PREFACE

1. ABOUT THIS GUIDE

This book describes the Device Mapper Multipath (DM-Multipath) feature of Red Hat Enterprise Linux for the Red Hat Enterprise Linux 6 release.

2. AUDIENCE

This book is intended to be used by system administrators managing systems running the Linux operating system. It requires familiarity with Red Hat Enterprise Linux.

3. RELATED DOCUMENTATION

For more information about using Red Hat Enterprise Linux 6, see the following resources:

- Installation Guide Documents relevant information regarding the installation of Red Hat Enterprise Linux 6.
- *Deployment Guide* Documents relevant information regarding the deployment, configuration and administration of Red Hat Enterprise Linux 6.
- Storage Administration Guide Provides instructions on how to effectively manage storage devices and file systems on Red Hat Enterprise Linux 6.

For more information about Red Hat Enterprise Linux 6, see the following resources:

- High Availability Add-On Overview Provides a high-level overview of the Red Hat High Availability Add-On.
- *Cluster Administration* Provides information about installing, configuring and managing the High Availability Add-On.
- Logical Volume Manager Administration Provides a description of the Logical Volume Manager (LVM), including information on running LVM in a clustered environment.
- Global File System 2: Configuration and Administration Provides information about installing, configuring, and maintaining Red Hat GFS2 (Red Hat Global File System 2).
- Load Balancer Administration Provides information on configuring high-performance systems and services with the Load Balancer Add-On, a set of integrated software components that provide Linux Virtual Servers (LVS) for balancing IP load across a set of real servers.
- Release Notes Provides information about the current release of Red Hat products.

Red Hat documents are available in HTML, PDF, and RPM versions on the Red Hat Enterprise Linux Documentation CD and online at https://access.redhat.com/site/documentation/.

4. WE NEED FEEDBACK!

If you find a typographical error in this manual, or if you have thought of a way to make this manual better, we would love to hear from you! Please submit a report in Bugzilla: http://bugzilla.redhat.com/ against the product **Red Hat Enterprise Linux 6** and the component **doc-DM_Multipath**. When submitting a bug report, be sure to mention the manual's identifier:

rh-DM_Multipath(EN)-6 (2017-3-8T15:15)

If you have a suggestion for improving the documentation, try to be as specific as possible when describing it. If you have found an error, include the section number and some of the surrounding text so we can find it easily.

CHAPTER 1. DEVICE MAPPER MULTIPATHING

Device mapper multipathing (DM-Multipath) allows you to configure multiple I/O paths between server nodes and storage arrays into a single device. These I/O paths are physical SAN connections that can include separate cables, switches, and controllers. Multipathing aggregates the I/O paths, creating a new device that consists of the aggregated paths.

This chapter provides a summary of the features of DM-Multipath that are new for the initial release of Red Hat Enterprise Linux 6. Following that, this chapter provides a high-level overview of DM Multipath and its components, as well as an overview of DM-Multipath setup.

1.1. NEW AND CHANGED FEATURES

This section lists new and changed features of DM-Multipath that are included with the initial and subsequent releases of Red Hat Enterprise Linux 6.

1.1.1. New and Changed Features for Red Hat Enterprise Linux 6.0

Red Hat Enterprise Linux 6.0 includes the following documentation and feature updates and changes.

For the Red Hat Enterprise Linux 6 release, the initial DM-Multipath setup procedure for a basic failover configuration has changed. You can now create the DM-Multipath configuration file and enable DM-Multipath with the mpathconf configuration utility, which can also load the device-mapper-multipath module, start the multipathd daemon, and set chkconfig to start the daemon automatically on reboot.

For information on the new setup procedure, see Section 3.1, "Setting Up DM-Multipath". For more information on the **mpathconf** command, see the **mpathconf**(5) man page.

- The Red Hat Enterprise Linux 6 release provides a new mode for setting up multipath devices, which you set with the find_multipaths configuration file parameter. In previous releases of Red Hat Enterprise Linux, multipath always tried to create a multipath device for every path that was not explicitly blacklisted. In Red Hat Enterprise Linux 6, however, if the find_multipaths configuration parameter is set to yes, then multipath will create a device only if one of three conditions are met:
 - There are at least two non-blacklisted paths with the same WWID.
 - The user manually forces the device creation, by specifying a device with the **multipath** command.
 - A path has the same WWID as a multipath device that was previously created (even if that
 multipath device does not currently exist). For instructions on the procedure to follow if you
 have previously created multipath devices when the **find_multipaths** parameter was not
 set, see Section 4.2, "Configuration File Blacklist".

This feature should allow most users to have multipath automatically choose the correct paths to make into multipath devices, without having to edit the blacklist.

For information on the **find_multipaths** configuration parameter, see Section 4.3, "Configuration File Defaults".

• The Red Hat Enterprise Linux 6 release provides two new path selector algorithms which determine which path to use for the next I/O operation: **queue-length** and **service-time**. The **queue-length** algorithm looks at the amount of outstanding I/O to the paths to determine

which path to use next. The **service-time** algorithm looks at the amount of outstanding I/O and the relative throughput of the paths to determine which path to use next. For more information on the path selector parameters in the configuration file, see Chapter 4, *The DM-Multipath Configuration File*.

- In the Red Hat Enterprise Linux 6 release, priority functions are no longer callout programs.
 Instead they are dynamic shared objects like the path checker functions. The prio_callout parameter has been replaced by the prio parameter. For descriptions of the supported prio functions, see Chapter 4, The DM-Multipath Configuration File.
- In Red Hat Enterprise Linux 6, the **multipath** command output has changed format. For information on the **multipath** command output, see Section 5.7, "Multipath Command Output".
- In the Red Hat Enterprise Linux 6 release, the location of the multipath **bindings** file is /etc/multipath/bindings.
- The Red Hat Enterprise Linux 6 release provides three new **defaults** parameters in the **multipath.conf** file: **checker_timeout**, **fast_io_fail_tmo**, and **dev_loss_tmo**. For information on these parameters, see Chapter 4, *The DM-Multipath Configuration File*.
- When the **user_friendly_names** option in the multipath configuration file is set to **yes**, the name of a multipath device is of the form **mpath** *n*. For the Red Hat Enterprise Linux 6 release, *n* is an alphabetic character, so that the name of a multipath device might be **mpatha** or **mpathb**. In previous releases, *n* was an integer.

1.1.2. New and Changed Features for Red Hat Enterprise Linux 6.1

Red Hat Enterprise Linux 6.1 includes the following documentation and feature updates and changes.

- This document now contains a new chapter, Section 5.3, "Moving root File Systems from a Single Path Device to a Multipath Device".
- This document now contains a new chapter, Section 5.4, "Moving swap File Systems from a Single Path Device to a Multipath Device".

1.1.3. New and Changed Features for Red Hat Enterprise Linux 6.2

Red Hat Enterprise Linux 6.2 includes the following documentation and feature updates and changes.

- The Red Hat Enterprise Linux 6.2 release provides a new multipath.conf parameter, rr_min_io_rq, in the defaults, devices, and multipaths sections of the multipath.conf file. The rr_min_io parameter no longer has an effect in Red Hat Enterprise Linux 6.2. For information on the rr_min_io_rq parameter, see Chapter 4, The DM-Multipath Configuration File.
- The **dev_loss_tmo** configuration file parameter can now be set to infinity, which sets the actual **sysfs** variable to 2147483647 seconds, or 68 years. For information on this parameter, see Chapter 4, *The DM-Multipath Configuration File*.
- The procedure described in Section 5.3, "Moving root File Systems from a Single Path Device to a Multipath Device" has been updated.

1.1.4. New and Changed Features for Red Hat Enterprise Linux 6.3

Red Hat Enterprise Linux 6.3 includes the following documentation and feature updates and changes.

- The default value of the **queue_without_daemon** configuration file parameter is now set to **no** by default.
- The default value of the max_fds configuration file parameter is now set to max by default.
- The user_friendly_names configuration file parameter is now configurable in the defaults, multipaths, and devices sections of the multipath.conf configuration file.
- The **defaults** section of the **multipath.conf** configuration file supports a new **hwtable regex match** parameter.

For information on the configuration file parameters, see Chapter 4, The DM-Multipath Configuration File.

1.1.5. New and Changed Features for Red Hat Enterprise Linux 6.4

Red Hat Enterprise Linux 6.4 includes the following documentation and feature updates and changes.

- The defaults section and the devices section of the multipath.conf configuration file support a new retain_attached_hardware_handler parameter and a new detect_prio parameter. For information on the configuration file parameters, see Chapter 4, The DM-Multipath Configuration File.
- This document contains a new section, Section 3.4, "Setting Up Multipathing in the initramfs File System".

1.1.6. New and Changed Features for Red Hat Enterprise Linux 6.5

Red Hat Enterprise Linux 6.5 includes the following documentation and feature updates and changes.

The defaults section of the multipath.conf configuration file supports a new replace_wwid_whitespace and a new reload_readwrite parameter. The defaults section of the multipath.conf file is documented in Table 4.1, "Multipath Configuration Defaults".

1.1.7. New and Changed Features for Red Hat Enterprise Linux 6.6

Red Hat Enterprise Linux 6.6 includes the following documentation and feature updates and changes.

- The **defaults** section of the **multipath.conf** configuration file supports a new **force_sync** parameter. The **defaults** section of the **multipath.conf** file is documented in Table 4.1, "Multipath Configuration Defaults".
- The **multipath** supports a **-w** and a **-W**, as described in Table 4.1, "Multipath Configuration Defaults".

1.1.8. New and Changed Features for Red Hat Enterprise Linux 6.7

Red Hat Enterprise Linux 6.7 includes the following documentation and feature updates and changes.

- This document includes a new section, Section 5.1, "Automatic Configuration File Generation with Multipath Helper". The Multipath Helper application gives you options to create multipath configurations with custom aliases, device blacklists, and settings for the characteristics of individual multipath devices.
- The **defaults** section of the **multipath.conf** configuration file supports a new **config dir**

parameter. The **defaults** section of the **multipath.conf** file is documented in Table 4.1, "Multipath Configuration Defaults".

• The **defaults**, **devices**, and **multipaths** sections of the **multipath.conf** configuration file now support the **delay_watch_checks** and **delay_wait_checks** configuration parameters. For information on the configuration parameters, see Chapter 4, *The DM-Multipath Configuration File*.

1.1.9. New and Changed Features for Red Hat Enterprise Linux 6.8

Red Hat Enterprise Linux 6.8 includes the following documentation and feature updates and changes.

- The **prio** configuration parameter now supports the **prio** "alua exclusive_pref_bit" setting, which will cause multipath to create a path group that contains only the path with the **pref** bit set and will give that path group the highest priority. For information on the configuration parameters, see Chapter 4, *The DM-Multipath Configuration File*.
- As of Red Hat Enterprise Linux release 6.8, the multipathd command supports new format
 commands that show the status of multipath devices and paths in "raw" format versions. For
 information on the multipathd command, see Section 5.12, "The multipathd Interactive
 Console and the multipathd Command".

1.1.10. New and Changed Features for Red Hat Enterprise Linux 6.9

Red Hat Enterprise Linux 6.9 includes the following documentation and feature updates and changes.

• The **defaults**, **devices**, and **multipaths** sections of the **multipath.conf** configuration file now support the **skip_kpartx** and **max_sectors_kb** configuration parameters. For information on the configuration parameters, see Chapter 4, *The DM-Multipath Configuration File*.

1.2. OVERVIEW OF DM-MULTIPATH

DM-Multipath can be used to provide:

Redundancy

DM-Multipath can provide failover in an active/passive configuration. In an active/passive configuration, only half the paths are used at any time for I/O. If any element of an I/O path (the cable, switch, or controller) fails, DM-Multipath switches to an alternate path.

Improved Performance

DM-Multipath can be configured in active/active mode, where I/O is spread over the paths in a round-robin fashion. In some configurations, DM-Multipath can detect loading on the I/O paths and dynamically re-balance the load.

Figure 1.1, "Active/Passive Multipath Configuration with One RAID Device" shows an active/passive configuration with two I/O paths from the server to a RAID device. There are 2 HBAs on the server, 2 SAN switches, and 2 RAID controllers.

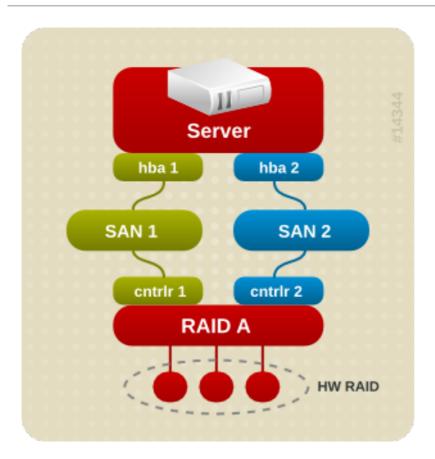

Figure 1.1. Active/Passive Multipath Configuration with One RAID Device

In this configuration, there is one I/O path that goes through hba1, SAN1, and controller 1 and a second I/O path that goes through hba2, SAN2, and controller2. There are many points of possible failure in this configuration:

- HBA failure
- FC cable failure
- SAN switch failure
- Array controller port failure

With DM-Multipath configured, a failure at any of these points will cause DM-Multipath to switch to the alternate I/O path.

Figure 1.2, "Active/Passive Multipath Configuration with Two RAID Devices" shows a more complex active/passive configuration with 2 HBAs on the server, 2 SAN switches, and 2 RAID devices with 2 RAID controllers each.

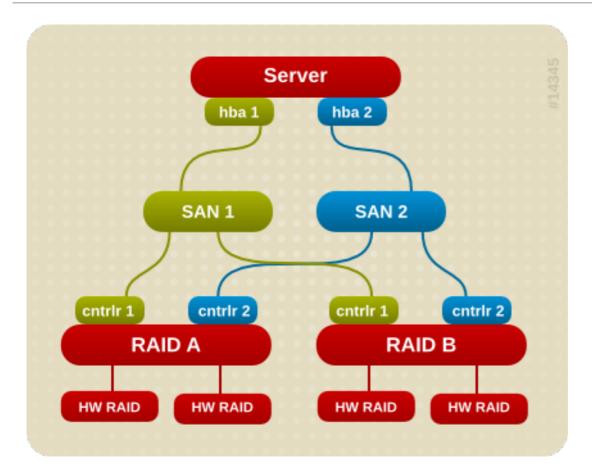

Figure 1.2. Active/Passive Multipath Configuration with Two RAID Devices

In the example shown in Figure 1.2, "Active/Passive Multipath Configuration with Two RAID Devices", there are two I/O paths to each RAID device (just as there are in the example shown in Figure 1.1, "Active/Passive Multipath Configuration with One RAID Device"). With DM-Multipath configured, a failure at any of the points of the I/O path to either of the RAID devices will cause DM-Multipath to switch to the alternate I/O path for that device.

Figure 1.3, "Active/Active Multipath Configuration with One RAID Device" shows an active/active configuration with 2 HBAs on the server, 1 SAN switch, and 2 RAID controllers. There are four I/O paths from the server to a storage device:

- hba1 to controller1
- hba1 to controller2
- hba2 to controller1
- hba2 to controller2

In this configuration, I/O can be spread among those four paths.

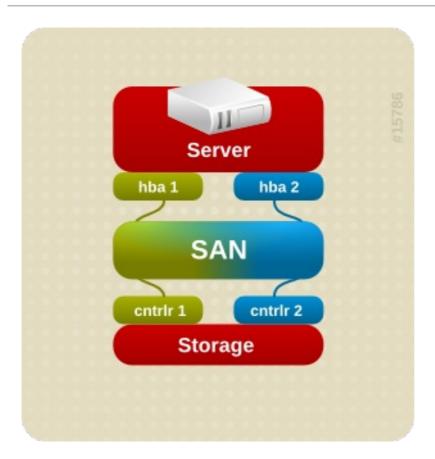

Figure 1.3. Active/Active Multipath Configuration with One RAID Device

1.3. STORAGE ARRAY SUPPORT

By default, DM-Multipath includes support for the most common storage arrays that support DM-Multipath. The supported devices can be found in the **multipath.conf.defaults** file. If your storage array supports DM-Multipath and is not configured by default in this file, you may need to add them to the DM-Multipath configuration file, **multipath.conf**. For information on the DM-Multipath configuration file, see Chapter 4, *The DM-Multipath Configuration File*.

Some storage arrays require special handling of I/O errors and path switching. These require separate hardware handler kernel modules.

1.4. DM-MULTIPATH COMPONENTS

Table 1.1, "DM-Multipath Components". describes the components of DM-Multipath.

Table 1.1. DM-Multipath Components

Component	Description
dm_multipath kernel module	Reroutes I/O and supports failover for paths and path groups.
mpathconf utility	Configures and enables device mapper multipathing.
multipath command	Lists and configures multipath devices. Normally started up with /etc/rc.sysinit, it can also be started up by a udev program whenever a block device is added.

Component	Description
multipathd daemon	Monitors paths; as paths fail and come back, it may initiate path group switches. Provides for interactive changes to multipath devices. This must be restarted for any changes to the /etc/multipath.conf file.
kpartx command	Creates device mapper devices for the partitions on a device It is necessary to use this command for DOS-based partitions with DM-MP. The kpartx is provided in its own package, but the device-mapper-multipath package depends on it.

1.5. DM-MULTIPATH SETUP OVERVIEW

DM-Multipath includes compiled-in default settings that are suitable for common multipath configurations. Setting up DM-multipath is often a simple procedure.

The basic procedure for configuring your system with DM-Multipath is as follows:

- 1. Install the **device-mapper-multipath** rpm.
- 2. Create the configuration file and enable multipathing with the **mpathconf** command. You can also start the multipath daemon with this command if you do not need to edit the configuration file.
- 3. If necessary, edit the **multipath.conf** configuration file to modify default values and save the updated file.
- 4. Start the multipath daemon.

For detailed setup instructions for multipath configuration see Chapter 3, Setting Up DM-Multipath.

CHAPTER 2. MULTIPATH DEVICES

Without DM-Multipath, each path from a server node to a storage controller is treated by the system as a separate device, even when the I/O path connects the same server node to the same storage controller. DM-Multipath provides a way of organizing the I/O paths logically, by creating a single multipath device on top of the underlying devices.

2.1. MULTIPATH DEVICE IDENTIFIERS

Each multipath device has a World Wide Identifier (WWID), which is guaranteed to be globally unique and unchanging. By default, the name of a multipath device is set to its WWID. Alternately, you can set the **user_friendly_names** option in the multipath configuration file, which sets the alias to a node-unique name of the form **mpathn**.

For example, a node with two HBAs attached to a storage controller with two ports by means of a single unzoned FC switch sees four devices: /dev/sda, /dev/sdb, dev/sdc, and /dev/sdd. DM-Multipath creates a single device with a unique WWID that reroutes I/O to those four underlying devices according to the multipath configuration. When the user_friendly_names configuration option is set to yes, the name of the multipath device is set to mpathn.

When new devices are brought under the control of DM-Multipath, the new devices may be seen in two different places under the /dev directory: /dev/mapper/mpathn and /dev/dm-n.

- The devices in /dev/mapper are created early in the boot process. Use these devices to access the multipathed devices, for example when creating logical volumes.
- Any devices of the form /dev/dm-n are for internal use only and should never be used.

For information on the multipath configuration defaults, including the **user_friendly_names** configuration option, see Section 4.3, "Configuration File Defaults".

You can also set the name of a multipath device to a name of your choosing by using the **alias** option in the **multipaths** section of the multipath configuration file. For information on the **multipaths** section of the multipath configuration file, see Section 4.4, "Multipaths Device Configuration Attributes".

2.2. CONSISTENT MULTIPATH DEVICE NAMES IN A CLUSTER

When the <code>user_friendly_names</code> configuration option is set to <code>yes</code>, the name of the multipath device is unique to a node, but it is not guaranteed to be the same on all nodes using the multipath device. Similarly, if you set the <code>alias</code> option for a device in the <code>multipaths</code> section of the <code>multipath.conf</code> configuration file, the name is not automatically consistent across all nodes in the cluster. This should not cause any difficulties if you use LVM to create logical devices from the multipath device, but if you require that your multipath device names be consistent in every node it is recommended that you not set the <code>user_friendly_names</code> option to <code>yes</code> and that you not configure aliases for the devices. By default, if you do not set <code>user_friendly_names</code> to <code>yes</code> or configure an alias for a device, a device name will be the WWID for the device, which is always the same.

If you want the system-defined user-friendly names to be consistent across all nodes in the cluster, however, you can follow this procedure:

- 1. Set up all of the multipath devices on one machine.
- 2. Disable all of your multipath devices on your other machines by running the following commands:

```
# service multipathd stop
# multipath -F
```

- 3. Copy the /etc/multipath/bindings file from the first machine to all the other machines in the cluster.
- 4. Re-enable the **multipathd** daemon on all the other machines in the cluster by running the following command:

```
# service multipathd start
```

If you add a new device, you will need to repeat this process.

Similarly, if you configure an alias for a device that you would like to be consistent across the nodes in the cluster, you should ensure that the **/etc/multipath.conf** file is the same for each node in the cluster by following the same procedure:

- 1. Configure the aliases for the multipath devices in the in the **multipath.conf** file on one machine.
- 2. Disable all of your multipath devices on your other machines by running the following commands:

```
# service multipathd stop
# multipath -F
```

- 3. Copy the /etc/multipath.conf file from the first machine to all the other machines in the cluster.
- 4. Re-enable the **multipathd** daemon on all the other machines in the cluster by running the following command:

```
# service multipathd start
```

When you add a new device you will need to repeat this process.

2.3. MULTIPATH DEVICE ATTRIBUTES

In addition to the **user_friendly_names** and **alias** options, a multipath device has numerous attributes. You can modify these attributes for a specific multipath device by creating an entry for that device in the **multipaths** section of the multipath configuration file. For information on the **multipaths** section of the multipath configuration file, see Section 4.4, "Multipaths Device Configuration Attributes".

2.4. MULTIPATH DEVICES IN LOGICAL VOLUMES

After creating multipath devices, you can use the multipath device names just as you would use a physical device name when creating an LVM physical volume. For example, if /dev/mapper/mpatha is the name of a multipath device, the following command will mark /dev/mapper/mpatha as a physical volume.

pvcreate /dev/mapper/mpatha

You can use the resulting LVM physical device when you create an LVM volume group just as you would use any other LVM physical device.

NOTE

If you attempt to create an LVM physical volume on a whole device on which you have configured partitions, the **pvcreate** command will fail. Note that the Anaconda and Kickstart installation programs create empty partition tables if you do not specify otherwise for every block device. If you wish to use the whole device rather than a partition, you must remove the existing partitions from the device. You can remove existing partitions with the **kpartx** -d and the **fdisk** commands. If your system has block devices that are greater that 2Tb, you can use the **parted** command to remove partitions.

When you create an LVM logical volume that uses active/passive multipath arrays as the underlying physical devices, you should include filters in the <code>lvm.conf</code> to exclude the disks that underlie the multipath devices. This is because if the array automatically changes the active path to the passive path when it receives I/O, multipath will failover and failback whenever LVM scans the passive path if these devices are not filtered. For active/passive arrays that require a command to make the passive path active, LVM prints a warning message when this occurs.

To filter all SCSI devices in the LVM configuration file (**lvm.conf**), include the following filter in the **devices** section of the file.

```
filter = [ "r/block/", "r/disk/", "r/sd.*/", "a/.*/" ]
```

CHAPTER 3. SETTING UP DM-MULTIPATH

This chapter provides step-by-step example procedures for configuring DM-Multipath. It includes the following procedures:

- Basic DM-Multipath setup
- Ignoring local disks
- Adding more devices to the configuration file
- Starting multipath in the **initramfs** file system

3.1. SETTING UP DM-MULTIPATH

Before setting up DM-Multipath on your system, ensure that your system has been updated and includes the **device-mapper-multipath** package.

You set up multipath with the **mpathconf** utility, which creates the multipath configuration file **/etc/multipath.conf**.

- If the /etc/multipath.conf file already exists, the mpathconf utility will edit it.
- If the /etc/multipath.conf file does not exist, the mpathconf utility will use the /usr/share/doc/device-mapper-multipath-0.4.9/multipath.conf file as the starting file.
- If the /usr/share/doc/device-mapper-multipath-0.4.9/multipath.conf file does not exist the mpathconf utility will create the /etc/multipath.conf file from scratch.

If you do not need to edit the **/etc/multipath.conf** file, you can set up DM-Multipath for a basic failover configuration by running the following command. This command enables the multipath configuration file and starts the **multipathd** daemon.

```
# mpathconf --enable --with_multipathd y
```

If you need to edit the **/etc/multipath.conf** file before starting the **multipathd** daemon. use the following procedure to set up DM-Multipath for a basic failover configuration.

1. Run the **mpathconf** command with the **--enable** option specified:

```
# mpathconf --enable
```

For information on additional options to the **mpathconf** command you may require, see the **mpathconf** man page or enter the **mpathconf** command with the **--help** option specified.

```
# mpathconf --help
usage: /sbin/mpathconf <command>

Commands:
Enable: --enable
Disable: --disable
Set user_friendly_names (Default n): --user_friendly_names <y|n>
Set find_multipaths (Default n): --find_multipaths <y|n>
```

```
Load the dm-multipath modules on enable (Default y): --with_module <y|n> start/stop/reload multipathd (Default n): --with_multipathd <y|n> chkconfig on/off multipathd (Default y): --with_chkconfig <y|n>
```

2. Edit the /etc/multipath.conf file if necessary. The default settings for DM-Multipath are compiled in to the system and do not need to be explicitly set in the /etc/multipath.conf file.

The default value of **path_grouping_policy** is set to **failover**, so in this example you do not need to edit the **/etc/multipath.conf** file. For information on changing the values in the configuration file to something other than the defaults, see Chapter 4, *The DM-Multipath Configuration File*.

The initial defaults section of the configuration file configures your system so that the names of the multipath devices are of the form **mpath***n*; without this setting, the names of the multipath devices would be aliased to the WWID of the device.

- 3. Save the configuration file and exit the editor, if necessary.
- 4. Execute the following command:

service multipathd start

Since the value of **user_friendly_names** is set to **yes** in the configuration file, the multipath devices will be created as **/dev/mapper/mpath** n. For information on setting the name of the device to an alias of your choosing, see Chapter 4, *The DM-Multipath Configuration File*.

If you do not want to use user friendly names, you can enter the following command:

```
# mpathconf --enable --user_friendly_names n
```

NOTE

If you find that you need to edit the multipath configuration file after you have started the multipath daemon, you must execute the **service multipathd reload** command for the changes to take effect.

3.2. IGNORING LOCAL DISKS WHEN GENERATING MULTIPATH DEVICES

Some machines have local SCSI cards for their internal disks. DM-Multipath is not recommended for these devices. If you set the **find_multipaths** configuration parameter to **yes**, you should not have to blacklist these devices. For information on the **find_multipaths** configuration parameter, see Section 4.3, "Configuration File Defaults".

If you do not set the **find_multipaths** configuration parameter to **yes**, can use the following procedure to modify the multipath configuration file to ignore the local disks when configuring multipath.

1. Determine which disks are the internal disks and mark them as the ones to blacklist.

In this example, /dev/sda is the internal disk. Note that as originally configured in the default multipath configuration file, executing the multipath -v2 shows the local disk, /dev/sda, in the multipath map.

For further information on the **multipath** command output, see Section 5.7, "Multipath Command Output".

```
# multipath -v2
create: SIBM-ESXSST336732LC F3ET0EP0Q000072428BX1 undef
WINSYS, SF2372
size=33 GB features="0" hwhandler="0" wp=undef
-+- policy='round-robin 0' prio=1 status=undef
  |- 0:0:0:0 sda 8:0 [------
device-mapper ioctl cmd 9 failed: Invalid argument
device-mapper ioctl cmd 14 failed: No such device or address
create: 3600a0b80001327d80000006d43621677 undef WINSYS,SF2372
size=12G features='0' hwhandler='0' wp=undef
-+- policy='round-robin 0' prio=1 status=undef
  |- 2:0:0:0 sdb 8:16 undef ready running
   - 3:0:0:0 sdf 8:80 undef ready running
create: 3600a0b80001327510000009a436215ec undef WINSYS,SF2372
size=12G features='0' hwhandler='0' wp=undef
`-+- policy='round-robin 0' prio=1 status=undef
  |- 2:0:0:1 sdc 8:32 undef ready running
   - 3:0:0:1 sdg 8:96 undef ready running
create: 3600a0b80001327d800000070436216b3 undef WINSYS,SF2372
size=12G features='0' hwhandler='0' wp=undef
`-+- policy='round-robin 0' prio=1 status=undef
  |- 2:0:0:2 sdd 8:48 undef ready running
   - 3:0:0:2 sdg 8:112 undef ready running
create: 3600a0b80001327510000009b4362163e undef WINSYS,SF2372
size=12G features='0' hwhandler='0' wp=undef
-+- policy='round-robin 0' prio=1 status=undef
  |- 2:0:0:3 sdd 8:64 undef ready running
   - 3:0:0:3 sdg 8:128 undef ready running
```

2. In order to prevent the device mapper from mapping /dev/sda in its multipath maps, edit the blacklist section of the /etc/multipath.conf file to include this device. Although you could blacklist the sda device using a devnode type, that would not be safe procedure since /dev/sda is not guaranteed to be the same on reboot. To blacklist individual devices, you can blacklist using the WWID of that device.

Note that in the output to the **multipath -v2** command, the WWID of the **/dev/sda** device is SIBM-ESXSST336732LC___F3ET0EP0Q000072428BX1. To blacklist this device, include the following in the **/etc/multipath.conf** file.

```
blacklist {
     wwid SIBM-ESXSST336732LC____F3ET0EP0Q000072428BX1
}
```

3. After you have updated the /etc/multipath.conf file, you must manually tell the

multipathd daemon to reload the file. The following command reloads the updated
/etc/multipath.conf file.

```
# service multipathd reload
```

4. Run the following command to remove the multipath device:

```
# multipath -f SIBM-ESXSST336732LC____F3ET0EP0Q000072428BX1
```

5. To check whether the device removal worked, you can enter the **multipath -ll** command to display the current multipath configuration. For information on the **multipath -ll** command, see Section 5.8, "Multipath Queries with multipath Command".

To check that the blacklisted device was not added back, you can enter the **multipath** command, as in the following example. The **multipath** command defaults to a verbosity level of **v2** if you do not specify specify a -v option.

```
# multipath
create: 3600a0b80001327d80000006d43621677 undef WINSYS,SF2372
size=12G features='0' hwhandler='0' wp=undef
`-+- policy='round-robin 0' prio=1 status=undef
  |- 2:0:0:0 sdb 8:16 undef ready running
  - 3:0:0:0 sdf 8:80 undef ready running
create: 3600a0b80001327510000009a436215ec undef WINSYS,SF2372
size=12G features='0' hwhandler='0' wp=undef
`-+- policy='round-robin 0' prio=1 status=undef
  |- 2:0:0:1 sdc 8:32 undef ready running
   - 3:0:0:1 sdg 8:96 undef ready running
create: 3600a0b80001327d800000070436216b3 undef WINSYS,SF2372
size=12G features='0' hwhandler='0' wp=undef
-+- policy='round-robin 0' prio=1 status=undef
  |- 2:0:0:2 sdd 8:48 undef ready running
  `- 3:0:0:2 sdg 8:112 undef ready running
create: 3600a0b80001327510000009b4362163e undef WINSYS,SF2372
size=12G features='0' hwhandler='0' wp=undef
`-+- policy='round-robin 0' prio=1 status=undef
  |- 2:0:0:3 sdd 8:64 undef ready running
  `- 3:0:0:3 sdg 8:128 undef ready running
```

3.3. CONFIGURING STORAGE DEVICES

By default, DM-Multipath includes support for the most common storage arrays that support DM-Multipath. The default configuration values, including supported devices, can be found in the **multipath.conf.defaults** file.

If you need to add a storage device that is not supported by default as a known multipath device, edit the /etc/multipath.conf file and insert the appropriate device information.

For example, to add information about the HP Open-V series the entry looks like this, where %n is the device name:

```
devices {
        device {
            vendor "HP"
            product "OPEN-V."
            getuid_callout "/lib/udev/scsi_id --whitelisted --device=/dev/%n"
        }
}
```

For more information on the **devices** section of the configuration file, see Section 4.5, "Configuration File Devices".

3.4. SETTING UP MULTIPATHING IN THE INITRAMFS FILE SYSTEM

You can set up multipathing in the **initramfs** file system. After configuring multipath, you can rebuild the **initramfs** file system with the multipath configuration files by executing the **dracut** command with the following options:

```
# dracut --force --add multipath --include /etc/multipath /etc/multipath
```

If you run multipath from the **initramfs** file system and you make any changes to the multipath configuration files, you must rebuild the **initramfs** file system for the changes to take effect.

CHAPTER 4. THE DM-MULTIPATH CONFIGURATION FILE

By default, DM-Multipath provides configuration values for the most common uses of multipathing. In addition, DM-Multipath includes support for the most common storage arrays that support DM-Multipath. The default configuration values and the supported devices can be found in the /usr/share/doc/device-mapper-multipath-0.4.9/multipath.conf.defaults file.

You can override the default configuration values for DM-Multipath by editing the **/etc/multipath.conf** configuration file. If necessary, you can also add a storage array that is not supported by default to the configuration file.

NOTE

You can run set up multipathing in the **initramfs** file system. If you run multipath from the **initramfs** file system and you make any changes to the multipath configuration files, you must rebuild the **initramfs** file system for the changes to take effect. For information on rebuilding the **initramfs** file system with multipath, see Section 3.4, "Setting Up Multipathing in the initramfs File System".

This chapter provides information on parsing and modifying the **multipath.conf** file. It contains sections on the following topics:

- Configuration file overview
- Configuration file blacklist
- Configuration file defaults
- Configuration file multipaths
- Configuration file devices

In the multipath configuration file, you need to specify only the sections that you need for your configuration, or that you wish to change from the default values specified in the **multipath.conf.defaults** file. If there are sections of the file that are not relevant to your environment or for which you do not need to override the default values, you can leave them commented out, as they are in the initial file.

The configuration file allows regular expression description syntax.

An annotated version of the configuration file can be found in /usr/share/doc/device-mapper-multipath-0.4.9/multipath.conf.annotated.

4.1. CONFIGURATION FILE OVERVIEW

The multipath configuration file is divided into the following sections:

blacklist

Listing of specific devices that will not be considered for multipath.

blacklist exceptions

Listing of multipath candidates that would otherwise be blacklisted according to the parameters of the blacklist section.

defaults

General default settings for DM-Multipath.

multipaths

Settings for the characteristics of individual multipath devices. These values overwrite what is specified in the **defaults** and **devices** sections of the configuration file.

devices

Settings for the individual storage controllers. These values overwrite what is specified in the **defaults** section of the configuration file. If you are using a storage array that is not supported by default, you may need to create a **devices** subsection for your array.

When the system determines the attributes of a multipath device, first it checks the multipath settings, then the per devices settings, then the multipath system defaults.

4.2. CONFIGURATION FILE BLACKLIST

The **blacklist** section of the multipath configuration file specifies the devices that will not be used when the system configures multipath devices. Devices that are blacklisted will not be grouped into a multipath device.

In older releases of Red Hat Enterprise Linux, multipath always tried to create a multipath device for every path that was not explicitly blacklisted. In Red Hat Enterprise Linux 6, however, if the **find_multipaths** configuration parameter is set to **yes**, then multipath will create a device only if one of three conditions are met:

- There are at least two non-blacklisted paths with the same WWID.
- The user manually forces the creation of the device by specifying a device with the **multipath** command.
- A path has the same WWID as a multipath device that was previously created (even if that
 multipath device does not currently exist). Whenever a multipath device is created, multipath
 remembers the WWID of the device so that it will automatically create the device again as soon
 as it sees a path with that WWID. This allows you to have multipath automatically choose the
 correct paths to make into multipath devices, without have to edit the multipath blacklist.

If you have previously created a multipath device without using the **find_multipaths** parameter and then you later set the parameter to **yes**, you may need to remove the WWIDs of any device you do not want created as a multipath device from the **/etc/multipath/wwids** file. The following shows a sample **/etc/multipath/wwids** file. The WWIDs are enclosed by slashes (/):

```
# Multipath wwids, Version : 1.0
# NOTE: This file is automatically maintained by multipath and
multipathd.
# You should not need to edit this file in normal circumstances.
#
# Valid WWIDs:
/3600d02300000000000e13955cc3757802/
/3600d0230000000000e13955cc3757801/
/3600d02300000000000e13955cc3757800/
```

```
/3600d02300069c9ce09d41c31f29d4c00/
/SWINSYS SF2372 0E13955CC3757802/
/3600d0230000000000e13955cc3757803/
```

With the **find_multipaths** parameter set to **yes**, you need to blacklist only the devices with multiple paths that you do not want to be multipathed. Because of this, it will generally not be necessary to blacklist devices.

If you do need to blacklist devices, you can do so according to the following criteria:

- By WWID, as described in Section 4.2.1, "Blacklisting by WWID"
- By device name, as described in Section 4.2.2, "Blacklisting By Device Name"
- By device type, as described in Section 4.2.3, "Blacklisting By Device Type"

By default, a variety of device types are blacklisted, even after you comment out the initial blacklist section of the configuration file. For information, see Section 4.2.2, "Blacklisting By Device Name".

4.2.1. Blacklisting by WWID

You can specify individual devices to blacklist by their World-Wide IDentification with a **wwid** entry in the **blacklist** section of the configuration file.

The following example shows the lines in the configuration file that would blacklist a device with a WWID of 26353900f02796769.

4.2.2. Blacklisting By Device Name

You can blacklist device types by device name so that they will not be grouped into a multipath device by specifying a **devnode** entry in the **blacklist** section of the configuration file.

The following example shows the lines in the configuration file that would blacklist all SCSI devices, since it blacklists all sd* devices.

```
blacklist {
          devnode "^sd[a-z]"
}
```

You can use a **devnode** entry in the **blacklist** section of the configuration file to specify individual devices to blacklist rather than all devices of a specific type. This is not recommended, however, since unless it is statically mapped by **udev** rules, there is no guarantee that a specific device will have the same name on reboot. For example, a device name could change from **/dev/sda** to **/dev/sdb** on reboot.

By default, the following **devnode** entries are compiled in the default blacklist; the devices that these entries blacklist do not generally support DM-Multipath. To enable multipathing on any of these devices, you would need to specify them in the **blacklist_exceptions** section of the configuration file, as described in Section 4.2.4, "Blacklist Exceptions".

```
blacklist {
      devnode "^(ram|raw|loop|fd|md|dm-|sr|scd|st)[0-9]*"
      devnode "^(td|hd)[a-z]"
}
```

4.2.3. Blacklisting By Device Type

You can specify specific device types in the **blacklist** section of the configuration file with a **device** section. The following example blacklists all IBM DS4200 and HP devices.

```
blacklist {
    device {
        vendor "IBM"
        product "3S42" #DS4200 Product 10
    }
    device {
        vendor "HP"
        product "*"
    }
}
```

4.2.4. Blacklist Exceptions

You can use the **blacklist_exceptions** section of the configuration file to enable multipathing on devices that have been blacklisted by default.

For example, if you have a large number of devices and want to multipath only one of them (with the WWID of 3600d023000000000013955cc3757803), instead of individually blacklisting each of the devices except the one you want, you could instead blacklist all of them, and then allow only the one you want by adding the following lines to the /etc/multipath.conf file.

When specifying devices in the **blacklist_exceptions** section of the configuration file, you must specify the exceptions in the same way they were specified in the blacklist. For example, a WWID exception will not apply to devices specified by a **devnode** blacklist entry, even if the blacklisted device is associated with that WWID. Similarly, **devnode** exceptions apply only to **devnode** entries, and **device** exceptions apply only to device entries.

4.3. CONFIGURATION FILE DEFAULTS

The /etc/multipath.conf configuration file includes a defaults section that sets the user_friendly_names parameter to yes, as follows.

```
defaults {
    user_friendly_names yes
}
```

This overwrites the default value of the **user_friendly_names** parameter.

The configuration file includes a template of configuration defaults. This section is commented out, as follows.

```
#defaults {
        udev dir
                                /dev
        polling interval
                                5
#
        path selector
                                "round-robin 0"
        path grouping policy
                                failover
        getuid callout
                                "/lib/udev/scsi id --whitelisted --
device=/dev/%n"
# prio
         const
# path checker directio
# rr min io 1000
# rr weight uniform
# failback manual
# no path retry fail
# user_friendly_names no
#}
```

To overwrite the default value for any of the configuration parameters, you can copy the relevant line from this template into the **defaults** section and uncomment it. For example, to overwrite the **path_grouping_policy** parameter so that it is **multibus** rather than the default value of **failover**, copy the appropriate line from the template to the initial **defaults** section of the configuration file, and uncomment it, as follows.

```
defaults {
    user_friendly_names yes
    path_grouping_policy multibus
}
```

Table 4.1, "Multipath Configuration Defaults" describes the attributes that are set in the **defaults** section of the **multipath.conf** configuration file. These values are used by DM-Multipath unless they are overwritten by the attributes specified in the **devices** and **multipaths** sections of the **multipath.conf** file.

NOTE

As of the Red Hat Enterprise Linux 6.0 release, the **mode**, **uid**, and **gid** parameters have been deprecated. Permissions for device-mapper devices (including mulitpath mappings) are set by means of **udev** rules. There is a template file in /usr/share/doc/device-mapper-version called 12-dm-permissions.rules which you can use and place in the /etc/udev/rules.d directory for it to take effect.

Table 4.1. Multipath Configuration Defaults

Attribute	Description
polling_interval	Specifies the interval between two path checks in seconds. For properly functioning paths, the interval between checks will gradually increase to (4 * polling_interval). The default value is 5.
udev_dir	The directory where udev device nodes are created. The default value is /dev .
multipath_dir	The directory where the dynamic shared objects are stored. The default value is system dependent, commonly /lib/multipath.
find_multipaths	Defines the mode for setting up multipath devices. If this parameter is set to yes , then multipath will not try to create a device for every non-blacklisted path. Instead multipath will create a device only if one of three conditions are met: - There are at least two non-blacklisted paths with the same WWID.
	- The user manually forces the creation of the device by specifying a device with the multipath command.
	- A path has the same WWID as a multipath device that was previously created. Whenever a multipath device is created with find_multipaths set, multipath remembers the WWID of the device so that it will automatically create the device again as soon as it sees a path with that WWID. This allows you to have multipath automatically choose the correct paths to make into multipath devices, without having to edit the multipath blacklist. For instructions on the procedure to follow if you have previously created multipath devices when the find_multipaths parameter was not set, see Section 4.2, "Configuration File Blacklist".
verbosity	The default verbosity. Higher values increase the verbosity level. Valid levels are between 0 and 6. The default value is 2 .

Attribute	Description
path_selector	Specifies the default algorithm to use in determining what path to use for the next I/O operation. Possible values include:
	round-robin 0: Loop through every path in the path group, sending the same amount of I/O to each.
	queue-length 0 : Send the next bunch of I/O down the path with the least number of outstanding I/O requests.
	service-time 0 : Send the next bunch of I/O down the path with the shortest estimated service time, which is determined by dividing the total size of the outstanding I/O to each path by its relative throughput.
	The default value is round-robin 0 .
path_grouping_policy	Specifies the default path grouping policy to apply to unspecified multipaths. Possible values include:
	failover: 1 path per priority group.
	multibus: all valid paths in 1 priority group.
	group_by_serial: 1 priority group per detected serial number.
	group_by_prio : 1 priority group per path priority value. Priorities are determined by callout programs specified as global, per-controller, or permultipath options.
	<pre>group_by_node_name: 1 priority group per target node name. Target node names are fetched in /sys/class/fc_transport/target*/node_name.</pre>
	The default value is failover .
getuid_callout	Specifies the default program and arguments to call out to obtain a unique path identifier. An absolute path is required.
	The default value is /lib/udev/scsi_idwhitelisteddevice=/dev/%n.

Attribute	Description
prio	Specifies the default function to call to obtain a path priority value. For example, the ALUA bits in SPC-3 provide an exploitable prio value. Possible values include:
	const: Set a priority of 1 to all paths.
	emc: Generate the path priority for EMC arrays.
	alua: Generate the path priority based on the SCSI-3 ALUA settings. As of Red Hat Enterprise Linux 6.8, if you specify prio "alua exclusive_pref_bit" in your device configuration, multipath will create a path group that contains only the path with the pref bit set and will give that path group the highest priority.
	tpg_pref: Generate the path priority based on the SCSI-3 ALUA settings, using the preferred port bit.
	ontap: Generate the path priority for NetApp arrays.
	rdac: Generate the path priority for LSI/Engenio RDAC controller.
	hp_sw : Generate the path priority for Compaq/HP controller in active/standby mode.
	hds: Generate the path priority for Hitachi HDS Modular storage arrays.
	The default value is const .

Attribute	Description
features	The default extra features of multipath devices, using the format: "number_of_features_plus_arguments feature1". Possible values for features include: queue_if_no_path, which is the same as setting no_path_retry to queue. For information on issues that may arise when using this feature, see Section 5.6, "Issues with queue_if_no_path feature". retain_attached_hw_handler: (Red Hat Enterprise Linux Release 6.4 and later) If this parameter is set to yes and the scsi layer has already attached a hardware handler to the path device, multipath will not force the device to use the hardware_handler specified by the multipath.conf file. If the scsi layer has not attached a hardware handler, multipath will continue to use its configured hardware handler as usual. The default value is no. pg_init_retries n: Retry path group initialization up to n times before failing where 1 <= n <= 50. pg_init_delay_msecs n: Wait n milliseconds between path group initialization retries where 0 <= n <= 60000.
path_checker	Specifies the default method used to determine the state of the paths. Possible values include: readsector0: Read the first sector of the device. tur: Issue a TEST UNIT READY to the device. emc_clariion: Query the EMC Clariion specific EVPD page 0xC0 to determine the path. hp_sw: Check the path state for HP storage arrays with Active/Standby firmware. rdac: Check the path stat for LSI/Engenio RDAC storage controller. directio: Read the first sector with direct I/O. The default value is directio.

Attribute	Description
failback	Manages path group failback.
	A value of immediate specifies immediate failback to the highest priority path group that contains active paths.
	A value of manual specifies that there should not be immediate failback but that failback can happen only with operator intervention.
	A value of followover specifies that automatic failback should be performed when the first path of a path group becomes active. This keeps a node from automatically failing back when another node requested the failover.
	A numeric value greater than zero specifies deferred failback, expressed in seconds.
	The default value is manual .
rr_min_io	Specifies the number of I/O requests to route to a path before switching to the next path in the current path group. This setting is only for systems running kernels older than 2.6.31. Newer systems should use rr_min_io_rq. The default value is 1000.
rr_min_io_rq	Specifies the number of I/O requests to route to a path before switching to the next path in the current path group, using request-based device-mapper-multipath. This setting should be used on systems running current kernels. On systems running kernels older than 2.6.31, use rr_min_io. The default value is 1.
rr_weight	If set to priorities , then instead of sending rr_min_io requests to a path before calling path_selector to choose the next path, the number of requests to send is determined by rr_min_io times the path's priority, as determined by the prio function. If set to uniform , all path weights are equal. The default value is uniform .
no_path_retry	A numeric value for this attribute specifies the number of times the system should attempt to use a failed path before disabling queuing.
	A value of fail indicates immediate failure, without queuing.
	A value of queue indicates that queuing should not stop until the path is fixed.
	The default value is 0.

Attribute	Description
user_friendly_names	If set to yes , specifies that the system should use the /etc/multipath/bindings file to assign a persistent and unique alias to the multipath, in the form of mpathn . If set to no , specifies that the system should use the WWID as the alias for the multipath. In either case, what is specified here will be overridden by any device-specific aliases you specify in the multipaths section of the configuration file. The default value is no .
queue_without_daemon	If set to no , the multipathd daemon will disable queuing for all devices when it is shut down. The default value is no .
flush_on_last_del	If set to yes , the multipathd daemon will disable queuing when the last path to a device has been deleted. The default value is no .
max_fds	Sets the maximum number of open file descriptors that can be opened by multipath and the multipathd daemon. This is equivalent to the ulimit -n command. As of the Red Hat Enterprise Linux 6.3 release, the default value is max , which sets this to the system limit from /proc/sys/fs/nr_open. For earlier releases, if this is not set the maximum number of open file descriptors is taken from the calling process; it is usually 1024. To be safe, this should be set to the maximum number of paths plus 32, if that number is greater than 1024.
checker_timeout	The timeout to use for prioritizers and path checkers that issue SCSI commands with an explicit timeout, in seconds. The default value is taken from sys/block/sdx/device/timeout.
fast_io_fail_tmo	The number of seconds the SCSI layer will wait after a problem has been detected on an FC remote port before failing I/O to devices on that remote port. This value should be smaller than the value of dev_loss_tmo . Setting this to off will disable the timeout. The default value is determined by the OS.
dev_loss_tmo	The number of seconds the SCSI layer will wait after a problem has been detected on an FC remote port before removing it from the system. Setting this to infinity will set this to 2147483647 seconds, or 68 years. The default value is determined by the OS.

Attribute	Description
hwtable_regex_match	(Red Hat Enterprise Linux Release 6.3 and later) Controls how multipath integrates the device configurations from the devices section of the configuration file with the built-in device configurations.
	Each device configuration in the devices section of the multipath.conf file will either create its own device configuration or it will modify one of the built-in device configurations. Prior to Red Hat Enterprise Linux 6.3, if the vendor, product, and revision strings in a user's device configuration exactly matched those strings in a built-in device configuration, the built-in configuration was modified by the options in the user's configuration. Otherwise, the user's device configuration was treated as a new configuration.
	If hwtable_regex_match is set to yes , a regular expression match is used instead. The vendor, product, and revision strings are all regular expressions. The user device configuration values for these options are matched against the built-in device configuration values. This match works the same way that an actual device's vendor product and revision strings are matched against a device configuration's strings to see which configuration should be used for the device. If the user's device configuration matches, then the built-in configuration is modified by the options in the user's configuration. Otherwise the user's device configuration is treated as a new configuration.
retain_attached_hw_ha ndler	(Red Hat Enterprise Linux Release 6.4 and later) If this parameter is set to yes and the scsi layer has already attached a hardware handler to the path device, multipath will not force the device to use the hardware_handler specified by the multipath.conf file. If the scsi layer has not attached a hardware handler, multipath will continue to use its configured hardware handler as usual. The default value is no .
detect_prio	(Red Hat Enterprise Linux Release 6.4 and later) If this is set to yes , multipath will first check if the device supports ALUA, and if so it will automatically assign the device the alua prioritizer. If the device does not support ALUA, it will determine the prioritizer as it always does. The default value is no .
replace_wwid_whitespa ce	(Red Hat Enterprise Linux Release 6.5 and later) If this is set to yes , the default getuid_callout for all devices that use this parameter will be changed to include replace-whitespace .
reload_readwrite	(Red Hat Enterprise Linux Release 6.5 and later) If this is set to yes , the multipathd daemon will listen to path device change events and if a device has become read/write it will reload the multipath device.
force_sync	(Red Hat Enterprise Linux Release 6.6 and later) If this is set to "yes", it prevents path checkers from running in async mode.

Attribute	Description
delay_watch_checks	(Red Hat Enterprise Linux Release 6.7 and later) If set to a value greater than 0, the multipathd daemon will watch paths that have recently become valid for the specified number of checks. If they fail again while they are being watched, when they next become valid they will not be used until they have stayed up for the number of consecutive checks specified with delay_wait_checks . This allows you to keep paths that may be unreliable from immediately being put back into use as soon as they come back online. The default value is no .
delay_wait_checks	(Red Hat Enterprise Linux Release 6.7 and later) If set to a value greater than 0, when a device that has recently come back online fails again within the number of checks specified with delay_watch_checks , the next time it comes back online it will be marked and delayed and it will not be used until it has passed the number of checks specified in delay_wait_checks . The default value is no .
config_dir	(Red Hat Enterprise Linux Release 6.7 and later) If set to anything other than "", multipath will search this directory alphabetically for files ending in ".conf" and it will read configuration information from them, just as if the information were in the <code>/etc/multipath.conf</code> file. This allows you to have one main configuration that you share between machines in addition to a separate machine-specific configuration file or files. The <code>config_dir</code> parameter must either be "" or a fully qualified directory name. This parameter can be set only in the main <code>/etc/multipath.conf</code> file and not in one of the files specified in the <code>config_dir</code> file itself. The default value is <code>/etc/multipath/conf.d</code> .
log_checker_err	If set to once , multipathd logs the first path checker error at verbosity level 2. Any later errors are logged at verbosity level 3 until the device is restored. If it is set to always , multipathd always logs the path checker error at verbosity level 2. The default value is always .
skip_kpartx	(Red Hat Enterprise Linux Release 6.9 and later) If set to yes , kpartx will not automatically create partitions on the device. This allows users to create a multipath device without creating partitions, even if the device has a partition table. The default value of this option is no .
max_sectors_kb	(Red Hat Enterprise Linux Release 6.9 and later) Sets the <code>max_sectors_kb</code> device queue parameter to the specified value on all underlying paths of a multipath device before the multipath device is first activated. When a multipath device is created, the device inherits the <code>max_sectors_kb</code> value from the path devices. Manually raising this value for the multipath device or lowering this value for the path devices can cause multipath to create I/O operations larger than the path devices allow. Using the <code>max_sectors_kb</code> parameter is an easy way to set these values before a multipath device is created on top of the path devices and prevent invalid-sized I/O operations from being passed. If this parameter is not set by the user, the path devices have it set by their device driver, and the multipath device inherits it from the path devices.

4.4. MULTIPATHS DEVICE CONFIGURATION ATTRIBUTES

Table 4.2, "Multipath Attributes" shows the attributes that you can set in the **multipaths** section of the **multipath.conf** configuration file for each specific multipath device. These attributes apply only to the one specified multipath. These defaults are used by DM-Multipath and override attributes set in the **defaults** and **devices** sections of the **multipath.conf** file.

Table 4.2. Multipath Attributes

Attribute	Description
wwid	Specifies the WWID of the multipath device to which the multipath attributes apply. This parameter is mandatory for this section of the multipath.conf file.
alias	Specifies the symbolic name for the multipath device to which the multipath attributes apply. If you are using user_friendly_names , do not set this value to mpathn ; this may conflict with an automatically assigned user friendly name and give you incorrect device node names.
path_grouping_policy	Specifies the default path grouping policy to apply to unspecified multipaths. Possible values include:
	failover = 1 path per priority group
	multibus = all valid paths in 1 priority group
	group_by_serial = 1 priority group per detected serial number
	group_by_prio = 1 priority group per path priority value
	<pre>group_by_node_name = 1 priority group per target node name</pre>
path_selector	Specifies the default algorithm to use in determining what path to use for the next I/O operation. Possible values include:
	round-robin 0: Loop through every path in the path group, sending the same amount of I/O to each.
	queue-length 0 : Send the next bunch of I/O down the path with the least number of outstanding I/O requests.
	service-time 0 : Send the next bunch of I/O down the path with the shortest estimated service time, which is determined by dividing the total size of the outstanding I/O to each path by its relative throughput.

Attribute	Description
failback	Manages path group failback.
	A value of immediate specifies immediate failback to the highest priority path group that contains active paths.
	A value of manual specifies that there should not be immediate failback but that failback can happen only with operator intervention.
	A value of followover specifies that automatic failback should be performed when the first path of a path group becomes active. This keeps a node from automatically failing back when another node requested the failover.
	A numeric value greater than zero specifies deferred failback, expressed in seconds.
prio	Specifies the default function to call to obtain a path priority value. For example, the ALUA bits in SPC-3 provide an exploitable prio value. Possible values include:
	const: Set a priority of 1 to all paths.
	emc: Generate the path priority for EMC arrays.
	alua: Generate the path priority based on the SCSI-3 ALUA settings. As of Red Hat Enterprise Linux 6.8, if you specify prio "alua exclusive_pref_bit" in your device configuration, multipath will create a path group that contains only the path with the pref bit set and will give that path group the highest priority.
	tpg_pref : Generate the path priority based on the SCSI-3 ALUA settings, using the preferred port bit.
	ontap: Generate the path priority for NetApp arrays.
	rdac: Generate the path priority for LSI/Engenio RDAC controller.
	hp_sw : Generate the path priority for Compaq/HP controller in active/standby mode.
	hds: Generate the path priority for Hitachi HDS Modular storage arrays.

Attribute	Description
no_path_retry	A numeric value for this attribute specifies the number of times the system should attempt to use a failed path before disabling queuing. A value of fail indicates immediate failure, without queuing. A value of queue indicates that queuing should not stop until the path is fixed.
rr_min_io	Specifies the number of I/O requests to route to a path before switching to the next path in the current path group. This setting is only for systems running kernels older that 2.6.31. Newer systems should use rr_min_io_rq. The default value is 1000.
rr_min_io_rq	Specifies the number of I/O requests to route to a path before switching to the next path in the current path group, using request-based device-mapper-multipath. This setting should be used on systems running current kernels. On systems running kernels older than 2.6.31, use rr_min_io. The default value is 1.
rr_weight	If set to priorities , then instead of sending rr_min_io requests to a path before calling path_selector to choose the next path, the number of requests to send is determined by rr_min_io times the path's priority, as determined by the prio function. If set to uniform , all path weights are equal.
flush_on_last_del	If set to yes , then multipath will disable queuing when the last path to a device has been deleted.
user_friendly_names	If set to yes , specifies that the system should use the /etc/multipath/bindings file to assign a persistent and unique alias to the multipath, in the form of mpathn . If set to no , specifies that the system should use use the WWID as the alias for the multipath. In either case, what is specified here will be overridden by any device-specific aliases you specify in the multipaths section of the configuration file.
delay_watch_checks	(Red Hat Enterprise Linux Release 6.7 and later) If set to a value greater than 0, the multipathd daemon will watch paths that have recently become valid for the specified number of checks. If they fail again while they are being watched, when they next become valid they will not be used until they have stayed up for the number of consecutive checks specified with delay_wait_checks . This allows you to keep paths that may be unreliable from immediately being put back into use as soon as they come back online.

Attribute	Description
delay_wait_checks	(Red Hat Enterprise Linux Release 6.7 and later) If set to a value greater than 0, when a device that has recently come back online fails again within the number of checks specified with delay_watch_checks , the next time it comes back online it will be marked and delayed and it will not be used until it has passed the number of checks specified in delay_wait_checks .
skip_kpartx	(Red Hat Enterprise Linux Release 6.9 and later) If set to yes , kpartx will not automatically create partitions on the device. This allows users to create a multipath device without creating partitions, even if the device has a partition table.
max_sectors_kb	(Red Hat Enterprise Linux Release 6.9 and later) Sets the max_sectors_kb device queue parameter to the specified value on all underlying paths of a multipath device before the multipath device is first activated. When a multipath device is created, the device inherits the max_sectors_kb value from the path devices. Manually raising this value for the multipath device or lowering this value for the path devices can cause multipath to create I/O operations larger than the path devices allow. Using the max_sectors_kb parameter is an easy way to set these values before a multipath device is created on top of the path devices and prevent invalid-sized I/O operations from being passed If this parameter is not set by the user, the path devices have it set by their device driver, and the multipath device inherits it from the path devices.

The following example shows multipath attributes specified in the configuration file for two specific multipath devices. The first device has a WWID of **3600508b4000156d70001200000b0000** and a symbolic name of **yellow**.

The second multipath device in the example has a WWID of **1DEC_____321816758474** and a symbolic name of **red**. In this example, the **rr weight** attributes is set to **priorities**.

```
multipaths {
      multipath {
             wwid
                                   3600508b4000156d70001200000b0000
             alias
                                   yellow
             path grouping policy multibus
             path selector
                                   "round-robin 0"
             failback
                                   manual
             rr_weight
                                   priorities
             no path retry
                                   5
      multipath {
             wwid
                                   1DEC 321816758474
             alias
                                   red
                                   priorities
             rr weight
       }
```

4.5. CONFIGURATION FILE DEVICES

Table 4.3, "Device Attributes" shows the attributes that you can set for each individual storage device in the **devices** section of the **multipath.conf** configuration file. These attributes are used by DM-Multipath unless they are overwritten by the attributes specified in the **multipaths** section of the **multipath.conf** file for paths that contain the device. These attributes override the attributes set in the **defaults** section of the **multipath.conf** file.

Many devices that support multipathing are included by default in a multipath configuration. The values for the devices that are supported by default are listed in the **multipath.conf.defaults** file. You probably will not need to modify the values for these devices, but if you do you can overwrite the default values by including an entry in the configuration file for the device that overwrites those values. You can copy the device configuration defaults from the **multipath.conf.defaults** file for the device and override the values that you want to change.

To add a device that is not configured automatically by default to this section of the configuration file, you need to set the **vendor** and **product** parameters. You can find these values by looking at /sys/block/device_name/device/vendor and /sys/block/device_name/device/model where device_name is the device to be multipathed, as in the following example:

```
# cat /sys/block/sda/device/vendor
WINSYS
# cat /sys/block/sda/device/model
SF2372
```

The additional parameters to specify depend on your specific device. If the device is active/active, you will usually not need to set additional parameters. You may want to set **path_grouping_policy** to **multibus**. Other parameters you may need to set are **no_path_retry** and **rr_min_io**, as described in Table 4.3, "Device Attributes".

If the device is active/passive, but it automatically switches paths with I/O to the passive path, you need to change the checker function to one that does not send I/O to the path to test if it is working (otherwise, your device will keep failing over). This almost always means that you set the **path_checker** to **tur**; this works for all SCSI devices that support the Test Unit Ready command, which most do.

Table 4.3. Device Attributes

Attribute	Description
vendor	Specifies the vendor name of the storage device to which the device attributes apply, for example COMPAQ .
product	Specifies the product name of the storage device to which the device attributes apply, for example HSV110 (C) COMPAQ.
revision	Specifies the product revision identifier of the storage device.
product_blacklist	Specifies a regular expression used to blacklist devices by product.

Attribute	Description
hardware_handler	Specifies a module that will be used to perform hardware specific actions when switching path groups or handling I/O errors. Possible values include:
	1 emc: hardware handler for EMC storage arrays.
	1 alua: hardware handler for SCSI-3 ALUA arrays.
	1 hp_sw: hardware handler for Compaq/HP controllers.
	1 rdac: hardware handler for the LSI/Engenio RDAC controllers.
path_grouping_policy	Specifies the default path grouping policy to apply to unspecified multipaths. Possible values include:
	failover = 1 path per priority group
	multibus = all valid paths in 1 priority group
	group_by_serial = 1 priority group per detected serial number
	<pre>group_by_prio = 1 priority group per path priority value</pre>
	<pre>group_by_node_name = 1 priority group per target node name</pre>
getuid_callout	Specifies the default program and arguments to call out to obtain a unique path identifier. An absolute path is required.
path_selector	Specifies the default algorithm to use in determining what path to use for the next I/O operation. Possible values include:
	round-robin 0: Loop through every path in the path group, sending the same amount of I/O to each.
	queue-length 0 : Send the next bunch of I/O down the path with the least number of outstanding I/O requests.
	service-time 0 : Send the next bunch of I/O down the path with the shortest estimated service time, which is determined by dividing the total size of the outstanding I/O to each path by its relative throughput.

Attribute	Description
path_checker	Specifies the default method used to determine the state of the paths. Possible values include:
	readsector0: Read the first sector of the device.
	tur: Issue a TEST UNIT READY to the device.
	emc_clariion: Query the EMC Clariion specific EVPD page 0xC0 to determine the path.
	hp_sw : Check the path state for HP storage arrays with Active/Standby firmware.
	rdac: Check the path stat for LSI/Engenio RDAC storage controller.
	directio: Read the first sector with direct I/O.
features	
	The default extra features of multipath devices, using the format: "number_of_features_plus_arguments feature1".
	Possible values for features include:
	<pre>queue_if_no_path, which is the same as setting no_path_retry to queue. For information on issues that may arise when using this feature, see Section 5.6, "Issues with queue_if_no_path feature".</pre>
	retain_attached_hw_handler: (Red Hat Enterprise Linux Release 6.4 and later) If this parameter is set to yes and the scsi layer has already attached a hardware handler to the path device, multipath will not force the device to use the hardware_handler specified by the multipath.conf file. If the scsi layer has not attached a hardware handler, multipath will continue to use its configured hardware handler as usual.
	pg_init_retries n : Retry path group initialization up to n times before failing where $1 \le n \le 50$.
	pg_init_delay_msecs n : Wait n milliseconds between path group initialization retries where $0 \le n \le 60000$.

Attribute	Description
prio	Specifies the default function to call to obtain a path priority value. For example, the ALUA bits in SPC-3 provide an exploitable prio value. Possible values include: const: Set a priority of 1 to all paths. emc: Generate the path priority for EMC arrays. alua: Generate the path priority based on the SCSI-3 ALUA settings. As of Red Hat Enterprise Linux 6.8, if you specify prio "alua exclusive_pref_bit" in your device configuration, multipath will create a path group that contains only the path with the pref bit set and will give that path group the highest priority. tpg_pref: Generate the path priority based on the SCSI-3 ALUA settings, using the preferred port bit. ontap: Generate the path priority for NetApp arrays. rdac: Generate the path priority for LSI/Engenio RDAC controller. hp_sw: Generate the path priority for Compaq/HP controller in active/standby mode. hds: Generate the path priority for Hitachi HDS Modular storage arrays.
failback	Manages path group failback. A value of immediate specifies immediate failback to the highest priority path group that contains active paths. A value of manual specifies that there should not be immediate failback but that failback can happen only with operator intervention. A value of followover specifies that automatic failback should be performed when the first path of a path group becomes active. This keeps a node from automatically failing back when another node requested the failover. A numeric value greater than zero specifies deferred failback, expressed in seconds.

Attribute	Description
rr_weight	If set to priorities , then instead of sending rr_min_io requests to a path before calling path_selector to choose the next path, the number of requests to send is determined by rr_min_io times the path's priority, as determined by the prio function. If set to uniform , all path weights are equal.
no_path_retry	A numeric value for this attribute specifies the number of times the system should attempt to use a failed path before disabling queuing.
	A value of fail indicates immediate failure, without queuing.
	A value of queue indicates that queuing should not stop until the path is fixed.
rr_min_io	Specifies the number of I/O requests to route to a path before switching to the next path in the current path group. This setting is only for systems running kernels older that 2.6.31. Newer systems should use rr_min_io_rq. The default value is 1000.
rr_min_io_rq	Specifies the number of I/O requests to route to a path before switching to the next path in the current path group, using request-based device-mapper-multipath. This setting should be used on systems running current kernels. On systems running kernels older than 2.6.31, use rr_min_io. The default value is 1.
fast_io_fail_tmo	The number of seconds the SCSI layer will wait after a problem has been detected on an FC remote port before failing I/O to devices on that remote port. This value should be smaller than the value of dev_loss_tmo. Setting this to off will disable the timeout.
dev_loss_tmo	The number of seconds the SCSI layer will wait after a problem has been detected on an FC remote port before removing it from the system. Setting this to infinity will set this to 2147483647 seconds, or 68 years.
flush_on_last_del	If set to yes , the multipathd daemon will disable queuing when the last path to a device has been deleted.
user_friendly_names	If set to yes , specifies that the system should use the <code>/etc/multipath/bindings</code> file to assign a persistent and unique alias to the multipath, in the form of <code>mpathn</code> . If set to <code>no</code> , specifies that the system should use use the WWID as the alias for the multipath. In either case, what is specified here will be overridden by any device-specific aliases you specify in the <code>multipaths</code> section of the configuration file. The default value is <code>no</code> .

Attribute	Description
retain_attached_hw_ha ndler	(Red Hat Enterprise Linux Release 6.4 and later) If this parameter is set to yes and the scsi layer has already attached a hardware handler to the path device, multipath will not force the device to use the hardware_handler specified by the multipath.conf file. If the scsi layer has not attached a hardware handler, multipath will continue to use its configured hardware handler as usual.
detect_prio	(Red Hat Enterprise Linux Release 6.4 and later) If this is set to yes , multipath will first check if the device supports ALUA, and if so it will automatically assign the device the alua prioritizer. If the device does not support ALUA, it will determine the prioritizer as it always does.
delay_watch_checks	(Red Hat Enterprise Linux Release 6.7 and later) If set to a value greater than 0, the multipathd daemon will watch paths that have recently become valid for the specified number of checks. If they fail again while they are being watched, when they next become valid they will not be used until they have stayed up for the number of consecutive checks specified with delay_wait_checks . This allows you to keep paths that may be unreliable from immediately being put back into use as soon as they come back online.
delay_wait_checks	(Red Hat Enterprise Linux Release 6.7 and later) If set to a value greater than 0, when a device that has recently come back online fails again within the number of checks specified with delay_watch_checks , the next time it comes back online it will be marked and delayed and it will not be used until it has passed the number of checks specified in delay_wait_checks .
skip_kpartx	(Red Hat Enterprise Linux Release 6.9 and later) If set to yes , kpartx will not automatically create partitions on the device. This allows users to create a multipath device without creating partitions, even if the device has a partition table.
max_sectors_kb	(Red Hat Enterprise Linux Release 6.9 and later) Sets the max_sectors_kb device queue parameter to the specified value on all underlying paths of a multipath device before the multipath device is first activated. When a multipath device is created, the device inherits the max_sectors_kb value from the path devices. Manually raising this value for the multipath device or lowering this value for the path devices can cause multipath to create I/O operations larger than the path devices allow. Using the max_sectors_kb parameter is an easy way to set these values before a multipath device is created on top of the path devices and prevent invalid-sized I/O operations from being passed If this parameter is not set by the user, the path devices have it set by their device driver, and the multipath device inherits it from the path devices.
all_devs	When this parameter is set to yes , all of the options set in this device configuration will override the values for those options in all of the other device configurations, both the ones in the configuration file and the built-in defaults.

The following example shows a **device** entry in the multipath configuration file.

```
# }
# device {
# vendor "COMPAQ "
# product "MSA1000 "
# path_grouping_policy multibus
# path_checker tur
# rr_weight priorities
# }
#}
```

The following configuration sets **no_path_retry** to **fail** for all of the built-in device configurations.

CHAPTER 5. DM-MULTIPATH ADMINISTRATION AND TROUBLESHOOTING

This chapter will provide information on administering DM-Multipath on a running system.

5.1. AUTOMATIC CONFIGURATION FILE GENERATION WITH MULTIPATH HELPER

You can generate a basic configuration for multipath devices on Red Hat Enterprise Linux with the Multipath Helper application. The application gives you options to create multipath configurations with custom aliases, device blacklists, and settings for the characteristics of individual multipath devices. Upon completion, the application generates an installation script that includes the configuration parameters you selected and it provides a **multipath.conf** configuration file for review.

The Multipath Helper application can be found at https://access.redhat.com/labsinfo/multipathhelper.

5.2. RESIZING AN ONLINE MULTIPATH DEVICE

If you need to resize an online multipath device, use the following procedure.

- 1. Resize your physical device.
- 2. Execute the following command to find the paths to the LUN:

```
# multipath -l
```

3. Resize your paths. For SCSI devices, writing a 1 to the **rescan** file for the device causes the SCSI driver to rescan, as in the following command:

```
# echo 1 > /sys/block/path_device/device/rescan
```

Ensure that you run this command for each of the path devices. For example, if your path devices are **sda**, **sdb**, **sde**, and **sdf**, you would run the following commands:

```
# echo 1 > /sys/block/sda/device/rescan
# echo 1 > /sys/block/sdb/device/rescan
# echo 1 > /sys/block/sde/device/rescan
# echo 1 > /sys/block/sdf/device/rescan
```

4. Resize your multipath device by executing the **multipathd resize** command:

```
# multipathd resize map multipath_device
```

5. Resize the file system (assuming no LVM or DOS partitions are used):

```
# resize2fs /dev/mapper/mpatha
```

5.3. MOVING ROOT FILE SYSTEMS FROM A SINGLE PATH DEVICE TO A MULTIPATH DEVICE

If you have installed your system on a single-path device and later add another path to the root file system, you will need to move your root file system to a multipathed device. This section documents the procedure for moving from a single-path to a multipathed device.

After ensuring that you have installed the **device-mapper-multipath** package, perform the following procedure:

1. Execute the following command to create the /etc/multipath.conf configuration file, load the multipath module, and set chkconfig for the multipathd to on:

```
# mpathconf --enable
```

For further information on using the **mpathconf** command to set up multipathing, see Section 3.1, "Setting Up DM-Multipath".

- 2. Edit the **blacklist** and **blacklist_exceptions** sections of the **/etc/multipath.conf** file, as described in Section 4.2, "Configuration File Blacklist".
- 3. To confirm that your configuration file is set up correctly, you can run the /sbin/multipath command with the -v3 option to check whether the multipath daemon tried to create a multipath device over your root device. The command will fail since the root the device is in use, but the output from the command should show the root device in the paths list.

You should look in the command output for a line of the following format:

```
WWID H:B:T:L devname MAJOR:MINOR
```

For example, if your root file system is set up on **sda** or one of its partitions, you would see a line in the output such as the following:

Later in the output, you should see the root device assigned to a multipath device:

```
time | devname: ownership set to mpathdev
```

For example, the output may appear as follows:

```
Jun 14 06:48:21 | sda: ownership set to mpatha
```

You will also see an indication that the command failed to create the multipath device with a line of the following format:

```
time | mpathdev: domap (0) failure for create/reload map
```

In the example noted above, you would see the following line in the command output:

```
Jun 14 06:48:21 | mpatha: domap (0) failure for create/reload map
```

4. To rebuild the **initramfs** file system with **multipath**, execute the **dracut** command with the following options:

```
# dracut --force --add multipath --include /etc/multipath
/etc/multipath
```

- 5. If your root device is not an LVM volume and it is mounted by device name, you may need to edit the **fstab** file to switch to the appropriate multipath device name. If your root device is an LVM device or is mounted by UUID or something else, this step is not necessary.
 - 1. Use the procedure described in Step 3 of running the /sbin/multipath command with the -v3 to determine the WWID of the root device.
 - 2. Set up an alias for the root device in the /etc/multipath.conf file:

```
multipaths {
    multipath {
        wwid WWID_of_root_device
        alias rootdev
    }
}
```

3. Edit the /etc/fstab and replace the old device path to the root device with the multipath device.

For example, if you had the following entry in the /etc/fstab file:

```
/dev/sda1 / ext4 defaults 1 1

You would change the entry to the following:

/dev/mapper/rootdev / ext4 defaults 1 1
```

If you need to edit the /etc/fstab file, you will also need to edit the /etc/grub.conf file and change the root parameter from root=/dev/sdal to root=/dev/mapper/rootdev.

The following example shows what this **grub.conf** file entry would look like before you edit it.

The following example shows what the **grub.conf** file entry would look like after you edit it.

- 6. Shut the machine down.
- 7. Configure the FC switch so that other paths are visible to the machine.
- 8. Boot the machine.
- 9. Check whether the root file system ('/') is on the multipathed device.

5.4. MOVING SWAP FILE SYSTEMS FROM A SINGLE PATH DEVICE TO A MULTIPATH DEVICE

By default, swap devices are set up as logical volumes. This does not require any special procedure for configuring them as multipath devices as long as you set up multipathing on the physical volumes that constitute the logical volume group. If your swap device is not an LVM volume, however, and it is mounted by device name, you may need to edit the **fstab** file to switch to the appropriate multipath device name.

 Determine the WWID number of the swap device by running the /sbin/multipath command with the -v3 option. The output from the command should show the swap device in the paths list.

You should look in the command output for a line of the following format, showing the swap device:

```
WWID H:B:T:L devname MAJOR:MINOR
```

For example, if your swap file system is set up on **sda** or one of its partitions, you would see a line in the output such as the following:

```
===== paths list =====
...
1ATA WDC WD800JD-75MSA3 WD-WMAM9F
1:0:0:0 sda 8:0
...
```

2. Set up an alias for the swap device in the /etc/multipath.conf file:

```
multipaths {
    multipath {
        wwid WWID_of_swap_device
        alias swapdev
    }
}
```

3. Edit the /etc/fstab and replace the old device path to the root device with the multipath device.

For example, if you had the following entry in the /etc/fstab file:

/dev/sda2 swap swap defaults 0 0

You would change the entry to the following:

/dev/mapper/swapdev swap swap defaults 0 0

5.5. ISSUES WITH LARGE NUMBER OF LUNS

When a large number of LUNs are added to a node, using multipathed devices can significantly increase the time it takes for the **udev** device manager to create device nodes for them. If you experience this problem, you can correct it by deleting the following line in /etc/udev/rules.d/40-multipath.rules:

```
KERNEL!="dm-[0-9]*", ACTION=="add", PROGRAM=="/bin/bash -c '/sbin/lsmod |
/bin/grep ^dm_multipath'", RUN+="/sbin/multipath -v0 %M:%m"
```

This line causes the **udev** device manager to run **multipath** every time a block device is added to the node. Even with this line removed, the **multipathd** daemon will still automatically create multipathed devices, and **multipath** will still be called during the boot process for nodes with multipathed root file systems. The only change is that multipathed devices will not be automatically created when the **multipathd** daemon is not running, which should not be a problem for the vast majority of multipath users.

5.6. ISSUES WITH QUEUE_IF_NO_PATH FEATURE

If a multipath device is configured with **features "1 queue_if_no_path"**, then any process that issues I/O will hang until one or more paths are restored. To avoid this, set the **no_path_retry N** parameter in the **/etc/multipath.conf** file (where **N** is the number of times the system should retry a path).

Setting the **no_path_retry** parameter overrides the feature option **features** "1 **queue_if_no_path**", even if this features option is set in the devices section and **no_path_retry** is set in the defaults section of the multipath configuration file.

If you need to use the **features "1 queue_if_no_path"** option and you experience the issue noted here, use the **dmsetup** command to edit the policy at runtime for a particular LUN (that is, for which all the paths are unavailable). For example, if you want to change the policy on the multipath device **mpathc** from "queue_if_no_path" to "fail_if_no_path", execute the following command.

```
dmsetup message mpathc 0 "fail_if_no_path"
```

Note that you must specify the **mpath***n* alias rather than the path.

5.7. MULTIPATH COMMAND OUTPUT

When you create, modify, or list a multipath device, you get a display of the current device setup. The format is as follows.

For each multipath device:

```
action_if_any: alias (wwid_if_different_from_alias)
dm_device_name_if_known vendor,product size=size features='features'
hwhandler='hardware_handler' wp=write_permission_if_known
```

For each path group:

```
-+- policy='scheduling_policy' prio=prio_if_known status=path_group_status_if_known
```

For each path:

```
`- host:channel:id:lun devnode major:minor dm_status_if_known path_status online status
```

For example, the output of a multipath command might appear as follows:

```
3600d0230000000000e13955cc3757800 dm-1 WINSYS,SF2372 size=269G features='0' hwhandler='0' wp=rw |-+- policy='round-robin 0' prio=1 status=active | `- 6:0:0:0 sdb 8:16 active ready running `-+- policy='round-robin 0' prio=1 status=enabled `- 7:0:0:0 sdf 8:80 active ready running
```

If the path is up and ready for I/O, the status of the path is **ready** or **ghost**. If the path is down, the status is **faulty** or **shaky**. The path status is updated periodically by the **multipathd** daemon based on the polling interval defined in the **/etc/multipath.conf** file.

The dm status is similar to the path status, but from the kernel's point of view. The dm status has two states: **failed**, which is analogous to **faulty**, and **active** which covers all other path states. Occasionally, the path state and the dm state of a device will temporarily not agree.

The possible values for *online_status* are *running* and *offline*. A status of *offline* means that this SCSI device has been disabled.

NOTE

When a multipath device is being created or modified, the path group status, the dm device name, the write permissions, and the dm status are not known. Also, the features are not always correct.

5.8. MULTIPATH QUERIES WITH MULTIPATH COMMAND

You can use the -l and -ll options of the **multipath** command to display the current multipath configuration. The -l option displays multipath topology gathered from information in **sysfs** and the device mapper. The -ll option displays the information the -l displays in addition to all other available components of the system.

When displaying the multipath configuration, there are three verbosity levels you can specify with the -v option of the multipath command. Specifying -v0 yields no output. Specifying -v1 outputs the created or updated multipath names only, which you can then feed to other tools such as kpartx. Specifying -v2 prints all detected paths, multipaths, and device maps.

The following example shows the output of a **multipath** -l command.

The following example shows the output of a **multipath** -ll command.

```
# multipath -ll
3600d02300000000000e13955cc3757801 dm-10 WINSYS,SF2372
size=269G features='0' hwhandler='0' wp=rw
|-+- policy='round-robin 0' prio=1 status=enabled
| `- 19:0:0:1 sdc 8:32 active ready running
`-+- policy='round-robin 0' prio=1 status=enabled
    `- 18:0:0:1 sdh 8:112 active ready running
3600d02300000000000e13955cc3757803 dm-2 WINSYS,SF2372
size=125G features='0' hwhandler='0' wp=rw
`-+- policy='round-robin 0' prio=1 status=active
|- 19:0:0:3 sde 8:64 active ready running
    `- 18:0:0:3 sdj 8:144 active ready running
```

5.9. MULTIPATH COMMAND OPTIONS

Table 5.1, "Useful **multipath** Command Options" describes some options of the **multipath** command that you may find useful.

Table 5.1. Useful multipath Command Options

Option	Description
-1	Display the current multipath configuration gathered from sysfs and the device mapper.
-11	Display the current multipath configuration gathered from sysfs , the device mapper, and all other available components on the system.
-f device	Remove the named multipath device.
-F	Remove all unused multipath devices.
-w device	(Red Hat Enterprise Linux 6.6 and later) Remove the wwid of the specified device from the wwids file.
-W	(Red Hat Enterprise Linux 6.6 and later) Reset the wwids file to include only the current multipath devices.

5.10. DETERMINING DEVICE MAPPER ENTRIES WITH THE DMSETUP COMMAND

You can use the **dmsetup** command to find out which device mapper entries match the multipathed devices.

The following command displays all the device mapper devices and their major and minor numbers. The minor numbers determine the name of the dm device. For example, a minor number of 3 corresponds to the multipathed device /dev/dm-3.

```
# dmsetup ls
mpathd (253:4)
                (253:12)
mpathep1
mpathfp1
                (253:11)
mpathb (253:3)
mpathgp1
                (253:14)
mpathhp1
                (253:13)
mpatha (253:2)
mpathh (253:9)
mpathg (253:8)
VolGroup00-LogVol01
                        (253:1)
mpathf (253:7)
VolGroup00-LogVol00
                        (253:0)
mpathe (253:6)
mpathbp1
                (253:10)
mpathd (253:5)
```

5.11. THE MULTIPATH DAEMON

If you find you have trouble implementing a multipath configuration, you should ensure that the multipath daemon is running, as described in Chapter 3, *Setting Up DM-Multipath*. The **multipathd** daemon must be running in order to use multipathed devices.

5.12. THE MULTIPATHD INTERACTIVE CONSOLE AND THE MULTIPATHD COMMAND

The **multipathd** -k command is an interactive interface to the **multipathd** daemon. Executing this command brings up an interactive multipath console, from which you can issue a number of commands. After executing this command, you can enter **help** to get a list of available commands, you can enter an interactive command, or you can enter **CTRL-D** to quit.

Note that you can issue any of the **multipathd** commands without entering interactive mode by using the following format.

```
# multipathd command argument
```

Some **multipathd** commands include a **format** option followed by a wildcard. You can display a list of available wildcards with the following command.

```
# multipathd show wildcards
```

The **multipathd** interactive console can be used to troubleshoot problems you may be having with your system. For example, the following command sequence displays the multipath configuration, including the defaults, before exiting the console.

```
# multipathd -k
```

```
> > show config
> > CTRL-D
```

The following command sequence ensures that multipath has picked up any changes to the **multipath.conf**,

```
# multipathd -k
> > reconfigure
> > CTRL-D
```

Use the following command sequence to ensure that the path checker is working properly.

```
# multipathd -k
> > show paths
> > CTRL-D
```

As of Red Hat Enterprise Linux release 6.8, the **multipathd** command supports new format commands that show the status of multipath devices and paths in "raw" format versions. In raw format, no headers are printed and the fields are not padded to align the columns with the headers. Instead, the fields print exactly as specified in the format string. This output can then be more easily used for scripting. You can display the wildcards used in the format string with the **multipathd show wildcards** command.

To following **multipathd** commands show the multipath devices that **multipathd** is monitoring, using a format string with multipath wildcards, in regular and raw format.

```
list|show maps|multipaths format $format
list|show maps|multipaths raw format $format
```

To following **multipathd** commands show the paths that **multipathd** is monitoring, using a format string with multipath wildcards, in regular and raw format.

```
list|show paths format $format
list|show paths raw format $format
```

The following commands show the difference between the non-raw and raw formats for the **multipathd** show **maps**. Note that in **raw** format there are no headers and only a single space between the columns.

5.13. CLEANING UP MULTIPATH FILES ON PACKAGE REMOVAL

If you should have occasion to remove the **device-mapper-multipath rpm**. file, note that this does not remove the **/etc/multipath.conf**, **/etc/multipath/bindings**, and **/etc/multipath/wwids** files. You may need to remove those files manually on subsequent installations of the **device-mapper-multipath** package.

APPENDIX A. REVISION HISTORY

Revision 10.0-4 Fri Jul 14 2017 Steven Levine

Update to version for 6.9 GA publication.

Revision 10.0-2 Wed Mar 8 2017 Steven Levine

Version for 6.9 GA publication.

Revision 10.0-1 Fri Dec 16 2016 Steven Levine

Version for 6.9 Beta publication.

Revision 9.0-13 Tue Nov 8 2016 Steven Levine

Small update for 6.8.

Revision 9.0-12 Wed Apr 27 2016 Steven Levine

Preparing document for 6.8 GA publication.

Revision 9.0-10 Wed Mar 9 2016 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.8 Beta release

Revision 8.0-5 Wed Jul 22 2015 Steven Levine

Republish for Red Hat Enterprise Linux 6.7

Revision 8.0-4 Wed Jul 8 2015 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.7

Revision 8.0-3 Thu Apr 23 2015 Steven Levine

Republish for Red Hat Enterprise Linux 6.7 Beta release

Revision 7.0-4 Thu Aug 7 2014 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.6

Revision 7.0-3 Thu Aug 7 2014 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.6 Beta release

Revision 6.0-6 Wed Nov 13 2013 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.5

Revision 6.0-5 Fri Sep 27 2013 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.5 Beta release

Revision 5.0-9 Mon Feb 18 2013 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.4

Revision 5.0-7 Mon Nov 26 2012 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.4 Beta release

Revision 4.0-3 Fri Jun 15 2012 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.3

Revision 3.0-3 Thu Dec 1 2011 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.2

Revision 3.0-1 Mon Sep 19 2011 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.2 Beta release

Revision 2.0-1 Thu May 19 2011 Steven Levine

Initial revision for Red Hat Enterprise Linux 6.1

Revision 1.0-1 Wed Nov 10 2010 Steven Levine

Initial revision for the Red Hat Enterprise Linux 6 release
