ABAP Type 'S': 2-byte Integer
INT1	**java.lang.Integer**	1	1	-	ABAP Type 'B': 1-byte Integer
DECF16	**java.match.BigDecimal**	8	8	16	ABAP Type 'decfloat16': 8-byte Decimal Floating Point Number

DECF34	**java.math.BigDecimal**	16	16	34	ABAP Type 'decfloat34': 16-byte Decimal Floating Point Number
STRING	**java.lang.String**	8	8	-	ABAP Type 'G': Variable length character string
XSTRING	**byte[]**	8	8	-	ABAP Type 'Y': Variable length byte array

111.6.3.2. Character field types

A character field contains a fixed sized character string that may use either a non-Unicode or Unicode character encoding in the underlying JCo and ABAP runtimes. Non-Unicode character strings encode one character per byte. Unicode character strings are encoded in two bytes using UTF-16 encoding. Character field values are represented in Java as **java.lang.String** objects and the underlying JCo runtime is responsible for the conversion to their ABAP representation.

A character field declares its field length in its associated **byteLength** and **unicodeByteLength** properties, which determine the length of the field's character string in each encoding system.

CHAR

A **CHAR** character field is a text field containing alphanumeric characters and corresponds to the ABAP type C.

NUM

A **NUM** character field is a numeric text field containing numeric characters only and corresponds to the ABAP type N.

DATE

A **DATE** character field is an 8 character date field with the year, month and day formatted as **YYYYMMDD** and corresponds to the ABAP type D.

TIME

A **TIME** character field is a 6 character time field with the hours, minutes and seconds formatted as **HHMMSS** and corresponds to the ABAP type T.

111.6.3.3. Numeric field types

A numeric field contains a number. The following numeric field types are supported:

INT

An **INT** numeric field is an integer field stored as a 4-byte integer value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type I. An **INT** field value is represented in Java as a **java.lang.Integer** object.

INT2

An **INT2** numeric field is an integer field stored as a 2-byte integer value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type S. An **INT2** field value is represented in Java as a **java.lang.Integer** object.

INT1

An **INT1** field is an integer field stored as a 1-byte integer value in the underlying JCo and ABAP runtimes value and corresponds to the ABAP type B. An **INT1** field value is represented in Java as a **java.lang.Integer** object.

FLOAT

A **FLOAT** field is a binary floating point number field stored as an 8-byte double value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type F. A **FLOAT** field declares the number of decimal digits that the field's value contains in its associated decimal property. In the case of a **FLOAT** field, this decimal property can have a value between 1 and 15 digits. A **FLOAT** field value is represented in Java as a **java.lang.Double** object.

BCD

A **BCD** field is a binary coded decimal field stored as a 1 to 16 byte packed number in the underlying JCo and ABAP runtimes and corresponds to the ABAP type P. A packed number stores two decimal digits per byte. A **BCD** field declares its field length in its associated **byteLength** and **unicodeByteLength** properties. In the case of a **BCD** field, these properties can have a value between 1 and 16 bytes, and both properties will have the same value. A **BCD** field declares the number of decimal digits that the field's value contains in its associated decimal property. In the case of a **BCD** field, this decimal property can have a value between 1 and 14 digits. A **BCD** field value is represented in Java as a **java.math.BigDecimal**.

DECF16

A **DECF16** field is a decimal floating point stored as an 8-byte IEEE 754 decimal64 floating point value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type **decfloat16**. The value of a **DECF16** field has 16 decimal digits. The value of a **DECF16** field is represented in Java as **java.math.BigDecimal**.

DECF34

A **DECF34** field is a decimal floating point stored as a 16-byte IEEE 754 decimal128 floating point value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type **decfloat34**. The value of a **DECF34** field has 34 decimal digits. The value of a **DECF34** field is represented in Java as **java.math.BigDecimal**.

111.6.3.4. Hexadecimal field types

A hexadecimal field contains raw binary data. The following hexadecimal field types are supported:

BYTE

A **BYTE** field is a fixed sized byte string stored as a byte array in the underlying JCo and ABAP runtimes and corresponds to the ABAP type X. A **BYTE** field declares its field length in its associated **byteLength** and **unicodeByteLength** properties. In the case of a **BYTE** field, these properties can have a value between 1 and 65535 bytes and both properties will have the same value. The value of a **BYTE** field is represented in Java as a **byte[]** object.

111.6.3.5. String field types

A string field references a variable length string value. The length of that string value is not fixed until runtime. The storage for the string value is dynamically created in the underlying JCo and ABAP runtimes. The storage for the string field itself is fixed and contains only a string header.

STRING

A **STRING** field refers to a character string stored in the underlying JCo and ABAP runtimes as an 8-byte value. It corresponds to the ABAP type G. The value of the **STRING** field is represented in Java as a **java.lang.String** object.

XSTRING

An **XSTRING** field refers to a byte string stored in the underlying JCo and ABAP runtimes as an 8-byte value. It corresponds to the ABAP type Y. The value of the **STRING** field is represented in Java as a **byte[]** object.

111.6.3.6. Complex field types

A complex field may be either a structure or table field type. The following table summarizes these complex field types.

Field Type	Corresponding Java Type	Byte Length	Unicode Byte Length	Number Decimals Digits	Description
STRUCTURE	**org.fusesource.camel.component.sap.model.rfc.Structure**	Total of individual field byte lengths	Total of individual field Unicode byte lengths	-	ABAP Type 'u' & 'v': Heterogeneous Structure
TABLE	**org.fusesource.camel.component.sap.model.rfc.Table**	Byte length of row structure	Unicode byte length of row structure	-	ABAP Type 'h': Table

111.6.3.7. Structure field types

A **STRUCTURE** field contains a structure object and is stored in the underlying JCo and ABAP runtimes as an ABAP structure record. It corresponds to either an ABAP type **u** or **v**. The value of a **STRUCTURE** field is represented in Java as a structure object with the interface **org.fusesource.camel.component.sap.model.rfc.Structure**.

111.6.3.8. Table field types

A **TABLE** field contains a table object and is stored in the underlying JCo and ABAP runtimes as an ABAP internal table. It corresponds to the ABAP type **h**. The value of the field is represented in Java by a table object with the interface **org.fusesource.camel.component.sap.model.rfc.Table**.

111.6.3.9. Table objects

A table object is a homogeneous list data structure containing rows of structure objects with the same structure. This interface extends both the **java.util.List** and **org.eclipse.emf.ecore.EObject** interfaces.

```
public interface Table<S extends Structure>
    extends org.eclipse.emf.ecore.EObject,
    java.util.List<S> {

    /**
```

```
     * Creates and adds a table row at the end of the row list
     */
    S add();

    /**
     * Creates and adds a table row at the index in the row list
     */
    S add(int index);

}
```

The list of rows in a table object is accessed and managed using the standard methods defined in the list interface. In addition, the table interface provides two factory methods for creating and adding structure objects to the row list.

Table objects are implemented in the component runtime using the Eclipse Modeling Framework (EMF) and support that framework's EObject interface. Instances of a table object have attached metadata which define and restrict the structure and contents of the rows it provides. This metadata can be accessed and introspected using the standard methods provided by EMF. Please refer to the EMF documentation for further details.

NOTE

Attempts to add or set a row structure value of the wrong type will throw an exception.

111.7. MESSAGE BODY FOR IDOC

111.7.1. IDoc message type

When using one of the IDoc Camel SAP endpoints, the type of the message body depends on which particular endpoint you are using.

For a **sap-idoc-destination** endpoint or a **sap-qidoc-destination** endpoint, the message body is of **Document** type:

```
org.fusesource.camel.component.sap.model.idoc.Document
```

For a **sap-idoclist-destination** endpoint, a **sap-qidoclist-destination** endpoint, or a **sap-idoclist-server** endpoint, the message body is of **DocumentList** type:

```
org.fusesource.camel.component.sap.model.idoc.DocumentList
```

111.7.2. The IDoc document model

For the Camel SAP component, an IDoc document is modeled using the Eclipse Modeling Framework (EMF), which provides a wrapper API around the underlying SAP IDoc API. The most important types in this model are:

```
org.fusesource.camel.component.sap.model.idoc.Document
org.fusesource.camel.component.sap.model.idoc.Segment
```

The **Document** type represents an IDoc document instance. In outline, the **Document** interface exposes the following methods:

```
// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface Document extends EObject {
    // Access the field values from the IDoc control record
    String getArchiveKey();
    void setArchiveKey(String value);
    String getClient();
    void setClient(String value);
    ...

    // Access the IDoc document contents
    Segment getRootSegment();
}
```

The following kinds of method are exposed by the **Document** interface:

Methods for accessing the control record

Most of the methods are for accessing or modifying field values of the IDoc control record. These methods are of the form *AttributeName*, where *AttributeName* is the name of a field value.

Method for accessing the document contents

The **getRootSegment** method provides access to the document contents (IDoc data records), returning the contents as a **Segment** object. Each **Segment** object can contain an arbitrary number of child segments, and the segments can be nested to an arbitrary degree.

Note, however, that the precise layout of the segment hierarchy is defined by the particular *IDoc type* of the document. When creating (or reading) a segment hierarchy, therefore, you must be sure to follow the exact structure as defined by the IDoc type.

The **Segment** type is used to access the data records of the IDoc document, where the segments are laid out in accordance with the structure defined by the document's IDoc type. In outline, the **Segment** interface exposes the following methods:

```
// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface Segment extends EObject, java.util.Map<String, Object> {
    // Returns the value of the '<em><b>Parent</b></em>' reference.
    Segment getParent();

    // Return an immutable list of all child segments
    <S extends Segment> EList<S> getChildren();

    // Returns a list of child segments of the specified segment type.
    <S extends Segment> SegmentList<S> getChildren(String segmentType);

    EList<String> getTypes();

    Document getDocument();

    String getDescription();

    String getType();
```

```
    String getDefinition();

    int getHierarchyLevel();

    String getIdocType();

    String getIdocTypeExtension();

    String getSystemRelease();

    String getApplicationRelease();

    int getNumFields();

    long getMaxOccurrence();

    long getMinOccurrence();

    boolean isMandatory();

    boolean isQualified();

    int getRecordLength();

    <T> T get(Object key, Class<T> type);
}
```

The **getChildren(String segmentType)** method is particularly useful for adding new (nested) children to a segment. It returns an object of type, **SegmentList**, which is defined as follows:

```
// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface SegmentList<S extends Segment> extends EObject, EList<S> {
    S add();

    S add(int index);
}
```

Hence, to create a data record of **E1SCU_CRE** type, you could use Java code like the following:

```
Segment rootSegment = document.getRootSegment();

Segment E1SCU_CRE_Segment = rootSegment.getChildren("E1SCU_CRE").add();
```

111.7.3. How an IDoc is related to a Document object

According to the SAP documentation, an IDoc document consists of the following main parts:

Control record

The control record (which contains the metadata for the IDoc document) is represented by the attributes on the **Document** object.

Data records

The data records are represented by the **Segment** objects, which are constructed as a nested hierarchy of segments. You can access the root segment through the **Document.getRootSegment** method.

Status records

In the Camel SAP component, the status records are **not** represented by the document model. But you do have access to the latest status value through the **status** attribute on the control record.

Example of creating a Document instance

The following example shows how to create an IDoc document with the IDoc type, **FLCUSTOMER_CREATEFROMDATA01**, using the IDoc model API in Java.

Example 111.1. Creating an IDoc Document in Java

```
// Java
import org.fusesource.camel.component.sap.model.idoc.Document;
import org.fusesource.camel.component.sap.model.idoc.Segment;
import org.fusesource.camel.component.sap.util.IDocUtil;

import org.fusesource.camel.component.sap.model.idoc.Document;
import org.fusesource.camel.component.sap.model.idoc.DocumentList;
import org.fusesource.camel.component.sap.model.idoc.IdocFactory;
import org.fusesource.camel.component.sap.model.idoc.IdocPackage;
import org.fusesource.camel.component.sap.model.idoc.Segment;
import org.fusesource.camel.component.sap.model.idoc.SegmentChildren;
...
//
// Create a new IDoc instance using the modeling classes
//

// Get the SAP Endpoint bean from the Camel context.
// In this example, it's a 'sap-idoc-destination' endpoint.
SapTransactionalIDocDestinationEndpoint endpoint =
    exchange.getContext().getEndpoint(
        "bean:SapEndpointBeanID",
        SapTransactionalIDocDestinationEndpoint.class
    );

// The endpoint automatically populates some required control record attributes
Document document = endpoint.createDocument()

// Initialize additional control record attributes
document.setMessageType("FLCUSTOMER_CREATEFROMDATA");
document.setRecipientPartnerNumber("QUICKCLNT");
document.setRecipientPartnerType("LS");
document.setSenderPartnerNumber("QUICKSTART");
document.setSenderPartnerType("LS");

Segment rootSegment = document.getRootSegment();

Segment E1SCU_CRE_Segment = rootSegment.getChildren("E1SCU_CRE").add();

Segment E1BPSCUNEW_Segment =
E1SCU_CRE_Segment.getChildren("E1BPSCUNEW").add();
E1BPSCUNEW_Segment.put("CUSTNAME", "Fred Flintstone");
E1BPSCUNEW_Segment.put("FORM", "Mr.");
```

```
E1BPSCUNEW_Segment.put("STREET", "123 Rubble Lane");
E1BPSCUNEW_Segment.put("POSTCODE", "01234");
E1BPSCUNEW_Segment.put("CITY", "Bedrock");
E1BPSCUNEW_Segment.put("COUNTR", "US");
E1BPSCUNEW_Segment.put("PHONE", "800-555-1212");
E1BPSCUNEW_Segment.put("EMAIL", "fred@bedrock.com");
E1BPSCUNEW_Segment.put("CUSTTYPE", "P");
E1BPSCUNEW_Segment.put("DISCOUNT", "005");
E1BPSCUNEW_Segment.put("LANGU", "E");
```

111.8. DOCUMENT ATTRIBUTES

IDoc Document Attributes table shows the control record attributes that you can set on the **Document** object.

Table 111.2. IDoc Document Attributes

Attribute	Length	SAP Field	Description
archiveKey	70	**ARCKEY**	EDI archive key
client	3	**MANDT**	Client
creationDate	8	**CREDAT**	Date IDoc was created
creationTime	6	**CRETIM**	Time IDoc was created
direction	1	**DIRECT**	Direction
eDIMessage	14	**REFMES**	Reference to message
eDIMessageGroup	14	**REFGRP**	Reference to message group
eDIMessageType	6	**STDMES**	EDI message type
eDIStandardFlag	1	**STD**	EDI standard
eDIStandardVersion	6	**STDVRS**	Version of EDI standard
eDITransmissionFile	14	**REFINT**	Reference to interchange file
iDocCompoundType	8	**DOCTYP**	IDoc type
iDocNumber	16	**DOCNUM**	IDoc number
iDocSAPRelease	4	**DOCREL**	SAP Release of IDoc

Attribute	Length	SAP Field	Description
iDocType	30	**IDOCTP**	Name of basic IDoc type
iDocTypeExtension	30	**CIMTYP**	Name of extension type
messageCode	3	**MESCOD**	Logical message code
messageFunction	3	**MESFCT**	Logical message function
messageType	30	**MESTYP**	Logical message type
outputMode	1	**OUTMOD**	Output mode
recipientAddress	10	**RCVSAD**	Receiver address (SADR)
recipientLogicalAddress	70	**RCVLAD**	Logical address of receiver
recipientPartnerFunction	2	**RCVPFC**	Partner function of receiver
recipientPartnerNumber	10	**RCVPRN**	Partner number of receiver
recipientPartnerType	2	**RCVPRT**	Partner type of receiver
recipientPort	10	**RCVPOR**	Receiver port (SAP System, EDI subsystem)
senderAddress		**SNDSAD**	Sender address (SADR)
senderLogicalAddress	70	**SNDLAD**	Logical address of sender
senderPartnerFunction	2	**SNDPFC**	Partner function of sender
senderPartnerNumber	10	**SNDPRN**	Partner number of sender
senderPartnerType	2	**SNDPRT**	Partner type of sender
senderPort	10	**SNDPOR**	Sender port (SAP System, EDI subsystem)

Attribute	Length	SAP Field	Description
serialization	20	**SERIAL**	EDI/ALE: Serialization field
status	2	**STATUS**	Status of IDoc
testFlag	1	**TEST**	Test flag

111.8.1. Setting document attributes in Java

When setting the control record attributes in Java, the usual convention for Java bean properties is followed. That is, a **name** attribute can be accessed through the **getName** and **setName** methods, for getting and setting the attribute value. For example, the **iDocType**, **iDocTypeExtension**, and **messageType** attributes can be set as follows on a **Document** object:

```
// Java
document.setIDocType("FLCUSTOMER_CREATEFROMDATA01");
document.setIDocTypeExtension("");
document.setMessageType("FLCUSTOMER_CREATEFROMDATA");
```

111.8.2. Setting document attributes in XML

When setting the control record attributes in XML, the attributes must be set on the **idoc:Document** element. For example, the **iDocType**, **iDocTypeExtension**, and **messageType** attributes can be set as follows:

```
<?xml version="1.0" encoding="ASCII"?>
<idoc:Document ...
        iDocType="FLCUSTOMER_CREATEFROMDATA01"
        iDocTypeExtension=""
        messageType="FLCUSTOMER_CREATEFROMDATA" ... >
  ...
</idoc:Document>
```

111.9. TRANSACTION SUPPORT

111.9.1. BAPI transaction model

The SAP Component supports the BAPI transaction model for outbound communication with SAP. A destination endpoint with a URL containing the transacted option set to **true** will, if necessary, initiate a stateful session on the outbound connection of the endpoint and register a Camel Synchronization object with the exchange. This synchronization object will call the BAPI service method **BAPI_TRANSACTION_COMMIT** and end the stateful session when the processing of the message exchange is complete. If the processing of the message exchange fails, the synchronization object will call the BAPI server method **BAPI_TRANSACTION_ROLLBACK** and end the stateful session.

111.9.2. RFC transaction model

The tRFC protocol accomplishes an AT-MOST-ONCE delivery and processing guarantee by identifying

each transactional request with a unique transaction identifier (TID). A TID accompanies each request sent in the protocol. A sending application using the tRFC protocol must identify each instance of a request with a unique TID when sending the request. An application may send a request with a given TID multiple times, but the protocol ensures that the request is delivered and processed in the receiving system at most once. An application may choose to resend a request with a given TID when encountering a communication or system error when sending the request, and is thus in doubt as to whether that request was delivered and processed in the receiving system. By resending a request when encountering a communication error, a client application using the tRFC protocol can thus ensure EXACTLY-ONCE delivery and processing guarantees for its request.

111.9.3. Which transaction model to use?

A BAPI transaction is an application level transaction, in the sense that it imposes ACID guarantees on the persistent data changes performed by a BAPI method or RFC function in the SAP database. An RFC transaction is a communication transaction, in the sense that it imposes delivery guarantees (AT-MOST-ONCE, EXACTLY-ONCE, EXACTLY-ONCE-IN-ORDER) on requests to a BAPI method and/or RFC function.

111.9.4. Transactional RFC destination endpoints

The following destination endpoints support RFC transactions:

- **sap-trfc-destination**
- **sap-qrfc-destination**

A single Camel route can include multiple transactional RFC destination endpoints, sending messages to multiple RFC destinations and even sending messages to the same RFC destination multiple times. This implies that the Camel SAP component potentially needs to keep track of **many** transaction IDs (TIDs) for each **Exchange** object passing along a route. Now if the route processing fails and must be retried, the situation gets quite complicated. The RFC transaction semantics demand that each RFC destination along the route must be invoked using the **same** TID that was used the first time around (and where the TIDs for each destinations are distinct from each other). In other words, the Camel SAP component must keep track of which TID was used at which point along the route, and remember this information, so that the TIDs can be replayed in the correct order.

By default, Camel does not provide a mechanism that enables an **Exchange** to know where it is in a route. To provide such a mechanism, it is necessary to install the **CurrentProcessorDefinitionInterceptStrategy** interceptor into the Camel runtime. This interceptor must be installed into the Camel runtime, in order for the Camel SAP component to keep track of the TIDs in a route.

111.9.5. Transactional RFC server endpoints

The following server endpoints support RFC transactions:

- **sap-trfc-server**

When a Camel exchange processing a transactional request encounters a processing error, Camel handles the processing error through its standard error handling mechanisms. If the Camel route processing the exchange is configured to propagate the error back to the caller, the SAP server endpoint that initiated the exchange takes note of the failure and the sending SAP system is notified of the error. The sending SAP system can then respond by sending another transaction request with the same TID to process the request again.

111.10. XML SERIALIZATION FOR RFC

SAP request and response objects support an XML serialization format which enable these objects to be serialized to and from an XML document.

111.10.1. XML namespace

Each RFC in a repository defines a specific XML namespace for the elements which compose the serialized forms of its Request and Response objects. The form of this namespace URL is as follows:

```
http://sap.fusesource.org/rfc/<Repository Name>/<RFC Name>
```

RFC namespace URLs have a common **http://sap.fusesource.org/rfc** prefix followed by the name of the repository in which the RFC's metadata is defined. The final component in the URL is the name of the RFC itself.

111.10.2. Request and response XML documents

An SAP request object will be serialized into an XML document with the root element of that document named Request and scoped by the namespace of the request's RFC.

```
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Request
    xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
   ...
</BOOK_FLIGHT:Request>
```

An SAP response object will be serialized into an XML document with the root element of that document named Response and scoped by the namespace of the response's RFC.

```
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Response
    xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
   ...
</BOOK_FLIGHT:Response>
```

111.10.3. Structure fields

Structure fields in parameter lists or nested structures are serialized as elements. The element name of the serialized structure corresponds to the field name of the structure within the enclosing parameter list, structure or table row entry it resides.

```
<BOOK_FLIGHT:FLTINFO
    xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
   ...
</BOOK_FLIGHT:FLTINFO>
```

Note that the type name of the structure element in the RFC namespace will correspond to the name of the record metadata object which defines the structure, as in the following example:

```
<xs:schema
    targetNamespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
    xmlns:xs="http://www.w3.org/2001/XMLSchema">
```

```
    ...
    <xs:complexType name="FLTINFO_STRUCTURE”>
    ...
    </xs:complexType>
    ...
</xs:schema>
```

This distinction will be important when specifying a JAXB bean to marshal and unmarshal the structure.

111.10.4. Table fields

Table fields in parameter lists or nested structures are serialized as elements. The element name of the serialized structure will correspond to the field name of the table within the enclosing parameter list, structure, or table row entry it resides. The table element will contain a series of row elements to hold the serialized values of the table’s row entries.

```
<BOOK_FLIGHT:CONNINFO
     xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
    <row ... > ... </row>
    ...
    <row ... > ... </row>
</BOOK_FLIGHT:CONNINFO>
```

Note that the type name of the table element in the RFC namespace corresponds to the name of the record metadata object which defines the row structure of the table suffixed by **_TABLE**. The type name of the table row element in the RFC name corresponds to the name of the record metadata object which defines the row structure of the table, as in the following example:

```
<xs:schema
     targetNamespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT"
     xmlns:xs="http://www.w3.org/2001/XMLSchema">
    ...
    <xs:complextType name="CONNECTION_INFO_STRUCTURE_TABLE”>
        <xs:sequence>
            <xs:element
                name="row”
                minOccures="0”
                maxOccurs="unbounded”
                type="CONNECTION_INFO_STRUCTURE”/>
            ...
            <xs:sequence>
        </xs:sequence>
    </xs:complexType>

    <xs:complextType name="CONNECTION_INFO_STRUCTURE”>
            ...
    </xs:complexType>
    ...
</xs:schema>
```

This distinction will be important when specifying a JAXB bean to marshal and unmarshal the structure.

111.10.5. Elementary fields

Elementary fields in parameter lists or nested structures are serialized as attributes on the element of the enclosing parameter list or structure. The attribute name of the serialized field corresponds to the field name of the field within the enclosing parameter list, structure, or table row entry it resides, as in the following example:

```
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Request
    xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT"
    CUSTNAME="James Legrand"
   PASSFORM="Mr"
   PASSNAME="Travelin Joe"
   PASSBIRTH="1990-03-17T00:00:00.000-0500"
   FLIGHTDATE="2014-03-19T00:00:00.000-0400"
   TRAVELAGENCYNUMBER="00000110"
   DESTINATION_FROM="SFO"
   DESTINATION_TO="FRA"/>
```

111.10.6. Date and time formats

Date and Time fields are serialized into attribute values using the following format:

```
yyyy-MM-dd'T'HH:mm:ss.SSSZ
```

Date fields will be serialized with only the year, month, day and timezone components set:

```
DEPDATE="2014-03-19T00:00:00.000-0400"
```

Time fields will be serialized with only the hour, minute, second, millisecond and timezone components set:

```
DEPTIME="1970-01-01T16:00:00.000-0500"
```

111.11. XML SERIALIZATION FOR IDOC

An IDoc message body can be serialized into an XML string format, with the help of a built-in type converter.

111.11.1. XML namespace

Each serialized IDoc is associated with an XML namespace, which has the following general format:

```
http://sap.fusesource.org/idoc/repositoryName/idocType/idocTypeExtension/systemRelease/applicationRelease
```

Both the *repositoryName* (name of the remote SAP metadata repository) and the *idocType* (IDoc document type) are mandatory, but the other components of the namespace can be left blank. For example, you could have an XML namespace like the following:

```
http://sap.fusesource.org/idoc/MY_REPO/FLCUSTOMER_CREATEFROMDATA01///
```

111.11.2. Built-in type converter

The Camel SAP component has a built-in type converter, which is capable of converting a **Document** object or a **DocumentList** object to and from a **String** type.

For example, to serialize a **Document** object to an XML string, you can simply add the following line to a route in XML DSL:

```
<convertBodyTo type="java.lang.String"/>
```

You can also use this approach to a serialized XML message into a **Document** object. For example, given that the current message body is a serialized XML string, you can convert it back into a **Document** object by adding the following line to a route in XML DSL:

```
<convertBodyTo type="org.fusesource.camel.component.sap.model.idoc.Document"/>
```

111.11.3. Sample IDoc message body in XML format

When you convert an IDoc message to a **String**, it is serialized into an XML document, where the root element is either **idoc:Document** (for a single document) or **idoc:DocumentList** (for a list of documents). It shows that a single IDoc document that has been serialized to an **idoc:Document** element.

Example 111.2. IDoc Message Body in XML

```
<?xml version="1.0" encoding="ASCII"?>
<idoc:Document
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:FLCUSTOMER_CREATEFROMDATA01---
="http://sap.fusesource.org/idoc/XXX/FLCUSTOMER_CREATEFROMDATA01///"
    xmlns:idoc="http://sap.fusesource.org/idoc"
    creationDate="2015-01-28T12:39:13.980-0500"
    creationTime="2015-01-28T12:39:13.980-0500"
    iDocType="FLCUSTOMER_CREATEFROMDATA01"
    iDocTypeExtension=""
    messageType="FLCUSTOMER_CREATEFROMDATA"
    recipientPartnerNumber="QUICKCLNT"
    recipientPartnerType="LS"
    senderPartnerNumber="QUICKSTART"
    senderPartnerType="LS">
  <rootSegment xsi:type="FLCUSTOMER_CREATEFROMDATA01---:ROOT" document="/">
    <segmentChildren parent="//@rootSegment">
      <E1SCU_CRE parent="//@rootSegment" document="/">
        <segmentChildren parent="//@rootSegment/@segmentChildren/@E1SCU_CRE.0">
          <E1BPSCUNEW parent="//@rootSegment/@segmentChildren/@E1SCU_CRE.0"
              document="/"
              CUSTNAME="Fred Flintstone" FORM="Mr."
              STREET="123 Rubble Lane"
              POSTCODE="01234"
              CITY="Bedrock"
              COUNTR="US"
              PHONE="800-555-1212"
              EMAIL="fred@bedrock.com"
              CUSTTYPE="P"
              DISCOUNT="005"
              LANGU="E"/>
```

```
        </segmentChildren>
      </E1SCU_CRE>
    </segmentChildren>
  </rootSegment>
</idoc:Document>
```

111.12. EXAMPLE 1: READING DATA FROM SAP

This example demonstrates a route that reads **FlightCustomer** business object data from SAP. The route invokes the **FlightCustomer** BAPI method, **BAPI_FLCUST_GETLIST**, using an SAP synchronous RFC destination endpoint to retrieve the data.

111.12.1. Java DSL for route

The Java DSL for the example route is as follows:

```
from("direct:getFlightCustomerInfo")
    .to("bean:createFlightCustomerGetListRequest")
    .to("sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST")
    .to("bean:returnFlightCustomerInfo");
```

111.12.2. XML DSL for route

And the Spring DSL for the same route is as follows:

```
<route>
    <from uri="direct:getFlightCustomerInfo"/>
    <to uri="bean:createFlightCustomerGetListRequest"/>
    <to uri="sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST"/>
    <to uri="bean:returnFlightCustomerInfo"/>
</route>
```

111.12.3. createFlightCustomerGetListRequest bean

The **createFlightCustomerGetListRequest** bean is responsible for building an SAP request object in its exchange method that is used in the RFC call of the subsequent SAP endpoint. The following code snippet demonstrates the sequence of operations to build the request object:

```
public void create(Exchange exchange) throws Exception {

    // Get SAP Endpoint to be called from context.
    SapSynchronousRfcDestinationEndpoint endpoint =
        exchange.getContext().getEndpoint("sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST",
                                          SapSynchronousRfcDestinationEndpoint.class);

    // Retrieve bean from message containing Flight Customer name to
    // look up.
    BookFlightRequest bookFlightRequest =
        exchange.getIn().getBody(BookFlightRequest.class);

    // Create SAP Request object from target endpoint.
```

```
    Structure request = endpoint.getRequest();

    // Add Customer Name to request if set
    if (bookFlightRequest.getCustomerName() != null &&
        bookFlightRequest.getCustomerName().length() > 0) {
            request.put("CUSTOMER_NAME",
                    bookFlightRequest.getCustomerName());
        }
    } else {
        throw new Exception("No Customer Name");
    }

    // Put request object into body of exchange message.
    exchange.getIn().setBody(request);
}
```

111.12.4. returnFlightCustomerInfo bean

The **returnFlightCustomerInfo** bean is responsible for extracting data from the SAP response object in its exchange method that it receives from the previous SAP endpoint. The following code snippet demonstrates the sequence of operations to extract the data from the response object:

```
public void createFlightCustomerInfo(Exchange exchange) throws Exception {

    // Retrieve SAP response object from body of exchange message.
    Structure flightCustomerGetListResponse =
        exchange.getIn().getBody(Structure.class);

    if (flightCustomerGetListResponse == null) {
        throw new Exception("No Flight Customer Get List Response");
    }

    // Check BAPI return parameter for errors
    @SuppressWarnings("unchecked")
    Table<Structure> bapiReturn =
        flightCustomerGetListResponse.get("RETURN", Table.class);
    Structure bapiReturnEntry = bapiReturn.get(0);
    if (bapiReturnEntry.get("TYPE", String.class) != "S") {
        String message = bapiReturnEntry.get("MESSAGE", String.class);
        throw new Exception("BAPI call failed: " + message);
    }

    // Get customer list table from response object.
    @SuppressWarnings("unchecked")
    Table<? extends Structure> customerList =
        flightCustomerGetListResponse.get("CUSTOMER_LIST", Table.class);

    if (customerList == null || customerList.size() == 0) {
        throw new Exception("No Customer Info.");
    }

    // Get Flight Customer data from first row of table.
    Structure customer = customerList.get(0);

    // Create bean to hold Flight Customer data.
```

```
    FlightCustomerInfo flightCustomerInfo = new FlightCustomerInfo();

    // Get customer id from Flight Customer data and add to bean.
    String customerId = customer.get("CUSTOMERID", String.class);
    if (customerId != null) {
        flightCustomerInfo.setCustomerNumber(customerId);
    }

    ...

    // Put bean into body of exchange message.
    exchange.getIn().setHeader("flightCustomerInfo", flightCustomerInfo);

}
```

111.13. EXAMPLE 2: WRITING DATA TO SAP

This example demonstrates a route that creates a **FlightTrip** business object instance in SAP. The route invokes the **FlightTrip** BAPI method, **BAPI_FLTRIP_CREATE**, using a destination endpoint to create the object.

111.13.1. Java DSL for route

The Java DSL for the example route is as follows:

```
from("direct:createFlightTrip")
    .to("bean:createFlightTripRequest")
    .to("sap-srfc-destination:nplDest:BAPI_FLTRIP_CREATE?transacted=true")
    .to("bean:returnFlightTripResponse");
```

111.13.2. XML DSL for route

And the Spring DSL for the same route is as follows:

```
<route>
    <from uri="direct:createFlightTrip"/>
    <to uri="bean:createFlightTripRequest"/>
    <to uri="sap-srfc-destination:nplDest:BAPI_FLTRIP_CREATE?transacted=true"/>
    <to uri="bean:returnFlightTripResponse"/>
</route>
```

111.13.3. Transaction support

Note that the URL for the SAP endpoint has the **transacted** option set to **true**. When this option is enabled, the endpoint ensures that an SAP transaction session has been initiated before invoking the RFC call. Because this endpoint's RFC creates new data in SAP, this option is necessary to make the route's changes permanent in SAP.

111.13.4. Populating request parameters

The **createFlightTripRequest** and **returnFlightTripResponse** beans are responsible for populating request parameters into the SAP request and extracting response parameters from the SAP response respectively, following the same sequence of operations as demonstrated in the previous example.

111.14. EXAMPLE 3: HANDLING REQUESTS FROM SAP

This example demonstrates a route which handles a request from SAP to the **BOOK_FLIGHT** RFC, which is implemented by the route. In addition, it demonstrates the component's XML serialization support, using JAXB to unmarshal and marshal SAP request objects and response objects to custom beans.

This route creates a **FlightTrip** business object on behalf of a travel agent, **FlightCustomer**. The route first unmarshals the SAP request object received by the SAP server endpoint into a custom JAXB bean. This custom bean is then multicasted in the exchange to three sub-routes, which gather the travel agent, flight connection, and passenger information required to create the flight trip. The final sub-route creates the flight trip object in SAP, as demonstrated in the previous example. The final sub-route also creates and returns a custom JAXB bean which is marshaled into an SAP response object and returned by the server endpoint.

111.14.1. Java DSL for route

The Java DSL for the example route is as follows:

```
DataFormat jaxb = new JaxbDataFormat("org.fusesource.sap.example.jaxb");

from("sap-srfc-server:nplserver:BOOK_FLIGHT")
    .unmarshal(jaxb)
    .multicast()
    .to("direct:getFlightConnectionInfo",
        "direct:getFlightCustomerInfo",
        "direct:getPassengerInfo")
    .end()
    .to("direct:createFlightTrip")
    .marshal(jaxb);
```

111.14.2. XML DSL for route

And the XML DSL for the same route is as follows:

```
<route>
    <from uri="sap-srfc-server:nplserver:BOOK_FLIGHT"/>
    <unmarshal>
        <jaxb contextPath="org.fusesource.sap.example.jaxb"/>
    </unmarshal>
    <multicast>
        <to uri="direct:getFlightConnectionInfo"/>
        <to uri="direct:getFlightCustomerInfo"/>
        <to uri="direct:getPassengerInfo"/>
    </multicast>
    <to uri="direct:createFlightTrip"/>
    <marshal>
        <jaxb contextPath="org.fusesource.sap.example.jaxb"/>
    </marshal>
</route>
```

111.14.3. BookFlightRequest bean

The following listing illustrates a JAXB bean which unmarshals from the serialized form of an SAP **BOOK_FLIGHT** request object:

```
@XmlRootElement(name="Request",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class BookFlightRequest {

    @XmlAttribute(name="CUSTNAME")
    private String customerName;

    @XmlAttribute(name="FLIGHTDATE")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date flightDate;

    @XmlAttribute(name="TRAVELAGENCYNUMBER")
    private String travelAgencyNumber;

    @XmlAttribute(name="DESTINATION_FROM")
    private String startAirportCode;

    @XmlAttribute(name="DESTINATION_TO")
    private String endAirportCode;

    @XmlAttribute(name="PASSFORM")
    private String passengerFormOfAddress;

    @XmlAttribute(name="PASSNAME")
    private String passengerName;

    @XmlAttribute(name="PASSBIRTH")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date passengerDateOfBirth;

    @XmlAttribute(name="CLASS")
    private String flightClass;

    ...
}
```

111.14.4. BookFlightResponse bean

The following listing illustrates a JAXB bean which marshals to the serialized form of an SAP **BOOK_FLIGHT** response object:

```
@XmlRootElement(name="Response",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class BookFlightResponse {

    @XmlAttribute(name="TRIPNUMBER")
    private String tripNumber;

    @XmlAttribute(name="TICKET_PRICE")
    private BigDecimal ticketPrice;
```

```
    @XmlAttribute(name="TICKET_TAX")
    private BigDecimal ticketTax;

    @XmlAttribute(name="CURRENCY")
    private String currency;

    @XmlAttribute(name="PASSFORM")
    private String passengerFormOfAddress;

    @XmlAttribute(name="PASSNAME")
    private String passengerName;

    @XmlAttribute(name="PASSBIRTH")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date passengerDateOfBirth;

    @XmlElement(name="FLTINFO")
    private FlightInfo flightInfo;

    @XmlElement(name="CONNINFO")
    private ConnectionInfoTable connectionInfo;

    ...
}
```

NOTE

The complex parameter fields of the response object are serialized as child elements of the response.

111.14.5. FlightInfo bean

The following listing illustrates a JAXB bean which marshals to the serialized form of the complex structure parameter **FLTINFO**:

```
@XmlRootElement(name="FLTINFO",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class FlightInfo {

    @XmlAttribute(name="FLIGHTTIME")
    private String flightTime;

    @XmlAttribute(name="CITYFROM")
    private String cityFrom;

    @XmlAttribute(name="DEPDATE")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date departureDate;

    @XmlAttribute(name="DEPTIME")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date departureTime;
```

```
    @XmlAttribute(name="CITYTO")
    private String cityTo;

    @XmlAttribute(name="ARRDATE")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date arrivalDate;

    @XmlAttribute(name="ARRTIME")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date arrivalTime;

    ...
}
```

111.14.6. ConnectionInfoTable bean

The following listing illustrates a JAXB bean which marshals to the serialized form of the complex table parameter, **CONNINFO**. Note that the name of the root element type of the JAXB bean corresponds to the name of the row structure type suffixed with **_TABLE** and the bean contains a list of row elements.

```
@XmlRootElement(name="CONNINFO_TABLE",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class ConnectionInfoTable {

    @XmlElement(name="row")
    List<ConnectionInfo> rows;

    ...
}
```

111.14.7. ConnectionInfo bean

The following listing illustrates a JAXB bean, which marshals to the serialized form of the above tables row elements:

```
@XmlRootElement(name="CONNINFO",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class ConnectionInfo {

    @XmlAttribute(name="CONNID")
    String connectionId;

    @XmlAttribute(name="AIRLINE")
    String airline;

    @XmlAttribute(name="PLANETYPE")
    String planeType;

    @XmlAttribute(name="CITYFROM")
    String cityFrom;

    @XmlAttribute(name="DEPDATE")
```

```
    @XmlJavaTypeAdapter(DateAdapter.class)
    Date departureDate;

    @XmlAttribute(name="DEPTIME")
    @XmlJavaTypeAdapter(DateAdapter.class)
    Date departureTime;

    @XmlAttribute(name="CITYTO")
    String cityTo;

    @XmlAttribute(name="ARRDATE")
    @XmlJavaTypeAdapter(DateAdapter.class)
    Date arrivalDate;

    @XmlAttribute(name="ARRTIME")
    @XmlJavaTypeAdapter(DateAdapter.class)
    Date arrivalTime;

    ...
}
```

CHAPTER 112. XQUERY

Camel supports XQuery to allow an Expression or Predicate to be used in the DSL.

For example, you could use XQuery to create a predicate in a Message Filter or as an expression for a Recipient List.

112.1. DEPENDENCIES

To use XQuery in your camel routes you need to add the a dependency on **camel-saxon** which implements the XQuery language. When using **xquery** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-saxon-starter</artifactId>
</dependency>
```

112.2. XQUERY LANGUAGE OPTIONS

The XQuery language supports 4 options, which are listed below.

Name	Default	Java Type	Description
type		**String**	Sets the class name of the result type (type from output) The default result type is NodeSet.
headerName		**String**	Name of header to use as input, instead of the message body.
configurationRef		**String**	Reference to a saxon configuration instance in the registry to use for xquery (requires camel-saxon). This may be needed to add custom functions to a saxon configuration, so these custom functions can be used in xquery expressions.
trim		**Boolean**	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

112.3. VARIABLES

The message body will be set as the **contextItem**. And the following variables are available as well:

Variable	Type	Description
exchange	Exchange	The current Exchange
in.body	Object	The message body

Variable	Type	Description
out.body	Object	**deprecated** The OUT message body (if any)
in.headers.*	Object	You can access the value of exchange.in.headers with key **foo** by using the variable which name is in.headers.foo
out.headers.*	Object	**deprecated** You can access the value of exchange.out.headers with key**foo** by using the variable which name is out.headers.foo variable
key name	Object	Any exchange.properties and exchange.in.headers and any additional parameters set using **setParameters(Map)**. These parameters are added with they own key name, for instance if there is an IN header with the key name **foo** then its added as**foo**.

112.4. EXAMPLE

```
from("queue:foo")
  .filter().xquery("//foo")
  .to("queue:bar")
```

You can also use functions inside your query, in which case you need an explicit type conversion, or you will get an **org.w3c.dom.DOMException: HIERARCHY_REQUEST_ERR**). You need to pass in the expected output type of the function. For example the concat function returns a **String** which is done as shown:

```
from("direct:start")
  .recipientList().xquery("concat('mock:foo.', /person/@city)", String.class);
```

And in XML DSL:

```
<route>
  <from uri="direct:start"/>
  <recipientList>
    <xquery type="java.lang.String">concat('mock:foo.', /person/@city</xquery>
  </recipientList>
</route>
```

112.4.1. Using namespaces

If you have a standard set of namespaces you wish to work with and wish to share them across many XQuery expressions you can use the **org.apache.camel.support.builder.Namespaces** when using Java DSL as shown:

```
Namespaces ns = new Namespaces("c", "http://acme.com/cheese");

from("direct:start")
  .filter().xquery("/c:person[@name='James']", ns)
  .to("mock:result");
```

Notice how the namespaces are provided to **xquery** with the **ns** variable that are passed in as the 2nd parameter.

Each namespace is a key=value pair, where the prefix is the key. In the XQuery expression then the namespace is used by its prefix, eg:

```
/c:person[@name='James']
```

The namespace builder supports adding multiple namespaces as shown:

```
Namespaces ns = new Namespaces("c", "http://acme.com/cheese")
                    .add("w", "http://acme.com/wine")
                    .add("b", "http://acme.com/beer");
```

When using namespaces in XML DSL then its different, as you setup the namespaces in the XML root tag (or one of the **camelContext**, **routes**, **route** tags).

In the XML example below we use Spring XML where the namespace is declared in the root tag **beans**, in the line with **xmlns:foo="http://example.com/person"**:

```
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:foo="http://example.com/person"
       xsi:schemaLocation="
       http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
       http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
spring.xsd">

  <camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring">
    <route>
      <from uri="activemq:MyQueue"/>
      <filter>
        <xquery>/foo:person[@name='James']</xquery>
        <to uri="mqseries:SomeOtherQueue"/>
      </filter>
    </route>
  </camelContext>
</beans>
```

This namespace uses **foo** as prefix, so the **<xquery>** expression uses **/foo:** to use this namespace.

112.5. USING XQUERY AS TRANSFORMATION

We can do a message translation using transform or setBody in the route, as shown below:

```
from("direct:start").
  transform().xquery("/people/person");
```

Notice that xquery will use DOMResult by default, so if we want to grab the value of the person node, using **text()** we need to tell XQuery to use String as result type, as shown:

```
from("direct:start").
  transform().xquery("/people/person/text()", String.class);
```

–

If you want to use Camel variables like headers, you have to explicitly declare them in the XQuery expression.

```
<transform>
  <xquery>
     declare variable $in.headers.foo external;
     element item {$in.headers.foo}
  </xquery>
</transform>
```

112.6. LOADING SCRIPT FROM EXTERNAL RESOURCE

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**. This is done using the following syntax: **"resource:scheme:location"**, e.g. to refer to a file on the classpath you can do:

```
.setHeader("myHeader").xquery("resource:classpath:myxquery.txt", String.class)
```

112.7. LEARNING XQUERY

XQuery is a very powerful language for querying, searching, sorting and returning XML. For help learning XQuery try these tutorials

- Mike Kay's XQuery Primer
- The W3Schools XQuery Tutorial

112.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
camel.component.xquery.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.xquery.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.xquery.configuration	To use a custom Saxon configuration. The option is a net.sf.saxon.Configuration type.		Configuration
camel.component.xquery.configuration-properties	To set custom Saxon configuration properties.		Map
camel.component.xquery.enabled	Whether to enable auto configuration of the xquery component. This is enabled by default.		Boolean
camel.component.xquery.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.xquery.module-u-r-i-resolver	To use the custom ModuleURIResolver. The option is a net.sf.saxon.lib.ModuleURIResolver type.		ModuleURIResolver
camel.language.xquery.configuration-ref	Reference to a saxon configuration instance in the registry to use for xquery (requires camel-saxon). This may be needed to add custom functions to a saxon configuration, so these custom functions can be used in xquery expressions.		String
camel.language.xquery.enabled	Whether to enable auto configuration of the xquery language. This is enabled by default.		Boolean
camel.language.xquery.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

Name	Description	Default	Type
camel.language.xquery.type	Sets the class name of the result type (type from output) The default result type is NodeSet.		String

CHAPTER 113. SCHEDULER

Only consumer is supported

The Scheduler component is used to generate message exchanges when a scheduler fires. This component is similar to the Timer component, but it offers more functionality in terms of scheduling. Also this component uses JDK **ScheduledExecutorService**. Where as the timer uses a JDK **Timer**.

You can only consume events from this endpoint.

113.1. DEPENDENCIES

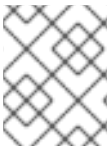
When using **scheduler** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-scheduler-starter</artifactId>
</dependency>
```

113.2. URI FORMAT

```
scheduler:name[?options]
```

Where **name** is the name of the scheduler, which is created and shared across endpoints. So if you use the same name for all your scheduler endpoints, only one scheduler thread pool and thread will be used - but you can configure the thread pool to allow more concurrent threads.



NOTE

The IN body of the generated exchange is **null**. So **exchange.getIn().getBody()** returns **null**.

113.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

113.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

113.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

113.4. COMPONENT OPTIONS

The Scheduler component supports 3 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
poolSize (scheduler)	Number of core threads in the thread pool used by the scheduling thread pool. Is by default using a single thread.	1	int

113.5. ENDPOINT OPTIONS

The Scheduler endpoint is configured using URI syntax:

```
scheduler:name
```

with the following path and query parameters:

113.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (consumer)	**Required** The name of the scheduler.		String

113.5.2. Query Parameters (21 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
poolSize (scheduler)	Number of core threads in the thread pool used by the scheduling thread pool. Is by default using a single thread.	1	int
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

113.6. MORE INFORMATION

This component is a scheduler Polling Consumer where you can find more information about the options above, and examples at the Polling Consumer page.

113.7. EXCHANGE PROPERTIES

When the timer is fired, it adds the following information as properties to the **Exchange**:

Name	Type	Description
Exchange.TIMER_NAME	**String**	The value of the **name** option.
Exchange.TIMER_FIRED_TIME	**Date**	The time when the consumer fired.

113.8. SAMPLE

To set up a route that generates an event every 60 seconds:

```
from("scheduler://foo?delay=60000").to("bean:myBean?method=someMethodName");
```

The above route will generate an event and then invoke the **someMethodName** method on the bean called **myBean** in the Registry such as JNDI or Spring.

And the route in Spring DSL:

```
<route>
  <from uri="scheduler://foo?delay=60000"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

113.9. FORCING THE SCHEDULER TO TRIGGER IMMEDIATELY WHEN COMPLETED

To let the scheduler trigger as soon as the previous task is complete, you can set the option **greedy=true**. But beware then the scheduler will keep firing all the time. So use this with caution.

113.10. FORCING THE SCHEDULER TO BE IDLE

There can be use cases where you want the scheduler to trigger and be greedy. But sometimes you want "tell the scheduler" that there was no task to poll, so the scheduler can change into idle mode using the backoff options. To do this you would need to set a property on the exchange with the key **Exchange.SCHEDULER_POLLED_MESSAGES** to a boolean value of false. This will cause the consumer to indicate that there was no messages polled.

The consumer will otherwise as by default return 1 message polled to the scheduler, every time the consumer has completed processing the exchange.

113.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.scheduler.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.scheduler.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.scheduler.enabled	Whether to enable auto configuration of the scheduler component. This is enabled by default.		Boolean
camel.component.scheduler.pool-size	Number of core threads in the thread pool used by the scheduling thread pool. Is by default using a single thread.	1	Integer

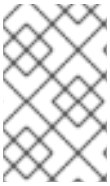
CHAPTER 114. SEDA

Both producer and consumer are supported

The SEDA component provides asynchronous SEDA behavior, so that messages are exchanged on a BlockingQueue and consumers are invoked in a separate thread from the producer.

Note that queues are only visible within a *single* CamelContext. If you want to communicate across **CamelContext** instances (for example, communicating between Web applications), see the component.

This component does not implement any kind of persistence or recovery, if the VM terminates while messages are yet to be processed. If you need persistence, reliability or distributed SEDA, try using either JMS or ActiveMQ.



NOTE

Synchronous
The Direct component provides synchronous invocation of any consumers when a producer sends a message exchange.

114.1. DEPENDENCIES

When using **seda** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-seda-starter</artifactId>
</dependency>
```

114.2. URI FORMAT

```
seda:someName[?options]
```

Where **someName** can be any string that uniquely identifies the endpoint within the current CamelContext.

114.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

114.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

114.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

114.4. COMPONENT OPTIONS

The SEDA component supports 10 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Sets the default number of concurrent threads processing exchanges.	1	int
defaultPollTimeout (consumer (advanced))	The timeout (in milliseconds) used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	int
defaultBlockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean

Name	Description	Default	Type
defaultDiscardWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will be discarded. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will give up sending and continue, meaning that the message was not sent to the SEDA queue.	false	boolean
defaultOfferTimeout (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, where a configured timeout can be added to the block case. Utilizing the .offer(timeout) method of the underlining java queue.		long
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
defaultQueueFactory (advanced)	Sets the default queue factory.		BlockingQueueFactory
queueSize (advanced)	Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).	1000	int

114.5. ENDPOINT OPTIONS

The SEDA endpoint is configured using URI syntax:

```
seda:name
```

with the following path and query parameters:

114.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (common)	**Required** Name of queue.		String

114.5.2. Query Parameters (18 parameters)

Name	Description	Default	Type
size (common)	The maximum capacity of the SEDA queue (i.e., the number of messages it can hold). Will by default use the defaultSize set on the SEDA component.	1000	int
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Number of concurrent threads processing exchanges.	1	int
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
limitConcurrentConsumers (consumer (advanced))	Whether to limit the number of concurrentConsumers to the maximum of 500. By default, an exception will be thrown if an endpoint is configured with a greater number. You can disable that check by turning this option off.	true	boolean

Name	Description	Default	Type
multipleConsumers (consumer (advanced))	Specifies whether multiple consumers are allowed. If enabled, you can use SEDA for Publish-Subscribe messaging. That is, you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.	false	boolean
pollTimeout (consumer (advanced))	The timeout (in milliseconds) used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	int
purgeWhenStopping (consumer (advanced))	Whether to purge the task queue when stopping the consumer/route. This allows to stop faster, as any pending messages on the queue is discarded.	false	boolean
blockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean
discardIfNoConsumers (producer)	Whether the producer should discard the message (do not add the message to the queue), when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.	false	boolean
discardWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will be discarded. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will give up sending and continue, meaning that the message was not sent to the SEDA queue.	false	boolean
failIfNoConsumers (producer)	Whether the producer should fail by throwing an exception, when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
offerTimeout (producer)	Offer timeout (in milliseconds) can be added to the block case when queue is full. You can disable timeout by using 0 or a negative value.		long
timeout (producer)	Timeout (in milliseconds) before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable timeout by using 0 or a negative value.	30000	long
waitForTaskToComplete (producer)	Option to specify whether the caller should wait for the async task to complete or not before continuing. The following three options are supported: Always, Never or IfReplyExpected. The first two values are self-explanatory. The last value, IfReplyExpected, will only wait if the message is Request Reply based. The default option is IfReplyExpected. Enum values: • Never • IfReplyExpected • Always	IfReplyExpected	WaitForTaskToComplete
queue (advanced)	Define the queue instance which will be used by the endpoint.		BlockingQueue

114.6. CHOOSING BLOCKINGQUEUE IMPLEMENTATION

By default, the SEDA component always intantiates LinkedBlockingQueue, but you can use different implementation, you can reference your own BlockingQueue implementation, in this case the size option is not used

```
<bean id="arrayQueue" class="java.util.ArrayBlockingQueue">
  <constructor-arg index="0" value="10" ><!-- size -->
  <constructor-arg index="1" value="true" ><!-- fairness -->
</bean>

<!-- ... and later -->
<from>seda:array?queue=#arrayQueue</from>
```

Or you can reference a BlockingQueueFactory implementation, 3 implementations are provided LinkedBlockingQueueFactory, ArrayBlockingQueueFactory and PriorityBlockingQueueFactory:

```
<bean id="priorityQueueFactory"
class="org.apache.camel.component.seda.PriorityBlockingQueueFactory">
  <property name="comparator">
    <bean class="org.apache.camel.demo.MyExchangeComparator" />
  </property>
</bean>

<!-- ... and later -->
<from>seda:priority?queueFactory=#priorityQueueFactory&size=100</from>
```

114.7. USE OF REQUEST REPLY

The SEDA component supports using Request Reply, where the caller will wait for the Async route to complete. For instance:

```
from("mina:tcp://0.0.0.0:9876?textline=true&sync=true").to("seda:input");

from("seda:input").to("bean:processInput").to("bean:createResponse");
```

In the route above, we have a TCP listener on port 9876 that accepts incoming requests. The request is routed to the **seda:input** queue. As it is a Request Reply message, we wait for the response. When the consumer on the **seda:input** queue is complete, it copies the response to the original message response.

114.8. CONCURRENT CONSUMERS

By default, the SEDA endpoint uses a single consumer thread, but you can configure it to use concurrent consumer threads. So instead of thread pools you can use:

```
from("seda:stageName?concurrentConsumers=5").process(...)
```

As for the difference between the two, note a *thread pool* can increase/shrink dynamically at runtime depending on load, whereas the number of concurrent consumers is always fixed.

114.9. THREAD POOLS

Be aware that adding a thread pool to a SEDA endpoint by doing something like:

```
from("seda:stageName").thread(5).process(...)
```

Can wind up with two **BlockQueues**: one from the SEDA endpoint, and one from the workqueue of the thread pool, which may not be what you want. Instead, you might wish to configure a Direct endpoint with a thread pool, which can process messages both synchronously and asynchronously. For example:

```
from("direct:stageName").thread(5).process(...)
```

You can also directly configure number of threads that process messages on a SEDA endpoint using the **concurrentConsumers** option.

114.10. SAMPLE

In the route below we use the SEDA queue to send the request to this async queue to be able to send a fire-and-forget message for further processing in another thread, and return a constant reply in this thread to the original caller.

We send a Hello World message and expects the reply to be OK.

```
@Test
public void testSendAsync() throws Exception {
    MockEndpoint mock = getMockEndpoint("mock:result");
    mock.expectedBodiesReceived("Hello World");

    // START SNIPPET: e2
    Object out = template.requestBody("direct:start", "Hello World");
    assertEquals("OK", out);
    // END SNIPPET: e2

    assertMockEndpointsSatisfied();
}

@Override
protected RouteBuilder createRouteBuilder() throws Exception {
    return new RouteBuilder() {
        // START SNIPPET: e1
        public void configure() throws Exception {
            from("direct:start")
                // send it to the seda queue that is async
                .to("seda:next")
                // return a constant response
                .transform(constant("OK"));

            from("seda:next").to("mock:result");
        }
        // END SNIPPET: e1
    };
}
```

The "Hello World" message will be consumed from the SEDA queue from another thread for further processing. Since this is from a unit test, it will be sent to a **mock** endpoint where we can do assertions in the unit test.

114.11. USING MULTIPLECONSUMERS

In this example we have defined two consumers.

```
@Test
public void testSameOptionsProducerStillOkay() throws Exception {
    getMockEndpoint("mock:foo").expectedBodiesReceived("Hello World");
    getMockEndpoint("mock:bar").expectedBodiesReceived("Hello World");

    template.sendBody("seda:foo", "Hello World");

    assertMockEndpointsSatisfied();
}

@Override
protected RouteBuilder createRouteBuilder() throws Exception {
    return new RouteBuilder() {
        @Override
        public void configure() throws Exception {
            from("seda:foo?multipleConsumers=true").routeId("foo").to("mock:foo");
            from("seda:foo?multipleConsumers=true").routeId("bar").to("mock:bar");
        }
    };
}
```

Since we have specified **multipleConsumers=true** on the seda foo endpoint we can have those two consumers receive their own copy of the message as a kind of pub-sub style messaging.

As the beans are part of an unit test they simply send the message to a mock endpoint.

114.12. EXTRACTING QUEUE INFORMATION

If needed, information such as queue size, etc. can be obtained without using JMX in this fashion:

```
SedaEndpoint seda = context.getEndpoint("seda:xxxx");
int size = seda.getExchanges().size();
```

114.13. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
camel.component.seda.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.seda.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.seda.concurrent-consumers	Sets the default number of concurrent threads processing exchanges.	1	Integer
camel.component.seda.default-block-when-full	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	Boolean
camel.component.seda.default-discard-when-full	Whether a thread that sends messages to a full SEDA queue will be discarded. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will give up sending and continue, meaning that the message was not sent to the SEDA queue.	false	Boolean
camel.component.seda.default-offer-timeout	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, where a configured timeout can be added to the block case. Utilizing the .offer(timeout) method of the underlining java queue.		Long
camel.component.seda.default-poll-timeout	The timeout (in milliseconds) used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	Integer
camel.component.seda.default-queue-factory	Sets the default queue factory. The option is a org.apache.camel.component.seda.BlockingQueueFactory<org.apache.camel.Exchange> type.		BlockingQueueFactory
camel.component.seda.enabled	Whether to enable auto configuration of the seda component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.seda.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.seda.queue-size	Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).	1000	Integer

CHAPTER 115. SERVLET

Only consumer is supported

The Servlet component provides HTTP based endpoints for consuming HTTP requests that arrive at a HTTP endpoint that is bound to a published Servlet.

NOTE

Stream

Servlet is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream **once**. If you find a situation where the message body appears to be empty or you need to access the data multiple times (eg: doing multicasting, or redelivery error handling) you should use Stream caching or convert the message body to a **String** which is safe to be read multiple times.

115.1. DEPENDENCIES

When using **servlet** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-servlet-starter</artifactId>
</dependency>
```

115.2. URI FORMAT

```
servlet://relative_path[?options]
```

115.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

115.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

115.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

115.4. COMPONENT OPTIONS

The Servlet component supports 11 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
muteException (consumer)	If enabled and an Exchange failed processing on the consumer side the response's body won't contain the exception's stack trace.	false	boolean
servletName (consumer)	Default name of servlet to use. The default name is CamelServlet.	Camel Servlet	String
attachmentMultipartBinding (consumer (advanced))	Whether to automatic bind multipart/form-data as attachments on the Camel Exchange. The options attachmentMultipartBinding=true and disableStreamCache=false cannot work together. Remove disableStreamCache to use AttachmentMultipartBinding. This is turned off by default as this may require servlet specific configuration to enable this when using Servlets.	false	boolean
fileNameExtWhitelist (consumer (advanced))	Whitelist of accepted filename extensions for accepting uploaded files. Multiple extensions can be separated by comma, such as txt,xml.		String

Name	Description	Default	Type
httpRegistry (consumer (advanced))	To use a custom org.apache.camel.component.servlet.HttpRegistry.		HttpRegistry
allowJavaSerializedObject (advanced)	Whether to allow java serialization when a request uses context-type=application/x-java-serialized-object. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
httpBinding (advanced)	To use a custom HttpBinding to control the mapping between Camel message and HttpClient.		HttpBinding
httpConfiguration (advanced)	To use the shared HttpConfiguration as base configuration.		HttpConfiguration
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy

115.5. ENDPOINT OPTIONS

The Servlet endpoint is configured using URI syntax:

```
servlet:contextPath
```

with the following path and query parameters:

115.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
contextPath (consumer)	**Required** The context-path to use.		String

115.5.2. Query Parameters (22 parameters)

Name	Description	Default	Type
chunked (consumer)	If this option is false the Servlet will disable the HTTP streaming and set the content-length header on the response.	true	boolean
disableStreamCache (common)	Determines whether or not the raw input stream from Servlet is cached or not (Camel will read the stream into a in memory/overflow to file, Stream caching) cache. By default Camel will cache the Servlet input stream to support reading it multiple times to ensure Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultHttpBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times. If you use Servlet to bridge/proxy an endpoint then consider enabling this option to improve performance, in case you do not need to read the message payload multiple times. The http producer will by default cache the response body stream. If this option is set to true, then the producers will not cache the response body stream but use the response stream as-is as the message body.	false	boolean
headerFilterStrategy (common)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
httpBinding (common (advanced))	To use a custom HttpBinding to control the mapping between Camel message and HttpClient.		HttpBinding
async (consumer)	Configure the consumer to work in async mode.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
httpMethodRestrict (consumer)	Used to only allow consuming if the HttpMethod matches, such as GET/POST/PUT etc. Multiple methods can be specified separated by comma.		String
matchOnUriPrefix (consumer)	Whether or not the consumer should try to find a target consumer by matching the URI prefix if no exact match is found.	false	boolean
muteException (consumer)	If enabled and an Exchange failed processing on the consumer side the response's body won't contain the exception's stack trace.	false	boolean
responseBufferSize (consumer)	To use a custom buffer size on the javax.servlet.ServletResponse.		Integer
servletName (consumer)	Name of the servlet to use.	Camel Servlet	String
transferException (consumer)	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was sent back serialized in the response as an application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the HttpOperationFailedException. The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
attachmentMultipartBinding (consumer (advanced))	Whether to automatic bind multipart/form-data as attachments on the Camel Exchange. The options attachmentMultipartBinding=true and disableStreamCache=false cannot work together. Remove disableStreamCache to use AttachmentMultipartBinding. This is turned off by default as this may require servlet specific configuration to enable this when using Servlets.	false	boolean
eagerCheckContentAvailable (consumer (advanced))	Whether to eager check whether the HTTP requests has content if the content-length header is 0 or not present. This can be turned on in case HTTP clients do not send streamed data.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
fileNameExtWhitelist (consumer (advanced))	Whitelist of accepted filename extensions for accepting uploaded files. Multiple extensions can be separated by comma, such as txt,xml.		String
mapHttpMessageBody (consumer (advanced))	If this option is true then IN exchange Body of the exchange will be mapped to HTTP body. Setting this to false will avoid the HTTP mapping.	true	boolean
mapHttpMessageFormUrlEncodedBody (consumer (advanced))	If this option is true then IN exchange Form Encoded body of the exchange will be mapped to HTTP. Setting this to false will avoid the HTTP Form Encoded body mapping.	true	boolean
mapHttpMessageHeaders (consumer (advanced))	If this option is true then IN exchange Headers of the exchange will be mapped to HTTP headers. Setting this to false will avoid the HTTP Headers mapping.	true	boolean
optionsEnabled (consumer (advanced))	Specifies whether to enable HTTP OPTIONS for this Servlet consumer. By default OPTIONS is turned off.	false	boolean
traceEnabled (consumer (advanced))	Specifies whether to enable HTTP TRACE for this Servlet consumer. By default TRACE is turned off.	false	boolean

115.6. MESSAGE HEADERS

Camel will apply the same Message Headers as the HTTP component.

Camel will also populate **all request.parameter** and **request.headers**. For example, if a client request has the URL, http://myserver/myserver?orderid=123, the exchange will contain a header named **orderid** with the value 123.

115.7. USAGE

You can consume only **from** endpoints generated by the Servlet component. Therefore, it should be used only as input into your Camel routes. To issue HTTP requests against other HTTP endpoints, use the HTTP component.

115.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 15 options, which are listed below.

Name	Description	Default	Type
camel.component.servlet.allow-java-serialized-object	Whether to allow java serialization when a request uses context-type=application/x-java-serialized-object. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	Boolean
camel.component.servlet.attachment-multipart-binding	Whether to automatic bind multipart/form-data as attachments on the Camel Exchange. The options attachmentMultipartBinding=true and disableStreamCache=false cannot work together. Remove disableStreamCache to use AttachmentMultipartBinding. This is turned off by default as this may require servlet specific configuration to enable this when using Servlet's.	false	Boolean
camel.component.servlet.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.servlet.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.servlet.enabled	Whether to enable auto configuration of the servlet component. This is enabled by default.		Boolean
camel.component.servlet.file-name-ext-whitelist	Whitelist of accepted filename extensions for accepting uploaded files. Multiple extensions can be separated by comma, such as txt,xml.		String

Name	Description	Default	Type
camel.component.servlet.header-filter-strategy	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		HeaderFilterStrategy
camel.component.servlet.http-binding	To use a custom HttpBinding to control the mapping between Camel message and HttpClient. The option is a org.apache.camel.http.common.HttpBinding type.		HttpBinding
camel.component.servlet.http-configuration	To use the shared HttpConfiguration as base configuration. The option is a org.apache.camel.http.common.HttpConfiguration type.		HttpConfiguration
camel.component.servlet.http-registry	To use a custom org.apache.camel.component.servlet.HttpRegistry. The option is a org.apache.camel.http.common.HttpRegistry type.		HttpRegistry
camel.component.servlet.mute-exception	If enabled and an Exchange failed processing on the consumer side the response's body won't contain the exception's stack trace.	false	Boolean
camel.component.servlet.servlet-name	Default name of servlet to use. The default name is CamelServlet.	Camel Servlet	String
camel.servlet.mapping.context-path	Context path used by the servlet component for automatic mapping.	/camel/*	String
camel.servlet.mapping.enabled	Enables the automatic mapping of the servlet component into the Spring web context.	true	Boolean
camel.servlet.mapping.servlet-name	The name of the Camel servlet.	Camel Servlet	String

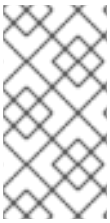
CHAPTER 116. SIMPLE

The Simple Expression Language was a really simple language when it was created, but has since grown more powerful. It is primarily intended for being a very small and simple language for evaluating **Expression** or **Predicate** without requiring any new dependencies or knowledge of other scripting languages such as Groovy.

The simple language is designed with intend to cover almost all the common use cases when little need for scripting in your Camel routes.

However, for much more complex use cases then a more powerful language is recommended such as:

- Groovy
- MVEL
- OGNL



NOTE

The simple language requires **camel-bean** JAR as classpath dependency if the simple language uses OGNL expressions, such as calling a method named **myMethod** on the message body: **${body.myMethod()}**. At runtime the simple language will then us its built-in OGNL support which requires the **camel-bean** component.

The simple language uses **${body}** placeholders for complex expressions or functions.

NOTE

See also the CSimple language which is compiled.

NOTE

Alternative syntax
You can also use the alternative syntax which uses **$simple{ }** as placeholders. This can be used in situations to avoid clashes when using for example Spring property placeholder together with Camel.

116.1. DEPENDENCIES

When using **simple** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-core-starter</artifactId>
</dependency>
```

116.2. SIMPLE LANGUAGE OPTIONS

The Simple language supports 2 options, which are listed below.

Name	Default	Java Type	Description
resultType		**String**	Sets the class name of the result type (type from output).
trim		**Boolean**	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

116.3. VARIABLES

Variable	Type	Description
camelId	String	the CamelContext name
camelContext.**OGNL**	Object	the CamelContext invoked using a Camel OGNL expression.
exchange	Exchange	the Exchange
exchange.**OGNL**	Object	the Exchange invoked using a Camel OGNL expression.
exchangeId	String	the exchange id
id	String	the message id
messageTimestamp	String	the message timestamp (millis since epoc) that this message originates from. Some systems like JMS, Kafka, AWS have a timestamp on the event/message, that Camel received. This method returns the timestamp, if a timestamp exists. The message timestamp and exchange created are not the same. An exchange always have a created timestamp which is the local timestamp when Camel created the exchange. The message timestamp is only available in some Camel components when the consumer is able to extract the timestamp from the source event. If the message has no timestamp then 0 is returned.
body	Object	the body
body.**OGNL**	Object	the body invoked using a Camel OGNL expression.
bodyAs(*type*)	Type	Converts the body to the given type determined by its classname. The converted body can be null.
bodyAs(*type*).**OGNL**	Object	Converts the body to the given type determined by its classname and then invoke methods using a Camel OGNL expression. The converted body can be null.

Variable	Type	Description
bodyOneLine	String	Converts the body to a String and removes all line-breaks so the string is in one line.
mandatoryBodyAs(*type*)	Type	Converts the body to the given type determined by its classname, and expects the body to be not null.
mandatoryBodyAs(*type*).**OGNL**	Object	Converts the body to the given type determined by its classname and then invoke methods using a Camel OGNL expression.
header.foo	Object	refer to the foo header
header[foo]	Object	refer to the foo header
headers.foo	Object	refer to the foo header
headers:foo	Object	refer to the foo header
headers[foo]	Object	refer to the foo header
header.foo[bar]	Object	regard foo header as a map and perform lookup on the map with bar as key
header.foo.**OGNL**	Object	refer to the foo header and invoke its value using a Camel OGNL expression.
headerAs(*key*,*type*)	Type	converts the header to the given type determined by its classname
headers	Map	refer to the headers
exchangeProperty.foo	Object	refer to the foo property on the exchange
exchangeProperty[foo]	Object	refer to the foo property on the exchange
exchangeProperty.foo.**OGNL**	Object	refer to the foo property on the exchange and invoke its value using a Camel OGNL expression.
sys.foo	String	refer to the JVM system property
sysenv.foo	String	refer to the system environment variable
env.foo	String	refer to the system environment variable

Variable	Type	Description
exception	Object	refer to the exception object on the exchange, is **null** if no exception set on exchange. Will fallback and grab caught exceptions (**Exchange.EXCEPTION_CAUGHT**) if the Exchange has any.
exception.**OGNL**	Object	refer to the exchange exception invoked using a Camel OGNL expression object
exception.message	String	refer to the exception.message on the exchange, is **null** if no exception set on exchange. Will fallback and grab caught exceptions (**Exchange.EXCEPTION_CAUGHT**) if the Exchange has any.
exception.stacktrace	String	refer to the exception.stracktrace on the exchange, is **null** if no exception set on exchange. Will fallback and grab caught exceptions (**Exchange.EXCEPTION_CAUGHT**) if the Exchange has any.
date:_command_	Date	evaluates to a Date object. Supported commands are: **now** for current timestamp, **exchangeCreated** for the timestamp when the current exchange was created, **header.xxx** to use the Long/Date object header with the key xxx. **exchangeProperty.xxx** to use the Long/Date object in the exchange property with the key xxx. **file** for the last modified timestamp of the file (available with a File consumer). Command accepts offsets such as: **now-24h** or **header.xxx+1h** or even **now+1h30m-100**.
date:_command:pattern_	String	Date formatting using **java.text.SimpleDateFormat** patterns.
date-with-timezone:_command:timezone:pattern_	String	Date formatting using **java.text.SimpleDateFormat** timezones and patterns.
bean:_bean expression_	Object	Invoking a bean expression using the language. Specifying a method name you must use dot as separator. We also support the ?method=methodname syntax that is used by the component. Camel will by default lookup a bean by the given name. However if you need to refer to a bean class (such as calling a static method) then you can prefix with type, such as **bean:type:fqnClassName**.
properties:key:default	String	Lookup a property with the given key. If the key does not exists or has no value, then an optional default value can be specified.
routeId	String	Returns the id of the current route the Exchange is being routed.
stepId	String	Returns the id of the current step the Exchange is being routed.

Variable	Type	Description
threadName	String	Returns the name of the current thread. Can be used for logging purpose.
hostname	String	Returns the local hostname (may be empty if not possible to resolve).
ref:xxx	Object	To lookup a bean from the Registry with the given id.
type:name.field	Object	To refer to a type or field by its FQN name. To refer to a field you can append .FIELD_NAME. For example, you can refer to the constant field from Exchange as: **org.apache.camel.Exchange.FILE_NAME**
null	null	represents a **null**
random(value)	Integer	returns a random Integer between 0 (included) and *value* (excluded)
random(min,max)	Integer	returns a random Integer between *min* (included) and *max* (excluded)
collate(group)	List	The collate function iterates the message body and groups the data into sub lists of specified size. This can be used with the Splitter EIP to split a message body and group/batch the splitted sub message into a group of N sub lists. This method works similar to the collate method in Groovy.
skip(number)	Iterator	The skip function iterates the message body and skips the first number of items. This can be used with the Splitter EIP to split a message body and skip the first N number of items.
messageHistory	String	The message history of the current exchange how it has been routed. This is similar to the route stack-trace message history the error handler logs in case of an unhandled exception.
messageHistory(false)	String	As messageHistory but without the exchange details (only includes the route stack-trace). This can be used if you do not want to log sensitive data from the message itself.

116.4. OGNL EXPRESSION SUPPORT

When using **OGNL** then **camel-bean** JAR is required to be on the classpath.

Camel's OGNL support is for invoking methods only. You cannot access fields. Camel support accessing the length field of Java arrays.

The Simple and Bean language now supports a Camel OGNL notation for invoking beans in a chain like fashion. Suppose the Message IN body contains a POJO which has a **getAddress()** method.

Then you can use Camel OGNL notation to access the address object:

```
simple("${body.address}")
simple("${body.address.street}")
simple("${body.address.zip}")
```

Camel understands the shorthand names for getters, but you can invoke any method or use the real name such as:

```
simple("${body.address}")
simple("${body.getAddress.getStreet}")
simple("${body.address.getZip}")
simple("${body.doSomething}")
```

You can also use the null safe operator (**?.**) to avoid NPE if for example the body does NOT have an address

```
simple("${body?.address?.street}")
```

It is also possible to index in **Map** or **List** types, so you can do:

```
simple("${body[foo].name}")
```

To assume the body is **Map** based and lookup the value with **foo** as key, and invoke the **getName** method on that value.

If the key has space, then you **must** enclose the key with quotes, for example 'foo bar':

```
simple("${body['foo bar'].name}")
```

You can access the **Map** or **List** objects directly using their key name (with or without dots) :

```
simple("${body[foo]}")
simple("${body[this.is.foo]}")
```

Suppose there was no value with the key **foo** then you can use the null safe operator to avoid the NPE as shown:

```
simple("${body[foo]?.name}")
```

You can also access **List** types, for example to get lines from the address you can do:

```
simple("${body.address.lines[0]}")
simple("${body.address.lines[1]}")
simple("${body.address.lines[2]}")
```

There is a special **last** keyword which can be used to get the last value from a list.

```
simple("${body.address.lines[last]}")
```

And to get the 2nd last you can subtract a number, so we can use **last-1** to indicate this:

```
simple("${body.address.lines[last-1]}")
```

And the 3rd last is of course:

```
simple("${body.address.lines[last-2]}")
```

And you can call the size method on the list with

```
simple("${body.address.lines.size}")
```

Camel supports the length field for Java arrays as well, eg:

```
String[] lines = new String[]{"foo", "bar", "cat"};
exchange.getIn().setBody(lines);

simple("There are ${body.length} lines")
```

And yes you can combine this with the operator support as shown below:

```
simple("${body.address.zip} > 1000")
```

116.5. OPERATOR SUPPORT

The parser is limited to only support a single operator.

To enable it the left value must be enclosed in $\\{ }. The syntax is:

```
${leftValue} OP rightValue
```

Where the **rightValue** can be a String literal enclosed in **' '**, **null**, a constant value or another expression enclosed in **$\{ }**.

NOTE

There **must** be spaces around the operator.

Camel will automatically type convert the rightValue type to the leftValue type, so it is able to eg. convert a string into a numeric, so you can use **>** comparison for numeric values.

The following operators are supported:

Operator	Description
==	equals
=~	equals ignore case (will ignore case when comparing String values)
>	greater than

Operator	Description
>=	greater than or equals
<	less than
⇐	less than or equals
!=	not equals
!=~	not equals ignore case (will ignore case when comparing String values)
contains	For testing if contains in a string based value
!contains	For testing if not contains in a string based value
~~	For testing if contains by ignoring case sensitivity in a string based value
!~~	For testing if not contains by ignoring case sensitivity in a string based value
regex	For matching against a given regular expression pattern defined as a String value
!regex	For not matching against a given regular expression pattern defined as a String value
in	For matching if in a set of values, each element must be separated by comma. If you want to include an empty value, then it must be defined using double comma, eg ',,bronze,silver,gold', which is a set of four values with an empty value and then the three medals.
!in	For matching if not in a set of values, each element must be separated by comma. If you want to include an empty value, then it must be defined using double comma, eg ',,bronze,silver,gold', which is a set of four values with an empty value and then the three medals.
is	For matching if the left hand side type is an instance of the value.
!is	For matching if the left hand side type is not an instance of the value.
range	For matching if the left hand side is within a range of values defined as numbers: **from..to**..
!range	For matching if the left hand side is not within a range of values defined as numbers: **from..to**. .
startsWith	For testing if the left hand side string starts with the right hand string.

Operator	Description
starts with	Same as the startsWith operator.
endsWith	For testing if the left hand side string ends with the right hand string.
ends with	Same as the endsWith operator.

And the following unary operators can be used:

Operator	Description
++	To increment a number by one. The left hand side must be a function, otherwise parsed as literal.
–	To decrement a number by one. The left hand side must be a function, otherwise parsed as literal.
\n	To use newline character.
\t	To use tab character.
\r	To use carriage return character.
\}	To use the } character as text. This may be needed when building a JSon structure with the simple language.

And the following logical operators can be used to group expressions:

Operator	Description
&&	The logical and operator is used to group two expressions.
	The logical or operator is used to group two expressions.

The syntax for AND is:

```
${leftValue} OP rightValue && ${leftValue} OP rightValue
```

And the syntax for OR is:

```
${leftValue} OP rightValue || ${leftValue} OP rightValue
```

Some examples:

```
// exact equals match
simple("${header.foo} == 'foo'")

// ignore case when comparing, so if the header has value FOO this will match
simple("${header.foo} =~ 'foo'")

// here Camel will type convert '100' into the type of header.bar and if it is an Integer '100' will also be converter to an Integer
simple("${header.bar} == '100'")

simple("${header.bar} == 100")

// 100 will be converter to the type of header.bar so we can do > comparison
simple("${header.bar} > 100")
```

116.5.1. Comparing with different types

When you compare with different types such as String and int, then you have to take a bit care. Camel will use the type from the left hand side as 1st priority. And fallback to the right hand side type if both values couldn't be compared based on that type.
This means you can flip the values to enforce a specific type. Suppose the bar value above is a String. Then you can flip the equation:

```
simple("100 < ${header.bar}")
```

which then ensures the int type is used as 1st priority.

This may change in the future if the Camel team improves the binary comparison operations to prefer numeric types to String based. It's most often the String type which causes problem when comparing with numbers.

```
// testing for null
simple("${header.baz} == null")

// testing for not null
simple("${header.baz} != null")
```

And a bit more advanced example where the right value is another expression

```
simple("${header.date} == ${date:now:yyyyMMdd}")

simple("${header.type} == ${bean:orderService?method=getOrderType}")
```

And an example with contains, testing if the title contains the word Camel

```
simple("${header.title} contains 'Camel'")
```

And an example with regex, testing if the number header is a 4 digit value:

```
simple("${header.number} regex '\\d{4}'")
```

And finally an example if the header equals any of the values in the list. Each element must be separated by comma, and no space around.
This also works for numbers etc, as Camel will convert each element into the type of the left hand side.

```
simple("${header.type} in 'gold,silver'")
```

And for all the last 3 we also support the negate test using not:

```
simple("${header.type} !in 'gold,silver'")
```

And you can test if the type is a certain instance, eg for instance a String

```
simple("${header.type} is 'java.lang.String'")
```

We have added a shorthand for all **java.lang** types so you can write it as:

```
simple("${header.type} is 'String'")
```

Ranges are also supported. The range interval requires numbers and both from and end are inclusive.
For instance to test whether a value is between 100 and 199:

```
simple("${header.number} range 100..199")
```

Notice we use **..** in the range without spaces. It is based on the same syntax as Groovy.

```
simple("${header.number} range '100..199'")
```

As the XML DSL does not have all the power as the Java DSL with all its various builder methods, you have to resort to use some other languages for testing with simple operators. Now you can do this with the simple language. In the sample below we want to test if the header is a widget order:

```
<from uri="seda:orders">
  <filter>
    <simple>${header.type} == 'widget'</simple>
    <to uri="bean:orderService?method=handleWidget"/>
  </filter>
</from>
```

116.5.2. Using and / or

If you have two expressions you can combine them with the **&&** or || operator.

For instance:

```
simple("${header.title} contains 'Camel' && ${header.type'} == 'gold'")
```

And of course the || is also supported. The sample would be:

```
simple("${header.title} contains 'Camel' || ${header.type'} == 'gold'")
```

116.6. EXAMPLES

In the XML DSL sample below we filter based on a header value:

```
<from uri="seda:orders">
  <filter>
    <simple>${header.foo}</simple>
    <to uri="mock:fooOrders"/>
  </filter>
</from>
```

The Simple language can be used for the predicate test above in the Message Filter pattern, where we test if the in message has a **foo** header (a header with the key **foo** exists). If the expression evaluates to **true** then the message is routed to the **mock:fooOrders** endpoint, otherwise the message is dropped.

The same example in Java DSL:

```
from("seda:orders")
   .filter().simple("${header.foo}")
      .to("seda:fooOrders");
```

You can also use the simple language for simple text concatenations such as:

```
from("direct:hello")
   .transform().simple("Hello ${header.user} how are you?")
   .to("mock:reply");
```

Notice that we must use $\\{ } placeholders in the expression now to allow Camel to parse it correctly.

And this sample uses the date command to output current date.

```
from("direct:hello")
   .transform().simple("The today is ${date:now:yyyyMMdd} and it is a great day.")
   .to("mock:reply");
```

And in the sample below we invoke the bean language to invoke a method on a bean to be included in the returned string:

```
from("direct:order")
   .transform().simple("OrderId: ${bean:orderIdGenerator}")
   .to("mock:reply");
```

Where **orderIdGenerator** is the id of the bean registered in the Registry. If using Spring then it is the Spring bean id.

If we want to declare which method to invoke on the order id generator bean we must prepend **.method name** such as below where we invoke the **generateId** method.

```
from("direct:order")
   .transform().simple("OrderId: ${bean:orderIdGenerator.generateId}")
   .to("mock:reply");
```

We can use the **?method=methodname** option that we are familiar with the Bean component itself:

```
from("direct:order")
    .transform().simple("OrderId: ${bean:orderIdGenerator?method=generateId}")
    .to("mock:reply");
```

You can also convert the body to a given type, for example to ensure that it is a String you can do:

```
<transform>
  <simple>Hello ${bodyAs(String)} how are you?</simple>
</transform>
```

There are a few types which have a shorthand notation, so we can use **String** instead of **java.lang.String**. These are: **byte[], String, Integer, Long**. All other types must use their FQN name, e.g. **org.w3c.dom.Document**.

It is also possible to lookup a value from a header **Map**:

```
<transform>
  <simple>The gold value is ${header.type[gold]}</simple>
</transform>
```

In the code above we lookup the header with name **type** and regard it as a **java.util.Map** and we then lookup with the key **gold** and return the value. If the header is not convertible to Map an exception is thrown. If the header with name **type** does not exist **null** is returned.

You can nest functions, such as shown below:

```
<setHeader name="myHeader">
  <simple>${properties:${header.someKey}}</simple>
</setHeader>
```

116.7. SETTING RESULT TYPE

You can now provide a result type to the Simple expression, which means the result of the evaluation will be converted to the desired type. This is most usable to define types such as booleans, integers, etc.

For example to set a header as a boolean type you can do:

```
.setHeader("cool", simple("true", Boolean.class))
```

And in XML DSL

```
<setHeader name="cool">
  <!-- use resultType to indicate that the type should be a java.lang.Boolean -->
  <simple resultType="java.lang.Boolean">true</simple>
</setHeader>
```

116.8. USING NEW LINES OR TABS IN XML DSLS

It is easier to specify new lines or tabs in XML DSLs as you can escape the value now

```
<transform>
  <simple>The following text\nis on a new line</simple>
</transform>
```

116.9. LEADING AND TRAILING WHITESPACE HANDLING

The trim attribute of the expression can be used to control whether the leading and trailing whitespace characters are removed or preserved. The default value is true, which removes the whitespace characters.

```
<setBody>
  <simple trim="false">You get some trailing whitespace characters.     </simple>
</setBody>
```

116.10. LOADING SCRIPT FROM EXTERNAL RESOURCE

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**. This is done using the following syntax: **"resource:scheme:location"**, e.g. to refer to a file on the classpath you can do:

```
.setHeader("myHeader").simple("resource:classpath:mysimple.txt")
```

116.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 147 options, which are listed below.

Name	Description	Default	Type
camel.cloud.consul.service-discovery.acl-token	Sets the ACL token to be used with Consul.		String
camel.cloud.consul.service-discovery.block-seconds	The seconds to wait for a watch event, default 10 seconds.	10	Integer
camel.cloud.consul.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.consul.service-discovery.connect-timeout-millis	Connect timeout for OkHttpClient.		Long

Name	Description	Default	Type
camel.cloud.consul.service-discovery.datacenter	The data center.		String
camel.cloud.consul.service-discovery.enabled	Enable the component.	true	Boolean
camel.cloud.consul.service-discovery.password	Sets the password to be used for basic authentication.		String
camel.cloud.consul.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.consul.service-discovery.read-timeout-millis	Read timeout for OkHttpClient.		Long
camel.cloud.consul.service-discovery.url	The Consul agent URL.		String
camel.cloud.consul.service-discovery.user-name	Sets the username to be used for basic authentication.		String
camel.cloud.consul.service-discovery.write-timeout-millis	Write timeout for OkHttpClient.		Long
camel.cloud.dns.service-discovery.configurations	Define additional configuration definitions.		Map

Name	Description	Default	Type
camel.cloud.dns.service-discovery.domain	The domain name;.		String
camel.cloud.dns.service-discovery.enabled	Enable the component.	true	Boolean
camel.cloud.dns.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.dns.service-discovery.proto	The transport protocol of the desired service.	_tcp	String
camel.cloud.etcd.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.etcd.service-discovery.enabled	Enable the component.	true	Boolean
camel.cloud.etcd.service-discovery.password	The password to use for basic authentication.		String
camel.cloud.etcd.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.etcd.service-discovery.service-path	The path to look for for service discovery.	/services/	String
camel.cloud.etcd.service-discovery.timeout	To set the maximum time an action could take to complete.		Long

Name	Description	Default	Type
camel.cloud.etcd.service-discovery.type	To set the discovery type, valid values are on-demand and watch.	on-demand	String
camel.cloud.etcd.service-discovery.uris	The URIs the client can connect to.		String
camel.cloud.etcd.service-discovery.user-name	The user name to use for basic authentication.		String
camel.cloud.kubernetes.service-discovery.api-version	Sets the API version when using client lookup.		String
camel.cloud.kubernetes.service-discovery.ca-cert-data	Sets the Certificate Authority data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.ca-cert-file	Sets the Certificate Authority data that are loaded from the file when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-cert-data	Sets the Client Certificate data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-cert-file	Sets the Client Certificate data that are loaded from the file when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-algo	Sets the Client Keystore algorithm, such as RSA when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-data	Sets the Client Keystore data when using client lookup.		String

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.client-key-file	Sets the Client Keystore data that are loaded from the file when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-passphrase	Sets the Client Keystore passphrase when using client lookup.		String
camel.cloud.kubernetes.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.kubernetes.service-discovery.dns-domain	Sets the DNS domain to use for DNS lookup.		String
camel.cloud.kubernetes.service-discovery.enabled	Enable the component.	true	Boolean
camel.cloud.kubernetes.service-discovery.lookup	How to perform service lookup. Possible values: client, dns, environment. When using client, then the client queries the kubernetes master to obtain a list of active pods that provides the service, and then random (or round robin) select a pod. When using dns the service name is resolved as name.namespace.svc.dnsDomain. When using dnssrv the service name is resolved with SRV query for .... svc... When using environment then environment variables are used to lookup the service. By default environment is used.	environment	String
camel.cloud.kubernetes.service-discovery.master-url	Sets the URL to the master when using client lookup.		String
camel.cloud.kubernetes.service-discovery.namespace	Sets the namespace to use. Will by default use namespace from the ENV variable KUBERNETES_MASTER.		String

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.oauth-token	Sets the OAUTH token for authentication (instead of username/password) when using client lookup.		String
camel.cloud.kubernetes.service-discovery.password	Sets the password for authentication when using client lookup.		String
camel.cloud.kubernetes.service-discovery.port-name	Sets the Port Name to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.port-protocol	Sets the Port Protocol to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.kubernetes.service-discovery.trust-certs	Sets whether to turn on trust certificate check when using client lookup.	false	Boolean
camel.cloud.kubernetes.service-discovery.username	Sets the username for authentication when using client lookup.		String
camel.cloud.ribbon.load-balancer.client-name	Sets the Ribbon client name.		String
camel.cloud.ribbon.load-balancer.configurations	Define additional configuration definitions.		Map

Name	Description	Default	Type
camel.cloud.ribbon.load-balancer.enabled	Enable the component.	true	Boolean
camel.cloud.ribbon.load-balancer.namespace	The namespace.		String
camel.cloud.ribbon.load-balancer.password	The password.		String
camel.cloud.ribbon.load-balancer.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.ribbon.load-balancer.username	The username.		String
camel.hystrix.allow-maximum-size-to-diverge-from-core-size	Allows the configuration for maximumSize to take effect. That value can then be equal to, or higher, than coreSize.	false	Boolean
camel.hystrix.circuit-breaker-enabled	Whether to use a HystrixCircuitBreaker or not. If false no circuit-breaker logic will be used and all requests permitted. This is similar in effect to circuitBreakerForceClosed() except that continues tracking metrics and knowing whether it should be open/closed, this property results in not even instantiating a circuit-breaker.	true	Boolean
camel.hystrix.circuit-breaker-error-threshold-percentage	Error percentage threshold (as whole number such as 50) at which point the circuit breaker will trip open and reject requests. It will stay tripped for the duration defined in circuitBreakerSleepWindowInMilliseconds; The error percentage this is compared against comes from HystrixCommandMetrics.getHealthCounts().	50	Integer

Name	Description	Default	Type
camel.hystrix.circuit-breaker-force-closed	If true the HystrixCircuitBreaker#allowRequest() will always return true to allow requests regardless of the error percentage from HystrixCommandMetrics.getHealthCounts(). The circuitBreakerForceOpen() property takes precedence so if it set to true this property does nothing.	false	Boolean
camel.hystrix.circuit-breaker-force-open	If true the HystrixCircuitBreaker.allowRequest() will always return false, causing the circuit to be open (tripped) and reject all requests. This property takes precedence over circuitBreakerForceClosed();.	false	Boolean
camel.hystrix.circuit-breaker-request-volume-threshold	Minimum number of requests in the metricsRollingStatisticalWindowInMilliseconds() that must exist before the HystrixCircuitBreaker will trip. If below this number the circuit will not trip regardless of error percentage.	20	Integer
camel.hystrix.circuit-breaker-sleep-window-in-milliseconds	The time in milliseconds after a HystrixCircuitBreaker trips open that it should wait before trying requests again.	5000	Integer
camel.hystrix.configurations	Define additional configuration definitions.		Map
camel.hystrix.core-pool-size	Core thread-pool size that gets passed to java.util.concurrent.ThreadPoolExecutor#setCorePoolSize(int).	10	Integer
camel.hystrix.enabled	Enable the component.	true	Boolean
camel.hystrix.execution-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to HystrixCommand.run(). Requests beyond the concurrent limit will be rejected. Applicable only when executionIsolationStrategy == SEMAPHORE.	20	Integer
camel.hystrix.execution-isolation-strategy	What isolation strategy HystrixCommand.run() will be executed with. If THREAD then it will be executed on a separate thread and concurrent requests limited by the number of threads in the thread-pool. If SEMAPHORE then it will be executed on the calling thread and concurrent requests limited by the semaphore count.	THREAD	String

Name	Description	Default	Type
camel.hystrix.execution-isolation-thread-interrupt-on-timeout	Whether the execution thread should attempt an interrupt (using Future#cancel) when a thread times out. Applicable only when executionIsolationStrategy() == THREAD.	true	Boolean
camel.hystrix.execution-timeout-enabled	Whether the timeout mechanism is enabled for this command.	true	Boolean
camel.hystrix.execution-timeout-in-milliseconds	Time in milliseconds at which point the command will timeout and halt execution. If executionIsolationThreadInterruptOnTimeout == true and the command is thread-isolated, the executing thread will be interrupted. If the command is semaphore-isolated and a HystrixObservableCommand, that command will get unsubscribed.	1000	Integer
camel.hystrix.fallback-enabled	Whether HystrixCommand.getFallback() should be attempted when failure occurs.	true	Boolean
camel.hystrix.fallback-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to HystrixCommand.getFallback(). Requests beyond the concurrent limit will fail-fast and not attempt retrieving a fallback.	10	Integer
camel.hystrix.group-key	Sets the group key to use. The default value is CamelHystrix.	Camel Hystrix	String
camel.hystrix.keep-alive-time	Keep-alive time in minutes that gets passed to ThreadPoolExecutor#setKeepAliveTime(long,TimeUnit).	1	Integer
camel.hystrix.max-queue-size	Max queue size that gets passed to BlockingQueue in HystrixConcurrencyStrategy.getBlockingQueue(int) This should only affect the instantiation of a threadpool - it is not eliglible to change a queue size on the fly. For that, use queueSizeRejectionThreshold().	-1	Integer
camel.hystrix.maximum-size	Maximum thread-pool size that gets passed to ThreadPoolExecutor#setMaximumPoolSize(int) . This is the maximum amount of concurrency that can be supported without starting to reject HystrixCommands. Please note that this setting only takes effect if you also set allowMaximumSizeToDivergeFromCoreSize.	10	Integer

Name	Description	Default	Type
camel.hystrix.metrics-health-snapshot-interval-in-milliseconds	Time in milliseconds to wait between allowing health snapshots to be taken that calculate success and error percentages and affect HystrixCircuitBreaker.isOpen() status. On high-volume circuits the continual calculation of error percentage can become CPU intensive thus this controls how often it is calculated.	500	Integer
camel.hystrix.metrics-rolling-percentile-bucket-size	Maximum number of values stored in each bucket of the rolling percentile. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-percentile-enabled	Whether percentile metrics should be captured using HystrixRollingPercentile inside HystrixCommandMetrics.	true	Boolean
camel.hystrix.metrics-rolling-percentile-window-buckets	Number of buckets the rolling percentile window is broken into. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	6	Integer
camel.hystrix.metrics-rolling-percentile-window-in-milliseconds	Duration of percentile rolling window in milliseconds. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10000	Integer
camel.hystrix.metrics-rolling-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-statistical-window-in-milliseconds	This property sets the duration of the statistical rolling window, in milliseconds. This is how long metrics are kept for the thread pool. The window is divided into buckets and rolls by those increments.	10000	Integer
camel.hystrix.queue-size-rejection-threshold	Queue size rejection threshold is an artificial max size at which rejections will occur even if maxQueueSize has not been reached. This is done because the maxQueueSize of a BlockingQueue can not be dynamically changed and we want to support dynamically changing the queue size that affects rejections. This is used by HystrixCommand when queuing a thread for execution.	5	Integer

Name	Description	Default	Type
camel.hystrix.request-log-enabled	Whether HystrixCommand execution and events should be logged to HystrixRequestLog.	true	Boolean
camel.hystrix.thread-pool-key	Sets the thread pool key to use. Will by default use the same value as groupKey has been configured to use.	Camel Hystrix	String
camel.hystrix.thread-pool-rolling-number-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10	Integer
camel.hystrix.thread-pool-rolling-number-statistical-window-in-milliseconds	Duration of statistical rolling window in milliseconds. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10000	Integer
camel.language.constant.enabled	Whether to enable auto configuration of the constant language. This is enabled by default.		Boolean
camel.language.constant.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.csimple.enabled	Whether to enable auto configuration of the csimple language. This is enabled by default.		Boolean
camel.language.csimple.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.exchangeproperty.enabled	Whether to enable auto configuration of the exchangeProperty language. This is enabled by default.		Boolean
camel.language.exchangeproperty.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.file.enabled	Whether to enable auto configuration of the file language. This is enabled by default.		Boolean
camel.language.file.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

Name	Description	Default	Type
camel.language.header.enabled	Whether to enable auto configuration of the header language. This is enabled by default.		Boolean
camel.language.header.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.ref.enabled	Whether to enable auto configuration of the ref language. This is enabled by default.		Boolean
camel.language.ref.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.simple.enabled	Whether to enable auto configuration of the simple language. This is enabled by default.		Boolean
camel.language.simple.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.tokenize.enabled	Whether to enable auto configuration of the tokenize language. This is enabled by default.		Boolean
camel.language.tokenize.group-delimiter	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.		String
camel.language.tokenize.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.resilience4j.automatic-transition-from-open-to-half-open-enabled	Enables automatic transition from OPEN to HALF_OPEN state once the waitDurationInOpenState has passed.	false	Boolean
camel.resilience4j.circuit-breaker-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreaker instance to lookup and use from the registry. When using this, then any other circuit breaker options are not in use.		String
camel.resilience4j.config-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreakerConfig instance to lookup and use from the registry.		String
camel.resilience4j.configurations	Define additional configuration definitions.		Map

Name	Description	Default	Type
camel.resilience4j.enabled	Enable the component.	true	Boolean
camel.resilience4j.failure-rate-threshold	Configures the failure rate threshold in percentage. If the failure rate is equal or greater than the threshold the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 50 percentage.		Float
camel.resilience4j.minimum-number-of-calls	Configures the minimum number of calls which are required (per sliding window period) before the CircuitBreaker can calculate the error rate. For example, if minimumNumberOfCalls is 10, then at least 10 calls must be recorded, before the failure rate can be calculated. If only 9 calls have been recorded the CircuitBreaker will not transition to open even if all 9 calls have failed. Default minimumNumberOfCalls is 100.	100	Integer
camel.resilience4j.permitted-number-of-calls-in-half-open-state	Configures the number of permitted calls when the CircuitBreaker is half open. The size must be greater than 0. Default size is 10.	10	Integer
camel.resilience4j.sliding-window-size	Configures the size of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. slidingWindowSize configures the size of the sliding window. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. The slidingWindowSize must be greater than 0. The minimumNumberOfCalls must be greater than 0. If the slidingWindowType is COUNT_BASED, the minimumNumberOfCalls cannot be greater than slidingWindowSize . If the slidingWindowType is TIME_BASED, you can pick whatever you want. Default slidingWindowSize is 100.	100	Integer

Name	Description	Default	Type
camel.resilience4j.sliding-window-type	Configures the type of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. Default slidingWindowType is COUNT_BASED.	COUNT_BASED	String
camel.resilience4j.slow-call-duration-threshold	Configures the duration threshold (seconds) above which calls are considered as slow and increase the slow calls percentage. Default value is 60 seconds.	60	Integer
camel.resilience4j.slow-call-rate-threshold	Configures a threshold in percentage. The CircuitBreaker considers a call as slow when the call duration is greater than slowCallDurationThreshold Duration. When the percentage of slow calls is equal or greater the threshold, the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 100 percentage which means that all recorded calls must be slower than slowCallDurationThreshold.		Float
camel.resilience4j.wait-duration-in-open-state	Configures the wait duration (in seconds) which specifies how long the CircuitBreaker should stay open, before it switches to half open. Default value is 60 seconds.	60	Integer
camel.resilience4j.writable-stack-trace-enabled	Enables writable stack traces. When set to false, Exception.getStackTrace returns a zero length array. This may be used to reduce log spam when the circuit breaker is open as the cause of the exceptions is already known (the circuit breaker is short-circuiting calls).	true	Boolean
camel.rest.api-component	The name of the Camel component to use as the REST API (such as swagger) If no API Component has been explicit configured, then Camel will lookup if there is a Camel component responsible for servicing and generating the REST API documentation, or if a org.apache.camel.spi.RestApiProcessorFactory is registered in the registry. If either one is found, then that is being used.		String

Name	Description	Default	Type
camel.rest.api-context-path	Sets a leading API context-path the REST API services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path.		String
camel.rest.api-context-route-id	Sets the route id to use for the route that services the REST API. The route will by default use an auto assigned route id.		String
camel.rest.api-host	To use an specific hostname for the API documentation (eg swagger) This can be used to override the generated host with this configured hostname.		String
camel.rest.api-property	Allows to configure as many additional properties for the api documentation (swagger). For example set property api.title to my cool stuff.		Map
camel.rest.api-vendor-extension	Whether vendor extension is enabled in the Rest APIs. If enabled then Camel will include additional information as vendor extension (eg keys starting with x-) such as route ids, class names etc. Not all 3rd party API gateways and tools supports vendor-extensions when importing your API docs.	false	Boolean
camel.rest.binding-mode	Sets the binding mode to use. The default value is off.		RestBindingMode
camel.rest.client-request-validation	Whether to enable validation of the client request to check whether the Content-Type and Accept headers from the client is supported by the Rest-DSL configuration of its consumes/produces settings. This can be turned on, to enable this check. In case of validation error, then HTTP Status codes 415 or 406 is returned. The default value is false.	false	Boolean
camel.rest.component	The Camel Rest component to use for the REST transport (consumer), such as netty-http, jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.component-property	Allows to configure as many additional properties for the rest component in use.		Map

Name	Description	Default	Type
camel.rest.consumer-property	Allows to configure as many additional properties for the rest consumer in use.		Map
camel.rest.context-path	Sets a leading context-path the REST services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path. Or for components such as camel-jetty or camel-netty-http that includes a HTTP server.		String
camel.rest.cors-headers	Allows to configure custom CORS headers.		Map
camel.rest.data-format-property	Allows to configure as many additional properties for the data formats in use. For example set property prettyPrint to true to have json outputted in pretty mode. The properties can be prefixed to denote the option is only for either JSON or XML and for either the IN or the OUT. The prefixes are: json.in. json.out. xml.in. xml.out. For example a key with value xml.out.mustBeJAXBElement is only for the XML data format for the outgoing. A key without a prefix is a common key for all situations.		Map
camel.rest.enable-cors	Whether to enable CORS headers in the HTTP response. The default value is false.	false	Boolean
camel.rest.endpoint-property	Allows to configure as many additional properties for the rest endpoint in use.		Map
camel.rest.host	The hostname to use for exposing the REST service.		String
camel.rest.host-name-resolver	If no hostname has been explicit configured, then this resolver is used to compute the hostname the REST service will be using.		RestHostNameResolver
camel.rest.json-data-format	Name of specific json data format to use. By default json-jackson will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String

Name	Description	Default	Type
camel.rest.port	The port number to use for exposing the REST service. Notice if you use servlet component then the port number configured here does not apply, as the port number in use is the actual port number the servlet component is using. eg if using Apache Tomcat its the tomcat http port, if using Apache Karaf its the HTTP service in Karaf that uses port 8181 by default etc. Though in those situations setting the port number here, allows tooling and JMX to know the port number, so its recommended to set the port number to the number that the servlet engine uses.		String
camel.rest.producer-api-doc	Sets the location of the api document (swagger api) the REST producer will use to validate the REST uri and query parameters are valid accordingly to the api document. This requires adding camel-swagger-java to the classpath, and any miss configuration will let Camel fail on startup and report the error(s). The location of the api document is loaded from classpath by default, but you can use file: or http: to refer to resources to load from file or http url.		String
camel.rest.producer-component	Sets the name of the Camel component to use as the REST producer.		String
camel.rest.scheme	The scheme to use for exposing the REST service. Usually http or https is supported. The default value is http.		String
camel.rest.skip-binding-on-error-code	Whether to skip binding on output if there is a custom HTTP error code header. This allows to build custom error messages that do not bind to json / xml etc, as success messages otherwise will do.	false	Boolean
camel.rest.use-x-forward-headers	Whether to use X-Forward headers for Host and related setting. The default value is true.	true	Boolean
camel.rest.xml-data-format	Name of specific XML data format to use. By default jaxb will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.api-context-id-pattern	**Deprecated** Sets an CamelContext id pattern to only allow Rest APIs from rest services within CamelContext's which name matches the pattern. The pattern name refers to the CamelContext name, to match on the current CamelContext only. For any other value, the pattern uses the rules from PatternHelper#matchPattern(String,String).		String

Name	Description	Default	Type
camel.rest.api-context-listing	**Deprecated** Sets whether listing of all available CamelContext's with REST services in the JVM is enabled. If enabled it allows to discover these contexts, if false then only the current CamelContext is in use.	false	Boolean

CHAPTER 117. SLACK

Both producer and consumer are supported

The Slack component allows you to connect to an instance of Slack and delivers a message contained in the message body via a pre established Slack incoming webhook.

117.1. DEPENDENCIES

When using **slack** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-slack-starter</artifactId>
</dependency>
```

117.2. URI FORMAT

To send a message to a channel.

```
slack:#channel[?options]
```

To send a direct message to a slackuser.

```
slack:@userID[?options]
```

117.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

117.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

117.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

117.4. COMPONENT OPTIONS

The Slack component supports 5 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
token (token)	The token to use.		String
webhookUrl (webhook)	The incoming webhook URL.		String

117.5. ENDPOINT OPTIONS

The Slack endpoint is configured using URI syntax:

```
slack:channel
```

with the following path and query parameters:

117.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
channel (common)	**Required** The channel name (syntax #name) or slackuser (syntax userName) to send a message directly to an user.		String

117.5.2. Query Parameters (29 parameters)

Name	Description	Default	Type
token (common)	The token to use.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
conversationType (consumer)	Type of conversation. Enum values: • PUBLIC_CHANNEL • PRIVATE_CHANNEL • MPIM • IM	PUBLIC_CHANNEL	ConversationType
maxResults (consumer)	The Max Result for the poll.	10	String

Name	Description	Default	Type
naturalOrder (consumer)	Create exchanges in natural order (oldest to newest) or not.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
serverUrl (consumer)	The Server URL of the Slack instance.		String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
iconEmoji (producer)	**Deprecated** Use a Slack emoji as an avatar.		String
iconUrl (producer)	**Deprecated** The avatar that the component will use when sending message to a channel or user.		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
username (producer)	**Deprecated** This is the username that the bot will have when sending messages to a channel or user.		String
webhookUrl (producer)	The incoming webhook URL.		String
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

117.6. CONFIGURING IN SPRINT XML

The Slack component with XML must be configured as a Spring or Blueprint bean that contains the incoming webhook url or the app token for the integration as a parameter.

```
<bean id="slack" class="org.apache.camel.component.slack.SlackComponent">
    <property name="webhookUrl"
value="https://hooks.slack.com/services/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"/>
    <property name="token" value="xoxb-12345678901-1234567890123-
xxxxxxxxxxxxxxxxxxxxxxxx"/>
</bean>
```

For Java you can configure this using Java code.

117.7. EXAMPLE

A CamelContext with Blueprint could be as:

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0" default-activation="lazy">

    <bean id="slack" class="org.apache.camel.component.slack.SlackComponent">
        <property name="webhookUrl"
value="https://hooks.slack.com/services/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"/>
    </bean>

    <camelContext xmlns="http://camel.apache.org/schema/blueprint">
        <route>
            <from uri="direct:test"/>
            <to uri="slack:#channel?iconEmoji=:camel:&amp;username=CamelTest"/>
        </route>
    </camelContext>

</blueprint>
```

117.8. PRODUCER

You can now use a token to send a message instead of WebhookUrl.

```
from("direct:test")
    .to("slack:#random?token=RAW(<YOUR_TOKEN>)");
```

You can now use the Slack API model to create blocks. You can read more about it here https://api.slack.com/block-kit.

```
public void testSlackAPIModelMessage() {
    Message message = new Message();
    message.setBlocks(Collections.singletonList(SectionBlock
            .builder()
            .text(MarkdownTextObject
                    .builder()
                    .text("*Hello from Camel!*")
                    .build())
            .build()));

    template.sendBody(test, message);
}
```

117.9. CONSUMER

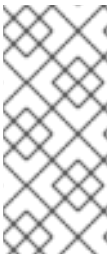
You can use also a consumer for messages in channel.

```
from("slack://general?token=RAW(<YOUR_TOKEN>)&maxResults=1")
    .to("mock:result");
```

In this way you'll get the last message from general channel. The consumer will take track of the timestamp of the last message consumed and in the next poll it will check from that timestamp.

You'll need to create a Slack app and use it on your workspace.

Use the 'Bot User OAuth Access Token' as token for the consumer endpoint.



NOTE

Add the corresponding history (**channels:history** or **groups:history** or **mpim:history** or **im:history**) and read (**channels:read** or **groups:read** or **mpim:read** or **im:read**) user token scope to your app to grant it permission to view messages in the corresponding channel. You will need to use the conversationType option to set it up too (**PUBLIC_CHANNEL**, **PRIVATE_CHANNEL**, **MPIM**, **IM**)

The naturalOrder option allows consuming messages from the oldest to the newest. Originally you would get the newest first and consume backward (message 3 ⇒ message 2 ⇒ message 1)

NOTE

You can use the conversationType option to read history and messages from a channel that is not only public (**PUBLIC_CHANNEL**,**PRIVATE_CHANNEL**, **MPIM**, **IM**)

117.10. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component.slack.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.slack.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.slack.enabled	Whether to enable auto configuration of the slack component. This is enabled by default.		Boolean
camel.component.slack.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.slack.token	The token to use.		String
camel.component.slack.webhook-url	The incoming webhook URL.		String

CHAPTER 118. SMB

Since Camel 4.3

Only consumer is supported.

The Server Message Block (SMB) component provides a way to connect natively to SMB file shares, such as those provided by Microsoft Windows or Samba.

118.1. DEPENDENCIES

When using **camel-smb** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-smb-starter</artifactId>
</dependency>
```

118.2. URI FORMAT

```
smb:address[:port]/shareName[?options]
```

118.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

118.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

118.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

118.4. COMPONENT OPTIONS

The SMB component supports 2 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

118.5. ENDPOINT OPTIONS

The SMB endpoint is configured using URI syntax:

```
smb:hostname:port/shareName
```

With the following *path* and *query* parameters:

118.5.1. Path Parameters (3 parameters)

Name	Description	Default	Type
hostname (consumer)	**Required** The share hostname or IP address.		String
port (consumer)	The share port number.	445	int
shareName (consumer)	The name of the share to connect to.		String

118.6. QUERY PARAMETERS (26 PARAMETERS)

Name	Description	Default	Type
idempotentRepository (consumer)	A pluggable repository org.apache.camel.spi.IdempotentRepository which by default use MemoryIdempotentRepository if none is specified.		IdempotentRepository
path (consumer)	**Required** The path, within the share, to consume the files from.		String
searchPattern (consumer)	The search pattern used to list the files.	*.txt	String
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
smbIoBean (advanced)	An optional SMB I/O bean to use to setup the file access attributes when reading/writing a file.		SmbIOBean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean

Name	Description	Default	Type
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean

Name	Description	Default	Type
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
domain (security)	The user domain.		String
password (security)	The password to access the share.		String
username (security)	The username required to access the share.		String

118.7. EXAMPLES

Following example shows how to poll all the files from an SMB file share and read the contents of these files:

```
private void process(Exchange exchange) throws IOException {
    final File file = exchange.getMessage().getBody(File.class);
    try (InputStream inputStream = file.getInputStream()) {
        LOG.debug("Read exchange: {}, with contents: {}", file.getFileInformation(), new
String(inputStream.readAllBytes()));
    }
}

public void configure() {
    fromF("smb:%s/%s?username=%s&password=%s&path=/", service.address(),
service.shareName(), service.userName(), service.password())
        .process(this::process)
        .to("mock:result");
}
```

NOTE

The File object provided is not a **java.io.File** instance, but, instead a **com.hierynomus.smbj.share.File** instance.

CHAPTER 119. SNMP

Since Camel 2.1

Both producer and consumer are supported

The SNMP component gives you the ability to poll SNMP capable devices or receiving traps

119.1. DEPENDENCIES

When using **snmp** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-snmp-starter</artifactId>
</dependency>
```

119.2. URI FORMAT

```
snmp://hostname[:port][?Options]
```

The component supports polling OID values from an SNMP enabled device and receiving traps.

119.3. SNMP PRODUCER

It can also be used to request information using GET method. The response body type is **org.apache.camel.component.snmp.SnmpMessage**.

119.4. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

119.4.1. Configuring component options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

119.4.2. Configuring endpoint options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL and DataFormat DSL as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

119.5. COMPONENT OPTIONS

The SNMP component supports 5 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
healthCheckConsumerEnabled (health)	Used for enabling or disabling all consumer based health checks from this component.	true	boolean
healthCheckProducerEnabled (health)	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true.	true	boolean

119.6. ENDPOINT OPTIONS

The SNMP endpoint is configured using URI syntax:

```
snmp:host:port
```

with the following path and query parameters:

119.6.1. Path Parameters (2 parameters)

Name	Description	Default	Type
host (common)	**Required** Hostname of the SNMP enabled device.		String
port (common)	**Required** Port number of the SNMP enabled device.		Integer

119.6.2. Query Parameters (36 parameters)

Name	Description	Default	Type
oids (common)	Defines which values you are interested in. Please have a look at the Wikipedia to get a better understanding. You may provide a single OID or a coma separated list of OIDs. Example: oids=1.3.6.1.2.1.1.3.0,1.3.6.1.2.1.25.3.2.1.5.1,1.3.6.1.2.1.25.3.5.1.1.1,1.3.6.1.2.1.43.5.1.1.11.1.		OIDList

Name	Description	Default	Type
protocol (common)	Here you can select which protocol to use. You can use either udp or tcp. Enum values: • tcp • udp	udp	String
retries (common)	Defines how often a retry is made before canceling the request.	2	int
snmpCommunity (common)	Sets the community octet string for the snmp request.	public	String
snmpContextEngineId (common)	Sets the context engine ID field of the scoped PDU.		String
snmpContextName (common)	Sets the context name field of this scoped PDU.		String
snmpVersion (common)	Sets the snmp version for the request. The value 0 means SNMPv1, 1 means SNMPv2c, and the value 3 means SNMPv3. Enum values: • 0 • 1 • 3	0	int
timeout (common)	Sets the timeout value for the request in millis.	1500	int
type (common)	Which operation to perform such as poll, trap, etc. Enum values: • TRAP • POLL • GET_NEXT		SnmpActionType
delay (consumer)	Sets update rate in seconds.	60000	long

Name	Description	Default	Type
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
treeList (consumer)	Sets the flag whether the scoped PDU will be displayed as the list if it has child elements in its tree.	false	boolean
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
authenticationPassphrase (security)	The authentication passphrase. If not null, authenticationProtocol must also be not null. RFC3414 11.2 requires passphrases to have a minimum length of 8 bytes. If the length of authenticationPassphrase is less than 8 bytes an IllegalArgumentException is thrown.		String
authenticationProtocol (security)	Authentication protocol to use if security level is set to enable authentication The possible values are: MD5, SHA1. Enum values: • MD5 • SHA1		String
privacyPassphrase (security)	The privacy passphrase. If not null, privacyProtocol must also be not null. RFC3414 11.2 requires passphrases to have a minimum length of 8 bytes. If the length of authenticationPassphrase is less than 8 bytes an IllegalArgumentException is thrown.		String
privacyProtocol (security)	The privacy protocol ID to be associated with this user. If set to null, this user only supports unencrypted messages.		String

Name	Description	Default	Type
securityLevel (security)	Sets the security level for this target. The supplied security level must be supported by the security model dependent information associated with the security name set for this target. The value 1 means: No authentication and no encryption. Anyone can create and read messages with this security level The value 2 means: Authentication and no encryption. Only the one with the right authentication key can create messages with this security level, but anyone can read the contents of the message. The value 3 means: Authentication and encryption. Only the one with the right authentication key can create messages with this security level, and only the one with the right encryption/decryption key can read the contents of the message. Enum values: • 1 • 2 • 3	3	int
securityName (security)	Sets the security name to be used with this target.		String

119.7. THE RESULT OF A POLL

Given the situation, that I poll for the following OIDs:

OIDs

```
1.3.6.1.2.1.1.3.0
1.3.6.1.2.1.25.3.2.1.5.1
1.3.6.1.2.1.25.3.5.1.1.1
1.3.6.1.2.1.43.5.1.1.11.1
```

The result will be the following:

Result of toString conversion

```
<?xml version="1.0" encoding="UTF-8"?>
<snmp>
  <entry>
    <oid>1.3.6.1.2.1.1.3.0</oid>
    <value>6 days, 21:14:28.00</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.25.3.2.1.5.1</oid>
```

```
    <value>2</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.25.3.5.1.1.1</oid>
    <value>3</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.43.5.1.1.11.1</oid>
    <value>6</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.1.1.0</oid>
    <value>My Very Special Printer Of Brand Unknown</value>
  </entry>
</snmp>
```

As you maybe recognized there is one more result than requested....1.3.6.1.2.1.1.1.0.
This one is filled in by the device automatically in this special case. So it may absolutely happen, that you receive more than you requested...be prepared.

OID starting with dot representation

```
.1.3.6.1.4.1.6527.3.1.2.21.2.1.50
```

As you may notice, default snmpVersion is 0 which means **version1** in the endpoint if it is not set explicitly. Make sure you explicitly set snmpVersion which is not default value, of course in a case of where you are able to query SNMP tables with different versions. Other possible values are **version2c** and **version3**.

119.8. EXAMPLES

Polling a remote device:

```
snmp:192.168.178.23:161?protocol=udp&type=POLL&oids=1.3.6.1.2.1.1.5.0
```

Setting up a trap receiver (**Note that no OID info is needed here!**):

```
snmp:127.0.0.1:162?protocol=udp&type=TRAP
```

You can get the community of SNMP TRAP with message header 'securityName', peer address of the SNMP TRAP with message header 'peerAddress'.

Routing example in Java: (converts the SNMP PDU to XML String)

```
from("snmp:192.168.178.23:161?protocol=udp&type=POLL&oids=1.3.6.1.2.1.1.5.0").
convertBodyTo(String.class).
to("activemq:snmp.states");
```

119.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component.snmp.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.snmp.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.snmp.enabled	Whether to enable auto configuration of the snmp component. This is enabled by default.		Boolean
camel.component.snmp.health-check-consumer-enabled	Used for enabling or disabling all consumer based health checks from this component.	true	Boolean
camel.component.snmp.health-check-producer-enabled	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true.	true	Boolean
camel.component.snmp.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 120. SOAP

SOAP is a Data Format which uses JAXB2 and JAX-WS annotations to marshal and unmarshal SOAP payloads. It provides the basic features of Apache CXF without need for the CXF Stack.

Namespace prefix mapping

See JAXB for details how you can control namespace prefix mappings when marshalling using SOAP data format.

120.1. DEPENDENCIES

When using **soap** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-soap-starter</artifactId>
</dependency>
```

120.2. SOAP OPTIONS

The SOAP dataformat supports 6 options, which are listed below.

Name	Default	Java Type	Description
contextPath		**String**	**Required** Package name where your JAXB classes are located.
encoding		**String**	To overrule and use a specific encoding.
elementNameStrategyRef		**String**	Refers to an element strategy to lookup from the registry. An element name strategy is used for two purposes. The first is to find a xml element name for a given object and soap action when marshaling the object into a SOAP message. The second is to find an Exception class for a given soap fault name. The following three element strategy class name is provided out of the box. QNameStrategy - Uses a fixed qName that is configured on instantiation. Exception lookup is not supported TypeNameStrategy - Uses the name and namespace from the XMLType annotation of the given type. If no namespace is set then package-info is used. Exception lookup is not supported ServiceInterfaceStrategy - Uses information from a webservice interface to determine the type name and to find the exception class for a SOAP fault All three classes is located in the package name org.apache.camel.dataformat.soap.name If you have generated the web service stub code with cxf-codegen or a similar tool then you probably will want to use the ServiceInterfaceStrategy. In the case you have no annotated service interface you should use QNameStrategy or TypeNameStrategy.

Name	Default	Java Type	Description
version		**String**	SOAP version should either be 1.1 or 1.2. Is by default 1.1.
namespacePrefixRef		**String**	When marshalling using JAXB or SOAP then the JAXB implementation will automatic assign namespace prefixes, such as ns2, ns3, ns4 etc. To control this mapping, Camel allows you to refer to a map which contains the desired mapping.
schema		**String**	To validate against an existing schema. Your can use the prefix classpath:, file: or http: to specify how the resource should by resolved. You can separate multiple schema files by using the ',' character.

120.3. ELEMENTNAMESTRATEGY

An element name strategy is used for two purposes. The first is to find a xml element name for a given object and soap action when marshaling the object into a SOAP message. The second is to find an Exception class for a given soap fault name.

Strategy	Usage
QNameStrategy	Uses a fixed qName that is configured on instantiation. Exception lookup is not supported
TypeNameStrategy	Uses the name and namespace from the @XMLType annotation of the given type. If no namespace is set then package-info is used. Exception lookup is not supported
ServiceInterfaceStrategy	Uses information from a webservice interface to determine the type name and to find the exception class for a SOAP fault

If you have generated the web service stub code with cxf-codegen or a similar tool then you probably will want to use the ServiceInterfaceStrategy. In the case you have no annotated service interface you should use QNameStrategy or TypeNameStrategy.

120.4. USING THE JAVA DSL

The following example uses a named DataFormat of *soap* which is configured with the package com.example.customerservice to initialize the JAXBContext. The second parameter is the ElementNameStrategy. The route is able to marshal normal objects as well as exceptions. (Note the below just sends a SOAP Envelope to a queue. A web service provider would actually need to be listening to the queue for a SOAP call to actually occur, in which case it would be a one way SOAP request. If you need request reply then you should look at the next example.)

```
SoapJaxbDataFormat soap = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
from("direct:start")
  .marshal(soap)
  .to("jms:myQueue");
```

NOTE

See also
As the SOAP dataformat inherits from the JAXB dataformat most settings apply here as well.

120.4.1. Using SOAP 1.2

Since Camel 2.11

```
SoapJaxbDataFormat soap = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
soap.setVersion("1.2");
from("direct:start")
  .marshal(soap)
  .to("jms:myQueue");
```

When using XML DSL there is a version attribute you can set on the <soapjaxb> element.

```
    <!-- Defining a ServiceInterfaceStrategy for retrieving the element name when marshalling -->
    <bean id="myNameStrategy"
class="org.apache.camel.dataformat.soap.name.ServiceInterfaceStrategy">
        <constructor-arg value="com.example.customerservice.CustomerService"/>
    <constructor-arg value="true"/>
    </bean>
```

And in the Camel route

```
<route>
  <from uri="direct:start"/>
  <marshal>
    <soapjaxb contentPath="com.example.customerservice" version="1.2"
elementNameStrategyRef="myNameStrategy"/>
  </marshal>
  <to uri="jms:myQueue"/>
</route>
```

120.5. MULTI-PART MESSAGES

Multi-part SOAP messages are supported by the ServiceInterfaceStrategy. The ServiceInterfaceStrategy must be initialized with a service interface definition that is annotated in accordance with JAX-WS 2.2 and meets the requirements of the Document Bare style. The target method must meet the following criteria, as per the JAX-WS specification: 1) it must have at most one **in** or **in**/**out** non-header parameter, 2) if it has a return type other than **void** it must have no **in**/**out** or **out** non-header parameters, 3) if it it has a return type of **void** it must have at most one **in**/**out** or **out** non-header parameter.

The ServiceInterfaceStrategy should be initialized with a boolean parameter that indicates whether the mapping strategy applies to the request parameters or response parameters.

```
ServiceInterfaceStrategy strat =  new
ServiceInterfaceStrategy(com.example.customerservice.multipart.MultiPartCustomerService.class,
true);
SoapJaxbDataFormat soapDataFormat = new
SoapJaxbDataFormat("com.example.customerservice.multipart", strat);
```

120.5.1. Holder Object mapping

JAX-WS specifies the use of a type-parameterized **javax.xml.ws.Holder** object for **In**/**Out** and **Out** parameters. You may use an instance of the parameterized-type directly. The camel-soap DataFormat marshals Holder values in accordance with the JAXB mapping for the class of the **Holder's value. No mapping is provided for \'Holder** objects in an unmarshalled response.

120.6. EXAMPLES

120.6.1. Webservice client

The following route supports marshalling the request and unmarshalling a response or fault.

```
String WS_URI = "cxf://http://myserver/customerservice?
serviceClass=com.example.customerservice&dataFormat=RAW";
SoapJaxbDataFormat soapDF = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
from("direct:customerServiceClient")
  .onException(Exception.class)
    .handled(true)
    .unmarshal(soapDF)
  .end()
  .marshal(soapDF)
  .to(WS_URI)
  .unmarshal(soapDF);
```

The below snippet creates a proxy for the service interface and makes a SOAP call to the above route.

```
import org.apache.camel.Endpoint;
import org.apache.camel.component.bean.ProxyHelper;
...

Endpoint startEndpoint = context.getEndpoint("direct:customerServiceClient");
ClassLoader classLoader = Thread.currentThread().getContextClassLoader();
// CustomerService below is the service endpoint interface, *not* the javax.xml.ws.Service subclass
CustomerService proxy = ProxyHelper.createProxy(startEndpoint, classLoader,
CustomerService.class);
GetCustomersByNameResponse response = proxy.getCustomersByName(new
GetCustomersByName());
```

120.6.2. Webservice Server

Using the following route sets up a webservice server that listens on jms queue customerServiceQueue and processes requests using the class CustomerServiceImpl. The customerServiceImpl of course

should implement the interface CustomerService. Instead of directly instantiating the server class it could be defined in a spring context as a regular bean.

```
SoapJaxbDataFormat soapDF = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
CustomerService serverBean = new CustomerServiceImpl();
from("jms://queue:customerServiceQueue")
  .onException(Exception.class)
    .handled(true)
    .marshal(soapDF)
  .end()
  .unmarshal(soapDF)
  .bean(serverBean)
  .marshal(soapDF);
```

120.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 7 options, which are listed below.

Name	Description	Default	Type
camel.dataformat.soapjaxb.context-path	Package name where your JAXB classes are located.		String
camel.dataformat.soapjaxb.element-name-strategy-ref	Refers to an element strategy to lookup from the registry. An element name strategy is used for two purposes. The first is to find a xml element name for a given object and soap action when marshaling the object into a SOAP message. The second is to find an Exception class for a given soap fault name. The following three element strategy class name is provided out of the box. QNameStrategy - Uses a fixed qName that is configured on instantiation. Exception lookup is not supported TypeNameStrategy - Uses the name and namespace from the XMLType annotation of the given type. If no namespace is set then package-info is used. Exception lookup is not supported ServiceInterfaceStrategy - Uses information from a webservice interface to determine the type name and to find the exception class for a SOAP fault All three classes is located in the package name org.apache.camel.dataformat.soap.name If you have generated the web service stub code with cxf-codegen or a similar tool then you probably will want to use the ServiceInterfaceStrategy. In the case you have no annotated service interface you should use QNameStrategy or TypeNameStrategy.		String
camel.dataformat.soapjaxb.enabled	Whether to enable auto configuration of the soapjaxb data format. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.dataformat.soapjaxb.encoding	To overrule and use a specific encoding.		String
camel.dataformat.soapjaxb.namespace-prefix-ref	When marshalling using JAXB or SOAP then the JAXB implementation will automatic assign namespace prefixes, such as ns2, ns3, ns4 etc. To control this mapping, Camel allows you to refer to a map which contains the desired mapping.		String
camel.dataformat.soapjaxb.schema	To validate against an existing schema. Your can use the prefix classpath:, file: or http: to specify how the resource should by resolved. You can separate multiple schema files by using the ',' character.		String
camel.dataformat.soapjaxb.version	SOAP version should either be 1.1 or 1.2. Is by default 1.1.	1.1	String

CHAPTER 121. SPLUNK

Since Camel 2.13

Both producer and consumer are supported

The Splunk component provides access to Splunk using the Splunk provided client api, and it enables you to publish and search for events in Splunk.

121.1. DEPENDENCIES

When using **splunk** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-splunk-starter</artifactId>
</dependency>
```

121.2. URI FORMAT

```
splunk://[endpoint]?[options]
```

121.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

121.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

121.3.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

121.4. COMPONENT OPTIONS

The Splunk component supports 6 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
splunkConfigurationFactory (advanced)	To use the SplunkConfigurationFactory.		SplunkConfigurationFactory
healthCheckConsumerEnabled (health)	Used for enabling or disabling all consumer based health checks from this component.	true	boolean

Name	Description	Default	Type
healthCheckProducerEnabled (health)	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true.	true	boolean

121.5. ENDPOINT OPTIONS

The Splunk endpoint is configured using URI syntax:

```
splunk:name
```

with the following path and query parameters:

121.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (common)	**Required** Name has no purpose.		String

121.5.2. Query Parameters (45 parameters)

Name	Description	Default	Type
app (common)	Splunk app.		String
connectionTimeout (common)	Timeout in MS when connecting to Splunk server.	5000	int
host (common)	Splunk host.	localhost	String
owner (common)	Splunk owner.		String
port (common)	Splunk port.	8089	int
scheme (common)	Splunk scheme.	https	String

Name	Description	Default	Type
count (consumer)	A number that indicates the maximum number of entities to return.		int
earliestTime (consumer)	Earliest time of the search time window.		String
initEarliestTime (consumer)	Initial start offset of the first search.		String
latestTime (consumer)	Latest time of the search time window.		String
savedSearch (consumer)	The name of the query saved in Splunk to run.		String
search (consumer)	The Splunk query to run.		String
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
streaming (consumer)	Sets streaming mode. Streaming mode sends exchanges as they are received, rather than in a batch.	false	boolean
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
eventHost (producer)	Override the default Splunk event host field.		String
index (producer)	Splunk index to write to.		String
raw (producer)	Should the payload be inserted raw.	false	boolean
source (producer)	Splunk source argument.		String
sourceType (producer)	Splunk sourcetype argument.		String
tcpReceiverLocalPort (producer)	Splunk tcp receiver port defined locally on splunk server. (For example if splunk port 9997 is mapped to 12345, tcpReceiverLocalPort has to be 9997).		Integer
tcpReceiverPort (producer)	Splunk tcp receiver port.		int
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel

Name	Description	Default	Type
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
password (security)	Password for Splunk.		String
sslProtocol (security)	Set the ssl protocol to use. Enum values: • TLSv1.2 • TLSv1.1 • TLSv1 • SSLv3	TLSv1.2	SSLSecurityProtocol

Name	Description	Default	Type
token (security)	User's token for Splunk. This takes precedence over password when both are set.		String
username (security)	Username for Splunk.		String
useSunHttpsHandler (security)	Use sun.net.www.protocol.https.Handler Https handler to establish the Splunk Connection. Can be useful when running in application servers to avoid app. server https handling.	false	boolean

121.6. PRODUCER ENDPOINTS

Endpoint	Description
stream	Streams data to a named index or the default if not specified. When using stream mode be aware of that Splunk has some internal buffer (about 1MB or so) before events gets to the index. If you need realtime, better use submit or tcp mode.
submit	submit mode. Uses Splunk rest api to publish events to a named index or the default if not specified.
tcp	tcp mode. Streams data to a tcp port, and requires a open receiver port in Splunk.

When publishing events the message body should contain a SplunkEvent. See comment under message body.

Example

```
    from("direct:start").convertBodyTo(SplunkEvent.class)
        .to("splunk://submit?
username=user&password=123&index=myindex&sourceType=someSourceType&source=mySource"
)...
```

In this example a converter is required to convert to a SplunkEvent class.

121.7. CONSUMER ENDPOINTS:

Endpoint	Description
normal	Performs normal search and requires a search query in the search option.

Endpoint	Description
realtime	Performs realtime search on live data and requires a search query in the search option.
savedsearch	Performs search based on a search query saved in splunk and requires the name of the query in the savedSearch option.

Example

```
    from("splunk://normal?delay=5000&username=user&password=123&initEarliestTime=-
10s&search=search index=myindex sourcetype=someSourcetype")
        .to("direct:search-result");
```

The **camel-splunk** component creates a route exchange per search result with a SplunkEvent in the body.

121.8. MESSAGE BODY

Splunk operates on data in key/value pairs. The SplunkEvent class is a placeholder for such data, and should be in the message body for the producer. Likewise it will be returned in the body per search result for the consumer.

You can send raw data to Splunk by setting the raw option on the producer endpoint. This is useful for, for example, json/xml and other payloads where Splunk has build in support.

121.9. USE CASES

Search Twitter for tweets with music and publish events to Splunk:

```
    from("twitter://search?
type=polling&keywords=music&delay=10&consumerKey=abc&consumerSecret=def&accessToken=hij&
ccessTokenSecret=xxx")
        .convertBodyTo(SplunkEvent.class)
        .to("splunk://submit?username=foo&password=bar&index=camel-
tweets&sourceType=twitter&source=music-tweets");
```

To convert a Tweet to a SplunkEvent you could use a converter like:

```
@Converter
public class Tweet2SplunkEvent {
  @Converter
  public static SplunkEvent convertTweet(Status status) {
    SplunkEvent data = new SplunkEvent("twitter-message", null);
    //data.addPair("source", status.getSource());
    data.addPair("from_user", status.getUser().getScreenName());
    data.addPair("in_reply_to", status.getInReplyToScreenName());
    data.addPair(SplunkEvent.COMMON_START_TIME, status.getCreatedAt());
    data.addPair(SplunkEvent.COMMON_EVENT_ID, status.getId());
```

```
        data.addPair("text", status.getText());
        data.addPair("retweet_count", status.getRetweetCount());
        if (status.getPlace() != null) {
            data.addPair("place_country", status.getPlace().getCountry());
            data.addPair("place_name", status.getPlace().getName());
            data.addPair("place_street", status.getPlace().getStreetAddress());
        }
        if (status.getGeoLocation() != null) {
            data.addPair("geo_latitude", status.getGeoLocation().getLatitude());
            data.addPair("geo_longitude", status.getGeoLocation().getLongitude());
        }
        return data;
    }
}
```

Search Splunk for tweets:

```
    from("splunk://normal?username=foo&password=bar&initEarliestTime=-2m&search=search
index=camel-tweets sourcetype=twitter")
        .log("${body}");
```

121.10. OTHER COMMENTS

Splunk comes with a variety of options for leveraging machine generated data with prebuilt apps for analyzing and displaying this. For example the jmx application could be used to publish jmx attributes, such as, route and jvm metrics to Splunk, and displaying this on a dashboard.

121.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 7 options, which are listed below.

Name	Description	Default	Type
camel.component.splunk.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.splunk.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.splunk.enabled	Whether to enable auto configuration of the splunk component. This is enabled by default.		Boolean
camel.component.splunk.health-check-consumer-enabled	Used for enabling or disabling all consumer based health checks from this component.	true	Boolean
camel.component.splunk.health-check-producer-enabled	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true.	true	Boolean
camel.component.splunk.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.splunk.splunk-configuration-factory	To use the SplunkConfigurationFactory. The option is a org.apache.camel.component.splunk.SplunkConfigurationFactory type.		SplunkConfigurationFactory

CHAPTER 122. SPRING BATCH

Since Camel 2.10

Only producer is supported

The Spring Batch component and support classes provide integration bridge between Camel and Spring Batch infrastructure.

122.1. DEPENDENCIES

When using **spring-batch** with Red Hat build of Camel Spring Boot, use the following Maven dependency to enable support for auto-configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-spring-batch-starter</artifactId>
</dependency>
```

122.2. URI FORMAT

```
spring-batch:jobName[?options]
```

Where, **jobName** represents the name of the Spring Batch job located in the Camel registry. If a JobRegistry is provided is used to locate the job.

This component is only used to define producer endpoints, that means you cannot use the Spring Batch component in a **from()** statement.

122.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

122.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

122.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

122.4. COMPONENT OPTIONS

The Spring Batch component supports 4 options, which are listed below.

Name	Description	Default	Type
jobLauncher (producer)	Explicitly specifies a JobLauncher to be used.		JobLauncher
jobRegistry (producer)	Explicitly specifies a JobRegistry to be used.		JobRegistry
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

122.5. ENDPOINT OPTIONS

The Spring Batch endpoint is configured using URI syntax:

```
spring-batch:jobName
```

Following are the path and query parameters:

122.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
jobName (producer)	**Required** The name of the Spring Batch job located in the registry.		String

122.5.2. Query Parameters (4 parameters)

Name	Description	Default	Type
jobFromHeader (producer)	Explicitly defines if the jobName should be taken from the headers instead of the URI.	false	boolean
jobLauncher (producer)	Explicitly specifies a JobLauncher to be used.		JobLauncher

Name	Description	Default	Type
jobRegistry (producer)	Explicitly specifies a JobRegistry to be used.		JobRegistry
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

122.6. USAGE

When Spring Batch component receives the message, it triggers the job execution. The job is executed using the **org.springframework.batch.core.launch.JobLaucher** instance resolved according to the following algorithm.

- if **JobLauncher** is manually set on the component, then use it.
- if **jobLauncherRef** option is set on the component, then search Camel Registry for the **JobLauncher** with the given name.
- if there is **JobLauncher** registered in the Camel Registry under **jobLauncher** name, then use it.
- if none of the steps above allow to resolve the **JobLauncher** and there is exactly one **JobLauncher** instance in the Camel Registry, then use it.

All headers found in the message are passed to the **JobLauncher** as job parameters. **String**, **Long**, **Double** and **java.util.Date** values are copied to the **org.springframework.batch.core.JobParametersBuilder** and other data types are converted to Strings.

122.7. EXAMPLES

Triggering the Spring Batch job execution:

```
from("direct:startBatch").to("spring-batch:myJob");
```

Triggering the Spring Batch job execution with the **JobLauncher** set explicitly.

```
from("direct:startBatch").to("spring-batch:myJob?jobLauncherRef=myJobLauncher");
```

A **JobExecution** instance returned by the **JobLauncher** is forwarded by the **SpringBatchProducer** as the output message. You can use the **JobExecution** instance to perform some operations using the Spring Batch API directly.

```
from("direct:startBatch").to("spring-batch:myJob").to("mock:JobExecutions");
...
MockEndpoint mockEndpoint = ...;
JobExecution jobExecution =
mockEndpoint.getExchanges().get(0).getIn().getBody(JobExecution.class);
BatchStatus currentJobStatus = jobExecution.getStatus();
```

122.8. SUPPORT CLASSES

Apart from the component, Camel Spring Batch also provides support classes that you can use to hook into Spring Batch infrastructure.

122.8.1. CamelItemReader

CamelItemReader can be used to read batch data directly from the Camel infrastructure.

For example, the snippet below configures Spring Batch to read data from JMS queue:

```
<bean id="camelReader"
class="org.apache.camel.component.spring.batch.support.CamelItemReader">
  <constructor-arg ref="consumerTemplate"/>
  <constructor-arg value="jms:dataQueue"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="camelReader" writer="someWriter" commit-interval="100"/>
    </batch:tasklet>
  </batch:step>
</batch:job>
```

122.8.2. CamelItemWriter

CamelItemWriter has similar purpose as **CamelItemReader**, but it is dedicated to write chunk of the processed data.

For example the snippet below configures Spring Batch to read data from JMS queue.

```
<bean id="camelwriter"
class="org.apache.camel.component.spring.batch.support.CamelItemWriter">
```

```
  <constructor-arg ref="producerTemplate"/>
  <constructor-arg value="jms:dataQueue"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="someReader" writer="camelwriter" commit-interval="100"/>
    </batch:tasklet>
  </batch:step>
</batch:job>
```

122.8.3. CamelItemProcessor

CamelItemProcessor is the implementation of Spring Batch **org.springframework.batch.item.ItemProcessor** interface. The latter implementation relays on Request Reply pattern to delegate the processing of the batch item to the Camel infrastructure. The item to process is sent to the Camel endpoint as the body of the message.

For example the snippet below performs simple processing of the batch item using the Direct endpoint and the Simple expression language.

```
<camel:camelContext>
  <camel:route>
    <camel:from uri="direct:processor"/>
    <camel:setExchangePattern pattern="InOut"/>
    <camel:setBody>
      <camel:simple>Processed ${body}</camel:simple>
    </camel:setBody>
  </camel:route>
</camel:camelContext>

<bean id="camelProcessor"
class="org.apache.camel.component.spring.batch.support.CamelItemProcessor">
  <constructor-arg ref="producerTemplate"/>
  <constructor-arg value="direct:processor"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="someReader" writer="someWriter" processor="camelProcessor" commit-
interval="100"/>
    </batch:tasklet>
  </batch:step>
</batch:job>
```

122.8.4. CamelJobExecutionListener

CamelJobExecutionListener is the implementation of the **org.springframework.batch.core.JobExecutionListener** interface sending job execution events to the Camel endpoint.

The **org.springframework.batch.core.JobExecution** instance produced by the Spring Batch is sent as a body of the message. To distinguish between before- and after-callbacks **SPRING_BATCH_JOB_EVENT_TYPE** header is set to the **BEFORE** or **AFTER** value.

The example snippet below sends Spring Batch job execution events to the JMS queue.

```
<bean id="camelJobExecutionListener"
class="org.apache.camel.component.spring.batch.support.CamelJobExecutionListener">
  <constructor-arg ref="producerTemplate"/>
  <constructor-arg value="jms:batchEventsBus"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="someReader" writer="someWriter" commit-interval="100"/>
    </batch:tasklet>
  </batch:step>
  <batch:listeners>
    <batch:listener ref="camelJobExecutionListener"/>
  </batch:listeners>
</batch:job>
```

122.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.component.spring-batch.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.spring-batch.enabled	Whether to enable auto-configuration of the spring-batch component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.spring-batch.job-launcher	Explicitly specifies a JobLauncher to be used. The option is a org.springframework.batch.core.launch.JobLauncher type.		JobLauncher
camel.component.spring-batch.job-registry	Explicitly specifies a JobRegistry to be used. The option is a org.springframework.batch.core.configuration.JobRegistry type.		JobRegistry
camel.component.spring-batch.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 123. SPRING JDBC

Since Camel 3.10

Only producer is supported

The Spring JDBC component is an extension of the JDBC component with one additional feature to integrate with Spring Transaction Manager.

123.1. DEPENDENCIES

When using **spring-jdbc** with Red Hat build of Camel Spring Boot use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-spring-jdbc-starter</artifactId>
</dependency>
```

The version is specified using BOM in the following way.

```
<dependencyManagement>
      <dependencies>
         <dependency>
            <groupId>com.redhat.camel.springboot.platform</groupId>
            <artifactId>camel-spring-boot-bom</artifactId>
            <version>${camel-spring-boot-version}</version>
            <type>pom</type>
            <scope>import</scope>
         </dependency>
      </dependencies>
   </dependencyManagement>
```

123.2. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

123.2.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

123.2.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

123.3. COMPONENT OPTIONS

The Spring JDBC component supports 4 options that are listed below.

Name	Description	Default	Type
dataSource (producer)	To use the DataSource instance instead of looking up the data source by name from the registry.		DataSource
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
connectionStrategy (advanced)	To use a custom strategy for working with connections. Do not use a custom strategy when using the spring-jdbc component because a special Spring ConnectionStrategy is used by default to support Spring Transactions.		ConnectionStrategy

123.4. ENDPOINT OPTIONS

The Spring JDBC endpoint is configured using URI syntax:

```
spring-jdbc:dataSourceName
```

Following are the path and query parameters:

123.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type

Name	Description	Default	Type
dataSourceName (producer)	**Required** Name of DataSource to lookup in the Registry. If the name is dataSource or default, then Camel will attempt to lookup a default DataSource from the registry, meaning if there is a only one instance of DataSource found, then this DataSource will be used.		String

123.4.2. Query Parameters (14 parameters)

Name	Description	Default	Type
allowNamedParameters (producer)	Whether to allow using named parameters in the queries.	true	boolean
outputClass (producer)	Specify the full package and class name to use as conversion when outputType=SelectOne or SelectList.		String
outputType (producer)	Determines the output the producer should use. Enum values: • SelectOne • SelectList • StreamList	SelectList	JdbcOutputType
parameters (producer)	Optional parameters to the java.sql.Statement. For example to set maxRows, fetchSize etc.		Map
readSize (producer)	The default maximum number of rows that can be read by a polling query. The default value is 0.		int

Name	Description	Default	Type
resetAutoCommit (producer)	Camel will set the autoCommit on the JDBC connection to be false, commit the change after executed the statement and reset the autoCommit flag of the connection at the end, if the resetAutoCommit is true. If the JDBC connection doesn't support to reset the autoCommit flag, you can set the resetAutoCommit flag to be false, and Camel will not try to reset the autoCommit flag. When used with XA transactions you most likely need to set it to false so that the transaction manager is in charge of committing this tx.	true	boolean
transacted (producer)	Whether transactions are in use.	false	boolean
useGetBytesForBlob (producer)	To read BLOB columns as bytes instead of string data. This may be needed for certain databases such as Oracle where you must read BLOB columns as bytes.	false	boolean
useHeadersAsParameters (producer)	Set this option to true to use the prepareStatementStrategy with named parameters. This allows to define queries with named placeholders, and use headers with the dynamic values for the query placeholders.	false	boolean

Name	Description	Default	Type
useJDBC4ColumnNameAndLabelSemantics (producer)	Sets whether to use JDBC 4 or JDBC 3.0 or older semantic when retrieving column name. JDBC 4.0 uses columnLabel to get the column name where as JDBC 3.0 uses both columnName or columnLabel. Unfortunately JDBC drivers behave differently so you can use this option to work out issues around your JDBC driver if you get problem using this component This option is default true.	true	boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
beanRowMapper (advanced)	To use a custom org.apache.camel.component.jdbc.BeanRowMapper when using outputClass. The default implementation will lower case the row names and skip underscores, and dashes. For example CUST_ID is mapped as custId.		BeanRowMapper
connectionStrategy (advanced)	To use a custom strategy for working with connections. Do not use a custom strategy when using the spring-jdbc component because a special Spring ConnectionStrategy is used by default to support Spring Transactions.		ConnectionStrategy
prepareStatementStrategy (advanced)	Allows the plugin to use a custom org.apache.camel.component.jdbc.JdbcPrepareStatementStrategy to control preparation of the query and prepared statement.		JdbcPrepareStatementStrategy

123.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options that are listed below.

Name	Description	Default	Type

Name	Description	Default	Type
camel.component.spring-jdbc.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.spring-jdbc.connection-strategy	To use a custom strategy for working with connections. Do not use a custom strategy when using the spring-jdbc component because a special Spring ConnectionStrategy is used by default to support Spring Transactions. The option is a org.apache.camel.component.jdbc.ConnectionStrategy type.		ConnectionStrategy
camel.component.spring-jdbc.enabled	Whether to enable auto configuration of the spring-jdbc component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.spring-jdbc.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 124. SPRING LDAP

Since Camel 2.11

Only producer is supported

The Spring LDAP component provides a Camel wrapper for Spring LDAP.

124.1. DEPENDENCIES

When using **spring-ldap** with Red Hat build of Camel Spring Boot, use the following Maven dependency to enable support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-spring-ldap-starter</artifactId>
</dependency>
```

124.2. URI FORMAT

```
spring-ldap:springLdapTemplate[?options]
```

Where **springLdapTemplate** is the name of the Spring LDAP Template bean. In this bean, you configure the URL and the credentials for your LDAP access.

124.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

124.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

124.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

124.4. COMPONENT OPTIONS

The Spring LDAP component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

124.5. ENDPOINT OPTIONS

The Spring LDAP endpoint is configured using URI syntax:

```
spring-ldap:templateName
```

Following are the path and query parameters:

124.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
templateName (producer)	**Required** Name of the Spring LDAP Template bean.		String

124.5.2. Query Parameters (3 parameters)

Name	Description	Default	Type

Name	Description	Default	Type
operation (producer)	**Required** The LDAP operation to be performed. Enum values: • SEARCH • BIND • UNBIND • AUTHENTICATE • MODIFY_ATTRIBUTES • FUNCTION_DRIVEN		LdapOperation
scope (producer)	The scope of the search operation. Enum values: • object • onelevel • subtree	subtree	String

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

124.6. USAGE

The component supports producer endpoints only. An attempt to create a consumer endpoint can result in an **UnsupportedOperationException**.
The body of the message must be a map (an instance of **java.util.Map**). Unless a base DN is specified in the configuration of your ContextSource, this map must contain at least an entry with the key **dn** (not needed for function_driven operation) that specifies the root node for the LDAP operation to be performed. Other entries of the map are operation-specific.

The body of the message remains unchanged for the **bind** and **unbind** operations. For the **search** and **function_driven** operations, the body is set to the result of the search, see http://static.springsource.org/spring-ldap/site/apidocs/org/springframework/ldap/core/LdapTemplate.html#search%28java.lang.String,%20ja

124.6.1. Search

The message body must have an entry with the key **filter**. The value must be a **String** representing a valid LDAP filter, see http://en.wikipedia.org/wiki/Lightweight_Directory_Access_Protocol#Search_and_Compare.

124.6.2. Bind

The message body must have an entry with the key **attributes**. The value must be an instance of javax.naming.directory.Attributes This entry specifies the LDAP node to be created.

124.6.3. Unbind

No further entries are necessary, the node with the specified **dn** is deleted.

124.6.4. Authenticate

The message body must have entries with the keys **filter** and **password**. The values must be an instance of **String** representing a valid LDAP filter and a user password, respectively.

124.6.5. Modify Attributes

The message body must have an entry with the key **modificationItems**. The value must be an instance of any array of type javax.naming.directory.ModificationItem

124.6.6. Function-Driven

The message body must have entries with the keys **function** and **request**. The **function** value must be of type **java.util.function.BiFunction<L, Q, S>**. The **L** type parameter must be of type **org.springframework.ldap.core.LdapOperations**. The **request** value must be the same type as the **Q** type parameter in the **function** and it must encapsulate the parameters expected by the LdapTemplate method being invoked within the **function**. The **S** type parameter represents the response type as returned by the LdapTemplate method being invoked. This operation allows dynamic invocation of LdapTemplate methods that are not covered by the operations mentioned above.

Key definitions

In order to avoid spelling errors, the following constants are defined in **org.apache.camel.springldap.SpringLdapProducer**:

- public static final String DN = "dn"
- public static final String FILTER = "filter"
- public static final String ATTRIBUTES = "attributes"
- public static final String PASSWORD = "password";
- public static final String MODIFICATION_ITEMS = "modificationItems";
- public static final String FUNCTION = "function";
- public static final String REQUEST = "request";

Following is an example of createMap function:

```
from(“direct:start”)
    .setBody(constant(createMap()))
    .to("spring-ldap:ldapTemplate?operation=BIND");
```

Here, createMap function returns Map object that contains information about attributes and domain name of ldap server.

```
private static Map<String, Object> createMap() {
    BasicAttributes basicAttributes = new BasicAttributes();
    basicAttributes.put("cn", "Name Surname");
```

```
    basicAttributes.put("sn", "Surname");
    basicAttributes.put("objectClass", "person");
    Map<String, Object> map = new HashMap<>();
    map.put(SpringLdapProducer.DN, "cn=LdapDN,dc=example,dc=org");
    map.put(SpringLdapProducer.ATTRIBUTES, basicAttributes);
    return map;
}
```

You must also configure ldap connection using Spring Boot auto-configuration or LdapTemplate Bean for the above example.

Example for Spring Boot auto-configuration:

```
spring.ldap.password=passwordforldapserver
spring.ldap.urls=urlForLdapServer
spring.ldap.username=usernameForLdapServer
```

124.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options that are listed below.

Name	Description	Default	Type
camel.component.spring-ldap.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.spring-ldap.enabled	Whether to enable auto configuration of the spring-ldap component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.spring-ldap.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 125. SPRING RABBITMQ

Since Camel 3.8

Both producer and consumer are supported

The Spring RabbitMQ component allows you to produce and consume messages from RabbitMQ instances using the Spring RabbitMQ client.

125.1. DEPENDENCIES

When using **spring-rabbitmq** with Red Hat build of Camel Spring Boot use the following Maven dependency to enable support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-spring-rabbitmq-starter</artifactId>
</dependency>
```

The version is specified using BOM in the following way.

```
<dependencyManagement>
        <dependencies>
           <dependency>
              <groupId>com.redhat.camel.springboot.platform</groupId>
              <artifactId>camel-spring-boot-bom</artifactId>
              <version>${camel-spring-boot-version}</version>
              <type>pom</type>
              <scope>import</scope>
           </dependency>
        </dependencies>
     </dependencyManagement>
```

125.2. URI FORMAT

```
spring-rabbitmq:exchangeName?[options]
```

The **exchangeName** determines the exchange to which the produced messages are sent to. In the case of consumers, the **exchangeName** determines the exchange the queue is bound to.

125.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

125.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

125.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

125.4. COMPONENT OPTIONS

The Spring RabbitMQ component supports 29 options that are listed below.

Name	Description	Default	Type
amqpAdmin (common)	**Autowired** Optional AMQP Admin service to use for auto declaring elements (queues, exchanges, bindings).		AmqpAdmin
connectionFactory (common)	**Autowired** The connection factory to be use. A connection factory must be configured either on the component or endpoint.		ConnectionFactory

Name	Description	Default	Type
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	boolean
autoDeclare (consumer)	Specifies whether the consumer should auto declare binding between exchange, queue and routing key when starting. Enabling this can be good for development to make it easy to standup exchanges, queues and bindings on the broker.	false	boolean
autoStartup (consumer)	Specifies whether the consumer container should auto-startup.	true	boolean

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
deadLetterExchange (consumer)	The name of the dead letter exchange.		String
deadLetterExchangeType (consumer)	The type of the dead letter exchange. Enum values: • direct • fanout • headers • topic	direct	String
deadLetterQueue (consumer)	The name of the dead letter queue.		String
deadLetterRoutingKey (consumer)	The routing key for the dead letter exchange.		String
maximumRetryAttempts (consumer)	How many times a Rabbitmq consumer will retry the same message if Camel failed to process the message.	5	int

Name	Description	Default	Type
rejectAndDontRequeue (consumer)	Whether a Rabbitmq consumer should reject the message without requeuing. This enables failed messages to be sent to a Dead Letter Exchange/Queue, if the broker is so configured.	true	boolean
retryDelay (consumer)	Delay in msec a Rabbitmq consumer will wait before redelivering a message that Camel failed to process.	1000	int
concurrentConsumers (consumer (advanced))	The number of consumers.	1	int
errorHandler (consumer (advanced))	To use a custom ErrorHandler for handling exceptions from the message listener (consumer).		ErrorHandler
listenerContainerFactory (consumer (advanced))	To use a custom factory for creating and configuring ListenerContainer to be used by the consumer for receiving messages.		ListenerContainerFactory
maxConcurrentConsumers (consumer (advanced))	The maximum number of consumers (available only with SMLC).		Integer
messageListenerContainerType (consumer (advanced))	The type of the MessageListenerContainer. Enum values: • DMLC • SMLC	DMLC	String

Name	Description	Default	Type
prefetchCount (consumer (advanced))	Tell the broker how many messages to send to each consumer in a single request. Often this can be set quite high to improve throughput.	250	int
retry (consumer (advanced))	Custom retry configuration to use. If this is configured then the other settings such as maximumRetryAttempts for retry are not in use.		RetryOperationsInterceptor
shutdownTimeout (consumer (advanced))	The time to wait for workers in milliseconds after the container is stopped. If any workers are active when the shutdown signal comes they will be allowed to finish processing as long as they can finish within this timeout.	5000	long
allowNullBody (producer)	Whether to allow sending messages with no body. If this option is false and the message body is null, then an MessageConversionException is thrown.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
replyTimeout (producer)	Specify the timeout in milliseconds to be used when waiting for a reply message when doing request/reply messaging. The default value is 5 seconds. A negative value indicates an indefinite timeout.	5000	long
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
ignoreDeclarationExceptions (advanced)	Switch on ignore exceptions such as mismatched properties when declaring.	false	boolean
messageConverter (advanced)	To use a custom MessageConverter so you can be in control how to map to/from a org.springframework.amqp.core.Message.		MessageConverter
messagePropertiesConverter (advanced)	To use a custom MessagePropertiesConverter so you can be in control how to map to/from a org.springframework.amqp.core.MessageProperties.		MessagePropertiesConverter
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy

125.5. ENDPOINT OPTIONS

The Spring RabbitMQ endpoint is configured using URI syntax:

```
spring-rabbitmq:exchangeName
```

Following are the path and query parameters:

125.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type

Name	Description	Default	Type
exchangeName (common)	**Required** The exchange name determines the exchange to which the produced messages will be sent to. In the case of consumers, the exchange name determines the exchange the queue will be bound to. Note: to use default exchange then do not use empty name, but use default instead.		String

125.5.2. Query Parameters (34 parameters)

Name	Description	Default	Type
connectionFactory (common)	The connection factory to be use. A connection factory must be configured either on the component or endpoint.		ConnectionFactory
disableReplyTo (common)	Specifies whether Camel ignores the ReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the ReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	boolean

Name	Description	Default	Type
routingKey (common)	The value of a routing key to use. Default is empty which is not helpful when using the default (or any direct) exchange, but fine if the exchange is a headers exchange for instance.		String
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	boolean

Name	Description	Default	Type
acknowledgeMode (consumer)	Flag controlling the behaviour of the container with respect to message acknowledgement. The most common usage is to let the container handle the acknowledgements (so the listener doesn't need to know about the channel or the message). Set to AcknowledgeMode.MANUAL if the listener will send the acknowledgements itself using Channel.basicAck(long, boolean). Manual acks are consistent with either a transactional or non-transactional channel, but if you are doing no other work on the channel at the same other than receiving a single message then the transaction is probably unnecessary. Set to AcknowledgeMode.NONE to tell the broker not to expect any acknowledgements, and it will assume all messages are acknowledged as soon as they are sent (this is autoack in native Rabbit broker terms). If AcknowledgeMode.NONE then the channel cannot be transactional (so the container will fail on start up if that flag is accidentally set). Enum values: • NONE • MANUAL • AUTO		AcknowledgeMode

Name	Description	Default	Type
asyncConsumer (consumer)	Whether the consumer processes the Exchange asynchronously. If enabled then the consumer may pickup the next message from the queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the consumer will pickup the next message from the queue.	false	boolean
autoDeclare (consumer)	Specifies whether the consumer should auto declare binding between exchange, queue and routing key when starting.	true	boolean
autoStartup (consumer)	Specifies whether the consumer container should auto-startup.	true	boolean
deadLetterExchange (consumer)	The name of the dead letter exchange.		String
deadLetterExchangeType (consumer)	The type of the dead letter exchange. Enum values: • direct • fanout • headers • topic	direct	String
deadLetterQueue (consumer)	The name of the dead letter queue.		String

Name	Description	Default	Type
deadLetterRoutingKey (consumer)	The routing key for the dead letter exchange.		String
exchangeType (consumer)	The type of the exchange. Enum values: • direct • fanout • headers • topic	direct	String
exclusive (consumer)	Set to true for an exclusive consumer.	false	boolean
maximumRetryAttempts (consumer)	How many times a Rabbitmq consumer will retry the same message if Camel failed to process the message.	5	int
noLocal (consumer)	Set to true for an no-local consumer.	false	boolean
queues (consumer)	The queue(s) to use for consuming messages. Multiple queue names can be separated by comma. If none has been configured then Camel will generate an unique id as the queue name for the consumer.		String
rejectAndDontRequeue (consumer)	Whether a Rabbitmq consumer should reject the message without requeuing. This enables failed messages to be sent to a Dead Letter Exchange/Queue, if the broker is so configured.	true	boolean

Name	Description	Default	Type
retryDelay (consumer)	Delay in msec a Rabbitmq consumer will wait before redelivering a message that Camel failed to process.	1000	int
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer (advanced))	The number of consumers.		Integer
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
maxConcurrentConsumers (consumer (advanced))	The maximum number of consumers (available only with SMLC).		Integer
messageListenerContainerType (consumer (advanced))	The type of the MessageListenerContainer. Enum values: • DMLC • SMLC	DMLC	String
prefetchCount (consumer (advanced))	Tell the broker how many messages to send in a single request. Often this can be set quite high to improve throughput.		Integer
retry (consumer (advanced))	Custom retry configuration to use. If this is configured then the other settings such as maximumRetryAttempts for retry are not in use.		RetryOperationsInterceptor
replyTimeout (producer)	Specify the timeout in milliseconds to be used when waiting for a reply message when doing request/reply messaging. The default value is 5 seconds. A negative value indicates an indefinite timeout.	5000	long

Name	Description	Default	Type
usePublisherConnection (producer)	Use a separate connection for publishers and consumers.	false	boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
args (advanced)	Specify arguments for configuring the different RabbitMQ concepts, a different prefix is required for each element: arg.consumer. arg.exchange. arg.queue. arg.binding. arg.dlq.exchange. arg.dlq.queue. arg.dlq.binding. For example to declare a queue with message ttl argument: args=arg.queue.x-message-ttl=60000.		Map

Name	Description	Default	Type
messageConverter (advanced)	To use a custom MessageConverter so you can be in control how to map to/from a org.springframework.amqp.core.Message.		MessageConverter
messagePropertiesConverter (advanced)	To use a custom MessagePropertiesConverter so you can be in control how to map to/from a org.springframework.amqp.core.MessageProperties.		MessagePropertiesConverter
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean

125.6. MESSAGE HEADERS

The Spring RabbitMQ component supports 2 message headers that are listed below:

Name	Description	Default	Type
CamelSpringRabbitmqRoutingOverrideKey (common) Constant: **ROUTING_OVERRIDE_KEY**	The exchange key.		String
CamelSpringRabbitmqExchangeOverrideName (common) Constant: **EXCHANGE_OVERRIDE_NAME**	The exchange name.		String

125.7. USING A CONNECTION FACTORY

To connect to RabbitMQ you must setup a **ConnectionFactory** (same as JMS) with the login details as described below.

It is recommended to use **CachingConnectionFactory** from spring-rabbit as it comes with connection pooling out of the box.

```
<bean id="rabbitConnectionFactory"
class="org.springframework.amqp.rabbit.connection.CachingConnectionFactory">
  <property name="uri" value="amqp://lolcalhost:5672"/>
</bean>
```

The **ConnectionFactory** is auto-detected by default, so you can just execute it.

```
<camelContext>
  <route>
    <from uri="direct:cheese"/>
    <to uri="spring-rabbitmq:foo?routingKey=cheese"/>
  </route>
</camelContext>
```

125.8. DEFAULT EXCHANGE NAME

To use default exchange name (which would be an empty exchange name in RabbitMQ) you must use **default** as name in the endpoint uri, like:

```
to("spring-rabbitmq:default?routingKey=foo")
```

125.9. AUTO DECLARE EXCHANGES, QUEUES AND BINDINGS

Before you can send or receive messages from RabbitMQ, you must first set up the exchanges, queues and bindings.

In development mode, Camel can automatically do this. You can enable this by setting **autoDeclare=true** on the **SpringRabbitMQComponent**.

Then Spring RabbitMQ automatically declares the elements and sets up the binding between the exchange, queue and routing keys.

The elements can be configured using the multi-valued **args** option.

For example to specify the queue as durable and exclusive, you can configure the endpoint uri with **arg.queue.durable=true&arg.queue.exclusive=true**.

Exchanges

Option	Type	Description	Default
autoDelete	boolean	True if the server should delete the exchange when it is no longer in use (if all bindings are deleted).	false
durable	boolean	A durable exchange will survive a server restart.	true

You can also configure any additional **x-** arguments. See details in the RabbitMQ documentation.

Queues

Option	Type	Description	Default
autoDelete	boolean	True if the server should delete the exchange when it is no longer in use (if all bindings are deleted).	false
durable	boolean	A durable queue will survive a server restart.	false
exclusive	boolean	Whether the queue is exclusive	false
x-dead-letter-exchange	String	The name of the dead letter exchange. If none configured then the component configured value is used.	
x-dead-letter-routing-key	String	The routing key for the dead letter exchange. If none configured then the component configured value is used.	

You can also configure any additional **x-** arguments, such as the message time to live using **x-message-ttl**, and many others. See details in the RabbitMQ documentation.

125.10. MAPPING FROM CAMEL TO RABBITMQ

The message body is mapped from Camel Message body to a **byte[]** which is the type that RabbitMQ uses for message body. Camel uses its type converter to convert the message body to byte array.

Spring Rabbit comes out of the box with support for mapping Java serialized objects but Camel Spring RabbitMQ does **not** support this due to security vulnerabilities and using Java objects is a bad design as it enforces strong coupling.

Custom message headers is mapped from Camel Message headers to RabbitMQ headers. This behaviour can be customized by configuring a new implementation of **HeaderFilterStrategy** on the Camel component.

125.11. REQUEST / REPLY

Request and reply messaging is supported using RabbitMQ direct reply-to .

The example below does request/reply, where the message is sent using the cheese exchange name and routing key *foo.bar*, which is being consumed by the 2nd Camel route, that prepends the message with `Hello `, and then sends back the message.

So if we send **World** as message body to *direct:start* then, we can see the message being logged

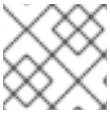
- log:request ⇒ World
- log:input ⇒ World
- log:response ⇒ Hello World

```
from("direct:start")
    .to("log:request")
    .to(ExchangePattern.InOut, "spring-rabbitmq:cheese?routingKey=foo.bar")
    .to("log:response");

from("spring-rabbitmq:cheese?queues=myqueue&routingKey=foo.bar")
    .to("log:input")
    .transform(body().prepend("Hello "));
```

125.12. REUSE ENDPOINT AND SEND TO DIFFERENT DESTINATIONS COMPUTED AT RUNTIME

If you need to send messages to a lot of different RabbitMQ exchanges, you must reuse an endpoint and specify the real destination in a message header. This allows Camel to reuse the same endpoint, but send to different exchanges. This greatly reduces the number of endpoints created and economizes on memory and thread resources.



NOTE

Using toD is easier than specifying the dynamic destination with headers.

You can specify using the following headers:

Header	Type	Description
CamelSpringRabbitmqExchangeOverrideName	**String**	The exchange name.
CamelSpringRabbitmqRoutingOverrideKey	**String**	The routing key.

For example, the following route shows how you can compute a destination at run time and use it to override the exchange appearing in the endpoint URL:

```
from("file://inbox")
  .to("bean:computeDestination")
  .to("spring-rabbitmq:dummy");
```

The exchange name, **dummy**, is just a placeholder. It must be provided as part of the RabbitMQ endpoint URL, but it is ignored in this example.

In the **computeDestination** bean, specify the real destination by setting the **CamelRabbitmqExchangeOverrideName** header as follows:

```
public void setExchangeHeader(Exchange exchange) {
    String region = ....
    exchange.getIn().setHeader("CamelSpringRabbitmqExchangeOverrideName", "order-" + region);
}
```

Camel reads this header and uses it as the exchange name instead of the one configured on the endpoint. So, in this example Camel sends the message to **spring-rabbitmq:order-emea**, assuming the **region** value was **emea**.

The producer removes both **CamelSpringRabbitmqExchangeOverrideName** and **CamelSpringRabbitmqRoutingOverrideKey** headers from the exchange and do not propagate them to the created Rabbitmq message in order to avoid the accidental loops in the routes (in scenarios when the message is forwarded to another RabbitMQ endpoint).

125.13. USING TOD

If you need to send messages to a lot of different exchanges, you must reuse an endpoint and specify the dynamic destinations with simple language using toD.

For example, you need to send messages to the exchange with order types, then you can use **toD** as follows:

```
from("direct:order")
  .toD("spring-rabbit:order-${header.orderType}");
```

125.14. SPRING BOOT AUTO-CONFIGURATION

The component supports 30 options that are listed below.

Name	Description	Default	Type
camel.component.spring-rabbitmq.allow-null-body	Whether to allow sending messages with no body. If this option is false and the message body is null, then an MessageConversionException is thrown.	false	Boolean

Name	Description	Default	Type
camel.component.spring-rabbitmq.amqp-admin	Optional AMQP Admin service to use for auto declaring elements (queues, exchanges, bindings). The option is a org.springframework.amqp.core.AmqpAdmin type.		AmqpAdmin
camel.component.spring-rabbitmq.auto-declare	Specifies whether the consumer should auto declare binding between exchange, queue and routing key when starting. Enabling this can be good for development to make it easy to standup exchanges, queues and bindings on the broker.	false	Boolean
camel.component.spring-rabbitmq.auto-startup	Specifies whether the consumer container should auto-startup.	true	Boolean
camel.component.spring-rabbitmq.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.spring-rabbitmq.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.spring-rabbitmq.concurrent-consumers	The number of consumers.	1	Integer
camel.component.spring-rabbitmq.connection-factory	The connection factory to be use. A connection factory must be configured either on the component or endpoint. The option is a org.springframework.amqp.rabbit.connection.ConnectionFactory type.		ConnectionFactory
camel.component.spring-rabbitmq.dead-letter-exchange	The name of the dead letter exchange.		String
camel.component.spring-rabbitmq.dead-letter-exchange-type	The type of the dead letter exchange.	direct	String
camel.component.spring-rabbitmq.dead-letter-queue	The name of the dead letter queue.		String

Name	Description	Default	Type
camel.component.spring-rabbitmq.dead-letter-routing-key	The routing key for the dead letter exchange.		String
camel.component.spring-rabbitmq.enabled	Whether to enable auto configuration of the spring-rabbitmq component. This is enabled by default.		Boolean
camel.component.spring-rabbitmq.error-handler	To use a custom ErrorHandler for handling exceptions from the message listener (consumer). The option is a org.springframework.util.ErrorHandler type.		ErrorHandler
camel.component.spring-rabbitmq.header-filter-strategy	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		HeaderFilterStrategy
camel.component.spring-rabbitmq.ignore-declaration-exceptions	Switch on ignore exceptions such as mismatched properties when declaring.	false	Boolean

Name	Description	Default	Type
camel.component.spring-rabbitmq.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.spring-rabbitmq.listener-container-factory	To use a custom factory for creating and configuring ListenerContainer to be used by the consumer for receiving messages. The option is a org.apache.camel.component.springrabbit.ListenerContainerFactory type.		ListenerContainerFactory
camel.component.spring-rabbitmq.max-concurrent-consumers	The maximum number of consumers (available only with SMLC).		Integer
camel.component.spring-rabbitmq.maximum-retry-attempts	How many times a Rabbitmq consumer will retry the same message if Camel failed to process the message.	5	Integer

Name	Description	Default	Type
camel.component.spring-rabbitmq.message-converter	To use a custom MessageConverter so you can be in control how to map to/from a org.springframework.amqp.core.Message. The option is a org.springframework.amqp.support.converter.MessageConverter type.		MessageConverter
camel.component.spring-rabbitmq.message-listener-container-type	The type of the MessageListenerContainer.	DMLC	String
camel.component.spring-rabbitmq.message-properties-converter	To use a custom MessagePropertiesConverter so you can be in control how to map to/from a org.springframework.amqp.core.MessageProperties. The option is a org.apache.camel.component.springrabbit.MessagePropertiesConverter type.		MessagePropertiesConverter
camel.component.spring-rabbitmq.prefetch-count	Tell the broker how many messages to send to each consumer in a single request. Often this can be set quite high to improve throughput.	250	Integer
camel.component.spring-rabbitmq.reject-and-dont-requeue	Whether a Rabbitmq consumer should reject the message without requeuing. This enables failed messages to be sent to a Dead Letter Exchange/Queue, if the broker is so configured.	true	Boolean

Name	Description	Default	Type
camel.component.spring-rabbitmq.reply-timeout	Specify the timeout in milliseconds to be used when waiting for a reply message when doing request/reply messaging. The default value is 5 seconds. A negative value indicates an indefinite timeout. The option is a long type.	5000	Long
camel.component.spring-rabbitmq.retry	Custom retry configuration to use. If this is configured then the other settings such as maximumRetryAttempts for retry are not in use. The option is a org.springframework.retry.interceptor.RetryOperationsInterceptor type.		RetryOperationsInterceptor
camel.component.spring-rabbitmq.retry-delay	Delay in msec a Rabbitmq consumer will wait before redelivering a message that Camel failed to process.	1000	Integer
camel.component.spring-rabbitmq.shutdown-timeout	The time to wait for workers in milliseconds after the container is stopped. If any workers are active when the shutdown signal comes they will be allowed to finish processing as long as they can finish within this timeout. The option is a long type.	5000	Long

Name	Description	Default	Type
camel.component.spring-rabbitmq.test-connection-on-startup	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	Boolean

CHAPTER 126. SPRING REDIS

The producer and consumer are supported.

This component allows sending and receiving messages from Redis. Redis is an advanced key-value store where keys can contain strings, hashes, lists, sets and sorted sets. In addition Redis provides pub/sub functionality for inter-app communications. Camel provides a producer for executing commands, a consumer for subscribing to pub/sub messages, and an idempotent repository for filtering out duplicate messages.

Prerequisites

To use this component, you must have a Redis server running.

126.1. DEPENDENCIES

When using **spring-redis** with Red Hat build of Camel Spring Boot, ensure you use the following Maven dependency to have support for auto-configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-spring-redis-starter</artifactId>
</dependency>
```

Use the BOM to get the version.

```
<dependencyManagement>
    <dependencies>
        <dependency>
            <groupId>com.redhat.camel.springboot.platform</groupId>
            <artifactId>camel-spring-boot-bom</artifactId>
            <version>${camel-spring-boot-version}</version>
            <type>pom</type>
            <scope>import</scope>
        </dependency>
    </dependencies>
</dependencyManagement>
```

126.2. URI FORMAT

```
spring-redis://host:port[?options]
```

126.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

126.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example, a component may have security settings, credentials for authentication, URLs for network connection.

Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

126.3.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL and DataFormat DSL as a *type safe* way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use Property Placeholders, which allows you to not hardcode URLs, port numbers, sensitive information, and other settings. In other words, placeholders allow you to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

126.4. COMPONENT OPTIONS

The Spring Redis component supports 4 options, which are listed below.

Name	Description	Default	Type
redisTemplate (common)	**Autowired** Reference to a pre-configured RedisTemplate instance to use.		RedisTemplate
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer uses the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy, you can use this to allow CamelContext and routes to start up in situations where a producer may otherwise fail during starting and cause the route to fail being started. By starting lazy, Camel's routing error handlers handle any startup failures while routing messages. Beware that when the first message is processed, creating, and starting, the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring of JDBC data sources, JMS connection factories, and AWS Clients.	true	boolean

126.5. ENDPOINT OPTIONS

The Spring Redis endpoint is configured using URI syntax:

```
spring-redis:host:port
```

with the following path and query parameters:

126.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
host (common)	**Required** The host where the Redis server is running.		String
port (common)	**Required** Redis server port number.		Integer

126.5.2. Query Parameters (10 parameters)

Name	Description	Default	Type
channels (common)	List of topic names or name patterns to subscribe to. Multiple names can be separated by a comma.		String
	Default command, which can be overridden by	SET	Command

Name	Description	Default	Type
command (common)	message header. Notice that the consumer only supports the following commands only: PSUBSCRIBE and SUBSCRIBE. Enum values: • PING • SET • GET • QUIT • EXISTS • DEL • TYPE • FLUSHDB • KEYS • RANDOMKEY • RENAME • RENAMENX • RENAMEX • DBSIZE • EXPIRE • EXPIREAT • TTL • SELECT • MOVE • FLUSHALL • GETSET • MGET • SETNX • SETEX • MSET • MSETNX • DECRBY • DECR • INCRBY • INCR		

Name	Description	Default	Type
	• APPEND • SUBSTR • HSET • HGET • HSETNX • HMSET • HMGET • HINCRBY • HEXISTS • HDEL • HLEN • HKEYS • HVALS • HGETALL • RPUSH • LPUSH • LLEN • LRANGE • LTRIM • LINDEX • LSET • LREM • LPOP • RPOP • RPOPLPUSH • SADD • SMEMBERS • SREM • SPOP • SMOVE • SCARD • SISMEMBER • SINTER		

Name	Description	Default	Type
	• SINTERSTORE • SUNION • SUNIONSTORE • SDIFF • SDIFFSTORE • SRANDMEMBER • ZADD • ZRANGE • ZREM • ZINCRBY • ZRANK • ZREVRANK • ZREVRANGE • ZCARD • ZSCORE • MULTI • DISCARD • EXEC • WATCH • UNWATCH • SORT • BLPOP • BRPOP • AUTH • SUBSCRIBE • PUBLISH • UNSUBSCRIBE • PSUBSCRIBE • PUNSUBSCRIBE • ZCOUNT • ZRANGEBYSCORE • ZREVRANGEBYSCORE • ZREMRANGEBYRANK		

Name	Description	Default	Type
	• ZREMRANGEBYSCORE • ZUNIONSTORE • ZINTERSTORE • SAVE • BGSAVE • BGREWRITEAOF • LASTSAVE • SHUTDOWN • INFO • MONITOR • SLAVEOF • CONFIG • STRLEN • SYNC • LPUSHX • PERSIST • RPUSHX • ECHO • LINSERT • DEBUG • BRPOPLPUSH • SETBIT • GETBIT • SETRANGE • GETRANGE • PEXPIRE • PEXPIREAT • GEOADD • GEODIST • GEOHASH • GEOPOS • GEORADIUS • GEORADIUSBYMEMBER		

Name	Description	Default	Type
connectionFactory (common)	Reference to a pre-configured RedisConnectionFactory instance to use.		RedisConnectionFactory
redisTemplate (common)	Reference to a pre-configured RedisTemplate instance to use.		RedisTemplate
serializer (common)	Reference to a pre-configured RedisSerializer instance to use.		RedisSerializer
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions that occurred while the consumer is trying to pick up incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. The consumer defaults to use the org.apache.camel.spi.ExceptionHandler to deal with exceptions. These exceptions log at WARN or ERROR level and ignored.	False	Boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. If you enable the bridgeErrorHandler option, this option is not used. By default, the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
listenerContainer (consumer (advanced))	Reference to a pre-configured RedisMessageListenerContainer instance to use.		RedisMessageListenerContainer

Name	Description	Default	Type
lazyStartProducer (Producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy, you can use this to allow CamelContext and routes to start up in situations where a producer may otherwise fail during starting and cause the route startup to fail. By deferring this startup to be lazy, the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	False	Boolean

126.6. MESSAGE HEADERS

The Spring Redis component supports 29 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelRedis.Command (producer) Constant: COMMAND	The command to perform.		String
CamelRedis.Key (common) Constant: KEY	The key.		String
CamelRedis.Keys (common) Constant: KEYS	The keys.		Collection
CamelRedis.Field (common) Constant: FIELD	The field.		String
CamelRedis.Fields (common) Constant: FIELDS	The fields.		Collection

Name	Description	Default	Type
CamelRedis.Value (common) Constant: VALUE	The value.		Object
CamelRedis.Values (common) Constant: VALUES	The values.		Map
CamelRedis.Start (common) Constant: START	Start.		Long
CamelRedis.End (common) Constant: END	End.		Long
CamelRedis.Timeout (common) Constant: TIMEOUT	The timeout.		Long
CamelRedis.Offset (common) Constant: OFFSET	The offset.		Long
CamelRedis.Destination (common) Constant: DESTINATION	The destination.		String
CamelRedis.Channel (common) Constant: CHANNEL	The channel.		byte[] or String
CamelRedis.Message (common) Constant: MESSAGE	The message.		Object

Name	Description	Default	Type
CamelRedis.Index (common) Constant: INDEX	The index.		Long
CamelRedis.Position (common) Constant: POSITION	The position.		String
CamelRedis.Pivot (common) Constant: PIVOT	The pivot.		String
CamelRedis.Count (common) Constant: COUNT	Count.		Long
CamelRedis.Timestamp (common) Constant: TIMESTAMP	The timestamp.		Long
CamelRedis.Pattern (common) Constant: PATTERN	The pattern.		byte[] or String
CamelRedis.Db (common) Constant: DB	The db.		Integer
CamelRedis.Score (common) Constant: SCORE	The score.		Double
CamelRedis.Min (common) Constant: MIN	The min.		Double

Name	Description	Default	Type
CamelRedis.Max (common) Constant: MAX	The max.		Double
CamelRedis.Increment (common) Constant: INCREMENT	Increment.		Double
CamelRedis.WithScore (common) Constant: WITHSCORE	WithScore.		Boolean
CamelRedis.Latitude (common) Constant: LATITUDE	Latitude.		Double
CamelRedis.Longitude (common) Constant: LONGITUDE	Latitude.		Double
CamelRedis.Radius (common) Constant: RADIUS	Radius.		Double

126.7. USAGE

Also, see the available unit tests.

Redis Producer

```
from(“direct:start”)
    .setHeader("CamelRedis.Key", constant(key))
    .setHeader("CamelRedis.Value", constant(value))
    .to("spring-redis://host:port?command=SET&redisTemplate=#redisTemplate");
```

Redis Consumer

```
from("spring-redis://host:port?command=SUBSCRIBE&channels=myChannel")
   .log("Received message: ${body}");
```

NOTE

Where '//host:port' is URL address for running Redis server.

126.7.1. Message headers evaluated by the Redis producer

The producer issues commands to the server and each command has a different set of parameters with specific types. The result from the command execution is returned in the message body.

Hash Commands	Description	Parameters	Result
HSET	Set the string value of a hash field	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.FIELD**/"CamelRedis.Field" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Void
HGET	Get the value of a hash field	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.FIELD**/"CamelRedis.Field" (String)	String
HSETNX	Set the value of a hash field, only if the field does not exist	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.FIELD**/"CamelRedis.Field" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Void
HMSET	Set multiple hash fields to multiple values	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUES**/"CamelRedis.Values" (Map<String, Object>)	Void
HMGET	Get the values of all the given hash fields	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.FIELDS**/"CamelRedis.Filds" (Collection<String>)	Collection<Object>
HINCRBY	Increment the integer value of a hash field by the given number	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.FIELD**/"CamelRedis.Field" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Long)	Long

Hash Commands	Description	Parameters	Result
HEXISTS	Determine if a hash field exists	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.FIELD**/"CamelRedis.Field" (String)	Boolean
HDEL	Delete one or more hash fields	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.FIELD**/"CamelRedis.Field" (String)	Void
HLEN	Get the number of fields in a hash	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Long
HKEYS	Get all the fields in a hash	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Set<String>
HVALS	Get all the values in a hash	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Collection<Object>
HGETALL	Get all the fields and values in a hash	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Map<String, Object>

List Commands	Description	Parameters	Result
RPUSH	Append one or multiple values to a list	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Long
RPUSHX	Append a value to a list, only if the list exists	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Long
LPUSH	Prepend one or multiple values to a list	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Long
LLEN	Get the length of a list	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Long

List Commands	Description	Parameters	Result
LRANGE	Get a range of elements from a list	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.START**/"CamelRedis.Start"Long), **RedisConstants.END**/"CamelRedis.End" (Long)	List<Object>
LTRIM	Trim a list to the specified range	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.START**/"CamelRedis.Start"Long), **RedisConstants.END**/"CamelRedis.End" (Long)	Void
LINDEX	Get an element from a list by its index	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.INDEX**/"CamelRedis.Index" (Long)	String
LINSERT	Insert an element before or after another element in a list	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.PIVOT**/"CamelRedis.Pivot" (String), **RedisConstants.POSITION**/"CamelRedis.Position" (String)	Long
LSET	Set the value of an element in a list by its index	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.INDEX**/"CamelRedis.Index" (Long)	Void
LREM	Remove elements from a list	**RedisConstants.KEY**/**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.COUNT**/"CamelRedis.Count" (Long)	Long
LPOP	Remove and get the first element in a list	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Object
RPOP	Remove and get the last element in a list	**RedisConstants.KEY**/"CamelRedis.Key" (String)	String

List Commands	Description	Parameters	Result
RPOPLPUSH	Remove the last element in a list, append it to another list and return it	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.DESTINATION**/"CamelRedis.Destination" (String)	Object
BRPOPLPUSH	Pop a value from a list, push it to another list and return it; or block until one is available	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.DESTINATION**/"CamelRedis.Destination" (String), **RedisConstants.TIMEOUT**/"CamelRedis.Timeout" (Long)	Object
BLPOP	Remove and get the first element in a list, or block until one is available	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.TIMEOUT**/"CamelRedis.Timeout" (Long)	Object
BRPOP	Remove and get the last element in a list, or block until one is available	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.TIMEOUT**/"CamelRedis.Timeout" (Long)	String

Set Commands	Description	Parameters	Result
SADD	Add one or more members to a set	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Boolean
SMEMBERS	Get all the members in a set	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Set<Object>
SREM	Remove one or more members from a set	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Boolean
SPOP	Remove and return a random member from a set	**RedisConstants.KEY**/"CamelRedis.Key" (String)	String
SMOVE	Move a member from one set to another	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.DESTINATION**/"CamelRedis.Destination" (String)	Boolean

Set Commands	Description	Parameters	Result
SCARD	Get the number of members in a set	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Long
SISMEMBER	Determine if a given value is a member of a set	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Boolean
SINTER	Intersect multiple sets	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.KEYS**/"CamelRedis.Keys" (String)	Set<Object>
SINTERSTORE	Intersect multiple sets and store the resulting set in a key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.KEYS**/"CamelRedis.Keys" (String), **RedisConstants.DESTINATION**/"CamelRedis.Destination" (String)	Void
SUNION	Add multiple sets	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.KEYS**/"CamelRedis.Keys" (String)	Set<Object>
SUNIONSTORE	Add multiple sets and store the resulting set in a key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.KEYS**/"CamelRedis.Keys" (String), **RedisConstants.DESTINATION**/"CamelRedis.Destination" (String)	Void
SDIFF	Subtract multiple sets	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.KEYS**/"CamelRedis.Keys" (String)	Set<Object>
SDIFFSTORE	Subtract multiple sets and store the resulting set in a key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.KEYS**/"CamelRedis.Keys" (String), **RedisConstants.DESTINATION**/"CamelRedis.Destination" (String)	Void
SRANDMEMBER	Get one or multiple random members from a set	**RedisConstants.KEY**/"CamelRedis.Key" (String)	String

Ordered set Commands	Description	Parameters	Result
ZADD	Add one or more members to a sorted set, or update its score if it already exists	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.SCORE**/"CamelRedis.Score" (Double)	Boolean
ZRANGE	Return a range of members in a sorted set, by index	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.START**/"CamelRedis.Start"Long), **RedisConstants.END**/"CamelRedis.End" (Long), **RedisConstants.WITHSCORE**/"CamelRedis.WithScore" (Boolean)	Object
ZREM	Remove one or more members from a sorted set	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Boolean
ZINCRBY	Increment the score of a member in a sorted set	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.INCREMENT**/"CamelRedis.Increment" (Double)	Double
ZRANK	Determine the index of a member in a sorted set	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Long
ZREVRANK	Determine the index of a member in a sorted set, with scores ordered from high to low	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Long
ZREVRANGE	Return a range of members in a sorted set, by index, with scores ordered from high to low	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.START**/"CamelRedis.Start"Long), **RedisConstants.END**/"CamelRedis.End" (Long), **RedisConstants.WITHSCORE**/"CamelRedis.WithScore" (Boolean)	Object
ZCARD	Get the number of members in a sorted set	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Long

Ordered set Commands	Description	Parameters	Result
ZCOUNT	Count the members in a sorted set with scores within the given values	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.MIN**/"CamelRedis.Min" (Double), **RedisConstants.MAX**/"CamelRedis.Max" (Double)	Long
ZRANGEBYSCORE	Return a range of members in a sorted set, by score	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.MIN**/"CamelRedis.Min" (Double), **RedisConstants.MAX**/"CamelRedis.Max" (Double)	Set<Object>
ZREVRANGEBYSCORE	Return a range of members in a sorted set, by score, with scores ordered from high to low	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.MIN**/"CamelRedis.Min" (Double), **RedisConstants.MAX**/"CamelRedis.Max" (Double)	Set<Object>
ZREMRANGEBYRANK	Remove all members in a sorted set within the given indexes	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.START**/"CamelRedis.Start"(Long), **RedisConstants.END**/"CamelRedis.End" (Long)	Void
ZREMRANGEBYSCORE	Remove all members in a sorted set within the given scores	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.START**/"CamelRedis.Start"(Long), **RedisConstants.END**/"CamelRedis.End" (Long)	Void
ZUNIONSTORE	Add multiple sorted sets and store the resulting sorted set in a new key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.KEYS**/"CamelRedis.Keys" (String), **RedisConstants.DESTINATION**/"CamelRedis.Destination" (String)	Void
ZINTERSTORE	Intersect multiple sorted sets and store the resulting sorted set in a new key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.KEYS**/"CamelRedis.Keys" (String), **RedisConstants.DESTINATION**/"CamelRedis.Destination" (String)	Void

String Commands	Description	Parameters	Result
SET	Set the string value of a key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Void
GET	Get the value of a key	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Object
STRLEN	Get the length of the value stored in a key	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Long
APPEND	Append a value to a key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (String)	Integer
SETBIT	Sets or clears the bit at offset in the string value stored at key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.OFFSET**/"CamelRedis.Offset" (Long), **RedisConstants.VALUE**/"CamelRedis.Value" (Boolean)	Void
GETBIT	Returns the bit value at offset in the string value stored at key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.OFFSET**/"CamelRedis.Offset" (Long)	Boolean
SETRANGE	Overwrite part of a string at key starting at the specified offset	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.OFFSET**/"CamelRedis.Offset" (Long)	Void
GETRANGE	Get a substring of the string stored at a key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.START**/"CamelRedis.Start"(Long), **RedisConstants.END**/"CamelRedis.End" (Long)	String
SETNX	Set the value of a key, only if the key does not exist	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Boolean

String Commands	Description	Parameters	Result
SETEX	Set the value and expiration of a key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.TIMEOUT**/"CamelRedis.Timeout" (Long), SECONDS	Void
DECRBY	Decrement the integer value of a key by the given number	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Long)	Long
DECR	Decrement the integer value of a key by one	**RedisConstants.KEY**/"CamelRedis.Key" (String),	Long
INCRBY	Increment the integer value of a key by the given amount	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Long)	Long
INCR	Increment the integer value of a key by one	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Long
MGET	Get the values of all the given keys	**RedisConstants.FIELDS**/"CamelRedis.Filds" (Collection<String>)	List<Object>
MSET	Set multiple keys to multiple values	**RedisConstants.VALUES**/"CamelRedis.Values" (Map<String, Object>)	Void
MSETNX	Set multiple keys to multiple values, only if none of the keys exist	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Void
GETSET	Set the string value of a key and return its old value	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Object

Key Commands	Description	Parameters	Result
EXISTS	Determine if a key exists	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Boolean
DEL	Delete a key	**RedisConstants.KEYS**/"CamelRedis.Keys" (String)	Void

Key Commands	Description	Parameters	Result
TYPE	Determine the type stored at key	**RedisConstants.KEY**/"CamelRedis.Key" (String)	DataType
KEYS	Find all keys matching the given pattern	**RedisConstants.PATERN**/"CamelRedis.Pattern" (String)	Collection<String>
RANDOMKEY	Return a random key from the keyspace	**RedisConstants.PATERN**/"CamelRedis.Pattern" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (String)	String
RENAME	Rename a key	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Void
RENAMENX	Rename a key, only if the new key does not exist	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (String)	Boolean
EXPIRE	Set a key's time to live in seconds	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.TIMEOUT**/"CamelRedis.Timeout" (Long)	Boolean
SORT	Sort the elements in a list, set or sorted set	**RedisConstants.KEY**/"CamelRedis.Key" (String)	List<Object>
PERSIST	Remove the expiration from a key	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Boolean
EXPIREAT	Set the expiration for a key as a UNIX timestamp	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.TIMESTAMP**/"CamelRedis.Timestamp" (Long)	Boolean
PEXPIRE	Set a key's time to live in milliseconds	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.TIMEOUT**/"CamelRedis.Timeout" (Long)	Boolean
PEXPIREAT	Set the expiration for a key as a UNIX timestamp specified in milliseconds	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.TIMESTAMP**/"CamelRedis.Timestamp" (Long)	Boolean
TTL	Get the time to live for a key	**RedisConstants.KEY**/"CamelRedis.Key" (String)	Long

Key Commands	Description	Parameters	Result
MOVE	Move a key to another database	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.DB**/"CamelRedis.Db" (Integer)	Boolean

Geo Commands	Description	Parameters	Result
GEOADD	Adds the specified geospatial items (latitude, longitude, name) to the specified key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.LATITUDE**/"CamelRedis.Latitude" (Double), **RedisConstants.LONGITUDE**/"CamelRedis.Longitude" (Double), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	Long
GEODIST	Return the distance between two members in the geospatial index for the specified key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUES**/"CamelRedis.Values" (Object[])	Distance
GEOHASH	Return valid Geohash strings representing the position of an element in the geospatial index for the specified key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	List<String>
GEOPOS	Return the positions (longitude, latitude) of an element in the geospatial index for the specified key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object)	List<Point>
GEORADIUS	Return the element in the geospatial index for the specified key, which is within the borders of the area specified with the central location and the maximum distance from the center (the radius)	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.LATITUDE**/"CamelRedis.Latitude" (Double), **RedisConstants.LONGITUDE**/"CamelRedis.Longitude" (Double), **RedisConstants.RADIUS**/"CamelRedis.Radius" (Double), **RedisConstants.COUNT**/"CamelRedis.Count" (Integer)	GeoResults

Geo Commands	Description	Parameters	Result
GEORADIUSBYMEMBER	This command is exactly like GEORADIUS with the sole difference that instead of taking, as the center of the area to query, a longitude and latitude value, it takes the name of a member already existing inside the geospatial index for the specified key	**RedisConstants.KEY**/"CamelRedis.Key" (String), **RedisConstants.VALUE**/"CamelRedis.Value" (Object), **RedisConstants.RADIUS**/"CamelRedis.Radius" (Double), **RedisConstants.COUNT**/"CamelRedis.Count" (Integer)	GeoResults

Other Commands	Description	Parameters	Result
MULTI	Mark the start of a transaction block	none	Void
DISCARD	Discard all commands issued after MULTI	none	Void
EXEC	Execute all commands issued after MULTI	none	Void
WATCH	Watch the given keys to determine the execution of the MULTI/EXEC block	**RedisConstants.KEYS**/"CamelRedis.Keys" (String)	Void
UNWATCH	Forget about all watched keys	none	Void
ECHO	Echo the given string	**RedisConstants.VALUE**/"CamelRedis.Value" (String)	String
PING	Ping the server	none	String
QUIT	Close the connection	none	Void
PUBLISH	Post a message to a channel	**RedisConstants.CHANNEL**/"CamelRedis.Channel" (String), **RedisConstants.MESSAGE**/"CamelRedis.Message" (Object)	Void

126.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.component.spring-redis.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatically configure JDBC data sources, JMS connection factories, AWS Clients, etc.	True	Boolean
camel.component.spring-redis.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions that occur while the consumer is trying to pick up incoming messages, or the likes, will be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	False	Boolean
camel.component.spring-redis.enabled	Whether to enable auto configuration of the spring-redis component. This is enabled by default.		Boolean
camel.component.spring-redis.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy, you can allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail start up. By deferring this startup to be lazy, the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	False	Boolean
camel.component.spring-redis.redis-template	Reference to a pre-configured RedisTemplate instance to use. The option is an org.springframework.data.redis.core.RedisTemplate type.		RedisTemplate

CHAPTER 127. SPRING SECURITY

Since Camel 2.3

The Camel Spring Security component provides role-based authorization for Camel routes. It leverages the authentication and user services provided by Spring Security (formerly Acegi Security) and adds a declarative, role-based policy system to control whether a route can be executed by a given principal.

If you are not familiar with the Spring Security authentication and authorization system, please review the current reference documentation on the SpringSource web site linked above.

127.1. DEPENDENCIES

When using **spring-security** with Red Hat build of Camel Spring Boot, use the following Maven dependency to enable support for auto-configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-spring-security-starter</artifactId>
</dependency>
```

127.2. CREATING AUTHORIZATION POLICIES

Access to a route is controlled by an instance of a **SpringSecurityAuthorizationPolicy** object. A policy object contains the name of the Spring Security authority (role) required to run a set of endpoints and references to Spring Security **AuthenticationManager** and **AccessDecisionManager** objects used to determine whether the current principal has been assigned that role. Policy objects may be configured as Spring beans or by using an **<authorizationPolicy>** element in Spring XML.

The **<authorizationPolicy>** element can contain the following attributes:

Name	Default Value	Description
id	**null**	The unique Spring bean identifier which is used to reference the policy in routes (required)
access	**null**	The Spring Security authority name that is passed to the access decision manager (required)
authenticationManager	**authenticationManager**	The name of the Spring Security **AuthenticationManager** object in the context
accessDecisionManager	**accessDecisionManager**	The name of the Spring Security **AccessDecisionManager** object in the context

Name	Default Value	Description
authenticationAdapter	DefaultAuthenticationAdapter	The name of a **camel-spring-security AuthenticationAdapter** object in the context that is used to convert a **javax.security.auth.Subject** into a Spring Security **Authentication** instance.
useThreadSecurityContext	**true**	If a **javax.security.auth.Subject** cannot be found in the In message header under Exchange.AUTHENTICATION, check the Spring Security **SecurityContextHolder** for an **Authentication** object.
alwaysReauthenticate	**false**	If set to true, the **SpringSecurityAuthorizationPolicy** will always call **AuthenticationManager.authenticate()** each time the policy is accessed.

127.3. CONTROLLING ACCESS TO CAMEL ROUTES

A Spring Security **AuthenticationManager** and **AccessDecisionManager** are required to use this component. Here is an example of how to configure these objects in Spring XML using the Spring Security namespace:

```
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:spring-security="http://www.springframework.org/schema/security"
  xsi:schemaLocation="http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
   http://www.springframework.org/schema/security
http://www.springframework.org/schema/security/spring-security.xsd">

  <bean id="accessDecisionManager"
class="org.springframework.security.access.vote.AffirmativeBased">
    <property name="allowIfAllAbstainDecisions" value="true"/>
    <property name="decisionVoters">
      <list>
        <bean class="org.springframework.security.access.vote.RoleVoter"/>
      </list>
    </property>
  </bean>

  <spring-security:authentication-manager alias="authenticationManager">
```

```
    <spring-security:authentication-provider user-service-ref="userDetailsService"/>
  </spring-security:authentication-manager>

  <spring-security:user-service id="userDetailsService">
    <spring-security:user name="jim" password="jimspassword" authorities="ROLE_USER,
ROLE_ADMIN"/>
    <spring-security:user name="bob" password="bobspassword" authorities="ROLE_USER"/>
  </spring-security:user-service>

</beans>
```

Now that the underlying security objects are set up, we can use them to configure an authorization policy and use that policy to control access to a route:

```
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:spring-security="http://www.springframework.org/schema/security"
  xsi:schemaLocation="http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
   http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-spring.xsd
   http://camel.apache.org/schema/spring-security http://camel.apache.org/schema/spring-
security/camel-spring-security.xsd
   http://www.springframework.org/schema/security
http://www.springframework.org/schema/security/spring-security.xsd">

   <!-- import the Spring security configuration  -->
   <import resource=
"classpath:org/apache/camel/component/spring/security/commonSecurity.xml"/>

   <authorizationPolicy id="admin" access="ROLE_ADMIN"
    authenticationManager="authenticationManager"
    accessDecisionManager="accessDecisionManager"
    xmlns="http://camel.apache.org/schema/spring-security"/>

   <camelContext id="myCamelContext" xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="direct:start"/>
      <!-- The exchange should be authenticated with the role -->
      <!-- of ADMIN before it is send to mock:endpoint -->
      <policy ref="admin">
        <to uri="mock:end"/>
      </policy>
    </route>
   </camelContext>
</beans>
```

In this example, the endpoint **mock:end** is only executed if:

- The *admin* **SpringSecurityAuthorizationPolicy** can locate a Spring Security **Authentication** object, that:
  - can be authenticated or is possible to authenticate
  - contains the **ROLE_ADMIN** authority

127.4. AUTHENTICATION

The process of obtaining security credentials that are used for authorization is not specified by this component. You can write your own processors or components which get authentication information from the exchange depending on your needs. For example, you can create a processor that gets credentials from an HTTP request header originating in the Jetty component. No matter how the credentials are collected, they need to be placed in the **Inmessage** or the **SecurityContextHolder** so the Camel Spring Security component can access them.

```
import javax.security.auth.Subject;
import org.apache.camel.*;
import org.apache.commons.codec.binary.Base64;
import org.springframework.security.authentication.*;

public class MyAuthService implements Processor {
    public void process(Exchange exchange) throws Exception {
        // get the username and password from the HTTP header
        // http://en.wikipedia.org/wiki/Basic_access_authentication
        String userpass = new
String(Base64.decodeBase64(exchange.getIn().getHeader("Authorization", String.class)));
        String[] tokens = userpass.split(":");

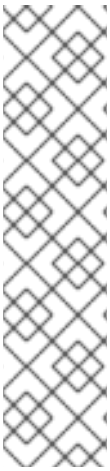
        // create an Authentication object
        UsernamePasswordAuthenticationToken authToken = new
UsernamePasswordAuthenticationToken(tokens[0], tokens[1]);

        // wrap it in a Subject
        Subject subject = new Subject();
        subject.getPrincipals().add(authToken);

        // place the Subject in the In message
        exchange.getIn().setHeader(Exchange.AUTHENTICATION, subject);

        // you could also do this if useThreadSecurityContext is set to true
        // SecurityContextHolder.getContext().setAuthentication(authToken);
    }
}
```

The **SpringSecurityAuthorizationPolicy** automatically authenticates the **Authentication** object if necessary.



NOTE

Be aware of these two issues when you use the **SecurityContextHolder** instead of or in addition to the **Exchange.AUTHENTICATION** header:

1. The context holder uses a thread-local variable to hold the **Authentication** object. Any routes that cross thread boundaries, like **seda** or **jms**, lose the **Authentication** object.

2. The Spring Security system expects that an **Authentication** object in the context is already authenticated and has roles.
   See the Spring Technical Overview, section 5.3.1: "What is authentication in Spring Security?" for more details.

The default behavior of **camel-spring-security** is to look for a **Subject** in the **Exchange.AUTHENTICATION** header. This **Subject** must contain at least one principal, which must be a subclass of **org.springframework.security.core.Authentication**.

You can customize the mapping of **Subject** to **Authentication** object by providing an implementation of the **org.apache.camel.component.spring.security.AuthenticationAdapter** to your **<authorizationPolicy>** bean.

This can be useful if you are working with components that do not use Spring Security but do provide a **Subject**.

At this time, only the CXF component populates the **Exchange.AUTHENTICATION** header.

127.5. HANDLING AUTHENTICATION AND AUTHORIZATION ERRORS

If authentication or authorization fails in the **SpringSecurityAuthorizationPolicy**, a **CamelAuthorizationException** is thrown. This can be handled using Camel's standard exception handling methods, like the Exception Clause. The **CamelAuthorizationException** has a reference to the ID of the policy which threw the exception so you can handle errors based on the policy as well as the type of exception.

```
<onException>
  <exception>org.springframework.security.authentication.AccessDeniedException</exception>
  <choice>
    <when>
      <simple>${exception.policyId} == 'user'</simple>
      <transform>
        <constant>You do not have ROLE_USER access!</constant>
      </transform>
    </when>
    <when>
      <simple>${exception.policyId} == 'admin'</simple>
      <transform>
        <constant>You do not have ROLE_ADMIN access!</constant>
      </transform>
    </when>
  </choice>
</onException>
```

127.6. SPRING BOOT AUTO-CONFIGURATION

The component has no Spring Boot auto configuration options.

CHAPTER 128. SPRING WEBSERVICE

Since Camel 2.6

Both producer and consumer are supported

The Spring WS component allows you to integrate with Spring Web Services. It offers both, *client*-side support for accessing web services, and *server*-side support for creating your own contract-first web services.

128.1. DEPENDENCIES

When using **spring-ws** with Red Hat build of Camel Spring Boot use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-ws</artifactId>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Use the BOM to get the version.

```
<dependencyManagement>
      <dependencies>
        <dependency>
          <groupId>com.redhat.camel.springboot.platform</groupId>
          <artifactId>camel-spring-boot-bom</artifactId>
          <version>${camel-spring-boot-version}</version>
          <type>pom</type>
          <scope>import</scope>
        </dependency>
      </dependencies>
  </dependencyManagement>
```

128.2. URI FORMAT

The URI scheme for this component is as follows

```
spring-ws:[mapping-type:]address[?options]
```

To expose a web service **mapping-type** needs to be set to any of the following:

Mapping type	Description
rootqname	Offers the option to map web service requests based on the qualified name of the root element contained in the message.
soapaction	Used to map web service requests based on the SOAP action specified in the header of the message.

Mapping type	Description
uri	In order to map web service requests that target a specific URI.
xpathresult	Used to map web service requests based on the evaluation of an XPath **expression** against the incoming message. The result of the evaluation should match the XPath result specified in the endpoint URI.
beanname	Allows you to reference an **org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher** object in order to integrate with existing (legacy) endpoint mappings like **PayloadRootQNameEndpointMapping**, **SoapActionEndpointMapping**, etc

As a consumer the **address** should contain a value relevant to the specified mapping-type (e.g. a SOAP action, XPath expression). As a producer the address should be set to the URI of the web service your calling upon.

128.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

128.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

128.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

128.4. COMPONENT OPTIONS

The Spring WebService component supports 4 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

128.5. ENDPOINT OPTIONS

The Spring WebService endpoint is configured using URI syntax:

```
spring-ws:type:lookupKey:webServiceEndpointUri
```

Following are the path and query parameters:

128.5.1. Path Parameters (4 parameters)

Name	Description	Default	Type
type (consumer)	Endpoint mapping type if endpoint mapping is used. rootqname - Offers the option to map web service requests based on the qualified name of the root element contained in the message. soapaction - Used to map web service requests based on the SOAP action specified in the header of the message. uri - In order to map web service requests that target a specific URI. xpathresult - Used to map web service requests based on the evaluation of an XPath expression against the incoming message. The result of the evaluation should match the XPath result specified in the endpoint URI. beanname - Allows you to reference an org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher object in order to integrate with existing (legacy) endpoint mappings like PayloadRootQNameEndpointMapping, SoapActionEndpointMapping, etc. Enum values: • ROOT_QNAME • ACTION • TO		EndpointMappingType

Name	Description	Default	Type
	• SOAP_ACTION • XPATHRESULT • URI • URI_PATH • BEANNAME		
lookupKey (consumer)	Endpoint mapping key if endpoint mapping is used.		String
webServiceEndpointUri (producer)	The default Web Service endpoint uri to use for the producer.		String
expression (consumer)	The XPath expression to use when option type=xpathresult. Then this option is required to be configured.		String

128.5.2. Query Parameters (21 parameters)

Name	Description	Default	Type
messageFilter (common)	Option to provide a custom MessageFilter. For example when you want to process your headers or attachments by your own.		MessageFilter
messageIdStrategy (common)	Option to provide a custom MessageIdStrategy to control generation of WS-Addressing unique message ids.		MessageIdStrategy

Name	Description	Default	Type
endpointDispatcher (consumer)	Spring org.springframework.ws.server.endpoint.MessageEndpoint for dispatching messages received by Spring-WS to a Camel endpoint, to integrate with existing (legacy) endpoint mappings like PayloadRootQNameEndpointMapping, SoapActionEndpointMapping, etc.		CamelEndpointDispatcher
endpointMapping (consumer)	Reference to an instance of org.apache.camel.component.spring.ws.bean.CamelEndpointMapping in the Registry/ApplicationContext. Only one bean is required in the registry to serve all Camel/Spring-WS endpoints. This bean is auto-discovered by the MessageDispatcher and used to map requests to Camel endpoints based on characteristics specified on the endpoint (like root QName, SOAP action, etc).		CamelSpringWSEndpointMapping

Name	Description	Default	Type
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern

Name	Description	Default	Type
allowResponseAttachmentOverride (producer)	Option to override soap response attachments in in/out exchange with attachments from the actual service layer. If the invoked service appends or rewrites the soap attachments this option when set to true, allows the modified soap attachments to be overwritten in in/out message attachments.	false	boolean
allowResponseHeaderOverride (producer)	Option to override soap response header in in/out exchange with header info from the actual service layer. If the invoked service appends or rewrites the soap header this option when set to true, allows the modified soap header to be overwritten in in/out message headers.	false	boolean
faultAction (producer)	Signifies the value for the faultAction response WS-Addressing Fault Action header that is provided by the method. See org.springframework.ws.soap.addressing.server.annotation.Action annotation for more details.		URI
faultTo (producer)	Signifies the value for the faultAction response WS-Addressing FaultTo header that is provided by the method. See org.springframework.ws.soap.addressing.server.annotation.Action annotation for more details.		URI

Name	Description	Default	Type
messageFactory (producer)	Option to provide a custom WebServiceMessageFactory. For example when you want Apache Axiom to handle web service messages instead of SAAJ.		WebServiceMessageFactory
messageSender (producer)	Option to provide a custom WebServiceMessageSender. For example to perform authentication or use alternative transports.		WebServiceMessageSender
outputAction (producer)	Signifies the value for the response WS-Addressing Action header that is provided by the method. See org.springframework.ws.soap.addressing.server.annotation.Action annotation for more details.		URI
replyTo (producer)	Signifies the value for the replyTo response WS-Addressing ReplyTo header that is provided by the method. See org.springframework.ws.soap.addressing.server.annotation.Action annotation for more details.		URI
soapAction (producer)	SOAP action to include inside a SOAP request when accessing remote web services.		String

Name	Description	Default	Type
timeout (producer)	Sets the socket read timeout (in milliseconds) while invoking a webservice using the producer, see URLConnection.setReadTimeout() and CommonsHttpMessageSender.setReadTimeout(). This option works when using the built-in message sender implementations: CommonsHttpMessageSender and HttpUrlConnectionMessageSender. One of these implementations will be used by default for HTTP based services unless you customize the Spring WS configuration options supplied to the component. If you are using a non-standard sender, it is assumed that you will handle your own timeout configuration. The built-in message sender HttpComponentsMessageSender is considered instead of CommonsHttpMessageSender which has been deprecated, see HttpComponentsMessageSender.setReadTimeout().		int
webServiceTemplate (producer)	Option to provide a custom WebServiceTemplate. This allows for full control over client-side web services handling; like adding a custom interceptor or specifying a fault resolver, message sender or message factory.		WebServiceTemplate

Name	Description	Default	Type
wsAddressingAction (producer)	WS-Addressing 1.0 action header to include when accessing web services. The To header is set to the address of the web service as specified in the endpoint URI (default Spring-WS behavior).		URI
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters

128.6. MESSAGE HEADERS

The Spring WebService component supports 7 message headers that are listed below:

Name	Description	Default	Type
CamelSpringWebserviceEndpointUri (producer) Constant: **SPRING_WS_ENDPOINT_URI**	The endpoint URI.		String
CamelSpringWebserviceSoapAction (producer) Constant: **SPRING_WS_SOAP_ACTION**	SOAP action to include inside a SOAP request when accessing remote web services.		String
CamelSpringWebserviceSoapHeader (producer) Constant: **SPRING_WS_SOAP_HEADER**	The soap header source.		Source
CamelSpringWebserviceAddressingAction (producer) Constant: **SPRING_WS_ADDRESSING_ACTION**	WS-Addressing 1.0 action header to include when accessing web services. The To header is set to the address of the web service as specified in the endpoint URI (default Spring-WS behavior).		URI
CamelSpringWebserviceAddressingFaultTo (producer) Constant: **SPRING_WS_ADDRESSING_PRODUCER_FAULT_TO**	Signifies the value for the faultAction response WS-Addressing FaultTo header that is provided by the method. See org.springframework.ws.soap.addressing.server.annotation.Action annotation for more details.		URI

Name	Description	Default	Type
CamelSpringWebserviceAddressingReplyTo (producer) Constant: **SPRING_WS_ADDRESSING_PRODUCER_REPLY_TO**	Signifies the value for the replyTo response WS-Addressing ReplyTo header that is provided by the method. See org.springframework.ws.soap.addressing.server.annotation.Action annotation for more details.		URI
breadcrumbId (consumer) Constant: **BREADCRUMB_ID**	The breadcrumb id.		String

128.7. ACCESSING WEB SERVICES

To call a web service at **http://foo.com/bar** simply define a route:

```
from("direct:example").to("spring-ws:http://foo.com/bar")
```

and send a message:

```
template.requestBody("direct:example", "<foobar xmlns=\"http://foo.com\"><msg>test message</msg></foobar>");
```

If you are calling a SOAP service, you must not include SOAP tags. Spring-WS performs the XML-to-SOAP marshaling.

128.8. SENDING SOAP AND WS-ADDRESSING ACTION HEADERS

When a remote web service requires a SOAP action or use of the WS-Addressing standard, you define your route as:

```
from("direct:example")
.to("spring-ws:http://foo.com/bar?soapAction=http://foo.com&wsAddressingAction=http://bar.com")
```

You can also override the endpoint options with header values.

```
template.requestBodyAndHeader("direct:example",
"<foobar xmlns=\"http://foo.com\"><msg>test message</msg></foobar>",
SpringWebserviceConstants.SPRING_WS_SOAP_ACTION, "http://baz.com");
```

128.9. USING SOAP HEADERS

You can provide the SOAP header as a Camel Message header when sending a message to a spring-ws endpoint. For example given the following SOAP header in a String:

```
String body = ...
String soapHeader = "<h:Header xmlns:h=\"http://www.webserviceX.NET/\">
<h:MessageID>1234567890</h:MessageID><h:Nested><h:NestedID>1111</h:NestedID>
</h:Nested></h:Header>";
```

We can set the body and header on the Camel Message as follows:

```
exchange.getIn().setBody(body);
exchange.getIn().setHeader(SpringWebserviceConstants.SPRING_WS_SOAP_HEADER,
soapHeader);
```

And then send the Exchange to a **spring-ws** endpoint to call the Web Service.

Similarly, the spring-ws consumer also enriches the Camel Message with the SOAP header.

For an example see this unit test.

128.10. THE HEADER AND ATTACHMENT PROPAGATION

Spring WS Camel supports propagation of the headers and attachments into Spring-WS WebServiceMessage response. The endpoint uses a "hook" with the MessageFilter (default implementation is provided by BasicMessageFilter) to propagate the exchange headers and attachments into WebServiceMessage response.

```
exchange.getOut().getHeaders().put("myCustom","myHeaderValue")
exchange.getIn().addAttachment("myAttachment", new DataHandler(...))
```

If the exchange header in the pipeline contains text, it generates Qname(key)=value attribute in the soap header. You must create a QName class directly and put any key into header.

128.11. HOW TO TRANSFORM THE SOAP HEADER USING A STYLESHEET

The header transformation filter (HeaderTransformationMessageFilter.java) can be used to transform the soap header for a soap request. If you want to use the header transformation filter, see the below example:

```
<bean id="headerTransformationFilter"
class="org.apache.camel.component.spring.ws.filter.impl.HeaderTransformationMessageFilter">
    <constructor-arg index="0" value="org/apache/camel/component/spring/ws/soap-header-
transform.xslt"/>
</bean>
```

Use the bead defined above in the camel endpoint

```
<route>
    <from uri="direct:stockQuoteWebserviceHeaderTransformation"/>
    <to uri="spring-ws:http://localhost?
webServiceTemplate=#webServiceTemplate&amp;soapAction=http://www.stockquotes.edu/GetQuote&
amp;messageFilter=#headerTransformationFilter"/>
</route>
```

128.12. HOW TO USE MTOM ATTACHMENTS

The BasicMessageFilter provides all required information for Apache Axiom in order to produce MTOM message. If you want to use Apache Camel Spring WS within Apache Axiom, here is an example: - Define the **messageFactory** as shown below, and Spring-WS populates your SOAP message with optimized attachments through an MTOM strategy.

```
<bean id="axiomMessageFactory"
class="org.springframework.ws.soap.axiom.AxiomSoapMessageFactory">
<property name="payloadCaching" value="false" />
<property name="attachmentCaching" value="true" />
<property name="attachmentCacheThreshold" value="1024" />
</bean>
```

- Add into your pom.xml the following dependencies

```
<dependency>
<groupId>org.apache.ws.commons.axiom</groupId>
<artifactId>axiom-api</artifactId>
<version>1.2.13</version>
</dependency>
<dependency>
<groupId>org.apache.ws.commons.axiom</groupId>
<artifactId>axiom-impl</artifactId>
<version>1.2.13</version>
<scope>runtime</scope>
</dependency>
```

- Add your attachment into the pipeline, for example using a Processor implementation.

```
private class Attachement implements Processor {
public void process(Exchange exchange) throws Exception
{ exchange.getOut().copyFrom(exchange.getIn()); File file = new File("testAttachment.txt");
exchange.getOut().addAttachment("test", new DataHandler(new FileDataSource(file)));  }
}
```

- Define endpoint (producer) as ussual, for example like this:

```
from("direct:send")
.process(new Attachement())
.to("spring-ws:http://localhost:8089/mySoapService?
soapAction=mySoap&messageFactory=axiomMessageFactory");
```

- Your producer now generates MTOM messages with optimized attachments.

128.13. THE CUSTOM HEADER AND ATTACHMENT FILTERING

If you need to provide your custom processing of either headers or attachments, extend existing BasicMessageFilter and override the appropriate methods or write a brand new implementation of the MessageFilter interface.
To use your custom filter, add either a global or a local message filter into your spring context.

- a) the global custom filter that provides the global configuration for all Spring-WS endpoints

```
<bean id="messageFilter" class="your.domain.myMessageFiler" scope="singleton" />
```

or

- b) the local messageFilter directly on the endpoint as follows:

```
to("spring-ws:http://yourdomain.com?messageFilter=#myEndpointSpecificMessageFilter");
```

For more information see CAMEL-5724

If you want to create your own MessageFilter, consider overriding the following methods in the default implementation of MessageFilter in class BasicMessageFilter:

```
protected void doProcessSoapHeader(Message inOrOut, SoapMessage soapMessage)
{your code /*no need to call super*/ }

protected void doProcessSoapAttachements(Message inOrOut, SoapMessage response)
{ your code /*no need to call super*/ }
```

128.14. USING A CUSTOM MESSAGESENDER AND MESSAGEFACTORY

A custom message sender or factory in the registry can be referenced like this:

```
from("direct:example")
.to("spring-ws:http://foo.com/bar?
messageFactory=#messageFactory&messageSender=#messageSender")
```

Spring configuration:

```
<!-- authenticate using HTTP Basic Authentication -->
<bean id="messageSender"
class="org.springframework.ws.transport.http.HttpComponentsMessageSender">
    <property name="credentials">
        <bean class="org.apache.commons.httpclient.UsernamePasswordCredentials">
            <constructor-arg index="0" value="admin"/>
            <constructor-arg index="1" value="secret"/>
        </bean>
    </property>
</bean>

<!-- force use of Sun SAAJ implementation, http://static.springsource.org/spring-
ws/sites/1.5/faq.html#saaj-jboss -->
<bean id="messageFactory" class="org.springframework.ws.soap.saaj.SaajSoapMessageFactory">
    <property name="messageFactory">
        <bean class="com.sun.xml.messaging.saaj.soap.ver1_1.SOAPMessageFactory1_1Impl"/>
    </property>
</bean>
```

128.15. EXPOSING WEB SERVICES

To expose a web service using this component, you first must set up a MessageDispatcher to look for endpoint mappings in a Spring XML file. If you want to run inside a servlet container, you must use a **MessageDispatcherServlet** configured in **web.xml**.

By default the **MessageDispatcherServlet** will look for a Spring XML named **/WEB-INF/spring-ws-servlet.xml**. To use Camel with Spring-WS the only mandatory bean in that XML file is **CamelEndpointMapping**. This bean allows the **MessageDispatcher** to dispatch web service requests to your routes.

web.xml

```
<web-app>
   <servlet>
      <servlet-name>spring-ws</servlet-name>
      <servlet-class>org.springframework.ws.transport.http.MessageDispatcherServlet</servlet-class>
      <load-on-startup>1</load-on-startup>
   </servlet>
   <servlet-mapping>
      <servlet-name>spring-ws</servlet-name>
      <url-pattern>/*</url-pattern>
   </servlet-mapping>
</web-app>
```

spring-ws-servlet.xml

```
<bean id="endpointMapping"
class="org.apache.camel.component.spring.ws.bean.CamelEndpointMapping" />

<bean id="wsdl" class="org.springframework.ws.wsdl.wsdl11.DefaultWsdl11Definition">
   <property name="schema">
      <bean class="org.springframework.xml.xsd.SimpleXsdSchema">
         <property name="xsd" value="/WEB-INF/foobar.xsd"/>
      </bean>
   </property>
   <property name="portTypeName" value="FooBar"/>
   <property name="locationUri" value="/"/>
   <property name="targetNamespace" value="http://example.com/"/>
</bean>
```

More information on setting up Spring-WS can be found in Writing Contract-First Web Services. Basically paragraph 3.6 "Implementing the Endpoint" is handled by this component (specifically paragraph 3.6.2 "Routing the Message to the Endpoint" is where **CamelEndpointMapping** comes in). See the Spring Web Services Example included in the Camel distribution.

128.16. ENDPOINT MAPPING IN ROUTES

With the XML configuration in-place, you can now use Camel's DSL to define what web service requests are handled by your endpoint:

The following route receives all web service requests that have a root element named "GetFoo" within the **http://example.com/** namespace.

```
from("spring-ws:rootqname:{http://example.com/}GetFoo?endpointMapping=#endpointMapping")
.convertBodyTo(String.class).to(mock:example)
```

The following route receives web service requests containing the **http://example.com/GetFoo** SOAP action.

```
from("spring-ws:soapaction:http://example.com/GetFoo?endpointMapping=#endpointMapping")
.convertBodyTo(String.class).to(mock:example)
```

The following route receives all requests sent to **http://example.com/foobar**.

```
from("spring-ws:uri:http://example.com/foobar?endpointMapping=#endpointMapping")
.convertBodyTo(String.class).to(mock:example)
```

The route below receives requests that contain the element **<foobar>abc</foobar>** anywhere inside the message (and the default namespace).

```
from("spring-ws:xpathresult:abc?expression=//foobar&endpointMapping=#endpointMapping")
.convertBodyTo(String.class).to(mock:example)
```

128.16.1. Alternative configuration, using existing endpoint mappings

For every endpoint with mapping-type **beanname** one bean of type **CamelEndpointDispatcher** with a corresponding name is required in the Registry/ApplicationContext. This bean acts as a bridge between the Camel endpoint and an existing endpoint mapping like **PayloadRootQNameEndpointMapping**.

The use of the **beanname** mapping-type is primarily meant for (legacy) situations where you are already using Spring-WS and have endpoint mappings defined in a Spring XML file. The **beanname** mapping-type allows you to wire your Camel route into an existing endpoint mapping. When you are starting from the beginning, you must define your endpoint mappings as Camel URI's (as illustrated above with **endpointMapping**) since it requires less configuration and is more expressive. You can also use vanilla Spring-WS with the help of annotations.

An example of a route using **beanname**:

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="spring-ws:beanname:QuoteEndpointDispatcher" />
        <to uri="mock:example" />
    </route>
</camelContext>

<bean id="legacyEndpointMapping"
class="org.springframework.ws.server.endpoint.mapping.PayloadRootQNameEndpointMapping">
    <property name="mappings">
        <props>
            <prop key="{http://example.com/}GetFuture">FutureEndpointDispatcher</prop>
            <prop key="{http://example.com/}GetQuote">QuoteEndpointDispatcher</prop>
        </props>
    </property>
</bean>

<bean id="QuoteEndpointDispatcher"
class="org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher" />
<bean id="FutureEndpointDispatcher"
class="org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher" />
```

128.17. POJO (UN)MARSHALLING

Camel's pluggable data formats offer support for pojo/xml marshalling using libraries such as JAXB, XStream, JibX, Castor and XMLBeans. You can use these data formats in your route to sent and receive pojo's to and from web services.

When *accessing* web services you can marshal the request and unmarshal the response message:

```
JaxbDataFormat jaxb = new JaxbDataFormat(false);
jaxb.setContextPath("com.example.model");

from("direct:example").marshal(jaxb).to("spring-ws:http://foo.com/bar").unmarshal(jaxb);
```

Similarly, when *providing* web services, you can unmarshal XML requests to POJOs and marshal the response message back to XML:

```
from("spring-ws:rootqname:{http://example.com/}GetFoo?
endpointMapping=#endpointMapping").unmarshal(jaxb)
.to("mock:example").marshal(jaxb);
```

128.18. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options that are listed below.

Name	Description	Default	Type
camel.component.spring-ws.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.spring-ws.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.spring-ws.enabled	Whether to enable auto configuration of the spring-ws component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.spring-ws.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages using Camel's routing error handlers. When the first message is processed then creating and starting the producer takes time and prolong the total processing time of the processing.	false	Boolean
camel.component.spring-ws.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean

CHAPTER 129. SQL

Both producer and consumer are supported

The SQL component allows you to work with databases using JDBC queries. The difference between this component and JDBC component is that in case of SQL the query is a property of the endpoint and it uses message payload as parameters passed to the query.

This component uses **spring-jdbc** behind the scenes for the actual SQL handling.

The SQL component also supports:

- a JDBC based repository for the Idempotent Consumer EIP pattern. See further below.
- a JDBC based repository for the Aggregator EIP pattern. See further below.

129.1. DEPENDENCIES

When using **sql** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-sql-starter</artifactId>
</dependency>
```

129.2. URI FORMAT

NOTE

This component can be used as a Transactional Client.

The SQL component uses the following endpoint URI notation:

```
sql:select * from table where id=# order by name[?options]
```

You can use named parameters by using :`#name_of_the_parameter` style as shown:

```
sql:select * from table where id=:#myId order by name[?options]
```

When using named parameters, Camel will lookup the names from, in the given precedence:

1. from message body if its a **java.util.Map**
2. from message headers

If a named parameter cannot be resolved, then an exception is thrown.

You can use Simple expressions as parameters as shown:

```
sql:select * from table where id=:#${exchangeProperty.myId} order by name[?options]
```

Notice that the standard ? symbol that denotes the parameters to an SQL query is substituted with the # symbol, because the ? symbol is used to specify options for the endpoint. The ? symbol replacement can be configured on endpoint basis.

You can externalize your SQL queries to files in the classpath or file system as shown:

```
sql:classpath:sql/myquery.sql[?options]
```

And the myquery.sql file is in the classpath and is just a plain text

```
-- this is a comment
select *
from table
where
  id = :#${exchangeProperty.myId}
order by
  name
```

In the file you can use multilines and format the SQL as you wish. And also use comments such as the – dash line.

129.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

129.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

129.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

129.4. COMPONENT OPTIONS

The SQL component supports 5 options, which are listed below.

Name	Description	Default	Type
dataSource (common)	**Autowired** Sets the DataSource to use to communicate with the database.		DataSource
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
usePlaceholder (advanced)	Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries. This option is default true.	true	boolean

129.5. ENDPOINT OPTIONS

The SQL endpoint is configured using URI syntax:

```
sql:query
```

_

with the following path and query parameters:

129.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
query (common)	**Required** Sets the SQL query to perform. You can externalize the query by using file: or classpath: as prefix and specify the location of the file.		String

129.5.2. Query Parameters (45 parameters)

Name	Description	Default	Type
allowNamedParameters (common)	Whether to allow using named parameters in the queries.	true	boolean
dataSource (common)	**Autowired** Sets the DataSource to use to communicate with the database at endpoint level.		DataSource
outputClass (common)	Specify the full package and class name to use as conversion when outputType=SelectOne.		String
outputHeader (common)	Store the query result in a header instead of the message body. By default, outputHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved.		String

Name	Description	Default	Type
outputType (common)	Make the output of consumer or producer to SelectList as List of Map, or SelectOne as single Java object in the following way: a) If the query has only single column, then that JDBC Column object is returned. (such as SELECT COUNT( ) FROM PROJECT will return a Long object. b) If the query has more than one column, then it will return a Map of that result. c) If the outputClass is set, then it will convert the query result into an Java bean object by calling all the setters that match the column names. It will assume your class has a default constructor to create instance with. d) If the query resulted in more than one rows, it throws an non-unique result exception. StreamList streams the result of the query using an Iterator. This can be used with the Splitter EIP in streaming mode to process the ResultSet in streaming fashion. Enum values: • SelectOne • SelectList • StreamList	SelectList	SqlOutputType
separator (common)	The separator to use when parameter values is taken from message body (if the body is a String type), to be inserted at # placeholders. Notice if you use named parameters, then a Map type is used instead. The default value is comma.	,	char
breakBatchOnConsumeFail (consumer)	Sets whether to break batch if onConsume failed.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
expectedUpdateCount (consumer)	Sets an expected update count to validate when using onConsume.	-1	int
maxMessagesPerPoll (consumer)	Sets the maximum number of messages to poll.		int

Name	Description	Default	Type
onConsume (consumer)	After processing each row then this query can be executed, if the Exchange was processed successfully, for example to mark the row as processed. The query can have parameter.		String
onConsumeBatchComplete (consumer)	After processing the entire batch, this query can be executed to bulk update rows etc. The query cannot have parameters.		String
onConsumeFailed (consumer)	After processing each row then this query can be executed, if the Exchange failed, for example to mark the row as failed. The query can have parameter.		String
routeEmptyResultSet (consumer)	Sets whether empty resultset should be allowed to be sent to the next hop. Defaults to false. So the empty resultset will be filtered out.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
transacted (consumer)	Enables or disables transaction. If enabled then if processing an exchange failed then the consumer breaks out processing any further exchanges to cause a rollback eager.	false	boolean
useIterator (consumer)	Sets how resultset should be delivered to route. Indicates delivery as either a list or individual object. defaults to true.	true	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern

Name	Description	Default	Type
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
processingStrategy (consumer (advanced))	Allows to plugin to use a custom org.apache.camel.component.sql.SqlProcessingStrategy to execute queries when the consumer has processed the rows/batch.		SqlProcessingStrategy
batch (producer)	Enables or disables batch mode.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
noop (producer)	If set, will ignore the results of the SQL query and use the existing IN message as the OUT message for the continuation of processing.	false	boolean
useMessageBodyForSql (producer)	Whether to use the message body as the SQL and then headers for parameters. If this option is enabled then the SQL in the uri is not used. Note that query parameters in the message body are represented by a question mark instead of a # symbol.	false	boolean
alwaysPopulateStatement (advanced)	If enabled then the populateStatement method from org.apache.camel.component.sql.SqlPrepareStatementStrategy is always invoked, also if there is no expected parameters to be prepared. When this is false then the populateStatement is only invoked if there is 1 or more expected parameters to be set; for example this avoids reading the message body/headers for SQL queries with no parameters.	false	boolean

Name	Description	Default	Type
parametersCount (advanced)	If set greater than zero, then Camel will use this count value of parameters to replace instead of querying via JDBC metadata API. This is useful if the JDBC vendor could not return correct parameters count, then user may override instead.		int
placeholder (advanced)	Specifies a character that will be replaced to in SQL query. Notice, that it is simple String.replaceAll() operation and no SQL parsing is involved (quoted strings will also change).	#	String
prepareStatementStrategy (advanced)	Allows to plugin to use a custom org.apache.camel.component.sql.SqlPrepareStatementStrategy to control preparation of the query and prepared statement.		SqlPrepareStatementStrategy
templateOptions (advanced)	Configures the Spring JdbcTemplate with the key/values from the Map.		Map
usePlaceholder (advanced)	Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries.	true	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long

Name	Description	Default	Type
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean

Name	Description	Default	Type
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

129.6. TREATMENT OF THE MESSAGE BODY

The SQL component tries to convert the message body to an object of **java.util.Iterator** type and then uses this iterator to fill the query parameters (where each query parameter is represented by a # symbol (or configured placeholder) in the endpoint URI). If the message body is not an array or collection, the conversion results in an iterator that iterates over only one object, which is the body itself.

For example, if the message body is an instance of **java.util.List**, the first item in the list is substituted into the first occurrence of # in the SQL query, the second item in the list is substituted into the second occurrence of #, and so on.

If **batch** is set to **true**, then the interpretation of the inbound message body changes slightly – instead of an iterator of parameters, the component expects an iterator that contains the parameter iterators; the size of the outer iterator determines the batch size.

You can use the option **useMessageBodyForSql** that allows to use the message body as the SQL statement, and then the SQL parameters must be provided in a header with the key **SqlConstants.SQL_PARAMETERS**. This allows the SQL component to work more dynamically as the SQL query is from the message body. Use templating (such as Velocity, Freemarker) for conditional processing, e.g. to include or exclude **where** clauses depending on the presence of query parameters.

129.7. RESULT OF THE QUERY

For **select** operations, the result is an instance of **List<Map<String, Object>>** type, as returned by the JdbcTemplate.queryForList() method. For **update** operations, a **NULL** body is returned as the **update** operation is only set as a header and never as a body.

NOTE

See Header Values for more information on the **update** operation.

By default, the result is placed in the message body. If the outputHeader parameter is set, the result is placed in the header. This is an alternative to using a full message enrichment pattern to add headers, it provides a concise syntax for querying a sequence or some other small value into a header. It is convenient to use outputHeader and outputType together:

```
from("jms:order.inbox")
    .to("sql:select order_seq.nextval from dual?outputHeader=OrderId&outputType=SelectOne")
    .to("jms:order.booking");
```

129.8. USING STREAMLIST

The producer supports outputType=StreamList that uses an iterator to stream the output of the query. This allows to process the data in a streaming fashion which for example can be used by the Splitter EIP to process each row one at a time, and load data from the database as needed.

```
from("direct:withSplitModel")
        .to("sql:select * from projects order by id?
outputType=StreamList&outputClass=org.apache.camel.component.sql.ProjectModel")
        .to("log:stream")
        .split(body()).streaming()
            .to("log:row")
            .to("mock:result")
        .end();
```

129.9. HEADER VALUES

When performing **update** operations, the SQL Component stores the update count in the following message headers:

Header	Description
CamelSqlUpdateCount	The number of rows updated for **update** operations, returned as an **Integer** object. This header is not provided when using outputType=StreamList.
CamelSqlRowCount	The number of rows returned for **select** operations, returned as an **Integer** object. This header is not provided when using outputType=StreamList.
CamelSqlQuery	Query to execute. This query takes precedence over the query specified in the endpoint URI. Note that query parameters in the header *are* represented by a **?** instead of a # symbol

When performing **insert** operations, the SQL Component stores the rows with the generated keys and number of these rows in the following message headers:

Header	Description
CamelSqlGeneratedKeysRowCount	The number of rows in the header that contains generated keys.

Header	Description
CamelSqlGeneratedKeyRows	Rows that contains the generated keys (a list of maps of keys).

129.10. GENERATED KEYS

If you insert data using SQL INSERT, then the RDBMS may support auto generated keys. You can instruct the SQL producer to return the generated keys in headers.
To do that set the header **CamelSqlRetrieveGeneratedKeys=true**. Then the generated keys will be provided as headers with the keys listed in the table above.

To specify which generated columns should be retrieved, set the header **CamelSqlGeneratedColumns** to a **String[]** or **int[]**, indicating the column names or indexes, respectively. Some databases requires this, such as Oracle. It may also be necessary to use the **parametersCount** option if the driver cannot correctly determine the number of parameters.

You can see more details in this unit test.

129.11. DATASOURCE

You can set a reference to a **DataSource** in the URI directly:

```
sql:select * from table where id=# order by name?dataSource=#myDS
```

129.12. USING NAMED PARAMETERS

In the given route below, we want to get all the projects from the projects table. Notice the SQL query has 2 named parameters, :#lic and :#min.
Camel will then lookup for these parameters from the message body or message headers. Notice in the example above we set two headers with constant value
for the named parameters:

```
from("direct:projects")
  .setHeader("lic", constant("ASF"))
  .setHeader("min", constant(123))
  .to("sql:select * from projects where license = :#lic and id > :#min order by id")
```

Though if the message body is a **java.util.Map** then the named parameters will be taken from the body.

```
from("direct:projects")
  .to("sql:select * from projects where license = :#lic and id > :#min order by id")
```

129.13. USING EXPRESSION PARAMETERS IN PRODUCERS

In the given route below, we want to get all the project from the database. It uses the body of the exchange for defining the license and uses the value of a property as the second parameter.

```
from("direct:projects")
  .setBody(constant("ASF"))
  .setProperty("min", constant(123))
  .to("sql:select * from projects where license = :#${body} and id > :#${exchangeProperty.min} order
by id")
```

129.13.1. Using expression parameters in consumers

When using the SQL component as consumer, you can now also use expression parameters (simple language) to build dynamic query parameters, such as calling a method on a bean to retrieve an id, date or something.

For example in the sample below we call the nextId method on the bean myIdGenerator:

```
from("sql:select * from projects where id = :#${bean:myIdGenerator.nextId}")
    .to("mock:result");
```

And the bean has the following method:

```
public static class MyIdGenerator {

    private int id = 1;

    public int nextId() {
        return id++;
    }
```

Notice that there is no existing **Exchange** with message body and headers, so the simple expression you can use in the consumer are most useable for calling bean methods as in this example.

129.14. USING IN QUERIES WITH DYNAMIC VALUES

The SQL producer allows to use SQL queries with IN statements where the IN values is dynamic computed. For example from the message body or a header etc.

To use IN you need to:

- prefix the parameter name with **in:**
- add **( )** around the parameter

An example explains this better. The following query is used:

```
-- this is a comment
select *
from projects
where project in (:#in:names)
order by id
```

In the following route:

```
from("direct:query")
    .to("sql:classpath:sql/selectProjectsIn.sql")
```

```
    .to("log:query")
    .to("mock:query");
```

Then the IN query can use a header with the key names with the dynamic values such as:

```
// use an array
template.requestBodyAndHeader("direct:query", "Hi there!", "names", new String[]{"Camel", "AMQ"});

// use a list
List<String> names = new ArrayList<String>();
names.add("Camel");
names.add("AMQ");

template.requestBodyAndHeader("direct:query", "Hi there!", "names", names);

// use a string separated values with comma
template.requestBodyAndHeader("direct:query", "Hi there!", "names", "Camel,AMQ");
```

The query can also be specified in the endpoint instead of being externalized (notice that externalizing makes maintaining the SQL queries easier)

```
from("direct:query")
    .to("sql:select * from projects where project in (:#in:names) order by id")
    .to("log:query")
    .to("mock:query");
```

129.15. USING THE JDBC BASED IDEMPOTENT REPOSITORY

In this section we will use the JDBC based idempotent repository.

NOTE

Abstract class
There is an abstract class
org.apache.camel.processor.idempotent.jdbc.AbstractJdbcMessageIdRepository
you can extend to build custom JDBC idempotent repository.

First we have to create the database table which will be used by the idempotent repository. We use the following schema:

```
CREATE TABLE CAMEL_MESSAGEPROCESSED ( processorName VARCHAR(255),
messageId VARCHAR(100) )
```

We added the createdAt column:

```
CREATE TABLE CAMEL_MESSAGEPROCESSED ( processorName VARCHAR(255),
messageId VARCHAR(100), createdAt TIMESTAMP )
```

NOTE

The SQL Server **TIMESTAMP** type is a fixed-length binary-string type. It does not map to any of the JDBC time types: **DATE**, **TIME**, or **TIMESTAMP**.

When working with concurrent consumers it is crucial to create a unique constraint on the columns processorName and messageId. Because the syntax for this constraint differs from database to database, we do not show it here.

129.15.1. Customize the JDBC idempotency repository

You have a few options to tune the **org.apache.camel.processor.idempotent.jdbc.JdbcMessageIdRepository** for your needs:

Parameter	Default Value	Description
createTableIfNotExists	true	Defines whether or not Camel should try to create the table if it doesn't exist.
tableName	CAMEL_MESSAGEPROCESSED	To use a custom table name instead of the default name: CAMEL_MESSAGEPROCESSED.
tableExistsString	SELECT 1 FROM CAMEL_MESSAGEPROCESSED WHERE 1 = 0	This query is used to figure out whether the table already exists or not. It must throw an exception to indicate the table doesn't exist.
createString	CREATE TABLE CAMEL_MESSAGEPROCESSED (processorName VARCHAR(255), messageId VARCHAR(100), createdAt TIMESTAMP)	The statement which is used to create the table.
queryString	SELECT COUNT(*) FROM CAMEL_MESSAGEPROCESSED WHERE processorName = ? AND messageId = ?	The query which is used to figure out whether the message already exists in the repository (the result is not equals to '0'). It takes two parameters. This first one is the processor name (**String**) and the second one is the message id (**String**).
insertString	INSERT INTO CAMEL_MESSAGEPROCESSED (processorName, messageId, createdAt) VALUES (?, ?, ?)	The statement which is used to add the entry into the table. It takes three parameter. The first one is the processor name (**String**), the second one is the message id (**String**) and the third one is the timestamp (**java.sql.Timestamp**) when this entry was added to the repository.
deleteString	DELETE FROM CAMEL_MESSAGEPROCESSED WHERE processorName = ? AND messageId = ?	The statement which is used to delete the entry from the database. It takes two parameter. This first one is the processor name (**String**) and the second one is the message id (**String**).

The option **tableName** can be used to use the default SQL queries but with a different table name. However if you want to customize the SQL queries then you can configure each of them individually.

129.15.2. Orphan Lock aware Jdbc IdempotentRepository

One of the limitations of **org.apache.camel.processor.idempotent.jdbc.JdbcMessageIdRepository** is that it does not handle orphan locks resulting from JVM crash or non graceful shutdown. This can result in unprocessed files/messages if this is implementation is used with camel-file, camel-ftp etc. if you need to address orphan locks processing then use **org.apache.camel.processor.idempotent.jdbc.JdbcOrphanLockAwareIdempotentRepository**. This repository keeps track of the locks held by an instance of the application. For each lock held, the application will send keep alive signals to the lock repository resulting in updating the createdAt column with the current Timestamp. When an application instance tries to acquire a lock if the, then there are three possibilities exist :

- lock entry does not exist then the lock is provided using the base implementation of **JdbcMessageIdRepository**.
- lock already exists and the createdAt < System.currentTimeMillis() - lockMaxAgeMillis. In this case it is assumed that an active instance has the lock and the lock is not provided to the new instance requesting the lock
- lock already exists and the createdAt > = System.currentTimeMillis() - lockMaxAgeMillis. In this case it is assumed that there is no active instance which has the lock and the lock is provided to the requesting instance. The reason behind is that if the original instance which had the lock, if it was still running, it would have updated the Timestamp on createdAt using its keepAlive mechanism

This repository has two additional configuration parameters

Parameter	Description
lockMaxAgeMillis	This refers to the duration after which the lock is considered orphaned i.e. if the currentTimestamp - createdAt >= lockMaxAgeMillis then lock is orphaned.
lockKeepAliveIntervalMillis	The frequency at which keep alive updates are done to createdAt Timestamp column.

129.15.3. Caching Jdbc IdempotentRepository

Some SQL implementations are not fast on a per query basis. The **JdbcMessageIdRepository** implementation does its idempotent checks individually within SQL transactions. Checking a mere 100 keys can take minutes. The **JdbcCachedMessageIdRepository** preloads an in-memory cache on start with the entire list of keys. This cache is then checked first before passing through to the original implementation.

As with all cache implementations, there are considerations that should be made with regard to stale data and your specific usage.

129.16. USING THE JDBC BASED AGGREGATION REPOSITORY

JdbcAggregationRepository is an **AggregationRepository** which on the fly persists the aggregated messages. This ensures that you will not loose messages, as the default aggregator will use an in memory only **AggregationRepository**. The **JdbcAggregationRepository** allows together with Camel to provide persistent support for the Aggregator.

Only when an Exchange has been successfully processed it will be marked as complete which happens when the **confirm** method is invoked on the **AggregationRepository**. This means if the same Exchange fails again it will be kept retried until it success.

You can use option **maximumRedeliveries** to limit the maximum number of redelivery attempts for a given recovered Exchange. You must also set the **deadLetterUri** option so Camel knows where to send the Exchange when the **maximumRedeliveries** was hit.

You can see some examples in the unit tests of camel-sql, for example **JdbcAggregateRecoverDeadLetterChannelTest.java**

129.16.1. Database

To be operational, each aggregator uses two table: the aggregation and completed one. By convention the completed has the same name as the aggregation one suffixed with **"_COMPLETED"**. The name must be configured in the Spring bean with the **RepositoryName** property. In the following example aggregation will be used.

The table structure definition of both table are identical: in both case a String value is used as key (**id**) whereas a Blob contains the exchange serialized in byte array.
However one difference should be remembered: the **id** field does not have the same content depending on the table.
In the aggregation table **id** holds the correlation Id used by the component to aggregate the messages.
In the completed table, **id** holds the id of the exchange stored in corresponding the blob field.

Here is the SQL query used to create the tables, just replace **"aggregation"** with your aggregator repository name.

```
CREATE TABLE aggregation (
 id varchar(255) NOT NULL,
 exchange blob NOT NULL,
 version BIGINT NOT NULL,
 constraint aggregation_pk PRIMARY KEY (id)
);
CREATE TABLE aggregation_completed (
 id varchar(255) NOT NULL,
 exchange blob NOT NULL,
 version BIGINT NOT NULL,
 constraint aggregation_completed_pk PRIMARY KEY (id)
);
```

129.17. STORING BODY AND HEADERS AS TEXT

You can configure the **JdbcAggregationRepository** to store message body and select(ed) headers as String in separate columns. For example to store the body, and the following two headers **companyName** and **accountName** use the following SQL:

```
CREATE TABLE aggregationRepo3 (
 id varchar(255) NOT NULL,
 exchange blob NOT NULL,
 version BIGINT NOT NULL,
 body varchar(1000),
 companyName varchar(1000),
 accountName varchar(1000),
 constraint aggregationRepo3_pk PRIMARY KEY (id)
```

```
);
CREATE TABLE aggregationRepo3_completed (
 id varchar(255) NOT NULL,
 exchange blob NOT NULL,
 version BIGINT NOT NULL,
 body varchar(1000),
 companyName varchar(1000),
 accountName varchar(1000),
 constraint aggregationRepo3_completed_pk PRIMARY KEY (id)
);
```

And then configure the repository to enable this behavior as shown below:

```
<bean id="repo3"
  class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="repositoryName" value="aggregationRepo3"/>
  <property name="transactionManager" ref="txManager3"/>
  <property name="dataSource" ref="dataSource3"/>
  <!-- configure to store the message body and following headers as text in the repo -->
  <property name="storeBodyAsText" value="true"/>
  <property name="headersToStoreAsText">
    <list>
      <value>companyName</value>
      <value>accountName</value>
    </list>
  </property>
</bean>
```

129.17.1. Codec (Serialization)

Since they can contain any type of payload, Exchanges are not serializable by design. It is converted into a byte array to be stored in a database BLOB field. All those conversions are handled by the **JdbcCodec** class. One detail of the code requires your attention: the **ClassLoadingAwareObjectInputStream**.

The **ClassLoadingAwareObjectInputStream** has been reused from the Apache ActiveMQ project. It wraps an **ObjectInputStream** and use it with the **ContextClassLoader** rather than the **currentThread** one. The benefit is to be able to load classes exposed by other bundles. This allows the exchange body and headers to have custom types object references.

129.17.2. Transaction

A Spring **PlatformTransactionManager** is required to orchestrate transaction.

129.17.2.1. Service (Start/Stop)

The **start** method verify the connection of the database and the presence of the required tables. If anything is wrong it will fail during starting.

129.17.3. Aggregator configuration

Depending on the targeted environment, the aggregator might need some configuration. As you already know, each aggregator should have its own repository (with the corresponding pair of table created in the database) and a data source. If the default lobHandler is not adapted to your database system, it can be injected with the **lobHandler** property.

Here is the declaration for Oracle:

```
<bean id="lobHandler" class="org.springframework.jdbc.support.lob.OracleLobHandler">
  <property name="nativeJdbcExtractor" ref="nativeJdbcExtractor"/>
</bean>
<bean id="nativeJdbcExtractor"
  class="org.springframework.jdbc.support.nativejdbc.CommonsDbcpNativeJdbcExtractor"/>
<bean id="repo"
  class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="transactionManager" ref="transactionManager"/>
  <property name="repositoryName" value="aggregation"/>
  <property name="dataSource" ref="dataSource"/>
  <!-- Only with Oracle, else use default -->
  <property name="lobHandler" ref="lobHandler"/>
</bean>
```

129.17.4. Optimistic locking

You can turn on **optimisticLocking** and use this JDBC based aggregation repository in a clustered environment where multiple Camel applications shared the same database for the aggregation repository. If there is a race condition there JDBC driver will throw a vendor specific exception which the **JdbcAggregationRepository** can react upon. To know which caused exceptions from the JDBC driver is regarded as an optimistick locking error we need a mapper to do this. Therefore there is a **org.apache.camel.processor.aggregate.jdbc.JdbcOptimisticLockingExceptionMapper** allows you to implement your custom logic if needed. There is a default implementation **org.apache.camel.processor.aggregate.jdbc.DefaultJdbcOptimisticLockingExceptionMapper** which works as follows:

The following check is done:

- If the caused exception is an **SQLException** then the SQLState is checked if starts with 23.
- If the caused exception is a **DataIntegrityViolationException**
- If the caused exception class name has "ConstraintViolation" in its name.
- Optional checking for FQN class name matches if any class names has been configured.

You can in addition add FQN classnames, and if any of the caused exception (or any nested) equals any of the FQN class names, then its an optimistick locking error.

Here is an example, where we define 2 extra FQN class names from the JDBC vendor.

```
<bean id="repo"
class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="transactionManager" ref="transactionManager"/>
  <property name="repositoryName" value="aggregation"/>
  <property name="dataSource" ref="dataSource"/>
  <property name="jdbcOptimisticLockingExceptionMapper" ref="myExceptionMapper"/>
</bean>
<!-- use the default mapper with extraFQN class names from our JDBC driver -->
<bean id="myExceptionMapper"
class="org.apache.camel.processor.aggregate.jdbc.DefaultJdbcOptimisticLockingExceptionMapper">
  <property name="classNames">
    <util:set>
```

```
      <value>com.foo.sql.MyViolationExceptoion</value>
      <value>com.foo.sql.MyOtherViolationExceptoion</value>
    </util:set>
  </property>
</bean>
```

129.17.5. Propagation behavior

JdbcAggregationRepository uses two distinct *transaction templates* from Spring-TX. One is read-only and one is used for read-write operations.

However, when using **JdbcAggregationRepository** within a route that itself uses **<transacted />** and there's common **PlatformTransactionManager** used, there may be a need to configure *propagation behavior* used by transaction templates inside **JdbcAggregationRepository**.

Here's a way to do it:

```
<bean id="repo"
class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="propagationBehaviorName" value="PROPAGATION_NESTED" />
</bean>
```

Propagation is specified by constants of **org.springframework.transaction.TransactionDefinition** interface, so **propagationBehaviorName** is convenient setter that allows to use names of the constants.

129.17.6. PostgreSQL case

There's special database that may cause problems with optimistic locking used by **JdbcAggregationRepository**. PostgreSQL marks connection as invalid in case of data integrity violation exception (the one with SQLState 23505). This makes the connection effectively unusable within nested transaction. Details can be found in the document..

org.apache.camel.processor.aggregate.jdbc.PostgresAggregationRepository extends **JdbcAggregationRepository** and uses special **INSERT .. ON CONFLICT ..** statement to provide optimistic locking behavior.

This statement is (with default aggregation table definition):

```
INSERT INTO aggregation (id, exchange) values (?, ?) ON CONFLICT DO NOTHING
```

Details can be found in PostgreSQL documentation.

When this clause is used, **java.sql.PreparedStatement.executeUpdate()** call returns **0** instead of throwing SQLException with SQLState=23505. Further handling is exactly the same as with generic **JdbcAggregationRepository**, but without marking PostgreSQL connection as invalid.

129.18. CAMEL SQL STARTER

A starter module is available to spring-boot users. When using the starter, the **DataSource** can be directly configured using spring-boot properties.

```
# Example for a mysql datasource
spring.datasource.url=jdbc:mysql://localhost/test
```

```
spring.datasource.username=dbuser
spring.datasource.password=dbpass
spring.datasource.driver-class-name=com.mysql.jdbc.Driver
```

To use this feature, add the following dependencies to your spring boot pom.xml file:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-sql-starter</artifactId>
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->
</dependency>

<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-jdbc</artifactId>
  <version>${spring-boot-version}</version>
</dependency>
```

You should also include the specific database driver, if needed.

129.19. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
camel.component.sql-stored.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.sql-stored.enabled	Whether to enable auto configuration of the sql-stored component. This is enabled by default.		Boolean
camel.component.sql-stored.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.sql.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.sql.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.sql.enabled	Whether to enable auto configuration of the sql component. This is enabled by default.		Boolean
camel.component.sql.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.sql.use-placeholder	Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries. This option is default true.	true	Boolean

CHAPTER 130. SQL STORED PROCEDURE

Since Camel 2.17

Only producer is supported

The SQL Stored component allows you to work with databases using JDBC Stored Procedure queries. This component is an extension to the SQL component but specialized for calling stored procedures.

This component uses **spring-jdbc** behind the scenes for the actual SQL handling.

130.1. DEPENDENCIES

When using **camel-sql** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-sql-starter</artifactId>
</dependency>
```

130.2. URI FORMAT

The SQL component uses the following endpoint URI notation:

```
sql-stored:template[?options]
```

Where template is the stored procedure template, where you declare the name of the stored procedure and the IN, INOUT, and OUT arguments.

You can also refer to the template in an external file on the file system or classpath such as:

```
sql-stored:classpath:sql/myprocedure.sql[?options]
```

Where sql/myprocedure.sql is a plain text file in the classpath with the template, as show:

```
SUBNUMBERS(
  INTEGER ${headers.num1},
  INTEGER ${headers.num2},
  INOUT INTEGER ${headers.num3} out1,
  OUT INTEGER out2
)
```

130.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

130.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

130.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

130.4. COMPONENT OPTIONS

The SQL Stored Procedure component supports 3 options, which are listed below.

Name	Description	Default	Type
dataSource (producer)	**Autowired** Sets the DataSource to use to communicate with the database.		DataSource
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

130.5. ENDPOINT OPTIONS

The SQL Stored Procedure endpoint is configured using URI syntax:

```
sql-stored:template
```

With the following *path* and *query* parameters:

130.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
template (producer)	**Required** Sets the stored procedure template to perform. You can externalize the template by using file: or classpath: as prefix and specify the location of the file.		String

130.5.2. Query Parameters (8 parameters)

Name	Description	Default	Type
batch (producer)	Enables or disables batch mode.	false	boolean
dataSource (producer)	Sets the DataSource to use to communicate with the database.		DataSource
function (producer)	Whether this call is for a function.	false	boolean
noop (producer)	If set, will ignore the results of the stored procedure template and use the existing IN message as the OUT message for the continuation of processing.	false	boolean

Name	Description	Default	Type
outputHeader (producer)	Store the template result in a header instead of the message body. By default, outputHeader == null and the template result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the template result and the original message body is preserved.		String
useMessageBodyForTemplate (producer)	Whether to use the message body as the stored procedure template and then headers for parameters. If this option is enabled then the template in the uri is not used.	false	boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
templateOptions (advanced)	Configures the Spring JdbcTemplate with the key/values from the Map.		Map

130.6. MESSAGE HEADERS

The SQL Stored Procedure component supports 3 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelSqlStoredTemplate (producer) Constant: SQL_STORED_TEMPLATE	The template.		String

Name	Description	Default	Type
CamelSqlStoredParameters (producer) Constant: SQL_STORED_PARAMETERS	The parameters.		Iterator
CamelSqlStoredUpdateCount (producer) Constant: SQL_STORED_UPDATE_COUNT	The update count.		Integer

130.7. DECLARING THE STORED PROCEDURE TEMPLATE

The template is declared using a syntax that would be similar to a Java method signature. The name of the stored procedure, and then the arguments enclosed in parentheses. An example explains this well:

```
<to uri="sql-stored:STOREDSAMPLE(INTEGER ${headers.num1},INTEGER
${headers.num2},INOUT INTEGER ${headers.num3} result1,OUT INTEGER result2)"/>
```

The arguments are declared by a type and then a mapping to the Camel message using simple expression. So, in this example, the first two parameters are IN values of INTEGER type, mapped to the message headers. The third parameter is INOUT, meaning it accepts an INTEGER and then returns a different INTEGER result. The last parameter is the OUT value, also an INTEGER type.

In SQL terms, the stored procedure could be declared as:

```
CREATE PROCEDURE STOREDSAMPLE(VALUE1 INTEGER, VALUE2 INTEGER, INOUT
RESULT1 INTEGER, OUT RESULT2 INTEGER)
```

130.7.1. IN Parameters

IN parameters take four parts separated by a space: parameter name, SQL type (with scale), type name, and value source.

Parameter name is optional and will be auto generated if not provided. It must be given between quotes(').

SQL type is required and can be an integer (positive or negative) or reference to integer field in some class. If SQL type contains a dot, then the component tries to resolve that class and read the given field. For example, SQL type **com.Foo.INTEGER** is read from the field INTEGER of class **com.Foo**. If the type doesn't contain comma then class to resolve the integer value will be **java.sql.Types**. Type can be postfixed by scale for example DECIMAL(10) would mean **java.sql.Types.DECIMAL** with scale 10.

Type name is optional and must be given between quotes(').

Value source is required. Value source populates the parameter value from the Exchange. It can be either a Simple expression or header location i.e. **:#<header name>**. For example, the Simple expression **${header.val}** would mean that parameter value will be read from the header **val**. Header location expression **:#val** would have identical effect.

```
<to uri="sql-stored:MYFUNC('param1' org.example.Types.INTEGER(10) ${header.srcValue})"/>
```

URI means that the stored procedure will be called with parameter name *param1*, it's SQL type is read from field INTEGER of class **org.example.Types** and scale will be set to 10. Input value for the parameter is passed from the header *srcValue*.

```
<to uri="sql-stored:MYFUNC('param1' 100 'mytypename' ${header.srcValue})"/>
```

URI is identical to previous on except SQL-type is 100 and type name is *mytypename*.

Actual call will be done using **org.springframework.jdbc.core.SqlParameter**.

130.7.2. OUT Parameters

OUT parameters work similarly IN parameters and contain three parts: SQL type(with scale), type name, and output parameter name.

SQL type works the same as IN parameters.

Type name is optional and also works the same as IN parameters.

Output parameter name is used for the OUT parameter name, as well as the header name where the result will be stored.

```
<to uri="sql-stored:MYFUNC(OUT org.example.Types.DECIMAL(10) outheader1)"/>
```

URI means that the OUT parameter's name is **outheader1** and result will be but into header **outheader1**.

```
<to uri="sql-stored:MYFUNC(OUT org.example.Types.NUMERIC(10) 'mytype' outheader1)"/>
```

This is identical to previous one but type name will be **mytype**.

Actual call will be done using **org.springframework.jdbc.core.SqlOutParameter**.

130.7.3. INOUT Parameters

INOUT parameters are a combination of all of the above. They receive a value from the exchange, as well as store a result as a message header. The only caveat is that the IN parameter's "name" is skipped. Instead, the OUT parameter's *name* defines both the SQL parameter name, and the result header name.

```
<to uri="sql-stored:MYFUNC(INOUT DECIMAL(10) ${headers.inheader} outheader)"/>
```

Actual call will be done using **org.springframework.jdbc.core.SqlInOutParameter**.

130.7.4. Query Timeout

You can configure query timeout (via **template.queryTimeout**) on statements used for query processing as shown:

```
<to uri="sql-stored:MYFUNC(INOUT DECIMAL(10) ${headers.inheader} outheader)?
template.queryTimeout=5000"/>
```

This will be overridden by the remaining transaction timeout when executing within a transaction that has a timeout specified at the transaction level.

130.8. CAMEL SQL STARTER

A starter module is available to spring boot users. When using the starter, the **DataSource** can be directly configured using spring-boot properties.

```
# Example for a mysql datasource
spring.datasource.url=jdbc:mysql://localhost/test
spring.datasource.username=dbuser
spring.datasource.password=dbpass
spring.datasource.driver-class-name=com.mysql.jdbc.Driver
```

To use this feature, add the following dependencies to your spring boot pom.xml file:

```
<dependency>
    <groupId>org.apache.camel.springboot</groupId>
    <artifactId>camel-sql-starter</artifactId>
</dependency>

<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-jdbc</artifactId>
    <version>${spring-boot-version}</version>
</dependency>
```

You can also include the specific database driver, if needed.

130.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
camel.component.sql-stored.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.sql-stored.enabled	Whether to enable auto configuration of the sql-stored component. This is enabled by default.		Boolean
camel.component.sql-stored.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.sql.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.sql.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.sql.enabled	Whether to enable auto configuration of the sql component. This is enabled by default.		Boolean
camel.component.sql.health-check-consumer-enabled	Used for enabling or disabling all consumer based health checks from this component.	true	Boolean

Name	Description	Default	Type
camel.component.sql.health-check-producer-enabled	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true.	true	Boolean
camel.component.sql.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.sql.row-mapper-factory	Factory for creating RowMapper. The option is a org.apache.camel.component.sql.RowMapperFactory type.		RowMapperFactory
camel.component.sql.use-placeholder	Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries. This option is default true.	true	Boolean

CHAPTER 131. SSH

Since Camel 2.10

Both producer and consumer are supported

The SSH component enables access to SSH servers so that you can send an SSH command and process the response.

131.1. DEPENDENCIES

When using **camel-ssh** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-ssh-starter</artifactId>
</dependency>
```

131.2. URI FORMAT

```
ssh:[username[:password]@]host[:port][?options]
```

131.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

131.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

131.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

131.4. COMPONENT OPTIONS

The SSH component supports 25 options, which are listed below.

Name	Description	Default	Type
failOnUnknownHost (common)	Specifies whether a connection to an unknown host should fail or not. This value is only checked when the property knownHosts is set.	false	boolean
knownHostsResource (common)	Sets the resource path for a known_hosts file.		String
timeout (common)	Sets the timeout in milliseconds to wait in establishing the remote SSH server connection. Defaults to 30000 milliseconds.	30000	long
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
pollCommand (consumer)	Sets the command string to send to the remote SSH server during every poll cycle. Only works with camel-ssh component being used as a consumer, i.e. from(ssh://...) You may need to end your command with a newline, and that must be URL encoded %0A.		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
channelType (advanced)	Sets the channel type to pass to the Channel as part of command execution. Defaults to exec.	exec	String
clientBuilder (advanced)	**Autowired** Instance of ClientBuilder used by the producer or consumer to create a new SshClient.		ClientBuilder
compressions (advanced)	Whether to use compression, and if so which.		String
configuration (advanced)	Component configuration.		SshConfiguration
shellPrompt (advanced)	Sets the shellPrompt to be dropped when response is read after command execution.		String
sleepForShellPrompt (advanced)	Sets the sleep period in milliseconds to wait reading response from shell prompt. Defaults to 100 milliseconds.	100	long
healthCheckConsumerEnabled (health)	Used for enabling or disabling all consumer based health checks from this component.	true	boolean

Name	Description	Default	Type
healthCheckProducerEnabled (health)	Used for enabling or disabling all producer based health checks from this component. **NOTE** By default all producer based health-checks are disabled. You can turn on producer checks globally by setting **camel.health.producersEnabled=true**.	true	boolean
certResource (security)	Sets the resource path of the certificate to use for Authentication. Will use **ResourceHelperKeyPairProvider** to resolve file based certificate, and depends on keyType setting.		String
certResourcePassword (security)	Sets the password to use in loading certResource, if certResource is an encrypted key.		String
ciphers (security)	Comma-separated list of allowed/supported ciphers in their order of preference.		String
kex (security)	Comma-separated list of allowed/supported key exchange algorithms in their order of preference.		String
keyPairProvider (security)	Sets the KeyPairProvider reference to use when connecting using Certificates to the remote SSH Server.		KeyPairProvider
keyType (security)	Sets the key type to pass to the KeyPairProvider as part of authentication. KeyPairProvider.loadKey(...) will be passed this value. From Camel 3.0.0 / 2.25.0, by default Camel will select the first available KeyPair that is loaded. Prior to this, a KeyType of 'ssh-rsa' was enforced by default.		String
macs (security)	Comma-separated list of allowed/supported message authentication code algorithms in their order of preference. The MAC algorithm is used for data integrity protection.		String
password (security)	Sets the password to use in connecting to remote SSH server. Requires keyPairProvider to be set to null.		String
signatures (security)	Comma-separated list of allowed/supported signature algorithms in their order of preference.		String

Name	Description	Default	Type
username (security)	Sets the username to use in logging into the remote SSH server.		String

131.5. ENDPOINT OPTIONS

The SSH endpoint is configured using URI syntax:

```
ssh:host:port
```

With the following *path* and *query* parameters:

131.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
host (common)	**Required** Sets the hostname of the remote SSH server.		String
port (common)	Sets the port number for the remote SSH server.	22	int

131.5.2. Query Parameters (39 parameters)

Name	Description	Default	Type
failOnUnknownHost (common)	Specifies whether a connection to an unknown host should fail or not. This value is only checked when the property knownHosts is set.	false	boolean
knownHostsResource (common)	Sets the resource path for a known_hosts file.		String
timeout (common)	Sets the timeout in milliseconds to wait in establishing the remote SSH server connection. Defaults to 30000 milliseconds.	30000	long
pollCommand (consumer)	Sets the command string to send to the remote SSH server during every poll cycle. Only works with camel-ssh component being used as a consumer, i.e. from(ssh://...) You may need to end your command with a newline, and that must be URL encoded %0A.		String

Name	Description	Default	Type
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
channelType (advanced)	Sets the channel type to pass to the Channel as part of command execution. Defaults to exec.	exec	String
clientBuilder (advanced)	**Autowired** Instance of ClientBuilder used by the producer or consumer to create a new SshClient.		ClientBuilder
compressions (advanced)	Whether to use compression, and if so which.		String
shellPrompt (advanced)	Sets the shellPrompt to be dropped when response is read after command execution.		String
sleepForShellPrompt (advanced)	Sets the sleep period in milliseconds to wait reading response from shell prompt. Defaults to 100 milliseconds.	100	long
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean

Name	Description	Default	Type
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean

Name	Description	Default	Type
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
certResource (security)	Sets the resource path of the certificate to use for Authentication. Will use ResourceHelperKeyPairProvider to resolve file based certificate, and depends on keyType setting.		String
certResourcePassword (security)	Sets the password to use in loading certResource, if certResource is an encrypted key.		String
ciphers (security)	Comma-separated list of allowed/supported ciphers in their order of preference.		String
kex (security)	Comma-separated list of allowed/supported key exchange algorithms in their order of preference.		String
keyPairProvider (security)	Sets the KeyPairProvider reference to use when connecting using Certificates to the remote SSH Server.		KeyPairProvider
keyType (security)	Sets the key type to pass to the KeyPairProvider as part of authentication. KeyPairProvider.loadKey(...) will be passed this value. From Camel 3.0.0 / 2.25.0, by default Camel will select the first available KeyPair that is loaded. Prior to this, a KeyType of 'ssh-rsa' was enforced by default.		String
macs (security)	Comma-separated list of allowed/supported message authentication code algorithms in their order of preference. The MAC algorithm is used for data integrity protection.		String

Name	Description	Default	Type
password (security)	Sets the password to use in connecting to remote SSH server. Requires keyPairProvider to be set to null.		String
signatures (security)	Comma-separated list of allowed/supported signature algorithms in their order of preference.		String
username (security)	Sets the username to use in logging into the remote SSH server.		String

131.6. MESSAGE HEADERS

The SSH component supports 4 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelSshUsername (common) Constant: USERNAME_HEADER	The user name.		String
CamelSshPassword (common) Constant: PASSWORD_HEADER	The password.		String
CamelSshStderr (common) Constant: STDERR	The value of this header is a InputStream with the standard error stream of the executable.		InputStream
CamelSshExitValue (common) Constant: EXIT_VALUE	The value of this header is the exit value that is returned, after the execution. By convention a non-zero status exit value indicates abnormal termination. Note that the exit value is OS dependent.		Integer

131.7. USAGE AS A PRODUCER ENDPOINT

When the SSH Component is used as a Producer (`.to("ssh://...")`), it sends the message body as the command to execute on the remote SSH server.

XML DSL example

Note that the command has an XML encoded newline (`
`).

```
<route id="camel-example-ssh-producer">
  <from uri="direct:exampleSshProducer"/>
  <setBody>
    <constant>features:list&#10;</constant>
  </setBody>
  <to uri="ssh://karaf:karaf@localhost:8101"/>
  <log message="${body}"/>
</route>
```

131.8. AUTHENTICATION

The SSH Component can authenticate against the remote SSH server using one of two mechanisms:

- Public Key certificate
- Username/password

Configuring how the SSH Component does authentication is based on how and which options are set.

1. First, it will look to see if the **certResource** option has been set, and if so, use it to locate the referenced Public Key certificate and use that for authentication.
2. If **certResource** is not set, it will look to see if a **keyPairProvider** has been set, and if so, it will use that for certificate-based authentication.
3. If neither **certResource** nor **keyPairProvider** are set, it will use the **username** and **password** options for authentication. Even though the **username** and **password** are provided in the endpoint configuration and headers set with **SshConstants.USERNAME_HEADER** (**CamelSshUsername**) and **SshConstants.PASSWORD_HEADER** (**CamelSshPassword**), the endpoint configuration is surpassed and credentials set in the headers are used.

The following route fragment shows an SSH polling consumer using a certificate from the classpath.

XML DSL

```
<route>
  <from uri="ssh://scott@localhost:8101?
certResource=classpath:test_rsa&amp;useFixedDelay=true&amp;delay=5000&amp;pollCommand=features:list%0A"/>
  <log message="${body}"/>
</route>
```

Java DSL

```
from("ssh://scott@localhost:8101?
certResource=classpath:test_rsa&useFixedDelay=true&delay=5000&pollCommand=features:list%0A"
)
    .log("${body}");
```

An example of using Public Key authentication is provided in **examples/camel-example-ssh-security**.

131.9. CERTIFICATE DEPENDENCIES

You need to add some additional runtime dependencies if you use certificate-based authentication. You may need to use later versions depending on what version of Camel you are using.

The component uses **sshd-core** library which is based on either **bouncycastle** or **eddsa** security providers. **camel-ssh** is picking explicitly **bouncycastle** as security provider.

```
<dependency>
  <groupId>org.apache.sshd</groupId>
  <artifactId>sshd-core</artifactId>
  <version>2.8.0</version>
</dependency>
<dependency>
  <groupId>org.bouncycastle</groupId>
  <artifactId>bcpg-jdk18on</artifactId>
  <version>1.71</version>
</dependency>
<dependency>
  <groupId>org.bouncycastle</groupId>
  <artifactId>bcpkix-jdk18on</artifactId>
  <version>1.71</version>
</dependency>
```

131.10. SPRING BOOT AUTO-CONFIGURATION

The component supports 26 options, which are listed below.

Name	Description	Default	Type
camel.component.ssh.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.ssh.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.ssh.cert-resource	Sets the resource path of the certificate to use for Authentication. Will use ResourceHelperKeyPairProvider to resolve file based certificate, and depends on keyType setting.		String
camel.component.ssh.cert-resource-password	Sets the password to use in loading certResource, if certResource is an encrypted key.		String
camel.component.ssh.channel-type	Sets the channel type to pass to the Channel as part of command execution. Defaults to exec.	exec	String
camel.component.ssh.ciphers	Comma-separated list of allowed/supported ciphers in their order of preference.		String
camel.component.ssh.client-builder	Instance of ClientBuilder used by the producer or consumer to create a new SshClient. The option is a org.apache.sshd.client.ClientBuilder type.		ClientBuilder
camel.component.ssh.compressions	Whether to use compression, and if so which.		String
camel.component.ssh.configuration	Component configuration. The option is a org.apache.camel.component.ssh.SshConfiguration type.		SshConfiguration
camel.component.ssh.enabled	Whether to enable auto configuration of the ssh component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.ssh.fail-on-unknown-host	Specifies whether a connection to an unknown host should fail or not. This value is only checked when the property knownHosts is set.	false	Boolean
camel.component.ssh.health-check-consumer-enabled	Used for enabling or disabling all consumer based health checks from this component.	true	Boolean
camel.component.ssh.health-check-producer-enabled	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true.	true	Boolean
camel.component.ssh.kex	Comma-separated list of allowed/supported key exchange algorithms in their order of preference.		String
camel.component.ssh.key-pair-provider	Sets the KeyPairProvider reference to use when connecting using Certificates to the remote SSH Server. The option is a org.apache.sshd.common.keyprovider.KeyPairProvider type.		KeyPairProvider
camel.component.ssh.key-type	Sets the key type to pass to the KeyPairProvider as part of authentication. KeyPairProvider.loadKey(...) will be passed this value. From Camel 3.0.0 / 2.25.0, by default Camel will select the first available KeyPair that is loaded. Prior to this, a KeyType of 'ssh-rsa' was enforced by default.		String
camel.component.ssh.known-hosts-resource	Sets the resource path for a known_hosts file.		String
camel.component.ssh.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.ssh.macs	Comma-separated list of allowed/supported message authentication code algorithms in their order of preference. The MAC algorithm is used for data integrity protection.		String
camel.component.ssh.password	Sets the password to use in connecting to remote SSH server. Requires keyPairProvider to be set to null.		String
camel.component.ssh.poll-command	Sets the command string to send to the remote SSH server during every poll cycle. Only works with camel-ssh component being used as a consumer, i.e. from(ssh://...) You may need to end your command with a newline, and that must be URL encoded %0A.		String
camel.component.ssh.shell-prompt	Sets the shellPrompt to be dropped when response is read after command execution.		String
camel.component.ssh.signatures	Comma-separated list of allowed/supported signature algorithms in their order of preference.		String
camel.component.ssh.sleep-for-shell-prompt	Sets the sleep period in milliseconds to wait reading response from shell prompt. Defaults to 100 milliseconds.	100	Long
camel.component.ssh.timeout	Sets the timeout in milliseconds to wait in establishing the remote SSH server connection. Defaults to 30000 milliseconds.	30000	Long
camel.component.ssh.username	Sets the username to use in logging into the remote SSH server.		String

CHAPTER 132. STUB

Both producer and consumer are supported

The Stub component provides a simple way to stub out any physical endpoints while in development or testing, allowing you for example to run a route without needing to actually connect to a specific specific SMTP or HTTP endpoint. Just add **stub:** in front of any endpoint URI to stub out the endpoint.

Internally the Stub component creates VM endpoints. The main difference between Stub and VM is that VM will validate the URI and parameters you give it, so putting vm: in front of a typical URI with query arguments will usually fail. Stub won't though, as it basically ignores all query parameters to let you quickly stub out one or more endpoints in your route temporarily.

132.1. DEPENDENCIES

When using **stub** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-stub-starter</artifactId>
</dependency>
```

132.2. URI FORMAT

```
stub:someUri
```

Where **someUri** can be any URI with any query parameters.

132.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

132.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

132.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

132.4. COMPONENT OPTIONS

The Stub component supports 10 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Sets the default number of concurrent threads processing exchanges.	1	int
defaultPollTimeout (consumer (advanced))	The timeout (in milliseconds) used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	int
defaultBlockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean
defaultDiscardWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will be discarded. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will give up sending and continue, meaning that the message was not sent to the SEDA queue.	false	boolean

Name	Description	Default	Type
defaultOfferTimeout (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, where a configured timeout can be added to the block case. Utilizing the .offer(timeout) method of the underlining java queue.		long
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
defaultQueueFactory (advanced)	Sets the default queue factory.		BlockingQueueFactory
queueSize (advanced)	Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).	1000	int

132.5. ENDPOINT OPTIONS

The Stub endpoint is configured using URI syntax:

```
stub:name
```

with the following path and query parameters:

132.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (common)	**Required** Name of queue.		String

132.5.2. Query Parameters (18 parameters)

Name	Description	Default	Type
size (common)	The maximum capacity of the SEDA queue (i.e., the number of messages it can hold). Will by default use the defaultSize set on the SEDA component.	1000	int
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Number of concurrent threads processing exchanges.	1	int
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
limitConcurrentConsumers (consumer (advanced))	Whether to limit the number of concurrentConsumers to the maximum of 500. By default, an exception will be thrown if an endpoint is configured with a greater number. You can disable that check by turning this option off.	true	boolean

Name	Description	Default	Type
multipleConsumers (consumer (advanced))	Specifies whether multiple consumers are allowed. If enabled, you can use SEDA for Publish-Subscribe messaging. That is, you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.	false	boolean
pollTimeout (consumer (advanced))	The timeout (in milliseconds) used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	int
purgeWhenStopping (consumer (advanced))	Whether to purge the task queue when stopping the consumer/route. This allows to stop faster, as any pending messages on the queue is discarded.	false	boolean
blockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean
discardIfNoConsumers (producer)	Whether the producer should discard the message (do not add the message to the queue), when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.	false	boolean
discardWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will be discarded. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will give up sending and continue, meaning that the message was not sent to the SEDA queue.	false	boolean
failIfNoConsumers (producer)	Whether the producer should fail by throwing an exception, when sending to a queue with no active consumers. Only one of the options discardIfNoConsumers and failIfNoConsumers can be enabled at the same time.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
offerTimeout (producer)	Offer timeout (in milliseconds) can be added to the block case when queue is full. You can disable timeout by using 0 or a negative value.		long
timeout (producer)	Timeout (in milliseconds) before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable timeout by using 0 or a negative value.	30000	long
waitForTaskToComplete (producer)	Option to specify whether the caller should wait for the async task to complete or not before continuing. The following three options are supported: Always, Never or IfReplyExpected. The first two values are self-explanatory. The last value, IfReplyExpected, will only wait if the message is Request Reply based. The default option is IfReplyExpected. Enum values: • Never • IfReplyExpected • Always	IfReplyExpected	WaitForTaskToComplete
queue (advanced)	Define the queue instance which will be used by the endpoint.		BlockingQueue

132.6. EXAMPLES

Here are a few samples of stubbing endpoint uris

```
stub:smtp://somehost.foo.com?user=whatnot&something=else
stub:http://somehost.bar.com/something
```

132.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
camel.component.stub.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.stub.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.stub.concurrent-consumers	Sets the default number of concurrent threads processing exchanges.	1	Integer
camel.component.stub.default-block-when-full	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	Boolean
camel.component.stub.default-discard-when-full	Whether a thread that sends messages to a full SEDA queue will be discarded. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will give up sending and continue, meaning that the message was not sent to the SEDA queue.	false	Boolean
camel.component.stub.default-offer-timeout	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, where a configured timeout can be added to the block case. Utilizing the .offer(timeout) method of the underlining java queue.		Long

Name	Description	Default	Type
camel.component.stub.default-poll-timeout	The timeout (in milliseconds) used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	Integer
camel.component.stub.default-queue-factory	Sets the default queue factory. The option is a org.apache.camel.component.seda.BlockingQueueFactory<org.apache.camel.Exchange> type.		BlockingQueueFactory
camel.component.stub.enabled	Whether to enable auto configuration of the stub component. This is enabled by default.		Boolean
camel.component.stub.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.stub.queue-size	Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).	1000	Integer

CHAPTER 133. TELEGRAM

Both producer and consumer are supported

The Telegram component provides access to the Telegram Bot API. It allows a Camel-based application to send and receive messages by acting as a Bot, participating in direct conversations with normal users, private and public groups or channels.

A Telegram Bot must be created before using this component, following the instructions at the Telegram Bot developers home. When a new Bot is created, the BotFather provides an **authorization token** corresponding to the Bot. The authorization token is a mandatory parameter for the camel-telegram endpoint.

NOTE

In order to allow the Bot to receive all messages exchanged within a group or channel (not just the ones starting with a '/' character), ask the BotFather to **disable the privacy mode**, using the **/setprivacy** command.

133.1. DEPENDENCIES

When using **telegram** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-telegram-starter</artifactId>
</dependency>
```

133.2. URI FORMAT

```
telegram:type[?options]
```

133.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

133.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

133.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

133.4. COMPONENT OPTIONS

The Telegram component supports 7 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
baseUri (advanced)	Can be used to set an alternative base URI, e.g. when you want to test the component against a mock Telegram API.		String
client (advanced)	To use a custom AsyncHttpClient.		AsyncHttpClient
clientConfig (advanced)	To configure the AsyncHttpClient to use a custom com.ning.http.client.AsyncHttpClientConfig instance.		AsyncHttpClientConfig
authorizationToken (security)	The default Telegram authorization token to be used when the information is not provided in the endpoints.		String

133.5. ENDPOINT OPTIONS

The Telegram endpoint is configured using URI syntax:

```
telegram:type
```

with the following path and query parameters:

133.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
type (common)	**Required** The endpoint type. Currently, only the 'bots' type is supported. Enum values: • bots		String

133.5.2. Query Parameters (30 parameters)

Name	Description	Default	Type

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
limit (consumer)	Limit on the number of updates that can be received in a single polling request.	100	Integer
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
timeout (consumer)	Timeout in seconds for long polling. Put 0 for short polling or a bigger number for long polling. Long polling produces shorter response time.	30	Integer
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy

Name	Description	Default	Type
chatId (producer)	The identifier of the chat that will receive the produced messages. Chat ids can be first obtained from incoming messages (eg. when a telegram user starts a conversation with a bot, its client sends automatically a '/start' message containing the chat id). It is an optional parameter, as the chat id can be set dynamically for each outgoing message (using body or headers).		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
baseUri (advanced)	Can be used to set an alternative base URI, e.g. when you want to test the component against a mock Telegram API.		String
bufferSize (advanced)	The initial in-memory buffer size used when transferring data between Camel and AHC Client.	4096	int
clientConfig (advanced)	To configure the AsyncHttpClient to use a custom com.ning.http.client.AsyncHttpClientConfig instance.		AsyncHttpClientConfig
proxyHost (proxy)	HTTP proxy host which could be used when sending out the message.		String
proxyPort (proxy)	HTTP proxy port which could be used when sending out the message.		Integer
proxyType (proxy)	HTTP proxy type which could be used when sending out the message. Enum values: • HTTP • SOCKS4 • SOCKS5	HTTP	TelegramProxyType

Name	Description	Default	Type
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultipler should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultipler should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService

Name	Description	Default	Type
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
authorizationToken (security)	**Required** The authorization token for using the bot (ask the BotFather).		String

133.5.3. Message Headers

Name	Description
CamelTelegramChatId	This header is used by the producer endpoint in order to resolve the chat id that will receive the message. The recipient chat id can be placed (in order of priority) in message body, in the **CamelTelegramChatId** header or in the endpoint configuration (**chatId** option). This header is also present in all incoming messages.
CamelTelegramMediaType	This header is used to identify the media type when the outgoing message is composed of pure binary data. Possible values are strings or enum values belonging to the **org.apache.camel.component.telegram.TelegramMediaType** enumeration.

Name	Description
CamelTelegramMediaTitleCaption	This header is used to provide a caption or title for outgoing binary messages.
CamelTelegramParseMode	This header is used to format text messages using HTML or Markdown (see **org.apache.camel.component.telegram.TelegramParseMode**).

133.6. USAGE

The Telegram component supports both consumer and producer endpoints. It can also be used in **reactive chat-bot mode** (to consume, then produce messages).

133.7. PRODUCER EXAMPLE

The following is a basic example of how to send a message to a Telegram chat through the Telegram Bot API.

in Java DSL

```
from("direct:start").to("telegram:bots?
authorizationToken=123456789:insertYourAuthorizationTokenHere");
```

or in Spring XML

```
<route>
   <from uri="direct:start"/>
   <to uri="telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere"/>
<route>
```

The code **123456789:insertYourAuthorizationTokenHere** is the **authorization token** corresponding to the Bot.

When using the producer endpoint without specifying the **chat id** option, the target chat will be identified using information contained in the body or headers of the message. The following message bodies are allowed for a producer endpoint (messages of type **OutgoingXXXMessage** belong to the package **org.apache.camel.component.telegram.model**)

Java Type	Description
OutgoingTextMessage	To send a text message to a chat
OutgoingPhotoMessage	To send a photo (JPG, PNG) to a chat
OutgoingAudioMessage	To send a mp3 audio to a chat

Java Type	Description
OutgoingVideoMessage	To send a mp4 video to a chat
OutgoingDocumentMessage	To send a file to a chat (any media type)
OutgoingStickerMessage	To send a sticker to a chat (WEBP)
OutgoingAnswerInlineQuery	To send answers to an inline query
EditMessageTextMessage	To edit text and game messages (editMessageText)
EditMessageCaptionMessage	To edit captions of messages (editMessageCaption)
EditMessageMediaMessage	To edit animation, audio, document, photo, or video messages. (editMessageMedia)
EditMessageReplyMarkupMessage	To edit only the reply markup of message. (editMessageReplyMarkup)
EditMessageDelete	To delete a message, including service messages. (deleteMessage)
SendLocationMessage	To send a location (setSendLocation)
EditMessageLiveLocationMessage	To send changes to a live location (editMessageLiveLocation)
StopMessageLiveLocationMessage	To stop updating a live location message sent by the bot or via the bot (for inline bots) before live_period expires (stopMessageLiveLocation)
SendVenueMessage	To send information about a venue (sendVenue)
byte[]	To send any media type supported. It requires the **CamelTelegramMediaType** header to be set to the appropriate media type
String	To send a text message to a chat. It gets converted automatically into a **OutgoingTextMessage**

133.8. CONSUMER EXAMPLE

The following is a basic example of how to receive all messages that telegram users are sending to the configured Bot. In Java DSL

```
from("telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere")
.bean(ProcessorBean.class)
```

or in Spring XML

```
<route>
  <from uri="telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere"/>
  <bean ref="myBean" />
<route>

<bean id="myBean" class="com.example.MyBean"/>
```

The **MyBean** is a simple bean that will receive the messages

```
public class MyBean {

  public void process(String message) {
    // or Exchange, or org.apache.camel.component.telegram.model.IncomingMessage (or both)

    // do process
  }

}
```

Supported types for incoming messages are

Java Type	Description
IncomingMessage	The full object representation of an incoming message
String	The content of the message, for text messages only

133.9. REACTIVE CHAT-BOT EXAMPLE

The reactive chat-bot mode is a simple way of using the Camel component to build a simple chat bot that replies directly to chat messages received from the Telegram users.

The following is a basic configuration of the chat-bot in Java DSL

```
from("telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere")
.bean(ChatBotLogic.class)
.to("telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere");
```

or in Spring XML

```
<route>
  <from uri="telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere"/>
  <bean ref="chatBotLogic" />
  <to uri="telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere"/>
<route>

<bean id="chatBotLogic" class="com.example.ChatBotLogic"/>
```

The **ChatBotLogic** is a simple bean that implements a generic String-to-String method.

```
public class ChatBotLogic {

    public String chatBotProcess(String message) {
        if( "do-not-reply".equals(message) ) {
            return null; // no response in the chat
        }

        return "echo from the bot: " + message; // echoes the message
    }

}
```

Every non-null string returned by the **chatBotProcess** method is automatically routed to the chat that originated the request (as the **CamelTelegramChatId** header is used to route the message).

133.10. GETTING THE CHAT ID

If you want to push messages to a specific Telegram chat when an event occurs, you need to retrieve the corresponding chat ID. The chat ID is not currently shown in the telegram client, but you can obtain it using a simple route.

First, add the bot to the chat where you want to push messages, then run a route like the following one.

```
from("telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere")
.to("log:INFO?showHeaders=true");
```

Any message received by the bot will be dumped to your log together with information about the chat (**CamelTelegramChatId** header).

Once you get the chat ID, you can use the following sample route to push message to it.

```
from("timer:tick")
.setBody().constant("Hello")
to("telegram:bots?
authorizationToken=123456789:insertYourAuthorizationTokenHere&chatId=123456")
```

Note that the corresponding URI parameter is simply **chatId**.

133.11. CUSTOMIZING KEYBOARD

You can customize the user keyboard instead of asking him to write an option. **OutgoingTextMessage** has the property **ReplyMarkup** which can be used for such thing.

```
from("telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere")
    .process(exchange -> {

        OutgoingTextMessage msg = new OutgoingTextMessage();
        msg.setText("Choose one option!");

        InlineKeyboardButton buttonOptionOneI = InlineKeyboardButton.builder()
                .text("Option One - I").build();

        InlineKeyboardButton buttonOptionOneII = InlineKeyboardButton.builder()
                .text("Option One - II").build();
```

```
        InlineKeyboardButton buttonOptionTwoI = InlineKeyboardButton.builder()
                .text("Option Two - I").build();

        ReplyKeyboardMarkup replyMarkup = ReplyKeyboardMarkup.builder()
                .keyboard()
                    .addRow(Arrays.asList(buttonOptionOneI, buttonOptionOneII))
                    .addRow(Arrays.asList(buttonOptionTwoI))
                    .close()
                .oneTimeKeyboard(true)
                .build();

        msg.setReplyMarkup(replyMarkup);

        exchange.getIn().setBody(msg);
    })
    .to("telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere");
```

If you want to disable it the next message must have the property **removeKeyboard** set on **ReplyKeyboardMarkup** object.

```
from("telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere")
    .process(exchange -> {

        OutgoingTextMessage msg = new OutgoingTextMessage();
        msg.setText("Your answer was accepted!");

        ReplyKeyboardMarkup replyMarkup = ReplyKeyboardMarkup.builder()
                .removeKeyboard(true)
                .build();

        msg.setReplyKeyboardMarkup(replyMarkup);

        exchange.getIn().setBody(msg);
    })
    .to("telegram:bots?authorizationToken=123456789:insertYourAuthorizationTokenHere");
```

133.12. WEBHOOK MODE

The Telegram component supports usage in the **webhook mode** using the **camel-webhook** component.

In order to enable webhook mode, users need first to add a REST implementation to their application. Maven users, for example, can add **netty-http** to their **pom.xml** file:

```
<dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-netty-http</artifactId>
    <version>{CamelSBVersion}</version>
    <!-- use the same version as your Camel core version -->
</dependency>
```

Once done, you need to prepend the webhook URI to the telegram URI you want to use.

In Java DSL:

```
from("webhook:telegram:bots?
authorizationToken=123456789:insertYourAuthorizationTokenHere").to("log:info");
```

Some endpoints will be exposed by your application and Telegram will be configured to send messages to them. You need to ensure that your server is exposed to the internet and to pass the right value of the **camel.component.webhook.configuration.webhook-external-url** property.

Refer to the **camel-webhook** component documentation for instructions on how to set it.

133.13. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
camel.component.telegram.authorization-token	The default Telegram authorization token to be used when the information is not provided in the endpoints.		String
camel.component.telegram.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.telegram.base-uri	Can be used to set an alternative base URI, e.g. when you want to test the component against a mock Telegram API.		String
camel.component.telegram.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.telegram.client	To use a custom AsyncHttpClient. The option is a org.asynchttpclient.AsyncHttpClient type.		AsyncHttpClient
camel.component.telegram.client-config	To configure the AsyncHttpClient to use a custom com.ning.http.client.AsyncHttpClientConfig instance. The option is a org.asynchttpclient.AsyncHttpClientConfig type.		AsyncHttpClientConfig

Name	Description	Default	Type
camel.component.telegram.enabled	Whether to enable auto configuration of the telegram component. This is enabled by default.		Boolean
camel.component.telegram.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 134. TIMER

Only consumer is supported

The Timer component is used to generate message exchanges when a timer fires You can only consume events from this endpoint.

134.1. DEPENDENCIES

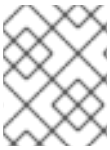
When using **timer** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-timer-starter</artifactId>
</dependency>
```

134.2. URI FORMAT

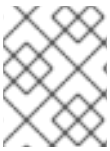
```
timer:name[?options]
```

Where **name** is the name of the **Timer** object, which is created and shared across endpoints. So if you use the same name for all your timer endpoints, only one **Timer** object and thread will be used.



NOTE

The IN body of the generated exchange is **null**. So **exchange.getIn().getBody()** returns **null**.



NOTE

Advanced Scheduler
See also the Quartz component that supports much more advanced scheduling.

134.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

134.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

134.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

134.4. COMPONENT OPTIONS

The Timer component supports 2 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

134.5. ENDPOINT OPTIONS

The Timer endpoint is configured using URI syntax:

```
timer:timerName
```

with the following path and query parameters:

134.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
timerName (consumer)	**Required** The name of the timer.		String

134.5.2. Query Parameters (13 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
delay (consumer)	Delay before first event is triggered.	1000	long
fixedRate (consumer)	Events take place at approximately regular intervals, separated by the specified period.	false	boolean
includeMetadata (consumer)	Whether to include metadata in the exchange such as fired time, timer name, timer count etc. This information is default included.	true	boolean
period (consumer)	If greater than 0, generate periodic events every period.	1000	long
repeatCount (consumer)	Specifies a maximum limit of number of fires. So if you set it to 1, the timer will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.		long
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
daemon (advanced)	Specifies whether or not the thread associated with the timer endpoint runs as a daemon. The default value is true.	true	boolean
pattern (advanced)	Allows you to specify a custom Date pattern to use for setting the time option using URI syntax.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean
time (advanced)	A java.util.Date the first event should be generated. If using the URI, the pattern expected is: yyyy-MM-dd HH:mm:ss or yyyy-MM-dd'T'HH:mm:ss.		Date
timer (advanced)	To use a custom Timer.		Timer

134.6. EXCHANGE PROPERTIES

When the timer is fired, it adds the following information as properties to the **Exchange**:

Name	Type	Description
Exchange.TIMER_NAME	**String**	The value of the **name** option.
Exchange.TIMER_TIME	**Date**	The value of the **time** option.
Exchange.TIMER_PERIOD	**long**	The value of the **period** option.
Exchange.TIMER_FIRED_TIME	**Date**	The time when the consumer fired.
Exchange.TIMER_COUNTER	**Long**	The current fire counter. Starts from 1.

134.7. SAMPLE

To set up a route that generates an event every 60 seconds:

```
from("timer://foo?fixedRate=true&period=60000").to("bean:myBean?method=someMethodName");
```

The above route will generate an event and then invoke the **someMethodName** method on the bean called **myBean** in the Registry.

And the route in Spring DSL:

```
<route>
  <from uri="timer://foo?fixedRate=true&amp;period=60000"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

134.8. FIRING AS SOON AS POSSIBLE

Since Camel 2.17

You may want to fire messages in a Camel route as soon as possible you can use a negative delay:

```
<route>
  <from uri="timer://foo?delay=-1"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

In this way the timer will fire messages immediately.

You can also specify a repeatCount parameter in conjunction with a negative delay to stop firing messages after a fixed number has been reached.

If you don't specify a repeatCount then the timer will continue firing messages until the route will be stopped.

134.9. FIRING ONLY ONCE

You may want to fire a message in a Camel route only once, such as when starting the route. To do that you use the repeatCount option as shown:

```
<route>
  <from uri="timer://foo?repeatCount=1"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

134.10. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.timer.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.timer.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.timer.enabled	Whether to enable auto configuration of the timer component. This is enabled by default.		Boolean

CHAPTER 135. TOKENIZE

The tokenizer language is a built-in language in **camel-core**, which is most often used with the Split EIP to split a message using a token-based strategy.

The tokenizer language is intended to tokenize text documents using a specified delimiter pattern. It can also be used to tokenize XML documents with some limited capability. For a truly XML-aware tokenization, the use of the XML Tokenize language is recommended as it offers a faster, more efficient tokenization specifically for XML documents.

135.1. DEPENDENCIES

When using **tokenize** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-core-starter</artifactId>
</dependency>
```

135.2. TOKENIZE OPTIONS

The Tokenize language supports 11 options, which are listed below.

Name	Default	Java Type	Description
token		**String**	**Required** The (start) token to use as tokenizer, for example you can use the new line token. You can use simple language as the token to support dynamic tokens.
endToken		**String**	The end token to use as tokenizer if using start/end token pairs. You can use simple language as the token to support dynamic tokens.
inheritNamespaceTagName		**String**	To inherit namespaces from a root/parent tag name when using XML You can use simple language as the tag name to support dynamic names.
headerName		**String**	Name of header to tokenize instead of using the message body.
regex		**Boolean**	If the token is a regular expression pattern. The default value is false.
xml		**Boolean**	Whether the input is XML messages. This option must be set to true if working with XML payloads.
includeTokens		**Boolean**	Whether to include the tokens in the parts when using pairs The default value is false.

Name	Default	Java Type	Description
group		**String**	To group N parts together, for example to split big files into chunks of 1000 lines. You can use simple language as the group to support dynamic group sizes.
groupDelimiter		**String**	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.
skipFirst		**Boolean**	To skip the very first element.
trim		**Boolean**	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

135.3. EXAMPLE

The following example shows how to take a request from the direct:a endpoint then split it into pieces using an Expression, then forward each piece to direct:b:

```
<route>
  <from uri="direct:a"/>
  <split>
    <tokenize token="\n"/>
    <to uri="direct:b"/>
  </split>
</route>
```

And in Java DSL:

```
from("direct:a")
    .split(body().tokenize("\n"))
        .to("direct:b");
```

135.4. SEE ALSO

For more examples see Split EIP.

135.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 147 options, which are listed below.

Name	Description	Default	Type
camel.cloud.consul.service-discovery.acl-token	Sets the ACL token to be used with Consul.		String
camel.cloud.consul.service-discovery.block-seconds	The seconds to wait for a watch event, default 10 seconds.	10	Integer
camel.cloud.consul.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.consul.service-discovery.connect-timeout-millis	Connect timeout for OkHttpClient.		Long
camel.cloud.consul.service-discovery.datacenter	The data center.		String
camel.cloud.consul.service-discovery.enabled	Enable the component.	true	Boolean
camel.cloud.consul.service-discovery.password	Sets the password to be used for basic authentication.		String
camel.cloud.consul.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.consul.service-discovery.read-timeout-millis	Read timeout for OkHttpClient.		Long

Name	Description	Default	Type
camel.cloud.consul.service-discovery.url	The Consul agent URL.		String
camel.cloud.consul.service-discovery.user-name	Sets the username to be used for basic authentication.		String
camel.cloud.consul.service-discovery.write-timeout-millis	Write timeout for OkHttpClient.		Long
camel.cloud.dns.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.dns.service-discovery.domain	The domain name;.		String
camel.cloud.dns.service-discovery.enabled	Enable the component.	true	Boolean
camel.cloud.dns.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.dns.service-discovery.proto	The transport protocol of the desired service.	_tcp	String
camel.cloud.etcd.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.etcd.service-discovery.enabled	Enable the component.	true	Boolean

Name	Description	Default	Type
camel.cloud.etcd.service-discovery.password	The password to use for basic authentication.		String
camel.cloud.etcd.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.etcd.service-discovery.service-path	The path to look for for service discovery.	/services/	String
camel.cloud.etcd.service-discovery.timeout	To set the maximum time an action could take to complete.		Long
camel.cloud.etcd.service-discovery.type	To set the discovery type, valid values are on-demand and watch.	on-demand	String
camel.cloud.etcd.service-discovery.uris	The URIs the client can connect to.		String
camel.cloud.etcd.service-discovery.user-name	The user name to use for basic authentication.		String
camel.cloud.kubernetes.service-discovery.api-version	Sets the API version when using client lookup.		String
camel.cloud.kubernetes.service-discovery.ca-cert-data	Sets the Certificate Authority data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.ca-cert-file	Sets the Certificate Authority data that are loaded from the file when using client lookup.		String

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.client-cert-data	Sets the Client Certificate data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-cert-file	Sets the Client Certificate data that are loaded from the file when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-algo	Sets the Client Keystore algorithm, such as RSA when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-data	Sets the Client Keystore data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-file	Sets the Client Keystore data that are loaded from the file when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-key-passphrase	Sets the Client Keystore passphrase when using client lookup.		String
camel.cloud.kubernetes.service-discovery.configurations	Define additional configuration definitions.		Map
camel.cloud.kubernetes.service-discovery.dns-domain	Sets the DNS domain to use for DNS lookup.		String
camel.cloud.kubernetes.service-discovery.enabled	Enable the component.	true	Boolean

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.lookup	How to perform service lookup. Possible values: client, dns, environment. When using client, then the client queries the kubernetes master to obtain a list of active pods that provides the service, and then random (or round robin) select a pod. When using dns the service name is resolved as name.namespace.svc.dnsDomain. When using dnssrv the service name is resolved with SRV query for .... svc... When using environment then environment variables are used to lookup the service. By default environment is used.	environment	String
camel.cloud.kubernetes.service-discovery.master-url	Sets the URL to the master when using client lookup.		String
camel.cloud.kubernetes.service-discovery.namespace	Sets the namespace to use. Will by default use namespace from the ENV variable KUBERNETES_MASTER.		String
camel.cloud.kubernetes.service-discovery.oauth-token	Sets the OAUTH token for authentication (instead of username/password) when using client lookup.		String
camel.cloud.kubernetes.service-discovery.password	Sets the password for authentication when using client lookup.		String
camel.cloud.kubernetes.service-discovery.port-name	Sets the Port Name to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.port-protocol	Sets the Port Protocol to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.trust-certs	Sets whether to turn on trust certificate check when using client lookup.	false	Boolean
camel.cloud.kubernetes.service-discovery.username	Sets the username for authentication when using client lookup.		String
camel.cloud.ribbon.load-balancer.client-name	Sets the Ribbon client name.		String
camel.cloud.ribbon.load-balancer.configurations	Define additional configuration definitions.		Map
camel.cloud.ribbon.load-balancer.enabled	Enable the component.	true	Boolean
camel.cloud.ribbon.load-balancer.namespace	The namespace.		String
camel.cloud.ribbon.load-balancer.password	The password.		String
camel.cloud.ribbon.load-balancer.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map
camel.cloud.ribbon.load-balancer.username	The username.		String

Name	Description	Default	Type
camel.hystrix.allow-maximum-size-to-diverge-from-core-size	Allows the configuration for maximumSize to take effect. That value can then be equal to, or higher, than coreSize.	false	Boolean
camel.hystrix.circuit-breaker-enabled	Whether to use a HystrixCircuitBreaker or not. If false no circuit-breaker logic will be used and all requests permitted. This is similar in effect to circuitBreakerForceClosed() except that continues tracking metrics and knowing whether it should be open/closed, this property results in not even instantiating a circuit-breaker.	true	Boolean
camel.hystrix.circuit-breaker-error-threshold-percentage	Error percentage threshold (as whole number such as 50) at which point the circuit breaker will trip open and reject requests. It will stay tripped for the duration defined in circuitBreakerSleepWindowInMilliseconds; The error percentage this is compared against comes from HystrixCommandMetrics.getHealthCounts().	50	Integer
camel.hystrix.circuit-breaker-force-closed	If true the HystrixCircuitBreaker#allowRequest() will always return true to allow requests regardless of the error percentage from HystrixCommandMetrics.getHealthCounts(). The circuitBreakerForceOpen() property takes precedence so if it set to true this property does nothing.	false	Boolean
camel.hystrix.circuit-breaker-force-open	If true the HystrixCircuitBreaker.allowRequest() will always return false, causing the circuit to be open (tripped) and reject all requests. This property takes precedence over circuitBreakerForceClosed();.	false	Boolean
camel.hystrix.circuit-breaker-request-volume-threshold	Minimum number of requests in the metricsRollingStatisticalWindowInMilliseconds() that must exist before the HystrixCircuitBreaker will trip. If below this number the circuit will not trip regardless of error percentage.	20	Integer
camel.hystrix.circuit-breaker-sleep-window-in-milliseconds	The time in milliseconds after a HystrixCircuitBreaker trips open that it should wait before trying requests again.	5000	Integer
camel.hystrix.configurations	Define additional configuration definitions.		Map

Name	Description	Default	Type
camel.hystrix.core-pool-size	Core thread-pool size that gets passed to java.util.concurrent.ThreadPoolExecutor#setCorePoolSize(int).	10	Integer
camel.hystrix.enabled	Enable the component.	true	Boolean
camel.hystrix.execution-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to HystrixCommand.run(). Requests beyond the concurrent limit will be rejected. Applicable only when executionIsolationStrategy == SEMAPHORE.	20	Integer
camel.hystrix.execution-isolation-strategy	What isolation strategy HystrixCommand.run() will be executed with. If THREAD then it will be executed on a separate thread and concurrent requests limited by the number of threads in the thread-pool. If SEMAPHORE then it will be executed on the calling thread and concurrent requests limited by the semaphore count.	THREAD	String
camel.hystrix.execution-isolation-thread-interrupt-on-timeout	Whether the execution thread should attempt an interrupt (using Future#cancel) when a thread times out. Applicable only when executionIsolationStrategy() == THREAD.	true	Boolean
camel.hystrix.execution-timeout-enabled	Whether the timeout mechanism is enabled for this command.	true	Boolean
camel.hystrix.execution-timeout-in-milliseconds	Time in milliseconds at which point the command will timeout and halt execution. If executionIsolationThreadInterruptOnTimeout == true and the command is thread-isolated, the executing thread will be interrupted. If the command is semaphore-isolated and a HystrixObservableCommand, that command will get unsubscribed.	1000	Integer
camel.hystrix.fallback-enabled	Whether HystrixCommand.getFallback() should be attempted when failure occurs.	true	Boolean
camel.hystrix.fallback-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to HystrixCommand.getFallback(). Requests beyond the concurrent limit will fail-fast and not attempt retrieving a fallback.	10	Integer

Name	Description	Default	Type
camel.hystrix.group-key	Sets the group key to use. The default value is CamelHystrix.	Camel Hystrix	String
camel.hystrix.keep-alive-time	Keep-alive time in minutes that gets passed to ThreadPoolExecutor#setKeepAliveTime(long,TimeUnit).	1	Integer
camel.hystrix.max-queue-size	Max queue size that gets passed to BlockingQueue in HystrixConcurrencyStrategy.getBlockingQueue(int) This should only affect the instantiation of a threadpool - it is not eliglible to change a queue size on the fly. For that, use queueSizeRejectionThreshold().	-1	Integer
camel.hystrix.maximum-size	Maximum thread-pool size that gets passed to ThreadPoolExecutor#setMaximumPoolSize(int) . This is the maximum amount of concurrency that can be supported without starting to reject HystrixCommands. Please note that this setting only takes effect if you also set allowMaximumSizeToDivergeFromCoreSize.	10	Integer
camel.hystrix.metrics-health-snapshot-interval-in-milliseconds	Time in milliseconds to wait between allowing health snapshots to be taken that calculate success and error percentages and affect HystrixCircuitBreaker.isOpen() status. On high-volume circuits the continual calculation of error percentage can become CPU intensive thus this controls how often it is calculated.	500	Integer
camel.hystrix.metrics-rolling-percentile-bucket-size	Maximum number of values stored in each bucket of the rolling percentile. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-percentile-enabled	Whether percentile metrics should be captured using HystrixRollingPercentile inside HystrixCommandMetrics.	true	Boolean
camel.hystrix.metrics-rolling-percentile-window-buckets	Number of buckets the rolling percentile window is broken into. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	6	Integer

Name	Description	Default	Type
camel.hystrix.metrics-rolling-percentile-window-in-milliseconds	Duration of percentile rolling window in milliseconds. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10000	Integer
camel.hystrix.metrics-rolling-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-statistical-window-in-milliseconds	This property sets the duration of the statistical rolling window, in milliseconds. This is how long metrics are kept for the thread pool. The window is divided into buckets and rolls by those increments.	10000	Integer
camel.hystrix.queue-size-rejection-threshold	Queue size rejection threshold is an artificial max size at which rejections will occur even if maxQueueSize has not been reached. This is done because the maxQueueSize of a BlockingQueue can not be dynamically changed and we want to support dynamically changing the queue size that affects rejections. This is used by HystrixCommand when queuing a thread for execution.	5	Integer
camel.hystrix.request-log-enabled	Whether HystrixCommand execution and events should be logged to HystrixRequestLog.	true	Boolean
camel.hystrix.thread-pool-key	Sets the thread pool key to use. Will by default use the same value as groupKey has been configured to use.	Camel Hystrix	String
camel.hystrix.thread-pool-rolling-number-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10	Integer
camel.hystrix.thread-pool-rolling-number-statistical-window-in-milliseconds	Duration of statistical rolling window in milliseconds. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10000	Integer
camel.language.constant.enabled	Whether to enable auto configuration of the constant language. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.language.constant.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.csimple.enabled	Whether to enable auto configuration of the csimple language. This is enabled by default.		Boolean
camel.language.csimple.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.exchangeproperty.enabled	Whether to enable auto configuration of the exchangeProperty language. This is enabled by default.		Boolean
camel.language.exchangeproperty.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.file.enabled	Whether to enable auto configuration of the file language. This is enabled by default.		Boolean
camel.language.file.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.header.enabled	Whether to enable auto configuration of the header language. This is enabled by default.		Boolean
camel.language.header.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.ref.enabled	Whether to enable auto configuration of the ref language. This is enabled by default.		Boolean
camel.language.ref.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.simple.enabled	Whether to enable auto configuration of the simple language. This is enabled by default.		Boolean
camel.language.simple.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.tokenize.enabled	Whether to enable auto configuration of the tokenize language. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.language.tokenize.group-delimiter	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.		String
camel.language.tokenize.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.resilience4j.automatic-transition-from-open-to-half-open-enabled	Enables automatic transition from OPEN to HALF_OPEN state once the waitDurationInOpenState has passed.	false	Boolean
camel.resilience4j.circuit-breaker-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreaker instance to lookup and use from the registry. When using this, then any other circuit breaker options are not in use.		String
camel.resilience4j.config-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreakerConfig instance to lookup and use from the registry.		String
camel.resilience4j.configurations	Define additional configuration definitions.		Map
camel.resilience4j.enabled	Enable the component.	true	Boolean
camel.resilience4j.failure-rate-threshold	Configures the failure rate threshold in percentage. If the failure rate is equal or greater than the threshold the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 50 percentage.		Float
camel.resilience4j.minimum-number-of-calls	Configures the minimum number of calls which are required (per sliding window period) before the CircuitBreaker can calculate the error rate. For example, if minimumNumberOfCalls is 10, then at least 10 calls must be recorded, before the failure rate can be calculated. If only 9 calls have been recorded the CircuitBreaker will not transition to open even if all 9 calls have failed. Default minimumNumberOfCalls is 100.	100	Integer

Name	Description	Default	Type
camel.resilience4j.permitted-number-of-calls-in-half-open-state	Configures the number of permitted calls when the CircuitBreaker is half open. The size must be greater than 0. Default size is 10.	10	Integer
camel.resilience4j.sliding-window-size	Configures the size of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. slidingWindowSize configures the size of the sliding window. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. The slidingWindowSize must be greater than 0. The minimumNumberOfCalls must be greater than 0. If the slidingWindowType is COUNT_BASED, the minimumNumberOfCalls cannot be greater than slidingWindowSize . If the slidingWindowType is TIME_BASED, you can pick whatever you want. Default slidingWindowSize is 100.	100	Integer
camel.resilience4j.sliding-window-type	Configures the type of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. Default slidingWindowType is COUNT_BASED.	COUNT_BASED	String
camel.resilience4j.slow-call-duration-threshold	Configures the duration threshold (seconds) above which calls are considered as slow and increase the slow calls percentage. Default value is 60 seconds.	60	Integer
camel.resilience4j.slow-call-rate-threshold	Configures a threshold in percentage. The CircuitBreaker considers a call as slow when the call duration is greater than slowCallDurationThreshold Duration. When the percentage of slow calls is equal or greater the threshold, the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 100 percentage which means that all recorded calls must be slower than slowCallDurationThreshold.		Float

Name	Description	Default	Type
camel.resilience4j.wait-duration-in-open-state	Configures the wait duration (in seconds) which specifies how long the CircuitBreaker should stay open, before it switches to half open. Default value is 60 seconds.	60	Integer
camel.resilience4j.writable-stack-trace-enabled	Enables writable stack traces. When set to false, Exception.getStackTrace returns a zero length array. This may be used to reduce log spam when the circuit breaker is open as the cause of the exceptions is already known (the circuit breaker is short-circuiting calls).	true	Boolean
camel.rest.api-component	The name of the Camel component to use as the REST API (such as swagger) If no API Component has been explicit configured, then Camel will lookup if there is a Camel component responsible for servicing and generating the REST API documentation, or if a org.apache.camel.spi.RestApiProcessorFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.api-context-path	Sets a leading API context-path the REST API services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path.		String
camel.rest.api-context-route-id	Sets the route id to use for the route that services the REST API. The route will by default use an auto assigned route id.		String
camel.rest.api-host	To use an specific hostname for the API documentation (eg swagger) This can be used to override the generated host with this configured hostname.		String
camel.rest.api-property	Allows to configure as many additional properties for the api documentation (swagger). For example set property api.title to my cool stuff.		Map
camel.rest.api-vendor-extension	Whether vendor extension is enabled in the Rest APIs. If enabled then Camel will include additional information as vendor extension (eg keys starting with x-) such as route ids, class names etc. Not all 3rd party API gateways and tools supports vendor-extensions when importing your API docs.	false	Boolean

Name	Description	Default	Type
camel.rest.binding-mode	Sets the binding mode to use. The default value is off.		RestBindingMode
camel.rest.client-request-validation	Whether to enable validation of the client request to check whether the Content-Type and Accept headers from the client is supported by the Rest-DSL configuration of its consumes/produces settings. This can be turned on, to enable this check. In case of validation error, then HTTP Status codes 415 or 406 is returned. The default value is false.	false	Boolean
camel.rest.component	The Camel Rest component to use for the REST transport (consumer), such as netty-http, jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.component-property	Allows to configure as many additional properties for the rest component in use.		Map
camel.rest.consumer-property	Allows to configure as many additional properties for the rest consumer in use.		Map
camel.rest.context-path	Sets a leading context-path the REST services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path. Or for components such as camel-jetty or camel-netty-http that includes a HTTP server.		String
camel.rest.cors-headers	Allows to configure custom CORS headers.		Map
camel.rest.data-format-property	Allows to configure as many additional properties for the data formats in use. For example set property prettyPrint to true to have json outputted in pretty mode. The properties can be prefixed to denote the option is only for either JSON or XML and for either the IN or the OUT. The prefixes are: json.in. json.out. xml.in. xml.out. For example a key with value xml.out.mustBeJAXBElement is only for the XML data format for the outgoing. A key without a prefix is a common key for all situations.		Map
camel.rest.enable-cors	Whether to enable CORS headers in the HTTP response. The default value is false.	false	Boolean

Name	Description	Default	Type
camel.rest.endpoint-property	Allows to configure as many additional properties for the rest endpoint in use.		Map
camel.rest.host	The hostname to use for exposing the REST service.		String
camel.rest.host-name-resolver	If no hostname has been explicit configured, then this resolver is used to compute the hostname the REST service will be using.		RestHostNameResolver
camel.rest.json-data-format	Name of specific json data format to use. By default json-jackson will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.port	The port number to use for exposing the REST service. Notice if you use servlet component then the port number configured here does not apply, as the port number in use is the actual port number the servlet component is using. eg if using Apache Tomcat its the tomcat http port, if using Apache Karaf its the HTTP service in Karaf that uses port 8181 by default etc. Though in those situations setting the port number here, allows tooling and JMX to know the port number, so its recommended to set the port number to the number that the servlet engine uses.		String
camel.rest.producer-api-doc	Sets the location of the api document (swagger api) the REST producer will use to validate the REST uri and query parameters are valid accordingly to the api document. This requires adding camel-swagger-java to the classpath, and any miss configuration will let Camel fail on startup and report the error(s). The location of the api document is loaded from classpath by default, but you can use file: or http: to refer to resources to load from file or http url.		String
camel.rest.producer-component	Sets the name of the Camel component to use as the REST producer.		String
camel.rest.scheme	The scheme to use for exposing the REST service. Usually http or https is supported. The default value is http.		String
camel.rest.skip-binding-on-error-code	Whether to skip binding on output if there is a custom HTTP error code header. This allows to build custom error messages that do not bind to json / xml etc, as success messages otherwise will do.	false	Boolean

Name	Description	Default	Type
camel.rest.use-x-forward-headers	Whether to use X-Forward headers for Host and related setting. The default value is true.	true	Boolean
camel.rest.xml-data-format	Name of specific XML data format to use. By default jaxb will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.api-context-id-pattern	**Deprecated** Sets an CamelContext id pattern to only allow Rest APIs from rest services within CamelContext's which name matches the pattern. The pattern name refers to the CamelContext name, to match on the current CamelContext only. For any other value, the pattern uses the rules from PatternHelper#matchPattern(String,String).		String
camel.rest.api-context-listing	**Deprecated** Sets whether listing of all available CamelContext's with REST services in the JVM is enabled. If enabled it allows to discover these contexts, if false then only the current CamelContext is in use.	false	Boolean

CHAPTER 136. VALIDATOR

Only producer is supported

The Validation component performs XML validation of the message body using the JAXP Validation API and based on any of the supported XML schema languages, which defaults to XML Schema

Note that the component also supports the following useful schema languages:

- RelaxNG Compact Syntax
- RelaxNG XML Syntax

The MSV component also supports RelaxNG XML Syntax.

136.1. DEPENDENCIES

When using **validator** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-validator-starter</artifactId>
</dependency>
```

136.2. URI FORMAT

```
validator:someLocalOrRemoteResource
```

Where **someLocalOrRemoteResource** is some URL to a local resource on the classpath or a full URL to a remote resource or resource on the file system which contains the XSD to validate against. For example:

- **msv:org/foo/bar.xsd**
- **msv:file:../foo/bar.xsd**
- **msv:http://acme.com/cheese.xsd**
- **validator:com/mypackage/myschema.xsd**

The Validation component is provided directly in the camel-core.

136.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

136.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

136.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

136.4. COMPONENT OPTIONS

The Validator component supports 3 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
resourceResolverFactory (advanced)	To use a custom LSResourceResolver which depends on a dynamic endpoint resource URI.		ValidatorResourceResolverFactory

136.5. ENDPOINT OPTIONS

The Validator endpoint is configured using URI syntax:

```
validator:resourceUri
```

with the following path and query parameters:

136.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
resourceUri (producer)	**Required** URL to a local resource on the classpath, or a reference to lookup a bean in the Registry, or a full URL to a remote resource or resource on the file system which contains the XSD to validate against.		String

136.5.2. Query Parameters (10 parameters)

Name	Description	Default	Type
failOnNullBody (producer)	Whether to fail if no body exists.	true	boolean
failOnNullHeader (producer)	Whether to fail if no header exists when validating against a header.	true	boolean
headerName (producer)	To validate against a header instead of the message body.		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
errorHandler (advanced)	To use a custom org.apache.camel.processor.validation.ValidatorErrorHandler. The default error handler captures the errors and throws an exception.		ValidatorErrorHandler
resourceResolver (advanced)	To use a custom LSResourceResolver. Do not use together with resourceResolverFactory.		LSResourceResolver
resourceResolverFactory (advanced)	To use a custom LSResourceResolver which depends on a dynamic endpoint resource URI. The default resource resolver factory resturns a resource resolver which can read files from the class path and file system. Do not use together with resourceResolver.		ValidatorResourceResolverFactory
schemaFactory (advanced)	To use a custom javax.xml.validation.SchemaFactory.		SchemaFactory
schemaLanguage (advanced)	Configures the W3C XML Schema Namespace URI.	http://www.w3.org/2001/XMLSchema	String
useSharedSchema (advanced)	Whether the Schema instance should be shared or not. This option is introduced to work around a JDK 1.6.x bug. Xerces should not have this issue.	true	boolean

136.6. EXAMPLE

The following example shows how to configure a route from endpoint **direct:start** which then goes to one of two endpoints, either **mock:valid** or **mock:invalid** based on whether or not the XML matches the given schema (which is supplied on the classpath).

136.7. ADVANCED: JMX METHOD CLEARCACHEDSCHEMA

You can force that the cached schema in the validator endpoint is cleared and reread with the next process call with the JMX operation **clearCachedSchema**. You can also use this method to programmatically clear the cache. This method is available on the **ValidatorEndpoint** class.

136.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.validator.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.validator.enabled	Whether to enable auto configuration of the validator component. This is enabled by default.		Boolean
camel.component.validator.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.validator.resource-resolver-factory	To use a custom LSResourceResolver which depends on a dynamic endpoint resource URI. The option is a org.apache.camel.component.validator.ValidatorResourceResolverFactory type.		ValidatorResourceResolverFactory

CHAPTER 137. VELOCITY

Since Camel 1.2

Only producer is supported

The Velocity component allows you to process a message using an Apache Velocity template. This can be ideal when using a template to generate responses for requests.

137.1. DEPENDENCIES

When using **velocity** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-velocity-starter</artifactId>
</dependency>
```

137.2. URI FORMAT

```
velocity:templateName[?options]
```

Where **templateName** is the classpath-local URI of the template to invoke; or the complete URL of the remote template (for example, file://folder/myfile.vm).

137.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

137.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

137.3.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

137.4. COMPONENT OPTIONS

The Velocity component supports 5 options, which are listed below.

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so impose a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this allows to specify dynamic templates via message header. However this can be seen as a potential security vulnerability if the header is coming from a malicious user, so use this with care.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
velocityEngine (advanced)	To use the VelocityEngine otherwise a new engine is created.		VelocityEngine

137.5. ENDPOINT OPTIONS

The Velocity endpoint is configured using URI syntax:

```
velocity:resourceUri
```

with the following path and query parameters:

137.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
resourceUri (producer)	**Required** Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

137.5.2. Query Parameters (7 parameters)

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so impose a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this allows to specify dynamic templates via message header. However this can be seen as a potential security vulnerability if the header is coming from a malicious user, so use this with care.	false	boolean
contentCache (producer)	Sets whether to use resource content cache or not.	false	boolean
encoding (producer)	Character encoding of the resource content.		String
loaderCache (producer)	Enables / disables the velocity resource loader cache which is enabled by default.	true	boolean

Name	Description	Default	Type
propertiesFile (producer)	The URI of the properties file which is used for VelocityEngine initialization.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

137.6. MESSAGE HEADERS

The Velocity component supports 4 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelVelocityResourceUri (producer) Constant: VELOCITY_RESOURCE_URI	The name of the velocity template.		String
CamelVelocityTemplate (producer) Constant: VELOCITY_TEMPLATE	The content of the velocity template.		String
CamelVelocityContext (producer) Constant: VELOCITY_CONTEXT	The velocity context to use.		Context

Name	Description	Default	Type
CamelVelocitySupplementalContext (producer) Constant: VELOCITY_SUPPLEMENTAL_CONTEXT	To add additional information to the used VelocityContext. The value of this header should be a Map with key/values that will added (override any existing key with the same name). This can be used to pre setup some common key/values you want to reuse in your velocity endpoints.		Map

Headers set during the Velocity evaluation are returned to the message and added as headers. Then it is possible to return values from Velocity to the Message.

For example, to set the header value of **fruit** in the Velocity template **.tm**:

```
$in.setHeader("fruit", "Apple")
```

The **fruit** header is now accessible from the **message.out.headers**.

137.7. VELOCITY CONTEXT

Camel will provide exchange information in the Velocity context (just a **Map**). The **Exchange** is transfered as:

key	value
exchange	The **Exchange** itself.
exchange.properties	The **Exchange** properties.
headers	The headers of the In message.
camelContext	The Camel Context instance.
request	The In message.
in	The In message.
body	The In message body.

key	value
out	The Out message (only for InOut message exchange pattern).
response	The Out message (only for InOut message exchange pattern).

You can setup a custom Velocity Context yourself by setting property **allowTemplateFromHeader=true** and setting the message header **CamelVelocityContext** just like this

```
VelocityContext velocityContext = new VelocityContext(variableMap);
exchange.getIn().setHeader("CamelVelocityContext", velocityContext);
```

137.8. HOT RELOADING

The Velocity template resource is, by default, hot reloadable for both file and classpath resources (expanded jar). If you set **contentCache=true**, Camel will only load the resource once, and thus hot reloading is not possible. This scenario can be used in production, when the resource never changes.

137.9. DYNAMIC TEMPLATES

Since Camel 2.1
Camel provides two headers by which you can define a different resource location for a template or the template content itself. If any of these headers is set then Camel uses this over the endpoint configured resource. This allows you to provide a dynamic template at runtime.

Header	Type	Description
CamelVelocityResourceUri	String	A URI for the template resource to use instead of the endpoint configured.
CamelVelocityTemplate	String	The template to use instead of the endpoint configured.

137.10. SAMPLES

For example, you can use:

```
from("activemq:My.Queue").
  to("velocity:com/acme/MyResponse.vm");
```

To use a Velocity template to formulate a response to a message for **InOut** message exchanges (where there is a **JMSReplyTo** header).

If you want to use **InOnly** and consume the message and send it to another destination, you could use the following route:

```
from("activemq:My.Queue").
  to("velocity:com/acme/MyResponse.vm").
  to("activemq:Another.Queue");
```

And to use the content cache, for example, for use in production, where the **.vm** template never changes:

```
from("activemq:My.Queue").
  to("velocity:com/acme/MyResponse.vm?contentCache=true").
  to("activemq:Another.Queue");
```

And a file based resource:

```
from("activemq:My.Queue").
  to("velocity:file://myfolder/MyResponse.vm?contentCache=true").
  to("activemq:Another.Queue");
```

It is possible to specify which template the component should use dynamically via a header, for example:

```
from("direct:in").
  setHeader("CamelVelocityResourceUri").constant("path/to/my/template.vm").
  to("velocity:dummy?allowTemplateFromHeader=true"");
```

It is possible to specify a template directly as a header the component should use dynamically via a header, so for example:

```
from("direct:in").
  setHeader("CamelVelocityTemplate").constant("Hi this is a velocity template that can do templating ${body}").
  to("velocity:dummy?allowTemplateFromHeader=true"");
```

137.11. THE EMAIL SAMPLE

In this sample, to use the Velocity templating for an order confirmation email. The email template is laid out in Velocity as:

letter.vm

```
Dear ${headers.lastName}, ${headers.firstName}

Thanks for the order of ${headers.item}.

Regards Camel Riders Bookstore
${body}
```

And the java code (from an unit test):

```
    private Exchange createLetter() {
        Exchange exchange = context.getEndpoint("direct:a").createExchange();
        Message msg = exchange.getIn();
```

```
        msg.setHeader("firstName", "Claus");
        msg.setHeader("lastName", "Ibsen");
        msg.setHeader("item", "Camel in Action");
        msg.setBody("PS: Next beer is on me, James");
        return exchange;
    }

    @Test
    public void testVelocityLetter() throws Exception {
        MockEndpoint mock = getMockEndpoint("mock:result");
        mock.expectedMessageCount(1);
        mock.message(0).body(String.class).contains("Thanks for the order of Camel in Action");

        template.send("direct:a", createLetter());

        mock.assertIsSatisfied();
    }

    @Override
    protected RouteBuilder createRouteBuilder() {
        return new RouteBuilder() {
            public void configure() {
                from("direct:a")
                    .to("velocity:org/apache/camel/component/velocity/letter.vm")
                    .to("mock:result");
            }
        };
    }
```

137.12. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component.velocity.allow-context-map-all	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so impose a potential security risk as this opens access to the full power of CamelContext API.	false	Boolean
camel.component.velocity.allow-template-from-header	Whether to allow to use resource template from header or not (default false). Enabling this allows to specify dynamic templates via message header. However this can be seen as a potential security vulnerability if the header is coming from a malicious user, so use this with care.	false	Boolean

Name	Description	Default	Type
camel.component.velocity.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.velocity.enabled	Whether to enable auto configuration of the velocity component. This is enabled by default.		Boolean
camel.component.velocity.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.velocity.velocity-engine	To use the VelocityEngine otherwise a new engine is created. The option is a org.apache.velocity.app.VelocityEngine type.		VelocityEngine

CHAPTER 138. VERT.X HTTP CLIENT

Since Camel 3.5

Only producer is supported

The Vert.x HTTP component provides the capability to produce messages to HTTP endpoints via the Vert.x Web Client.

138.1. DEPENDENCIES

When using **vertx-http** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-vertx-http-starter</artifactId>
</dependency>
```

138.2. URI FORMAT

```
vertx-http:hostname[:port][/resourceUri][?options]
```

138.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

138.3.1. Configuring component options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

138.3.2. Configuring endpoint options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL and DataFormat DSL as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

138.4. COMPONENT OPTIONS

The Vert.x HTTP Client component supports 19 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
responsePayloadAsByteArray (producer)	Whether the response body should be byte or as io.vertx.core.buffer.Buffer.	true	boolean
allowJavaSerializedObject (advanced)	Whether to allow java serialization when a request has the Content-Type application/x-java-serialized-object This is disabled by default. If you enable this, be aware that Java will deserialize the incoming data from the request. This can be a potential security risk.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
vertx (advanced)	To use an existing vertx instead of creating a new instance.		Vertx
vertxHttpBinding (advanced)	A custom VertxHttpBinding which can control how to bind between Vert.x and Camel.		VertxHttpBinding

Name	Description	Default	Type
vertxOptions (advanced)	To provide a custom set of vertx options for configuring vertx.		VertxOptions
webClientOptions (advanced)	To provide a custom set of options for configuring vertx web client.		WebClientOptions
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
proxyHost (proxy)	The proxy server host address.		String
proxyPassword (proxy)	The proxy server password if authentication is required.		String
proxyPort (proxy)	The proxy server port.		Integer
proxyType (proxy)	The proxy server type. Enum values: • HTTP • SOCKS4 • SOCKS5		ProxyType
proxyUsername (proxy)	The proxy server username if authentication is required.		String
basicAuthPassword (security)	The password to use for basic authentication.		String
basicAuthUsername (security)	The user name to use for basic authentication.		String
bearerToken (security)	The bearer token to use for bearer token authentication.		String
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

138.5. ENDPOINT OPTIONS

The Vert.x HTTP Client endpoint is configured using URI syntax:

```
vertx-http:httpUri
```

with the following path and query parameters:

138.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
httpUri (producer)	**Required** The HTTP URI to connect to.		URI

138.5.2. Query Parameters (23 parameters)

Name	Description	Default	Type
connectTimeout (producer)	The amount of time in milliseconds until a connection is established. A timeout value of zero is interpreted as an infinite timeout.	60000	int
cookieStore (producer)	A custom CookieStore to use when session management is enabled. If this option is not set then an in-memory CookieStore is used.	InMemoryCookieStore	CookieStore
headerFilterStrategy (producer)	A custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.	VertxHttpHeaderFilterStrategy	HeaderFilterStrategy
httpMethod (producer)	The HTTP method to use. The HttpMethod header cannot override this option if set.		HttpMethod
okStatusCodeRange (producer)	The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included.	200-299	String
responsePayloadAsByteArray (producer)	Whether the response body should be byte or as io.vertx.core.buffer.Buffer.	true	boolean

Name	Description	Default	Type
sessionManagement (producer)	Enables session management via WebClientSession. By default the client is configured to use an in-memory CookieStore. The cookieStore option can be used to override this.	false	boolean
throwExceptionOnFailure (producer)	Disable throwing HttpOperationFailedException in case of failed responses from the remote server.	true	boolean
timeout (producer)	The amount of time in milliseconds after which if the request does not return any data within the timeout period a TimeoutException fails the request. Setting zero or a negative value disables the timeout.	-1	long
transferException (producer)	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was sent back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of HttpOperationFailedException. The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Camel will deserialize the incoming data from the request to a Java object, which can be a potential security risk.	false	boolean
useCompression (producer)	Set whether compression is enabled to handled compressed (E.g gzipped) responses.	false	boolean
vertxHttpBinding (producer)	A custom VertxHttpBinding which can control how to bind between Vert.x and Camel.		VertxHttpBinding
webClientOptions (producer)	Sets customized options for configuring the Vert.x WebClient.		WebClientOptions
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
proxyHost (proxy)	The proxy server host address.		String
proxyPassword (proxy)	The proxy server password if authentication is required.		String
proxyPort (proxy)	The proxy server port.		Integer
proxyType (proxy)	The proxy server type. Enum values: • HTTP • SOCKS4 • SOCKS5		ProxyType
proxyUsername (proxy)	The proxy server username if authentication is required.		String
basicAuthPassword (security)	The password to use for basic authentication.		String
basicAuthUsername (security)	The user name to use for basic authentication.		String
bearerToken (security)	The bearer token to use for bearer token authentication.		String
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters

138.6. MESSAGE HEADERS

The Vert.x HTTP Client component supports 8 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelHttpMethod (producer) Constant: HTTP_METHOD	The http method.		HttpMethod

Name	Description	Default	Type
CamelHttpResponseCode (producer) Constant: HTTP_RESPONSE_CODE	The HTTP response code from the external server.		Integer
CamelHttpResponseText (producer) Constant: HTTP_RESPONSE_TEXT	The HTTP response text from the external server.		String
Content-Type (producer) Constant: CONTENT_TYPE	The HTTP content type. Is set on both the IN and OUT message to provide a content type, such as text/html.		String
CamelHttpQuery (producer) Constant: HTTP_QUERY	URI parameters. Will override existing URI parameters set directly on the endpoint.		String
CamelHttpUri (producer) Constant: HTTP_URI	URI to call. Will override the existing URI set directly on the endpoint. This URI is the URI of the http server to call. Its not the same as the Camel endpoint URI, where you can configure endpoint options such as security etc. This header does not support that, its only the URI of the http server.		String
CamelHttpPath (producer) Constant: HTTP_PATH	Request URI's path, the header will be used to build the request URI with the HTTP_URI.		String
Content-Encoding (producer) Constant: CONTENT_ENCODING	The HTTP content encoding. Is set to provide a content encoding, such as gzip.		String

138.7. USAGE

The following example shows how to send a request to an HTTP endpoint.

You can override the URI configured on the **vertx-http** producer via headers **Exchange.HTTP_URI** and **Exchange.HTTP_PATH**.

```
from("direct:start")
    .to("vertx-http:https://camel.apache.org");
```

138.8. URI PARAMETERS

The **vertx-http** producer supports URI parameters to be sent to the HTTP server. The URI parameters can either be set directly on the endpoint URI, or as a header with the key **Exchange.HTTP_QUERY** on the message.

138.9. RESPONSE CODE

Camel will handle according to the HTTP response code:

- Response code is in the range 100..299, Camel regards it as a success response.
- Response code is in the range 300..399, Camel regards it as a redirection response and will throw a **HttpOperationFailedException** with the information.
- Response code is 400+, Camel regards it as an external server failure and will throw a **HttpOperationFailedException** with the information.

138.10. THROWEXCEPTIONONFAILURE

The option, **throwExceptionOnFailure**, can be set to **false** to prevent the **HttpOperationFailedException** from being thrown for failed response codes. This allows you to get any response from the remote server.

138.11. EXCEPTIONS

HttpOperationFailedException exception contains the following information:

- The HTTP status code
- The HTTP status line (text of the status code)
- Redirect location, if server returned a redirect
- Response body as a **java.lang.String**, if server provided a body as response

138.12. HTTP METHOD

The following algorithm determines the HTTP method to be used:

1. Use method provided as endpoint configuration (**httpMethod**).
2. Use method provided in header (**Exchange.HTTP_METHOD**).
3. **GET** if query string is provided in header.

4. **GET** if endpoint is configured with a query string.
5. **POST** if there is data to send (body is not **null**).
6. **GET** otherwise.

138.13. HTTP FORM PARAMETERS

You can send HTTP form parameters in one of two ways.

1. Set the **Exchange.CONTENT_TYPE** header to the value **application/x-www-form-urlencoded** and ensure the message body is a **String** formatted as form variables. For example, **param1=value1&param2=value2**.
2. Set the message body as a MultiMap which allows you to configure form parameter names and values.

138.14. MULTIPART FORM DATA

You can upload text or binary files by setting the message body as a MultipartForm.

138.15. CUSTOMIZING VERT.X WEB CLIENT OPTIONS

When finer control of the Vert.x Web Client configuration is required, you can bind a custom WebClientOptions instance to the registry.

```
WebClientOptions options = new WebClientOptions().setMaxRedirects(5)
    .setIdleTimeout(10)
    .setConnectTimeout(3);

camelContext.getRegistry.bind("clientOptions", options);
```

Then reference the options on the **vertx-http** producer.

```
from("direct:start")
    .to("vertx-http:http://localhost:8080?webClientOptions=#clientOptions")
```

138.15.1. SSL

The Vert.x HTTP component supports SSL/TLS configuration through the Camel JSSE Configuration Utility .

It is also possible to configure SSL options by providing a custom **WebClientOptions**.

138.16. SESSION MANAGEMENT

Session management can be enabled via the **sessionManagement** URI option. When enabled, an in-memory cookie store is used to track cookies. This can be overridden by providing a custom **CookieStore** via the **cookieStore** URI option.

138.17. SPRING BOOT AUTO-CONFIGURATION

The component supports 20 options, which are listed below.

Name	Description	Default	Type
camel.component.vertx-http.allow-java-serialized-object	Whether to allow java serialization when a request has the Content-Type application/x-java-serialized-object This is disabled by default. If you enable this, be aware that Java will deserialize the incoming data from the request. This can be a potential security risk.	false	Boolean
camel.component.vertx-http.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.vertx-http.basic-auth-password	The password to use for basic authentication.		String
camel.component.vertx-http.basic-auth-username	The user name to use for basic authentication.		String
camel.component.vertx-http.bearer-token	The bearer token to use for bearer token authentication.		String
camel.component.vertx-http.enabled	Whether to enable auto configuration of the vertx-http component. This is enabled by default.		Boolean
camel.component.vertx-http.header-filter-strategy	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		HeaderFilterStrategy
camel.component.vertx-http.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.vertx-http.proxy-host	The proxy server host address.		String
camel.component.vertx-http.proxy-password	The proxy server password if authentication is required.		String
camel.component.vertx-http.proxy-port	The proxy server port.		Integer
camel.component.vertx-http.proxy-type	The proxy server type.		ProxyType
camel.component.vertx-http.proxy-username	The proxy server username if authentication is required.		String
camel.component.vertx-http.response-payload-as-byte-array	Whether the response body should be byte or as io.vertx.core.buffer.Buffer.	true	Boolean
camel.component.vertx-http.ssl-context-parameters	To configure security using SSLContextParameters. The option is a org.apache.camel.support.jsse.SSLContextParameters type.		SSLContextParameters
camel.component.vertx-http.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.vertx-http.vertx	To use an existing vertx instead of creating a new instance. The option is a io.vertx.core.Vertx type.		Vertx
camel.component.vertx-http.vertx-http-binding	A custom VertxHttpBinding which can control how to bind between Vert.x and Camel. The option is a org.apache.camel.component.vertx.http.VertxHttpBinding type.		VertxHttpBinding

Name	Description	Default	Type
camel.component.vertx-http.vertx-options	To provide a custom set of vertx options for configuring vertx. The option is a io.vertx.core.VertxOptions type.		VertxOptions
camel.component.vertx-http.web-client-options	To provide a custom set of options for configuring vertx web client. The option is a io.vertx.ext.web.client.WebClientOptions type.		WebClientOptions

CHAPTER 139. VERT.X WEBSOCKET

Since Camel 3.5

Both producer and consumer are supported

The http://vertx.io/Vertx] WebSocket component provides WebSocket capabilities as a WebSocket server, or as a client to connect to an existing WebSocket.

139.1. DEPENDENCIES

When using **vertx-websocket** with Red Hat build of Camel Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-vertx-websocket-starter</artifactId>
</dependency>
```

139.2. URI FORMAT

```
vertx-websocket://hostname[:port][/resourceUri][?options]
```

139.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

139.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

139.3.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

139.4. COMPONENT OPTIONS

The Vert.x WebSocket component supports 11 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
allowOriginHeader (advanced)	Whether the WebSocket client should add the Origin header to the WebSocket handshake request.	true	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
defaultHost (advanced)	Default value for host name that the WebSocket should bind to.	0.0.0.0	String
defaultPort (advanced)	Default value for the port that the WebSocket should bind to.	0	int

Name	Description	Default	Type
originHeaderUrl (advanced)	The value of the Origin header that the WebSocket client should use on the WebSocket handshake request. When not specified, the WebSocket client will automatically determine the value for the Origin from the request URL.		String
router (advanced)	To provide a custom vertx router to use on the WebSocket server.		Router
vertx (advanced)	To use an existing vertx instead of creating a new instance.		Vertx
vertxOptions (advanced)	To provide a custom set of vertx options for configuring vertx.		VertxOptions
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

139.5. ENDPOINT OPTIONS

The Vert.x WebSocket endpoint is configured using URI syntax:

```
vertx-websocket:host:port/path
```

with the following path and query parameters:

139.5.1. Path Parameters (3 parameters)

Name	Description	Default	Type
host (common)	**Required** WebSocket hostname, such as localhost or a remote host when in client mode.		String
port (common)	**Required** WebSocket port number to use.		int
path (common)	WebSocket path to use.		String

139.5.2. Query Parameters (18 parameters)

Name	Description	Default	Type
allowedOriginPattern (consumer)	Regex pattern to match the origin header sent by WebSocket clients.		String
allowOriginHeader (consumer)	Whether the WebSocket client should add the Origin header to the WebSocket handshake request.	true	boolean
consumeAsClient (consumer)	When set to true, the consumer acts as a WebSocket client, creating exchanges on each received WebSocket event.	false	boolean
fireWebSocketConnectionEvents (consumer)	Whether the server consumer will create a message exchange when a new WebSocket peer connects or disconnects.	false	boolean
maxReconnectAttempts (consumer)	When consumeAsClient is set to true this sets the maximum number of allowed reconnection attempts to a previously closed WebSocket. A value of 0 (the default) will attempt to reconnect indefinitely.	0	int
originHeaderUrl (consumer)	The value of the Origin header that the WebSocket client should use on the WebSocket handshake request. When not specified, the WebSocket client will automatically determine the value for the Origin from the request URL.		String
reconnectInitialDelay (consumer)	When consumeAsClient is set to true this sets the initial delay in milliseconds before attempting to reconnect to a previously closed WebSocket.	0	int
reconnectInterval (consumer)	When consumeAsClient is set to true this sets the interval in milliseconds at which reconnecting to a previously closed WebSocket occurs.	1000	int
router (consumer)	To use an existing vertx router for the HTTP server.		Router
serverOptions (consumer)	Sets customized options for configuring the HTTP server hosting the WebSocket for the consumer.		HttpServerOptions
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
clientOptions (producer)	Sets customized options for configuring the WebSocket client used in the producer.		HttpClientOptions
clientSubProtocols (producer)	Comma separated list of WebSocket subprotocols that the client should use for the Sec-WebSocket-Protocol header.		String
sendToAll (producer)	To send to all websocket subscribers. Can be used to configure at the endpoint level, instead of providing the VertxWebsocketConstants.SEND_TO_ALL header on the message. Note that when using this option, the host name specified for the vertx-websocket producer URI must match one used for an existing vertx-websocket consumer. Note that this option only applies when producing messages to endpoints hosted by the vertx-websocket consumer and not to an externally hosted WebSocket.	false	boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters

139.6. MESSAGE HEADERS

The Vert.x WebSocket component supports 4 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelVertxWebsocket.connectionKey (common) Constant: CONNECTION_KEY	Sends the message to the client with the given connection key. You can use a comma separated list of keys to send a message to multiple clients. Note that this option only applies when producing messages to endpoints hosted by the vertx-websocket consumer and not to an externally hosted WebSocket.		String
CamelVertxWebsocket.sendToAll (producer) Constant: SEND_TO_ALL	Sends the message to all clients which are currently connected. You can use the sendToAll option on the endpoint instead of using this header. Note that this option only applies when producing messages to endpoints hosted by the vertx-websocket consumer and not to an externally hosted WebSocket.		boolean
CamelVertxWebsocket.remoteAddress (consumer) Constant: REMOTE_ADDRESS	The remote address.		SocketAddress
CamelVertxWebsocket.event (consumer) Constant: EVENT	The WebSocket event that triggered the message exchange. Enum values: • CLOSE • ERROR • MESSAGE • OPEN		VertxWebsocketEvent

139.7. USAGE

The following example shows how to expose a WebSocket on http://localhost:8080/echo and returns an 'echo' response back to the same channel:

```
from("vertx-websocket:localhost:8080/echo")
    .transform().simple("Echo: ${body}")
    .to("vertx-websocket:localhost:8080/echo");
```

It is also possible to configure the consumer to connect as a WebSocket client on a remote address with the **consumeAsClient** option:

```
from("vertx-websocket:my.websocket.com:8080/chat?consumeAsClient=true")
    .log("Got WebSocket message ${body}");
```

139.8. PATH AND QUERY PARAMETERS

The WebSocket server consumer supports the configuration of parameterized paths. The path parameter value will be set as a Camel exchange header:

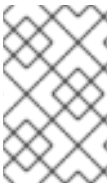
```
from("vertx-websocket:localhost:8080/chat/{user}")
    .log("New message from ${header.user} >>> ${body}")
```

You can also retrieve any query parameter values that were used by the WebSocket client to connect to the server endpoint:

```
from("direct:sendChatMessage")
    .to("vertx-websocket:localhost:8080/chat/camel?role=admin");

from("vertx-websocket:localhost:8080/chat/{user}")
    .log("New message from ${header.user} (${header.role}) >>> ${body}")
```

139.9. SENDING MESSAGES TO PEERS CONNECTED TO THE VERTX-WEBSOCKET SERVER CONSUMER



NOTE

This section only applies when producing messages to a WebSocket hosted by the camel-vertx-websocket consumer. It is not relevant when producing messages to an externally hosted WebSocket.

To send a message to all peers connected to a WebSocket hosted by the vertx-websocket server consumer, use the **sendToAll=true** endpoint option, or the **CamelVertxWebsocket.sendToAll** header.

```
from("vertx-websocket:localhost:8080/chat")
    .log("Got WebSocket message ${body}");

from("direct:broadcastMessage")
    .setBody().constant("This is a broadcast message!")
    .to("vertx-websocket:localhost:8080/chat?sendToAll=true");
```

Alternatively, you can send messages to specific peers by using the **CamelVertxWebsocket.connectionKey** header. Multiple peers can be specified as a comma separated list.

The value of the **connectionKey** can be determined whenever a peer triggers an event on the vertx-websocket consumer, where a unique key identifying the peer will be propagated via the **CamelVertxWebsocket.connectionKey** header.

```
from("vertx-websocket:localhost:8080/chat")
```

```
    .log("Got WebSocket message ${body}");

from("direct:broadcastMessage")
    .setBody().constant("This is a broadcast message!")
    .setHeader(VertxWebsocketConstants.CONNECTION_KEY).constant("key-1,key-2,key-3")
    .to("vertx-websocket:localhost:8080/chat");
```

139.10. SSL

By default, the **ws://** protocol is used, but secure connections with **wss://** are supported by configuring the consumer or producer via the **sslContextParameters** URI parameter and the Camel JSSE Configuration Utility.

139.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 12 options, which are listed below.

Name	Description	Default	Type
camel.component.vertx-websocket.allow-origin-header	Whether the WebSocket client should add the Origin header to the WebSocket handshake request.	true	Boolean
camel.component.vertx-websocket.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.vertx-websocket.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.vertx-websocket.default-host	Default value for host name that the WebSocket should bind to.	0.0.0.0	String
camel.component.vertx-websocket.default-port	Default value for the port that the WebSocket should bind to.	0	Integer

Name	Description	Default	Type
camel.component.vertx-websocket.enabled	Whether to enable auto configuration of the vertx-websocket component. This is enabled by default.		Boolean
camel.component.vertx-websocket.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.vertx-websocket.origin-header-url	The value of the Origin header that the WebSocket client should use on the WebSocket handshake request. When not specified, the WebSocket client will automatically determine the value for the Origin from the request URL.		String
camel.component.vertx-websocket.router	To provide a custom vertx router to use on the WebSocket server. The option is a io.vertx.ext.web.Router type.		Router
camel.component.vertx-websocket.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.vertx-websocket.vertx	To use an existing vertx instead of creating a new instance. The option is a io.vertx.core.Vertx type.		Vertx
camel.component.vertx-websocket.vertx-options	To provide a custom set of vertx options for configuring vertx. The option is a io.vertx.core.VertxOptions type.		VertxOptions

CHAPTER 140. WEBHOOK

Only consumer is supported

The Webhook meta component allows other Camel components to configure webhooks on a remote webhook provider and listening for them.

The following components currently provide webhook endpoints:

- **Telegram**

Typically, other components that support webhook will bring this dependency transitively.

140.1. DEPENDENCIES

When using **webhook** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-webhook-starter</artifactId>
</dependency>
```

140.2. URI FORMAT

```
webhook:endpoint[?options]
```

140.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

140.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

140.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

140.4. COMPONENT OPTIONS

The Webhook component supports 8 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
webhookAutoRegister (consumer)	Automatically register the webhook at startup and unregister it on shutdown.	true	boolean
webhookBasePath (consumer)	The first (base) path element where the webhook will be exposed. It's a good practice to set it to a random string, so that it cannot be guessed by unauthorized parties.		String
webhookComponentName (consumer)	The Camel Rest component to use for the REST transport, such as netty-http.		String
webhookExternalUrl (consumer)	The URL of the current service as seen by the webhook provider.		String
webhookPath (consumer)	The path where the webhook endpoint will be exposed (relative to basePath, if any).		String
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
configuration (advanced)	Set the default configuration for the webhook meta-component.		WebhookConfiguration

140.5. ENDPOINT OPTIONS

The Webhook endpoint is configured using URI syntax:

```
webhook:endpointUri
```

with the following path and query parameters:

140.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
endpointUri (consumer)	**Required** The delegate uri. Must belong to a component that supports webhooks.		String

140.5.2. Query Parameters (8 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
webhookAutoRegister (consumer)	Automatically register the webhook at startup and unregister it on shutdown.	true	boolean
webhookBasePath (consumer)	The first (base) path element where the webhook will be exposed. It's a good practice to set it to a random string, so that it cannot be guessed by unauthorized parties.		String
webhookComponentName (consumer)	The Camel Rest component to use for the REST transport, such as netty-http.		String

Name	Description	Default	Type
webhookExternalUrl (consumer)	The URL of the current service as seen by the webhook provider.		String
webhookPath (consumer)	The path where the webhook endpoint will be exposed (relative to basePath, if any).		String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern

140.6. EXAMPLES

Examples of webhook component are provided in the documentation of the delegate components that support it.

140.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 9 options, which are listed below.

Name	Description	Default	Type
camel.component.webhook.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.webhook.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.webhook.configuration	Set the default configuration for the webhook meta-component. The option is a org.apache.camel.component.webhook.WebhookConfiguration type.		WebhookConfiguration
camel.component.webhook.enabled	Whether to enable auto configuration of the webhook component. This is enabled by default.		Boolean
camel.component.webhook.webhook-auto-register	Automatically register the webhook at startup and unregister it on shutdown.	true	Boolean
camel.component.webhook.webhook-base-path	The first (base) path element where the webhook will be exposed. It's a good practice to set it to a random string, so that it cannot be guessed by unauthorized parties.		String
camel.component.webhook.webhook-component-name	The Camel Rest component to use for the REST transport, such as netty-http.		String
camel.component.webhook.webhook-external-url	The URL of the current service as seen by the webhook provider.		String
camel.component.webhook.webhook-path	The path where the webhook endpoint will be exposed (relative to basePath, if any).		String

CHAPTER 141. XJ

Since Camel 3.0

Only producer is supported

The XJ component allows you to convert XML and JSON documents directly forth and back without the need of intermediate java objects. You can even specify an XSLT stylesheet to convert directly to the target JSON / XML (domain) model.

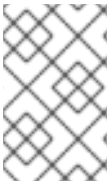
141.1. DEPENDENCIES

When using **xj** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-xj-starter</artifactId>
</dependency>
```

141.2. URI FORMAT

```
xj:templateName?transformDirection=XML2JSON|JSON2XML[&options]
```



NOTE

The XJ component extends the XSLT component and therefore it supports all options provided by the XSLT component as well. At least look at the XSLT component documentation how to configure the xsl template.

The **transformDirection** option is mandatory and must be either XML2JSON or JSON2XML. The **templateName** parameter allows to use *identify transforma* by specifying the name **identity**.

141.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

141.3.1. Configuring component options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

141.3.2. Configuring endpoint options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL and DataFormat DSL as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

141.4. COMPONENT OPTIONS

The XJ component supports 11 options, which are listed below.

Name	Description	Default	Type
contentCache (producer)	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
saxonConfiguration (advanced)	To use a custom Saxon configuration.		Configuration
saxonConfigurationProperties (advanced)	To set custom Saxon configuration properties.		Map
saxonExtensionFunctions (advanced)	Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can use commas to separate multiple values to lookup.		String
secureProcessing (advanced)	Feature for XML secure processing (see javax.xml.XMLConstants). This is enabled by default. However, when using Saxon Professional you may need to turn this off to allow Saxon to be able to use Java extension functions.	true	boolean
transformerFactoryClass (advanced)	To use a custom XSLT transformer factory, specified as a FQN class name.		String
transformerFactoryConfigurationStrategy (advanced)	A configuration strategy to apply on freshly created instances of TransformerFactory.		TransformerFactoryConfigurationStrategy
uriResolver (advanced)	To use a custom UriResolver. Should not be used together with the option 'uriResolverFactory'.		URIResolver
uriResolverFactory (advanced)	To use a custom UriResolver which depends on a dynamic endpoint resource URI. Should not be used together with the option 'uriResolver'.		XsltUriResolverFactory

141.5. ENDPOINT OPTIONS

The XJ endpoint is configured using URI syntax:

```
xj:resourceUri
```

with the following path and query parameters:

141.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
resourceUri (producer)	**Required** Path to the template. The following is supported by the default URIResolver. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

141.5.2. Query Parameters (19 parameters)

Name	Description	Default	Type
allowStAX (producer)	Whether to allow using StAX as the javax.xml.transform.Source. You can enable this if the XSLT library supports StAX such as the Saxon library (camel-saxon). The Xalan library (default in JVM) does not support StAXSource.	true	boolean
contentCache (producer)	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	boolean
deleteOutputFile (producer)	If you have output=file then this option dictates whether or not the output file should be deleted when the Exchange is done processing. For example suppose the output file is a temporary file, then it can be a good idea to delete it after use.	false	boolean
failOnNullBody (producer)	Whether or not to throw an exception if the input body is null.	true	boolean

Name	Description	Default	Type
output (producer)	Option to specify which output type to use. Possible values are: string, bytes, DOM, file. The first three options are all in memory based, where as file is streamed directly to a java.io.File. For file you must specify the filename in the IN header with the key XsltConstants.XSLT_FILE_NAME which is also CamelXsltFileName. Also any paths leading to the filename must be created beforehand, otherwise an exception is thrown at runtime. Enum values: • string • bytes • DOM • file	string	XsltOutput
transformDirection (producer)	**Required** Transform direction. Either XML2JSON or JSON2XML. Enum values: • XML2JSON • JSON2XML		TransformDirection
transformerCacheSize (producer)	The number of javax.xml.transform.Transformer object that are cached for reuse to avoid calls to Template.newTransformer().	0	int
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
entityResolver (advanced)	To use a custom org.xml.sax.EntityResolver with javax.xml.transform.sax.SAXSource.		EntityResolver

Name	Description	Default	Type
errorListener (advanced)	Allows to configure to use a custom javax.xml.transform.ErrorListener. Beware when doing this then the default error listener which captures any errors or fatal errors and store information on the Exchange as properties is not in use. So only use this option for special use-cases.		ErrorListener
resultHandlerFactory (advanced)	Allows you to use a custom org.apache.camel.builder.xml.ResultHandlerFactory which is capable of using custom org.apache.camel.builder.xml.ResultHandler types.		ResultHandlerFactory
saxonConfiguration (advanced)	To use a custom Saxon configuration.		Configuration
saxonExtensionFunctions (advanced)	Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can comma to separate multiple values to lookup.		String
secureProcessing (advanced)	Feature for XML secure processing (see javax.xml.XMLConstants). This is enabled by default. However, when using Saxon Professional you may need to turn this off to allow Saxon to be able to use Java extension functions.	true	boolean
transformerFactory (advanced)	To use a custom XSLT transformer factory.		TransformerFactory
transformerFactoryClass (advanced)	To use a custom XSLT transformer factory, specified as a FQN class name.		String
transformerFactoryConfigurationStrategy (advanced)	A configuration strategy to apply on freshly created instances of TransformerFactory.		TransformerFactoryConfigurationStrategy
uriResolver (advanced)	To use a custom javax.xml.transform.URIResolver.		URIResolver
xsltMessageLogger (advanced)	A consumer to messages generated during XSLT transformations.		XsltMessageLogger

141.6. MESSAGE HEADERS

The XJ component supports 1 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelXsltFileName (producer) Constant: XSLT_FILE_NAME	The XSLT file name.		String

141.7. USING XJ ENDPOINTS

141.7.1. Converting JSON to XML

The following route does an "identity" transform of the message because no xslt stylesheet is given. In the context of xml to xml transformations, "Identity" transform means that the output document is just a copy of the input document. In case of XJ it means it transforms the json document to an equivalent xml representation.

```
from("direct:start").
  to("xj:identity?transformDirection=JSON2XML");
```

Sample:

The input:

```
{
  "firstname": "camel",
  "lastname": "apache",
  "personalnumber": 42,
  "active": true,
  "ranking": 3.1415926,
  "roles": [
    "a",
    {
      "x": null
    }
  ],
  "state": {
    "needsWater": true
  }
}
```

will output

```
<?xml version="1.0" encoding="UTF-8"?>
<object xmlns:xj="http://camel.apache.org/component/xj" xj:type="object">
    <object xj:name="firstname" xj:type="string">camel</object>
    <object xj:name="lastname" xj:type="string">apache</object>
    <object xj:name="personalnumber" xj:type="int">42</object>
    <object xj:name="active" xj:type="boolean">true</object>
```

```
    <object xj:name="ranking" xj:type="float">3.1415926</object>
    <object xj:name="roles" xj:type="array">
        <object xj:type="string">a</object>
        <object xj:type="object">
            <object xj:name="x" xj:type="null">null</object>
        </object>
    </object>
    <object xj:name="state" xj:type="object">
        <object xj:name="needsWater" xj:type="boolean">true</object>
    </object>
</object>
```

As can be seen in the output above, XJ writes some metadata in the resulting xml that can be used in further processing:

- XJ metadata nodes are always in the **http://camel.apache.org/component/xj** namespace.
- JSON key names are placed in the xj:name attribute.
- The parsed JSON type can be found in the xj:type attribute. The above example already contains all possible types.
- Generated XML elements are always named "object".

Now we can apply a stylesheet, for example:

```
<?xml version="1.0" encoding="UTF-8" ?>
<xsl:stylesheet version="1.0"
                xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                xmlns:xj="http://camel.apache.org/component/xj"
                exclude-result-prefixes="xj">

    <xsl:output omit-xml-declaration="no" encoding="UTF-8" method="xml" indent="yes"/>

    <xsl:template match="/">
        <person>
            <xsl:apply-templates select="//object"/>
        </person>
    </xsl:template>

    <xsl:template match="object[@xj:type != 'object' and @xj:type != 'array' and string-
length(@xj:name) > 0]">
        <xsl:variable name="name" select="@xj:name"/>
        <xsl:element name="{$name}">
            <xsl:value-of select="text()"/>
        </xsl:element>
    </xsl:template>

    <xsl:template match="@*|node()"/>
</xsl:stylesheet>
```

to the above sample by specifying the template on the endpoint:

```
from("direct:start").
  to("xj:com/example/json2xml.xsl?transformDirection=JSON2XML");
```

and get the following output:

```
<?xml version="1.0" encoding="UTF-8"?>
<person>
    <firstname>camel</firstname>
    <lastname>apache</lastname>
    <personalnumber>42</personalnumber>
    <active>true</active>
    <ranking>3.1415926</ranking>
    <x>null</x>
    <needsWater>true</needsWater>
</person>
```

141.7.2. Converting XML to JSON

Based on the explanations above an "identity" transform will be performed when no stylesheet is given:

```
from("direct:start").
  to("xj:identity?transformDirection=XML2JSON");
```

Given the sample input

```
<?xml version="1.0" encoding="UTF-8"?>
<person>
    <firstname>camel</firstname>
    <lastname>apache</lastname>
    <personalnumber>42</personalnumber>
    <active>true</active>
    <ranking>3.1415926</ranking>
    <roles>
        <entry>a</entry>
        <entry>
            <x>null</x>
        </entry>
    </roles>
    <state>
        <needsWater>true</needsWater>
    </state>
</person>
```

will result in

```
{
  "firstname": "camel",
  "lastname": "apache",
  "personalnumber": "42",
  "active": "true",
  "ranking": "3.1415926",
  "roles": [
    "a",
    {
      "x": "null"
    }
  ],
```

```
  "state": {
    "needsWater": "true"
  }
}
```

You may have noted that the input xml and output json is very similar to the examples above when converting from json to xml altough nothing special is done here. We only transformed an arbitrary XML document to json. XJ uses the following rules by default:

- The XML root element can be named somehow, it will always end in a json root object declaration '\{}'
- The json key name is the name of the xml element
- If there is an name clash as in "<roles>" above where two "<entry>" elements exists a json array will be generated.
- XML elements with text-only-child-nodes will result in the usual key/string-value pair. Mixed content elements results in key/child-object pair as seen in "<state>" above.

Now we can apply again a stylesheet, for example:

```
<?xml version="1.0" encoding="UTF-8" ?>
<xsl:stylesheet version="1.0"
                xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                xmlns:xj="http://camel.apache.org/component/xj"
                exclude-result-prefixes="xj">

    <xsl:output omit-xml-declaration="no" encoding="UTF-8" method="xml" indent="yes"/>

    <xsl:template match="/">
        <xsl:apply-templates/>
    </xsl:template>

    <xsl:template match="personalnumber">
        <xsl:element name="{local-name()}">
            <xsl:attribute name="xj:type">
                <xsl:value-of select="'int'"/>
            </xsl:attribute>
            <xsl:apply-templates/>
        </xsl:element>
    </xsl:template>

    <xsl:template match="active|needsWater">
        <xsl:element name="{local-name()}">
            <xsl:attribute name="xj:type">
                <xsl:value-of select="'boolean'"/>
            </xsl:attribute>
            <xsl:apply-templates/>
        </xsl:element>
    </xsl:template>

    <xsl:template match="ranking">
        <xsl:element name="{local-name()}">
            <xsl:attribute name="xj:type">
                <xsl:value-of select="'float'"/>
```

```
            </xsl:attribute>
            <xsl:apply-templates/>
        </xsl:element>
    </xsl:template>

    <xsl:template match="roles">
        <xsl:element name="{local-name()}">
            <xsl:attribute name="xj:type">
                <xsl:value-of select="'array'"/>
            </xsl:attribute>
            <xsl:apply-templates/>
        </xsl:element>
    </xsl:template>

    <xsl:template match="*[normalize-space(text()) = 'null']">
        <xsl:element name="{local-name()}">
            <xsl:attribute name="xj:type">
                <xsl:value-of select="'null'"/>
            </xsl:attribute>
            <xsl:apply-templates/>
        </xsl:element>
    </xsl:template>

    <xsl:template match="@*|node()">
        <xsl:copy>
            <xsl:apply-templates select="@*|node()"/>
        </xsl:copy>
    </xsl:template>
</xsl:stylesheet>
```

to the sample above by specifying the template on the endpoint:

```
from("direct:start").
  to("xj:com/example/xml2json.xsl?transformDirection=XML2JSON");
```

and get the following output:

```
{
  "firstname": "camel",
  "lastname": "apache",
  "personalnumber": 42,
  "active": true,
  "ranking": 3.1415926,
  "roles": [
    "a",
    {
      "x": null
    }
  ],
  "state": {
    "needsWater": true
  }
}
```

Note, this transformation resulted in exactly the same json document as we used as input to the json2xml convertion. The following XML document is that what is passed to XJ after xsl transformation:

```
<?xml version="1.0" encoding="UTF-8"?>
<person>
    <firstname>camel</firstname>
    <lastname>apache</lastname>
    <personalnumber xmlns:xj="http://camel.apache.org/component/xj"
xj:type="int">42</personalnumber>
    <active xmlns:xj="http://camel.apache.org/component/xj" xj:type="boolean">true</active>
    <ranking xmlns:xj="http://camel.apache.org/component/xj" xj:type="float">3.1415926</ranking>
    <roles xmlns:xj="http://camel.apache.org/component/xj" xj:type="array">
        <entry>a</entry>
        <entry>
            <x xj:type="null">null</x>
        </entry>
    </roles>
    <state>
        <needsWater xmlns:xj="http://camel.apache.org/component/xj"
xj:type="boolean">true</needsWater>
    </state>
</person>
```

In the stylesheet we just provided the minimal required type hints to get the same result. The supported type hints are exactly the same as XJ writes to a XML document when converting from json to xml.

In the end that means that we can feed back in the result document from the json to xml transformation sample above:

```
<?xml version="1.0" encoding="UTF-8"?>
<object xmlns:xj="http://camel.apache.org/component/xj" xj:type="object">
    <object xj:name="firstname" xj:type="string">camel</object>
    <object xj:name="lastname" xj:type="string">apache</object>
    <object xj:name="personalnumber" xj:type="int">42</object>
    <object xj:name="active" xj:type="boolean">true</object>
    <object xj:name="ranking" xj:type="float">3.1415926</object>
    <object xj:name="roles" xj:type="array">
        <object xj:type="string">a</object>
        <object xj:type="object">
            <object xj:name="x" xj:type="null">null</object>
        </object>
    </object>
    <object xj:name="state" xj:type="object">
        <object xj:name="needsWater" xj:type="boolean">true</object>
    </object>
</object>
```

and get the same output again:

```
{
  "firstname": "camel",
  "lastname": "apache",
  "personalnumber": 42,
  "active": true,
  "ranking": 3.1415926,
```

```
  "roles": [
    "a",
    {
      "x": null
    }
  ],
  "state": {
    "needsWater": true
  }
}
```

As seen in the example above: * xj:type lets you specify exactly the desired output type * xj:name lets you overrule the json key name. This is required when you want to generate key names which contains chars that aren't allowed in XML element names.

141.7.2.1. Available type hints

@xj:type=	Description
object	Generate a json object
array	Generate a json array
string	Generate a json string
int	Generate a json number without fractional part
float	Generate a json number with fractional part
boolean	Generate a json boolean
null	Generate an empty value, using the word null

141.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 12 options, which are listed below.

Name	Description	Default	Type
camel.component.xj.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.xj.content-cache	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	Boolean
camel.component.xj.enabled	Whether to enable auto configuration of the xj component. This is enabled by default.		Boolean
camel.component.xj.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.xj.saxon-configuration	To use a custom Saxon configuration. The option is a net.sf.saxon.Configuration type.		Configuration
camel.component.xj.saxon-configuration-properties	To set custom Saxon configuration properties.		Map
camel.component.xj.saxon-extension-functions	Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can use commas to separate multiple values to lookup.		String
camel.component.xj.secure-processing	Feature for XML secure processing (see javax.xml.XMLConstants). This is enabled by default. However, when using Saxon Professional you may need to turn this off to allow Saxon to be able to use Java extension functions.	true	Boolean
camel.component.xj.transformer-factory-class	To use a custom XSLT transformer factory, specified as a FQN class name.		String

Name	Description	Default	Type
camel.component.xj.transformer-factory-configuration-strategy	A configuration strategy to apply on freshly created instances of TransformerFactory. The option is a org.apache.camel.component.xslt.TransformerFactoryConfigurationStrategy type.		TransformerFactoryConfigurationStrategy
camel.component.xj.uri-resolver	To use a custom UriResolver. Should not be used together with the option 'uriResolverFactory'. The option is a javax.xml.transform.URIResolver type.		URIResolver
camel.component.xj.uri-resolver-factory	To use a custom UriResolver which depends on a dynamic endpoint resource URI. Should not be used together with the option 'uriResolver'. The option is a org.apache.camel.component.xslt.XsltUriResolverFactory type.		XsltUriResolverFactory

CHAPTER 142. XML TOKENIZE

The XML Tokenize language is a built-in language in **camel-xml-jaxp**, which is a truly XML-aware tokenizer that can be used with the Split EIP as the conventional Tokenize to efficiently and effectively tokenize XML documents..

XML Tokenize is capable of not only recognizing XML namespaces and hierarchical structures of the document but also more efficiently tokenizing XML documents than the conventional Tokenize language.

142.1. DEPENDENCIES

When using **xtokenize** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-xml-jaxp-starter</artifactId>
</dependency>
```

Additional dependency

In order to use this component, an additional dependency is required as follows:

```
<dependency>
    <groupId>org.codehaus.woodstox</groupId>
    <artifactId>woodstox-core-asl</artifactId>
    <version>4.4.1</version>
</dependency>
```

or

```
    <dependency>
      <groupId>org.apache.camel.springboot</groupId>
      <artifactId>camel-stax-starter</artifactId>
    </dependency>
```

142.2. XML TOKENIZER OPTIONS

The XML Tokenize language supports 4 options, which are listed below.

Name	Default	Java Type	Description
headerName		**String**	Name of header to tokenize instead of using the message body.

Name	Default	Java Type	Description
mode		**Enum**	The extraction mode. The available extraction modes are: i - injecting the contextual namespace bindings into the extracted token (default) w - wrapping the extracted token in its ancestor context u - unwrapping the extracted token to its child content t - extracting the text content of the specified element. Enum values: • i • w • u • t
group		**Integer**	To group N parts together.
trim		**Boolean**	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

142.3. EXAMPLE

See Split EIP which has examples using the XML Tokenize language.

142.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.language.xtokenize.enabled	Whether to enable auto configuration of the xtokenize language. This is enabled by default.		Boolean
camel.language.xtokenize.mode	The extraction mode. The available extraction modes are: i - injecting the contextual namespace bindings into the extracted token (default) w - wrapping the extracted token in its ancestor context u - unwrapping the extracted token to its child content t - extracting the text content of the specified element.		String
camel.language.xtokenize.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

CHAPTER 143. XPATH

Camel supports XPath to allow an Expression or Predicate to be used in the DSL.

For example, you could use XPath to create a predicate in a Message Filter or as an expression for a Recipient List.

143.1. DEPENDENCIES

When using **xpath** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-xpath-starter</artifactId>
</dependency>
```

143.2. XPATH LANGUAGE OPTIONS

The XPath language supports 10 options, which are listed below.

Name	Default	Java Type	Description
documentType		**String**	Name of class for document type The default value is org.w3c.dom.Document.
resultType		**Enum**	Sets the class name of the result type (type from output) The default result type is NodeSet. Enum values: • NUMBER • STRING • BOOLEAN • NODESET • NODE
saxon		**Boolean**	Whether to use Saxon.
factoryRef		**String**	References to a custom XPathFactory to lookup in the registry.
objectModel		**String**	The XPath object model to use.
logNamespaces		**Boolean**	Whether to log namespaces which can assist during troubleshooting.

Name	Default	Java Type	Description
headerName		**String**	Name of header to use as input, instead of the message body.
threadSafety		**Boolean**	Whether to enable thread-safety for the returned result of the xpath expression. This applies to when using NODESET as the result type, and the returned set has multiple elements. In this situation there can be thread-safety issues if you process the NODESET concurrently such as from a Camel Splitter EIP in parallel processing mode. This option prevents concurrency issues by doing defensive copies of the nodes. It is recommended to turn this option on if you are using camel-saxon or Saxon in your application. Saxon has thread-safety issues which can be prevented by turning this option on.
preCompile		**Boolean**	Whether to enable pre-compiling the xpath expression during initialization phase. pre-compile is enabled by default. This can be used to turn off, for example in cases the compilation phase is desired at the starting phase, such as if the application is ahead of time compiled (for example with camel-quarkus) which would then load the xpath factory of the built operating system, and not a JVM runtime.
trim		**Boolean**	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

143.3. NAMESPACES

You can easily use namespaces with XPath expressions using the **Namespaces** helper class.

143.4. VARIABLES

Variables in XPath is defined in different namespaces. The default namespace is **http://camel.apache.org/schema/spring**.

Namespace URI	Local part	Type	Description
http://camel.apache.org/xml/in/	in	Message	the message
http://camel.apache.org/xml/out/	out	Message	**deprecated** the output message (do not use)
http://camel.apache.org/xml/function/	functions	Object	Additional functions

Namespace URI	Local part	Type	Description
http://camel.apache.org/xml/variables/environment-variables	env	Object	OS environment variables
http://camel.apache.org/xml/variables/system-properties	system	Object	Java System properties
http://camel.apache.org/xml/variables/exchange-property		Object	the exchange property

Camel will resolve variables according to either:

- namespace given
- no namespace given

143.4.1. Namespace given

If the namespace is given then Camel is instructed exactly what to return. However, when resolving Camel will try to resolve a header with the given local part first, and return it. If the local part has the value **body** then the body is returned instead.

143.4.2. No namespace given

If there is no namespace given then Camel resolves only based on the local part. Camel will try to resolve a variable in the following steps:

- from **variables** that has been set using the **variable(name, value)** fluent builder
- from **message.in.header** if there is a header with the given key
- from **exchange.properties** if there is a property with the given key

143.5. FUNCTIONS

Camel adds the following XPath functions that can be used to access the exchange:

Function	Argument	Type	Description
in:body	none	Object	Will return the message body.
in:header	the header name	Object	Will return the message header.
out:body	none	Object	**deprecated** Will return the out message body.

Function	Argument	Type	Description
out:header	the header name	Object	**deprecated** Will return the out message header.
function:properties	key for property	String	To use a .
function:simple	simple expression	Object	To evaluate a language.

NOTE

function:properties and **function:simple** is not supported when the return type is a **NodeSet**, such as when using with a Split EIP.

Here's an example showing some of these functions in use.

143.5.1. Functions example

If you prefer to configure your routes in your Spring XML file then you can use XPath expressions as follows

```
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="
      http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
      http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
spring.xsd">

  <camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring"
                xmlns:foo="http://example.com/person">
    <route>
      <from uri="activemq:MyQueue"/>
      <filter>
        <xpath>/foo:person[@name='James']</xpath>
        <to uri="mqseries:SomeOtherQueue"/>
      </filter>
    </route>
  </camelContext>
</beans>
```

Notice how we can reuse the namespace prefixes, **foo** in this case, in the XPath expression for easier namespace based XPath expressions.

143.6. STREAM BASED MESSAGE BODIES

If the message body is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream **once**. So often when you use XPath as Message Filter or Content Based Router then you need to access the data multiple times, and you should use Stream Caching or convert the message body to a **String** prior which is safe to be re-read multiple times.

```
from("queue:foo").
  filter().xpath("//foo")).
  to("queue:bar")
```

```
from("queue:foo").
  choice().xpath("//foo")).to("queue:bar").
  otherwise().to("queue:others");
```

143.7. SETTING RESULT TYPE

The XPath expression will return a result type using native XML objects such as **org.w3c.dom.NodeList**. However, many times you want a result type to be a **String**. To do this you have to instruct the XPath which result type to use.

In Java DSL:

```
xpath("/foo:person/@id", String.class)
```

In XML DSL you use the **resultType** attribute to provide the fully qualified classname.

```
<xpath resultType="java.lang.String">/foo:person/@id</xpath>
```

NOTE

Classes from **java.lang** can omit the FQN name, so you can use **resultType="String"**

Using **@XPath** annotation:

```
@XPath(value = "concat('foo-',//order/name/)", resultType = String.class) String name)
```

Where we use the xpath function concat to prefix the order name with **foo-**. In this case we have to specify that we want a **String** as result type, so the concat function works.

143.8. USING XPATH ON HEADERS

Some users may have XML stored in a header. To apply an XPath to a header's value you can do this by defining the 'headerName' attribute.

```
<xpath headerName="invoiceDetails">/invoice/@orderType = 'premium'</xpath>
```

And in Java DSL you specify the headerName as the 2nd parameter as shown:

```
xpath("/invoice/@orderType = 'premium'", "invoiceDetails")
```

143.9. EXAMPLE

Here is a simple example using an XPath expression as a predicate in a Message Filter:

```
from("direct:start")
    .filter().xpath("/person[@name='James']")
        .to("mock:result");
```

And in XML

```
<route>
  <from uri="direct:start"/>
  <filter>
    <xpath>/person[@name='James']</xpath>
    <to uri="mock:result"/>
  </filter>
</route>
```

143.10. USING NAMESPACES

If you have a standard set of namespaces you wish to work with and wish to share them across many XPath expressions you can use the **org.apache.camel.support.builder.Namespaces** when using Java DSL as shown:

```
Namespaces ns = new Namespaces("c", "http://acme.com/cheese");

from("direct:start")
    .filter(xpath("/c:person[@name='James']", ns))
        .to("mock:result");
```

Notice how the namespaces are provided to **xpath** with the **ns** variable that are passed in as the 2nd parameter.

Each namespace is a key=value pair, where the prefix is the key. In the XPath expression then the namespace is used by its prefix, eg:

```
/c:person[@name='James']
```

The namespace builder supports adding multiple namespaces as shown:

```
Namespaces ns = new Namespaces("c", "http://acme.com/cheese")
                    .add("w", "http://acme.com/wine")
                    .add("b", "http://acme.com/beer");
```

When using namespaces in XML DSL then its different, as you setup the namespaces in the XML root tag (or one of the **camelContext**, **routes**, **route** tags).

In the XML example below we use Spring XML where the namespace is declared in the root tag **beans**, in the line with **xmlns:foo="http://example.com/person"**:

```
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:foo="http://example.com/person"
       xsi:schemaLocation="
       http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
       http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-spring.xsd
```

```
    ">

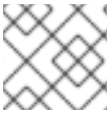
  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="direct:start"/>
      <filter>
        <xpath logNamespaces="true">/foo:person[@name='James']</xpath>
        <to uri="mock:result"/>
      </filter>
    </route>
  </camelContext>

</beans>
```

This namespace uses **foo** as prefix, so the **<xpath>** expression uses **/foo:** to use this namespace.

143.11. USING @XPATH ANNOTATION FOR BEAN INTEGRATION

You can use Bean Integration to invoke a method on a bean and use various languages such as **@XPath** to extract a value from the message and bind it to a method parameter.



NOTE

The default **@XPath** annotation has SOAP and XML namespaces available.

```
public class Foo {

    @Consume(uri = "activemq:my.queue")
    public void doSomething(@XPath("/person/@name") String name, String xml) {
        // process the inbound message here
    }
}
```

143.12. USING XPATHBUILDER WITHOUT AN EXCHANGE

You can now use the **org.apache.camel.language.xpath.XPathBuilder** without the need for an **Exchange**. This comes handy if you want to use it as a helper to do custom XPath evaluations.

It requires that you pass in a **CamelContext** since a lot of the moving parts inside the **XPathBuilder** requires access to the Camel Type Converter and hence why **CamelContext** is needed.

For example, you can do something like this:

```
boolean matches = XPathBuilder.xpath("/foo/bar/@xyz").matches(context, "<foo><bar xyz='cheese'/>
</foo>"));
```

This will match the given predicate.

You can also evaluate as shown in the following three examples:

```
String name = XPathBuilder.xpath("foo/bar").evaluate(context, "<foo><bar>cheese</bar></foo>",
String.class);
Integer number = XPathBuilder.xpath("foo/bar").evaluate(context, "<foo><bar>123</bar></foo>",
```

```
Integer.class);
Boolean bool = XPathBuilder.xpath("foo/bar").evaluate(context, "<foo><bar>true</bar></foo>",
Boolean.class);
```

Evaluating with a **String** result is a common requirement and make this simpler:

```
String name = XPathBuilder.xpath("foo/bar").evaluate(context, "<foo><bar>cheese</bar></foo>");
```

143.13. USING SAXON WITH XPATHBUILDER

You need to add **camel-saxon** as dependency to your project.

It's now easier to use Saxon with the XPathBuilder which can be done in several ways as shown below

- Using a custom XPathFactory
- Using ObjectModel

143.13.1. Setting a custom XPathFactory using System Property

Camel now supports reading the JVM system property **javax.xml.xpath.XPathFactory** that can be used to set a custom XPathFactory to use.

This unit test shows how this can be done to use Saxon instead:

Camel will log at **INFO** level if it uses a non default XPathFactory such as:

```
XPathBuilder  INFO  Using system property
javax.xml.xpath.XPathFactory:http://saxon.sf.net/jaxp/xpath/om with value:
                net.sf.saxon.xpath.XPathFactoryImpl when creating XPathFactory
```

To use Apache Xerces you can configure the system property

```
-Djavax.xml.xpath.XPathFactory=org.apache.xpath.jaxp.XPathFactoryImpl
```

143.13.2. Enabling Saxon from XML DSL

Similarly to Java DSL, to enable Saxon from XML DSL you have three options:

Referring to a custom factory:

```
<xpath factoryRef="saxonFactory" resultType="java.lang.String">current-dateTime()</xpath>
```

And declare a bean with the factory:

```
<bean id="saxonFactory" class="net.sf.saxon.xpath.XPathFactoryImpl"/>
```

Specifying the object model:

```
<xpath objectModel="http://saxon.sf.net/jaxp/xpath/om" resultType="java.lang.String">current-
dateTime()</xpath>
```

And the recommended approach is to set **saxon=true** as shown:

```
<xpath saxon="true" resultType="java.lang.String">current-dateTime()</xpath>
```

143.14. NAMESPACE AUDITING TO AID DEBUGGING

Many XPath-related issues that users frequently face are linked to the usage of namespaces. You may have some misalignment between the namespaces present in your message, and those that your XPath expression is aware of or referencing. XPath predicates or expressions that are unable to locate the XML elements and attributes due to namespaces issues may simply look like *they are not working*, when in reality all there is to it is a lack of namespace definition.

Namespaces in XML are completely necessary, and while we would love to simplify their usage by implementing some magic or voodoo to wire namespaces automatically, truth is that any action down this path would disagree with the standards and would greatly hinder interoperability.

Therefore, the utmost we can do is assist you in debugging such issues by adding two new features to the XPath Expression Language and are thus accessible from both predicates and expressions.

143.14.1. Logging the Namespace Context of your XPath expression/predicate

Every time a new XPath expression is created in the internal pool, Camel will log the namespace context of the expression under the **org.apache.camel.language.xpath.XPathBuilder** logger. Since Camel represents Namespace Contexts in a hierarchical fashion (parent-child relationships), the entire tree is output in a recursive manner with the following format:

```
[me: {prefix -> namespace}, {prefix -> namespace}], [parent: [me: {prefix -> namespace}, {prefix -> namespace}], [parent: [me: {prefix -> namespace}]]]
```

Any of these options can be used to activate this logging:

- Enable TRACE logging on the **org.apache.camel.language.xpath.XPathBuilder** logger, or some parent logger such as **org.apache.camel** or the root logger
- Enable the **logNamespaces** option as indicated in the following section, in which case the logging will occur on the INFO level

143.14.2. Auditing namespaces

Camel is able to discover and dump all namespaces present on every incoming message before evaluating an XPath expression, providing all the richness of information you need to help you analyse and pinpoint possible namespace issues.

To achieve this, it in turn internally uses another specially tailored XPath expression to extract all namespace mappings that appear in the message, displaying the prefix and the full namespace URI(s) for each individual mapping.

Some points to take into account:

- The implicit XML namespace (**xmlns:xml="http://www.w3.org/XML/1998/namespace"**) is suppressed from the output because it adds no value
- Default namespaces are listed under the **DEFAULT** keyword in the output

- Keep in mind that namespaces can be remapped under different scopes. Think of a top-level 'a' prefix which in inner elements can be assigned a different namespace, or the default namespace changing in inner scopes. For each discovered prefix, all associated URIs are listed.

You can enable this option in Java DSL and XML DSL:

Java DSL:

```
XPathBuilder.xpath("/foo:person/@id", String.class).logNamespaces()
```

XML DSL:

```
<xpath logNamespaces="true" resultType="String">/foo:person/@id</xpath>
```

The result of the auditing will be appeared at the INFO level under the **org.apache.camel.language.xpath.XPathBuilder** logger and will look like the following:

```
2012-01-16 13:23:45,878 [stSaxonWithFlag] INFO  XPathBuilder  - Namespaces discovered in message:
{xmlns:a=[http://apache.org/camel], DEFAULT=[http://apache.org/default],
xmlns:b=[http://apache.org/camelA, http://apache.org/camelB]}
```

143.15. LOADING SCRIPT FROM EXTERNAL RESOURCE

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**. This is done using the following syntax: **"resource:scheme:location"**, eg to refer to a file on the classpath you can do:

```
.setHeader("myHeader").xpath("resource:classpath:myxpath.txt", String.class)
```

143.16. SPRING BOOT AUTO-CONFIGURATION

The component supports 9 options, which are listed below.

Name	Description	Default	Type
camel.language.xpath.document-type	Name of class for document type The default value is org.w3c.dom.Document.		String
camel.language.xpath.enabled	Whether to enable auto configuration of the xpath language. This is enabled by default.		Boolean
camel.language.xpath.factory-ref	References to a custom XPathFactory to lookup in the registry.		String
camel.language.xpath.log-namespaces	Whether to log namespaces which can assist during troubleshooting.	false	Boolean

Name	Description	Default	Type
camel.language.xpath.object-model	The XPath object model to use.		String
camel.language.xpath.pre-compile	Whether to enable pre-compiling the xpath expression during initialization phase. pre-compile is enabled by default. This can be used to turn off, for example in cases the compilation phase is desired at the starting phase, such as if the application is ahead of time compiled (for example with camel-quarkus) which would then load the xpath factory of the built operating system, and not a JVM runtime.	true	Boolean
camel.language.xpath.saxon	Whether to use Saxon.	false	Boolean
camel.language.xpath.thread-safety	Whether to enable thread-safety for the returned result of the xpath expression. This applies to when using NODESET as the result type, and the returned set has multiple elements. In this situation there can be thread-safety issues if you process the NODESET concurrently such as from a Camel Splitter EIP in parallel processing mode. This option prevents concurrency issues by doing defensive copies of the nodes. It is recommended to turn this option on if you are using camel-saxon or Saxon in your application. Saxon has thread-safety issues which can be prevented by turning this option on.	false	Boolean
camel.language.xpath.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

CHAPTER 144. XSLT

Only producer is supported

The XSLT component allows you to process a message using an XSLT template. This can be ideal when using Templating to generate response for requests.

144.1. DEPENDENCIES

When using **xslt** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-xslt-starter</artifactId>
</dependency>
```

144.2. URI FORMAT

```
xslt:templateName[?options]
```

The URI format contains **templateName**, which can be one of the following:

- the classpath-local URI of the template to invoke
- the complete URL of the remote template.

You can append query options to the URI in the following format:

?option=value&option=value&...

Table 144.1. Table 1. Example URIs

URI	Description
xslt:com/acme/mytransform.xsl	Refers to the file com/acme/mytransform.xsl on the classpath
xslt:file:///foo/bar.xsl	Refers to the file /foo/bar.xsl
xslt:http://acme.com/cheese/foo.xsl	Refers to the remote http resource

144.3. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

144.3.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

144.3.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

144.4. COMPONENT OPTIONS

The XSLT component supports 7 options, which are listed below.

Name	Description	Default	Type
contentCache (producer)	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
transformerFactoryClass (advanced)	To use a custom XSLT transformer factory, specified as a FQN class name.		String
transformerFactoryConfigurationStrategy (advanced)	A configuration strategy to apply on freshly created instances of TransformerFactory.		TransformerFactoryConfigurationStrategy
uriResolver (advanced)	To use a custom UriResolver. Should not be used together with the option 'uriResolverFactory'.		URIResolver
uriResolverFactory (advanced)	To use a custom UriResolver which depends on a dynamic endpoint resource URI. Should not be used together with the option 'uriResolver'.		XsltUriResolverFactory

144.5. ENDPOINT OPTIONS

The XSLT endpoint is configured using URI syntax:

```
xslt:resourceUri
```

with the following path and query parameters:

144.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
resourceUri (producer)	**Required** Path to the template. The following is supported by the default URIResolver. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

144.5.2. Query Parameters (13 parameters)

Name	Description	Default	Type
contentCache (producer)	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	boolean
deleteOutputFile (producer)	If you have output=file then this option dictates whether or not the output file should be deleted when the Exchange is done processing. For example suppose the output file is a temporary file, then it can be a good idea to delete it after use.	false	boolean
failOnNullBody (producer)	Whether or not to throw an exception if the input body is null.	true	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
output (producer)	Option to specify which output type to use. Possible values are: string, bytes, DOM, file. The first three options are all in memory based, where as file is streamed directly to a java.io.File. For file you must specify the filename in the IN header with the key Exchange.XSLT_FILE_NAME which is also CamelXsltFileName. Also any paths leading to the filename must be created beforehand, otherwise an exception is thrown at runtime. Enum values: • string • bytes • DOM • file	string	XsltOutput

Name	Description	Default	Type
transformerCacheSize (producer)	The number of javax.xml.transform.Transformer object that are cached for reuse to avoid calls to Template.newTransformer().	0	int
entityResolver (advanced)	To use a custom org.xml.sax.EntityResolver with javax.xml.transform.sax.SAXSource.		EntityResolver
errorListener (advanced)	Allows to configure to use a custom javax.xml.transform.ErrorListener. Beware when doing this then the default error listener which captures any errors or fatal errors and store information on the Exchange as properties is not in use. So only use this option for special use-cases.		ErrorListener
resultHandlerFactory (advanced)	Allows you to use a custom org.apache.camel.builder.xml.ResultHandlerFactory which is capable of using custom org.apache.camel.builder.xml.ResultHandler types.		ResultHandlerFactory
transformerFactory (advanced)	To use a custom XSLT transformer factory.		TransformerFactory
transformerFactoryClass (advanced)	To use a custom XSLT transformer factory, specified as a FQN class name.		String
transformerFactoryConfigurationStrategy (advanced)	A configuration strategy to apply on freshly created instances of TransformerFactory.		TransformerFactoryConfigurationStrategy
uriResolver (advanced)	To use a custom javax.xml.transform.URIResolver.		URIResolver

144.6. USING XSLT ENDPOINTS

The following format is an example of using an XSLT template to formulate a response for a message for InOut message exchanges (where there is a **JMSReplyTo** header)

```
from("activemq:My.Queue").
  to("xslt:com/acme/mytransform.xsl");
```

If you want to use InOnly and consume the message and send it to another destination you could use the following route:

```
from("activemq:My.Queue").
  to("xslt:com/acme/mytransform.xsl").
  to("activemq:Another.Queue");
```

144.7. GETTING USEABLE PARAMETERS INTO THE XSLT

By default, all headers are added as parameters which are then available in the XSLT.
To make the parameters useable, you will need to declare them.

```
<setHeader name="myParam"><constant>42</constant></setHeader>
<to uri="xslt:MyTransform.xsl"/>
```

The parameter also needs to be declared in the top level of the XSLT for it to be available:

```
<xsl: ..... >

  <xsl:param name="myParam"/>

   <xsl:template ...>
```

144.8. SPRING XML VERSIONS

To use the above examples in Spring XML you would use something like the following code:

```
<camelContext xmlns="http://activemq.apache.org/camel/schema/spring">
  <route>
    <from uri="activemq:My.Queue"/>
    <to uri="xslt:org/apache/camel/spring/processor/example.xsl"/>
    <to uri="activemq:Another.Queue"/>
  </route>
</camelContext>
```

144.9. USING XSL:INCLUDE

Camel provides its own implementation of **URIResolver**. This allows Camel to load included files from the classpath.

For example the include file in the following code will be located relative to the starting endpoint.

```
<xsl:include href="staff_template.xsl"/>
```

This means that Camel will locate the file in the **classpath** as
org/apache/camel/component/xslt/staff_template.xsl

You can use **classpath:** or **file:** to instruct Camel to look either in the classpath or file system. If you omit the prefix then Camel uses the prefix from the endpoint configuration. If no prefix is specified in the endpoint configuration, the default is **classpath:**.

You can also refer backwards in the include paths. In the following example, the xsl file will be resolved under **org/apache/camel/component**.

```
    <xsl:include href="../staff_other_template.xsl"/>
```

144.10. USING XSL:INCLUDE AND DEFAULT PREFIX

Camel will use the prefix from the endpoint configuration as the default prefix.

You can explicitly specify **file:** or **classpath:** loading. The two loading types can be mixed in a XSLT script, if necessary.

144.11. DYNAMIC STYLESHEETS

To provide a dynamic stylesheet at runtime you can define a dynamic URI. See How to use a dynamic URI in to() for more information.

144.12. ACCESSING WARNINGS, ERRORS AND FATALERRORS FROM XSLT ERRORLISTENER

Any warning/error or fatalError is stored on the current Exchange as a property with the keys **Exchange.XSLT_ERROR**, **Exchange.XSLT_FATAL_ERROR**, or **Exchange.XSLT_WARNING** which allows end users to get hold of any errors happening during transformation.

For example in the stylesheet below, we want to terminate if a staff has an empty dob field. And to include a custom error message using xsl:message.

```
<xsl:template match="/">
  <html>
    <body>
      <xsl:for-each select="staff/programmer">
        <p>Name: <xsl:value-of select="name"/><br />
          <xsl:if test="dob="">
            <xsl:message terminate="yes">Error: DOB is an empty string!</xsl:message>
          </xsl:if>
        </p>
      </xsl:for-each>
    </body>
  </html>
</xsl:template>
```

The exception is stored on the Exchange as a warning with the key **Exchange.XSLT_WARNING.**

144.13. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type

Name	Description	Default	Type
camel.component.xslt.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.xslt.content-cache	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	Boolean
camel.component.xslt.enabled	Whether to enable auto configuration of the xslt component. This is enabled by default.		Boolean
camel.component.xslt.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.xslt.transformer-factory-class	To use a custom XSLT transformer factory, specified as a FQN class name.		String
camel.component.xslt.transformer-factory-configuration-strategy	A configuration strategy to apply on freshly created instances of TransformerFactory. The option is a org.apache.camel.component.xslt.TransformerFactoryConfigurationStrategy type.		TransformerFactoryConfigurationStrategy
camel.component.xslt.uri-resolver	To use a custom UriResolver. Should not be used together with the option 'uriResolverFactory'. The option is a javax.xml.transform.URIResolver type.		URIResolver
camel.component.xslt.uri-resolver-factory	To use a custom UriResolver which depends on a dynamic endpoint resource URI. Should not be used together with the option 'uriResolver'. The option is a org.apache.camel.component.xslt.XsltUriResolverFactory type.		XsltUriResolverFactory

CHAPTER 145. XSLT SAXON

Since Camel 3.0

Only producer is supported

The XSLT Saxon component allows you to process a message using an XSLT template using Saxon. This is ideal when using Templating to generate responses for requests.

145.1. DEPENDENCIES

When using **xslt-saxon** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-xslt-saxon-starter</artifactId>
</dependency>
```

145.2. URI FORMAT

```
xslt-saxon:templateName[?options]
```

The URI format contains **templateName**, which can be one of the following:

- the classpath-local URI of the template to invoke
- the complete URL of the remote template.

You can append query options to the URI in the following format:

```
?option=value&option=value&…
```

Table 145.1. Example URIs

URI	Description
xslt-saxon:com/acme/mytransform.xsl	Refers to the file com/acme/mytransform.xsl on the classpath
xslt-saxon:file:///foo/bar.xsl	Refers to the file /foo/bar.xsl
xslt-saxon:http://acme.com/cheese/foo.xsl	Refers to the remote http resource

145.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

145.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the Component DSL, in a configuration file (application.properties|yaml), or directly with Java code.

145.3.2. Configuring Endpoint Options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the Endpoint DSL as a type safe way of configuring endpoints.

A good practice when configuring options is to use Property Placeholders, which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

145.4. COMPONENT OPTIONS

The XSLT Saxon component supports 11 options, which are listed below.

Name	Description	Default	Type
contentCache (producer)	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
saxonConfiguration (advanced)	To use a custom Saxon configuration.		Configuration
saxonConfigurationProperties (advanced)	To set custom Saxon configuration properties.		Map
saxonExtensionFunctions (advanced)	Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can use commas to separate multiple values to lookup.		String
secureProcessing (advanced)	Feature for XML secure processing (see javax.xml.XMLConstants). This is enabled by default. However, when using Saxon Professional you may need to turn this off to allow Saxon to be able to use Java extension functions.	true	boolean
transformerFactoryClass (advanced)	To use a custom XSLT transformer factory, specified as a FQN class name.		String
transformerFactoryConfigurationStrategy (advanced)	A configuration strategy to apply on freshly created instances of TransformerFactory.		TransformerFactoryConfigurationStrategy
uriResolver (advanced)	To use a custom UriResolver. Should not be used together with the option 'uriResolverFactory'.		URIResolver
uriResolverFactory (advanced)	To use a custom UriResolver which depends on a dynamic endpoint resource URI. Should not be used together with the option 'uriResolver'.		XsltUriResolverFactory

145.5. ENDPOINT OPTIONS

The XSLT Saxon endpoint is configured using URI syntax:

```
xslt-saxon:resourceUri
```

–

with the following path and query parameters:

145.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
resourceUri (producer)	**Required** Path to the template. The following is supported by the default URIResolver. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

145.5.2. Query Parameters (18 parameters)

Name	Description	Default	Type
allowStAX (producer)	Whether to allow using StAX as the javax.xml.transform.Source. You can enable this if the XSLT library supports StAX such as the Saxon library (camel-saxon). The Xalan library (default in JVM) does not support StAXSource.	true	boolean
contentCache (producer)	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	boolean
deleteOutputFile (producer)	If you have output=file then this option dictates whether or not the output file should be deleted when the Exchange is done processing. For example suppose the output file is a temporary file, then it can be a good idea to delete it after use.	false	boolean
failOnNullBody (producer)	Whether or not to throw an exception if the input body is null.	true	boolean

Name	Description	Default	Type
output (producer)	Option to specify which output type to use. Possible values are: string, bytes, DOM, file. The first three options are all in memory based, where as file is streamed directly to a java.io.File. For file you must specify the filename in the IN header with the key XsltConstants.XSLT_FILE_NAME which is also CamelXsltFileName. Also any paths leading to the filename must be created beforehand, otherwise an exception is thrown at runtime. Enum values: • string • bytes • DOM • file	string	XsltOutput
transformerCacheSize (producer)	The number of javax.xml.transform.Transformer object that are cached for reuse to avoid calls to Template.newTransformer().	0	int
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
entityResolver (advanced)	To use a custom org.xml.sax.EntityResolver with javax.xml.transform.sax.SAXSource.		EntityResolver
errorListener (advanced)	Allows to configure to use a custom javax.xml.transform.ErrorListener. Beware when doing this then the default error listener which captures any errors or fatal errors and store information on the Exchange as properties is not in use. So only use this option for special use-cases.		ErrorListener

Name	Description	Default	Type
resultHandlerFactory (advanced)	Allows you to use a custom org.apache.camel.builder.xml.ResultHandlerFactory which is capable of using custom org.apache.camel.builder.xml.ResultHandler types.		ResultHandlerFactory
saxonConfiguration (advanced)	To use a custom Saxon configuration.		Configuration
saxonExtensionFunctions (advanced)	Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can comma to separate multiple values to lookup.		String
secureProcessing (advanced)	Feature for XML secure processing (see javax.xml.XMLConstants). This is enabled by default. However, when using Saxon Professional you may need to turn this off to allow Saxon to be able to use Java extension functions.	true	boolean
transformerFactory (advanced)	To use a custom XSLT transformer factory.		TransformerFactory
transformerFactoryClass (advanced)	To use a custom XSLT transformer factory, specified as a FQN class name.		String
transformerFactoryConfigurationStrategy (advanced)	A configuration strategy to apply on freshly created instances of TransformerFactory.		TransformerFactoryConfigurationStrategy
uriResolver (advanced)	To use a custom javax.xml.transform.URIResolver.		URIResolver
xsltMessageLogger (advanced)	A consumer to messages generated during XSLT transformations.		XsltMessageLogger

145.6. USING XSLT ENDPOINTS

The following format is an example of using an XSLT template to formulate a response for a message for **InOut** message exchanges (where there is a **JMSReplyTo** header).

```
from("activemq:My.Queue").
  to("xslt-saxon:com/acme/mytransform.xsl");
```

If you want to use **InOnly** and consume the message and send it to another destination you could use the following route:

```
from("activemq:My.Queue").
  to("xslt-saxon:com/acme/mytransform.xsl").
  to("activemq:Another.Queue");
```

145.7. GETTING USEABLE PARAMETERS INTO THE XSLT

By default, all headers are added as parameters which are then available in the XSLT. To make the parameters useable, you will need to declare them.

```
<setHeader name="myParam"><constant>42</constant></setHeader>
<to uri="xslt:MyTransform.xsl"/>
```

The parameter also needs to be declared in the top level of the XSLT for it to be available:

```
<xsl: ..... >

  <xsl:param name="myParam"/>

   <xsl:template ...>
```

145.8. SPRING XML VERSIONS

To use the above examples in Spring XML, use something like the following code:

```
<camelContext xmlns="http://activemq.apache.org/camel/schema/spring">
  <route>
    <from uri="activemq:My.Queue"/>
    <to uri="xslt-saxon:org/apache/camel/spring/processor/example.xsl"/>
    <to uri="activemq:Another.Queue"/>
  </route>
</camelContext>
```

145.9. USING XSL:INCLUDE

Camel provides its own implementation of **URIResolver**. This allows Camel to load included files from the classpath. For example the include file in the following code will be located relative to the starting endpoint.

```
<xsl:include href="staff_template.xsl"/>
```

This means that Camel will locate the file in the **classpath** as **org/apache/camel/component/xslt/staff_template.xsl**. You can use **classpath:** or **file:** to instruct Camel to look either in the classpath or file system. If you omit the prefix then Camel uses the prefix from the endpoint configuration. If no prefix is specified in the endpoint configuration, the default is **classpath:**.

You can also refer backwards in the include paths. In the following example, the xsl file will be resolved under **org/apache/camel/component**.

```
    <xsl:include href="../staff_other_template.xsl"/>
```

145.10. USING XSL:INCLUDE AND DEFAULT PREFIX

Camel uses the prefix from the endpoint configuration as the default prefix. You can explicitly specify **file:** or **classpath:** loading. The two loading types can be mixed in a XSLT script, if necessary.

145.11. USING SAXON EXTENSION FUNCTIONS

Since Saxon 9.2, writing extension functions has been supplemented by a new mechanism, referred to as integrated extension functions. You can now easily use camel as shown in the below example:

```
SimpleRegistry registry = new SimpleRegistry();
registry.put("function1", new MyExtensionFunction1());
registry.put("function2", new MyExtensionFunction2());

CamelContext context = new DefaultCamelContext(registry);
context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("direct:start")
            .to("xslt-saxon:org/apache/camel/component/xslt/extensions/extensions.xslt?
saxonExtensionFunctions=#function1,#function2");
    }
});
```

With Spring XML:

```
<bean id="function1" class="org.apache.camel.component.xslt.extensions.MyExtensionFunction1"/>
<bean id="function2" class="org.apache.camel.component.xslt.extensions.MyExtensionFunction2"/>

<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:extensions"/>
    <to uri="xslt-saxon:org/apache/camel/component/xslt/extensions/extensions.xslt?
saxonExtensionFunctions=#function1,#function2"/>
  </route>
</camelContext>
```

145.12. DYNAMIC STYLESHEETS

To provide a dynamic stylesheet at runtime you can define a dynamic URI. See How to use a dynamic URI in to() for more information.

145.13. ACCESSING WARNINGS, ERRORS AND FATALERRORS FROM XSLT ERRORLISTENER

Any warning/error or fatalError is stored on the current Exchange as a property with the keys **Exchange.XSLT_ERROR**, **Exchange.XSLT_FATAL_ERROR**, or **Exchange.XSLT_WARNING** which allows end users to get hold of any errors happening during transformation.

For example, in the stylesheet below, we want to determinate whether a staff has an empty dob field. And to include a custom error message using xsl:message.

```
<xsl:template match="/">
```

```
<html>
  <body>
    <xsl:for-each select="staff/programmer">
      <p>Name: <xsl:value-of select="name"/><br />
        <xsl:if test="dob=''">
          <xsl:message terminate="yes">Error: DOB is an empty string!</xsl:message>
        </xsl:if>
      </p>
    </xsl:for-each>
  </body>
</html>
</xsl:template>
```

The exception is stored on the Exchange as a warning with the key **Exchange.XSLT_WARNING.**

145.14. SPRING BOOT AUTO-CONFIGURATION

The component supports 12 options, which are listed below.

Name	Description	Default	Type
camel.component.xslt-saxon.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.xslt-saxon.content-cache	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	Boolean
camel.component.xslt-saxon.enabled	Whether to enable auto configuration of the xslt-saxon component. This is enabled by default.		Boolean
camel.component.xslt-saxon.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.xslt-saxon.saxon-configuration	To use a custom Saxon configuration. The option is a net.sf.saxon.Configuration type.		Configuration
camel.component.xslt-saxon.saxon-configuration-properties	To set custom Saxon configuration properties.		Map
camel.component.xslt-saxon.saxon-extension-functions	Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can use commas to separate multiple values to lookup.		String
camel.component.xslt-saxon.secure-processing	Feature for XML secure processing (see javax.xml.XMLConstants). This is enabled by default. However, when using Saxon Professional you may need to turn this off to allow Saxon to be able to use Java extension functions.	true	Boolean
camel.component.xslt-saxon.transformer-factory-class	To use a custom XSLT transformer factory, specified as a FQN class name.		String
camel.component.xslt-saxon.transformer-factory-configuration-strategy	A configuration strategy to apply on freshly created instances of TransformerFactory. The option is a org.apache.camel.component.xslt.TransformerFactoryConfigurationStrategy type.		TransformerFactoryConfigurationStrategy
camel.component.xslt-saxon.uri-resolver	To use a custom UriResolver. Should not be used together with the option 'uriResolverFactory'. The option is a javax.xml.transform.URIResolver type.		URIResolver
camel.component.xslt-saxon.uri-resolver-factory	To use a custom UriResolver which depends on a dynamic endpoint resource URI. Should not be used together with the option 'uriResolver'. The option is a org.apache.camel.component.xslt.XsltUriResolverFactory type.		XsltUriResolverFactory

CHAPTER 146. YAML DSL

Since Camel 3.9

The YAML DSL provides the capability to define your Camel routes, route templates & REST DSL configuration in YAML.

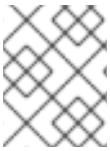
146.1. DEFINING A ROUTE

A route is a collection of elements defined as follows:

```
- from: 1
    uri: "direct:start"
    steps: 2
      - filter:
          expression:
            simple: "${in.header.continue} == true"
          steps:
            - to:
                uri: "log:filtered"
      - to:
          uri: "log:original"
```

Where,

1. Route entry point, by default **from** and **rest** are supported.
2. Processing steps



NOTE

Each step represents a YAML map that has a single entry where the field name is the EIP name.

As a general rule, each step provides all the parameters the related definition declares, but there are some minor differences/enhancements:

- Output Aware Steps

Some steps, such as **filter** and **split**, have their own pipeline when an exchange matches the filter expression or for the items generated by the split expression. You can define these pipelines in the **steps** field:

```
filter:
  expression:
    simple: "${in.header.continue} == true"
    steps:
      - to:
          uri: "log:filtered"
```

- Expression Aware Steps

Some EIP, such as **filter** and **split**, supports the definition of an expression through the **expression** field:

Explicit Expression field

```
filter:
  expression:
    simple: "${in.header.continue} == true"
```

To make the DSL less verbose, you can omit the **expression** field.

Implicit Expression field

```
filter:
  simple: "${in.header.continue} == true"
```

In general, expressions can be defined inline, such as within the examples above but if you need provide more information, you can 'unroll' the expression definition and configure any single parameter the expression defines.

Full Expression definition

```
filter:
  tokenize:
    token: "<"
    end-token: ">"
```

- Data Format Aware Steps

The EIP **marshal** and **unmarshal** supports the definition of data formats:

```
marshal:
  json:
    library: Gson
```

NOTE

In case you want to use the data-format's default settings, you need to place an empty block as data format parameters, like **json: {}**

146.2. DEFINING ENDPOINTS

To define an endpoint with the YAML DSL you have two options:

- Using a classic Camel URI:

```
- from:
    uri: "timer:tick?period=1s"
    steps:
      - to:
          uri: "telegram:bots?authorizationToken=XXX"
```

- Using URI and parameters:

```
- from:
```

```
    uri: "timer://tick"
    parameters:
      period: "1s"
    steps:
      - to:
          uri: "telegram:bots"
          parameters:
            authorizationToken: "XXX"
```

146.3. DEFINING BEANS

In addition to the general support for creating beans provided by Camel Main, the YAML DSL provide a convenient syntax to define and configure them:

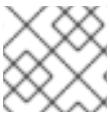
```
- beans:
  - name: beanFromMap (1)
    type: com.acme.MyBean (2)
    properties: (3)
      foo: bar
```

Where,

1. The name of the bean which will bound the instance to the Camel Registry.
2. The full qualified class name of the bean
3. The properties of the bean to be set

The properties of the bean can be defined using either a map or properties style, as shown in the example below:

```
- beans:
  # map style
  - name: beanFromMap
    type: com.acme.MyBean
    properties:
      field1: 'f1'
      field2: 'f2'
      nested:
        field1: 'nf1'
        field2: 'nf2'
  # properties style
  - name: beanFromProps
    type: com.acme.MyBean
    properties:
      field1: 'f1_p'
      field2: 'f2_p'
      nested.field1: 'nf1_p'
      nested.field2: 'nf2_p'
```



NOTE

The **beans** elements is only used as root element.

146.4. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

146.4.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with Component DSL in a configuration file (application.properties|yaml), or directly with Java code.

146.4.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use Endpoint DSL and DataFormat DSL as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use Property Placeholders for urls, port numbers, sensitive information, and other settings.

Placeholders allows you to externalize the configuration from your code, giving you more flexible and reusable code.

146.5. CONFIGURING OPTIONS ON LANGUAGES

Some languages have additional configurations that you may need to use.

For example, the JSONPath can be configured to ignore JSON parsing errors. This is intended when you use a Content Based Router and want to route the message to different endpoints. The JSON payload of the message can be in different forms, meaning that the JSonPath expressions in some cases would fail with an exception, and other times not. In this situation you must set **suppress-exception** to true, as shown below:

```
- from:
    uri: "direct:start"
    steps:
      - choice:
          when:
          - jsonpath:
              expression: "person.middlename"
              suppress-exceptions: true
            steps:
```

```
      - to: "mock:middle"
    - jsonpath:
        expression: "person.lastname"
        suppress-exceptions: true
      steps:
      - to: "mock:last"
    otherwise:
      steps:
        - to: "mock:other"
```

In the route above, the following message would have failed the JSonPath expression **person.middlename** because the JSON payload does not have a **middlename** field. To remedy this, we have suppressed the exception.

```
{
  "person": {
    "firstname": "John",
    "lastname": "Doe"
  }
}
```

146.6. EXTERNAL EXAMPLES

You can find a set of examples using **main-yaml** in Camel examples that demonstrate how to create the Camel Routes with YAML. You can also refer to Camel Kamelets where each Kamelet is defined using YAML.

CHAPTER 147. ZIP FILE

The Zip File Data Format is a message compression and de-compression format. Messages can be marshalled (compressed) to Zip files containing a single entry, and Zip files containing a single entry can be unmarshalled (decompressed) to the original file contents. This data format supports ZIP64, as long as Java 7 or later is being used].

147.1. DEPENDENCIES

When using **zipfile** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-zipfile-starter</artifactId>
</dependency>
```

147.2. ZIPFILE OPTIONS

The Zip File dataformat supports 4 options, which are listed below.

Name	Default	Java Type	Description
usingIterator		**Boolean**	If the zip file has more then one entry, the setting this option to true, allows to work with the splitter EIP, to split the data using an iterator in a streaming mode.
allowEmptyDirectory		**Boolean**	If the zip file has more then one entry, setting this option to true, allows to get the iterator even if the directory is empty.
preservePathElements		**Boolean**	If the file name contains path elements, setting this option to true, allows the path to be maintained in the zip file.
maxDecompressedSize		**Integer**	Set the maximum decompressed size of a zip file (in bytes). The default value if not specified corresponds to 1 gigabyte. An IOException will be thrown if the decompressed size exceeds this amount. Set to -1 to disable setting a maximum decompressed size.

147.3. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload using Zip file compression, and send it to an ActiveMQ queue called MY_QUEUE.

```
from("direct:start")
    .marshal().zipFile()
    .to("activemq:queue:MY_QUEUE");
```

The name of the Zip entry inside the created Zip file is based on the incoming **CamelFileName** message

header, which is the standard message header used by the file component. Additionally, the outgoing **CamelFileName** message header is automatically set to the value of the incoming **CamelFileName** message header, with the ".zip" suffix. So for example, if the following route finds a file named "test.txt" in the input directory, the output will be a Zip file named "test.txt.zip" containing a single Zip entry named "test.txt":

```
from("file:input/directory?antInclude=*/.txt")
    .marshal().zipFile()
    .to("file:output/directory");
```

If there is no incoming **CamelFileName** message header (for example, if the file component is not the consumer), then the message ID is used by default, and since the message ID is normally a unique generated ID, you will end up with filenames like **ID-MACHINENAME-2443-1211718892437-1-0.zip**. If you want to override this behavior, then you can set the value of the **CamelFileName** header explicitly in your route:

```
from("direct:start")
    .setHeader(Exchange.FILE_NAME, constant("report.txt"))
    .marshal().zipFile()
    .to("file:output/directory");
```

This route would result in a Zip file named "report.txt.zip" in the output directory, containing a single Zip entry named "report.txt".

147.4. UNMARSHAL

In this example we unmarshal a Zip file payload from an ActiveMQ queue called MY_QUEUE to its original format, and forward it for processing to the **UnZippedMessageProcessor**.

```
from("activemq:queue:MY_QUEUE")
    .unmarshal().zipFile()
    .process(new UnZippedMessageProcessor());
```

If the zip file has more then one entry, the usingIterator option of ZipFileDataFormat to be true, and you can use splitter to do the further work.

```
ZipFileDataFormat zipFile = new ZipFileDataFormat();
zipFile.setUsingIterator(true);

from("file:src/test/resources/org/apache/camel/dataformat/zipfile/?delay=1000&noop=true")
    .unmarshal(zipFile)
    .split(body(Iterator.class)).streaming()
        .process(new UnZippedMessageProcessor())
    .end();
```

Or you can use the ZipSplitter as an expression for splitter directly like this

```
from("file:src/test/resources/org/apache/camel/dataformat/zipfile?delay=1000&noop=true")
    .split(new ZipSplitter()).streaming()
        .process(new UnZippedMessageProcessor())
    .end();
```

147.4.1. Aggregate

NOTE

This aggregation strategy requires eager completion check to work properly.

In this example we aggregate all text files found in the input directory into a single Zip file that is stored in the output directory.

```
from("file:input/directory?antInclude=*/.txt")
    .aggregate(constant(true), new ZipAggregationStrategy())
        .completionFromBatchConsumer().eagerCheckCompletion()
        .to("file:output/directory");
```

The outgoing **CamelFileName** message header is created using java.io.File.createTempFile, with the ".zip" suffix. If you want to override this behavior, then you can set the value of the **CamelFileName** header explicitly in your route:

```
from("file:input/directory?antInclude=*/.txt")
    .aggregate(constant(true), new ZipAggregationStrategy())
        .completionFromBatchConsumer().eagerCheckCompletion()
        .setHeader(Exchange.FILE_NAME, constant("reports.zip"))
        .to("file:output/directory");
```

147.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.dataformat.zipfile.allow-empty-directory	If the zip file has more then one entry, setting this option to true, allows to get the iterator even if the directory is empty.	false	Boolean
camel.dataformat.zipfile.enabled	Whether to enable auto configuration of the zipfile data format. This is enabled by default.		Boolean
camel.dataformat.zipfile.max-decompressed-size	Set the maximum decompressed size of a zip file (in bytes). The default value if not specified corresponds to 1 gigabyte. An IOException will be thrown if the decompressed size exceeds this amount. Set to -1 to disable setting a maximum decompressed size.	1073741824	Long
camel.dataformat.zipfile.preserve-path-elements	If the file name contains path elements, setting this option to true, allows the path to be maintained in the zip file.	false	Boolean
camel.dataformat.zipfile.using-iterator	If the zip file has more then one entry, the setting this option to true, allows to work with the splitter EIP, to split the data using an iterator in a streaming mode.	false	Boolean
