Abstract

This document provides information on Eventing features such as event sources and sinks, brokers, triggers, channels, and subscriptions.

Table of Contents

CHAPTER 1. KNATIVE EVENTING	6
1.1. KNATIVE EVENTING USE CASES:	6
CHAPTER 2. EVENT SOURCES	7
2.1. EVENT SOURCES	7
2.2. EVENT SOURCE IN THE ADMINISTRATOR PERSPECTIVE	7
2.2.1. Creating an event source by using the Administrator perspective	7
2.3. CREATING AN API SERVER SOURCE	8
2.3.1. Creating an API server source by using the web console	8
2.3.2. Creating an API server source by using the Knative CLI	11
2.3.2.1. Knative CLI sink flag	14
2.3.3. Creating an API server source by using YAML files	15
2.4. CREATING A PING SOURCE	19
2.4.1. Creating a ping source by using the web console	19
2.4.2. Creating a ping source by using the Knative CLI	22
2.4.2.1. Knative CLI sink flag	23
2.4.3. Creating a ping source by using YAML	24
2.5. SOURCE FOR APACHE KAFKA	27
2.5.1. Creating an Apache Kafka event source by using the web console	27
2.5.2. Creating an Apache Kafka event source by using the Knative CLI	28
2.5.2.1. Knative CLI sink flag	30
2.5.3. Creating an Apache Kafka event source by using YAML	30
2.5.4. Configuring SASL authentication for Apache Kafka sources	32
2.6. CUSTOM EVENT SOURCES	33
2.6.1. Sink binding	34
2.6.1.1. Creating a sink binding by using YAML	34
2.6.1.2. Creating a sink binding by using the Knative CLI	37
2.6.1.2.1. Knative CLI sink flag	40
2.6.1.3. Creating a sink binding by using the web console	41
2.6.1.4. Sink binding reference	44
2.6.1.4.1. Subject parameter	45
2.6.1.4.2. CloudEvent overrides	47
2.6.1.4.3. The include label	48
2.6.1.5. Integrating Service Mesh with SinkBinding	48
2.6.2. Container source	51
2.6.2.1. Guidelines for creating a container image	51
2.6.2.2. Creating and managing container sources by using the Knative CLI	54
2.6.2.3. Creating a container source by using the web console	55
2.6.2.4. Container source reference	56
2.6.2.4.1. CloudEvent overrides	57
2.6.2.5. Integrating Service Mesh with ContainerSource	58
2.7. CONNECTING AN EVENT SOURCE TO AN EVENT SINK BY USING THE DEVELOPER PERSPECTIVE	60
2.7.1. Connect an event source to an event sink by using the Developer perspective	60
CHAPTER 3. EVENT SINKS	61
3.1. EVENT SINKS	61
3.1.1. Knative CLI sink flag	61
3.2. CREATING EVENT SINKS	61
3.3. SINK FOR APACHE KAFKA	62
3.3.1. Creating an Apache Kafka sink by using YAML	62
3.3.2. Creating an event sink for Apache Kafka by using the OpenShift Container Platform web console	63

3.3.3. Configuring security for Apache Kafka sinks	64
CHAPTER 4. BROKERS	67
4.1. BROKERS	67
4.2. BROKER TYPES	67
4.2.1. Default broker implementation for development purposes	67
4.2.2. Production-ready Knative broker implementation for Apache Kafka	67
4.3. CREATING BROKERS	68
4.3.1. Creating a broker by using the Knative CLI	68
4.3.2. Creating a broker by annotating a trigger	69
4.3.3. Creating a broker by labeling a namespace	70
4.3.4. Deleting a broker that was created by injection	72
4.3.5. Creating a broker by using the web console	72
4.3.6. Creating a broker by using the Administrator perspective	73
4.3.7. Next steps	74
4.3.8. Additional resources	74
4.4. CONFIGURING THE DEFAULT BROKER BACKING CHANNEL	74
4.5. CONFIGURING THE DEFAULT BROKER CLASS	75
4.6. KNATIVE BROKER IMPLEMENTATION FOR APACHE KAFKA	77
4.6.1. Creating an Apache Kafka broker when it is not configured as the default broker type	77
4.6.1.1. Creating an Apache Kafka broker by using YAML	77
4.6.1.2. Creating an Apache Kafka broker that uses an externally managed Kafka topic	78
4.6.1.3. Knative Broker implementation for Apache Kafka with isolated data plane	79
4.6.1.4. Creating a Knative broker for Apache Kafka that uses an isolated data plane	80
4.6.2. Configuring Apache Kafka broker settings	81
4.6.3. Security configuration for the Knative broker implementation for Apache Kafka	83
4.6.3.1. Configuring TLS authentication for Apache Kafka brokers	83
4.6.3.2. Configuring SASL authentication for Apache Kafka brokers	84
4.6.4. Additional resources	85
4.7. MANAGING BROKERS	85
4.7.1. Managing brokers using the CLI	85
4.7.1.1. Listing existing brokers by using the Knative CLI	86
4.7.1.2. Describing an existing broker by using the Knative CLI	86
4.7.2. Connect a broker to a sink using the Developer perspective	87
CHAPTER 5. TRIGGERS	88
5.1. TRIGGERS OVERVIEW	88
5.1.1. Configuring event delivery ordering for triggers	88
5.1.2. Next steps	89
5.2. CREATING TRIGGERS	89
5.2.1. Creating a trigger by using the Administrator perspective	89
5.2.2. Creating a trigger by using the Developer perspective	90
5.2.3. Creating a trigger by using the Knative CLI	91
5.3. LIST TRIGGERS FROM THE COMMAND LINE	91
5.3.1. Listing triggers by using the Knative CLI	92
5.4. DESCRIBE TRIGGERS FROM THE COMMAND LINE	92
5.4.1. Describing a trigger by using the Knative CLI	92
5.5. CONNECTING A TRIGGER TO A SINK	93
5.6. FILTERING TRIGGERS FROM THE COMMAND LINE	93
5.6.1. Filtering events with triggers by using the Knative CLI	94
5.7. UPDATING TRIGGERS FROM THE COMMAND LINE	94
5.7.1. Updating a trigger by using the Knative CLI	94
5.8. DELETING TRIGGERS FROM THE COMMAND LINE	95

5.8.1. Deleting a trigger by using the Knative CLI	95
CHAPTER 6. CHANNELS	96
6.1. CHANNELS AND SUBSCRIPTIONS	96
6.1.1. Channel implementation types	97
6.2. CREATING CHANNELS	97
6.2.1. Creating a channel by using the Administrator perspective	97
6.2.2. Creating a channel by using the Developer perspective	98
6.2.3. Creating a channel by using the Knative CLI	98
6.2.4. Creating a default implementation channel by using YAML	99
6.2.5. Creating a channel for Apache Kafka by using YAML	100
6.2.6. Next steps	101
6.3. CONNECTING CHANNELS TO SINKS	101
6.3.1. Creating a subscription by using the Developer perspective	101
6.3.2. Creating a subscription by using YAML	102
6.3.3. Creating a subscription by using the Knative CLI	103
6.3.4. Creating a subscription by using the Administrator perspective	105
6.3.5. Next steps	106
6.4. DEFAULT CHANNEL IMPLEMENTATION	106
6.4.1. Configuring the default channel implementation	106
6.5. SECURITY CONFIGURATION FOR CHANNELS	107
6.5.1. Configuring TLS authentication for Knative channels for Apache Kafka	107
6.5.2. Configuring SASL authentication for Knative channels for Apache Kafka	108
CHAPTER 7. SUBSCRIPTIONS	111
7.1. CREATING SUBSCRIPTIONS	111
7.1.1. Creating a subscription by using the Administrator perspective	111
7.1.2. Creating a subscription by using the Developer perspective	111
7.1.3. Creating a subscription by using YAML	113
7.1.4. Creating a subscription by using the Knative CLI	114
7.1.5. Next steps	115
7.2. MANAGING SUBSCRIPTIONS	116
7.2.1. Describing subscriptions by using the Knative CLI	116
7.2.2. Listing subscriptions by using the Knative CLI	116
7.2.3. Updating subscriptions by using the Knative CLI	117
CHAPTER 8. EVENT DELIVERY	118
8.1. CONFIGURABLE EVENT DELIVERY PARAMETERS	118
8.2. EXAMPLES OF CONFIGURING EVENT DELIVERY PARAMETERS	118
8.3. CONFIGURING EVENT DELIVERY ORDERING FOR TRIGGERS	120
CHAPTER 9. EVENT DISCOVERY	122
9.1. LISTING EVENT SOURCES AND EVENT SOURCE TYPES	122
9.2. LISTING EVENT SOURCE TYPES FROM THE COMMAND LINE	122
9.2.1. Listing available event source types by using the Knative CLI	122
9.3. LISTING EVENT SOURCE TYPES FROM THE DEVELOPER PERSPECTIVE	122
9.3.1. Viewing available event source types within the Developer perspective	123
9.4. LISTING EVENT SOURCES FROM THE COMMAND LINE	123
9.4.1. Listing available event sources by using the Knative CLI	123
CHAPTER 10. TUNING EVENTING CONFIGURATION	125
10.1. OVERRIDING KNATIVE EVENTING SYSTEM DEPLOYMENT CONFIGURATIONS	125
10.1.1. Overriding deployment configurations	125
10.2. HIGH AVAILABILITY	126

10.2.1. Configuring high availability replicas for Knative Eventing	127
10.2.2. Configuring high availability replicas for the Knative broker implementation for Apache Kafka	128
CHAPTER 11. CONFIGURING KUBE-RBAC-PROXY FOR EVENTING	130
11.1. CONFIGURING KUBE-RBAC-PROXY RESOURCES FOR EVENTING	130

CHAPTER 1. KNATIVE EVENTING

Knative Eventing on OpenShift Container Platform enables developers to use an [event-driven architecture](#) with serverless applications. An event-driven architecture is based on the concept of decoupled relationships between event producers and event consumers.

Event producers create events, and event *sinks*, or consumers, receive events. Knative Eventing uses standard HTTP POST requests to send and receive events between event producers and sinks. These events conform to the [CloudEvents specifications](#), which enables creating, parsing, sending, and receiving events in any programming language.

1.1. KNATIVE EVENTING USE CASES:

Knative Eventing supports the following use cases:

Publish an event without creating a consumer

You can send events to a broker as an HTTP POST, and use binding to decouple the destination configuration from your application that produces events.

Consume an event without creating a publisher

You can use a trigger to consume events from a broker based on event attributes. The application receives events as an HTTP POST.

To enable delivery to multiple types of sinks, Knative Eventing defines the following generic interfaces that can be implemented by multiple Kubernetes resources:

Addressable resources

Able to receive and acknowledge an event delivered over HTTP to an address defined in the **status.address.url** field of the event. The Kubernetes **Service** resource also satisfies the addressable interface.

Callable resources

Able to receive an event delivered over HTTP and transform it, returning **0** or **1** new events in the HTTP response payload. These returned events may be further processed in the same way that events from an external event source are processed.

CHAPTER 2. EVENT SOURCES

2.1. EVENT SOURCES

A Knative *event source* can be any Kubernetes object that generates or imports cloud events, and relays those events to another endpoint, known as a *sink*. Sourcing events is critical to developing a distributed system that reacts to events.

You can create and manage Knative event sources by using the **Developer** perspective in the OpenShift Container Platform web console, the Knative (**kn**) CLI, or by applying YAML files.

Currently, OpenShift Serverless supports the following event source types:

API server source

Brings Kubernetes API server events into Knative. The API server source sends a new event each time a Kubernetes resource is created, updated or deleted.

Ping source

Produces events with a fixed payload on a specified cron schedule.

Kafka event source

Connects an Apache Kafka cluster to a sink as an event source.

You can also create a [custom event source](#).

2.2. EVENT SOURCE IN THE ADMINISTRATOR PERSPECTIVE

Sourcing events is critical to developing a distributed system that reacts to events.

2.2.1. Creating an event source by using the Administrator perspective

A Knative *event source* can be any Kubernetes object that generates or imports cloud events, and relays those events to another endpoint, known as a *sink*.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console and are in the **Administrator** perspective.
- You have cluster administrator permissions on OpenShift Container Platform, or you have cluster or dedicated administrator permissions on Red Hat OpenShift Service on AWS or OpenShift Dedicated.

Procedure

1. In the **Administrator** perspective of the OpenShift Container Platform web console, navigate to **Serverless → Eventing**.
2. In the **Create** list, select **Event Source**. You will be directed to the **Event Sources** page.
3. Select the event source type that you want to create.

2.3. CREATING AN API SERVER SOURCE

The API server source is an event source that can be used to connect an event sink, such as a Knative service, to the Kubernetes API server. The API server source watches for Kubernetes events and forwards them to the Knative Eventing broker.

2.3.1. Creating an API server source by using the web console

After Knative Eventing is installed on your cluster, you can create an API server source by using the web console. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create an event source.

Prerequisites

- You have logged in to the OpenShift Container Platform web console.
- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have installed the OpenShift CLI (**oc**).

PROCEDURE

If you want to re-use an existing service account, you can modify your existing **ServiceAccount** resource to include the required permissions instead of creating a new resource.

1. Create a service account, role, and role binding for the event source as a YAML file:

```
apiVersion: v1
kind: ServiceAccount
metadata:
  name: events-sa
  namespace: default 1
---
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: event-watcher
  namespace: default 2
rules:
- apiGroups:
  - ""
  resources:
  - events
  verbs:
  - get
  - list
  - watch
---
```

```

apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: k8s-ra-event-watcher
  namespace: default 3
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: Role
  name: event-watcher
subjects:
  - kind: ServiceAccount
    name: events-sa
    namespace: default 4

```

- 1 2 3 4 Change this namespace to the namespace that you have selected for installing the event source.

2. Apply the YAML file:

```
$ oc apply -f <filename>
```

3. In the **Developer** perspective, navigate to **+Add → Event Source**. The **Event Sources** page is displayed.
4. Optional: If you have multiple providers for your event sources, select the required provider from the **Providers** list to filter the available event sources from the provider.
5. Select **ApiServerSource** and then click **Create Event Source**. The **Create Event Source** page is displayed.
6. Configure the **ApiServerSource** settings by using the **Form view** or **YAML view**:

NOTE

You can switch between the **Form view** and **YAML view**. The data is persisted when switching between the views.

- a. Enter **v1** as the **APIVERSION** and **Event** as the **KIND**.
 - b. Select the **Service Account Name** for the service account that you created.
 - c. In the **Target** section, select your event sink. This can be either a **Resource** or a **URI**:
 - i. Select **Resource** to use a channel, broker, or service as an event sink for the event source.
 - ii. Select **URI** to specify a Uniform Resource Identifier (URI) where the events are routed to.
7. Click **Create**.

Verification

- After you have created the API server source, check that it is connected to the event sink by viewing it in the **Topology** view.

The screenshot displays the OpenShift console's Topology view. On the left, a diagram shows a source (REV event-...-vn85s) connected to a sink (AS testevents). The sink is highlighted with a dashed box and a 100% connection indicator. The right-hand panel shows details for the 'testevents' service, including its Knative Service name, Sink URI, and deployment information.

NOTE

If a URI sink is used, you can modify the URI by right-clicking on **URI sink** → **Edit URI**.

Deleting the API server source

1. Navigate to the **Topology** view.
2. Right-click the API server source and select **Delete ApiServerSource**.

The screenshot shows the OpenShift console's Topology view. A context menu is open over the API server source (REV hellow...wcrsq). The menu options include Edit Application Grouping, Move Sink, Edit Labels, Edit Annotations, Edit ApiServerSource, and Delete ApiServerSource. The left-hand navigation pane is visible, showing the 'Developer' section selected.

2.3.2. Creating an API server source by using the Knative CLI

You can use the **kn source apiserver create** command to create an API server source by using the **kn** CLI. Using the **kn** CLI to create an API server source provides a more streamlined and intuitive user interface than modifying YAML files directly.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have installed the OpenShift CLI (**oc**).
- You have installed the Knative (**kn**) CLI.

PROCEDURE

If you want to re-use an existing service account, you can modify your existing **ServiceAccount** resource to include the required permissions instead of creating a new resource.

1. Create a service account, role, and role binding for the event source as a YAML file:

```

apiVersion: v1
kind: ServiceAccount
metadata:
  name: events-sa
  namespace: default 1
---
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: event-watcher
  namespace: default 2
rules:
- apiGroups:
  - ""
  resources:
  - events
  verbs:
  - get
  - list
  - watch
---
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
  name: k8s-ra-event-watcher
  namespace: default 3
roleRef:
  apiGroup: rbac.authorization.k8s.io

```

```
kind: Role
name: event-watcher
subjects:
- kind: ServiceAccount
  name: events-sa
  namespace: default 4
```

- 1 2 3 4 Change this namespace to the namespace that you have selected for installing the event source.

2. Apply the YAML file:

```
$ oc apply -f <filename>
```

3. Create an API server source that has an event sink. In the following example, the sink is a broker:

```
$ kn source apiserver create <event_source_name> --sink broker:<broker_name> --
resource "event:v1" --service-account <service_account_name> --mode Resource
```

4. To check that the API server source is set up correctly, create a Knative service that dumps incoming messages to its log:

```
$ kn service create event-display --image quay.io/openshift-knative/showcase
```

5. If you used a broker as an event sink, create a trigger to filter events from the **default** broker to the service:

```
$ kn trigger create <trigger_name> --sink ksvc:event-display
```

6. Create events by launching a pod in the default namespace:

```
$ oc create deployment event-origin --image quay.io/openshift-knative/showcase
```

7. Check that the controller is mapped correctly by inspecting the output generated by the following command:

```
$ kn source apiserver describe <source_name>
```

Example output

```
Name:          mysource
Namespace:     default
Annotations:   sources.knative.dev/creator=developer,
sources.knative.dev/lastModifier=developer
Age:          3m
ServiceAccountName: events-sa
Mode:         Resource
Sink:
  Name:        default
  Namespace:   default
  Kind:        Broker (eventing.knative.dev/v1)
Resources:
```

```

Kind:    event (v1)
Controller: false
Conditions:
  OK TYPE          AGE REASON
  ++ Ready         3m
  ++ Deployed      3m
  ++ SinkProvided  3m
  ++ SufficientPermissions 3m
  ++ EventTypesProvided 3m

```

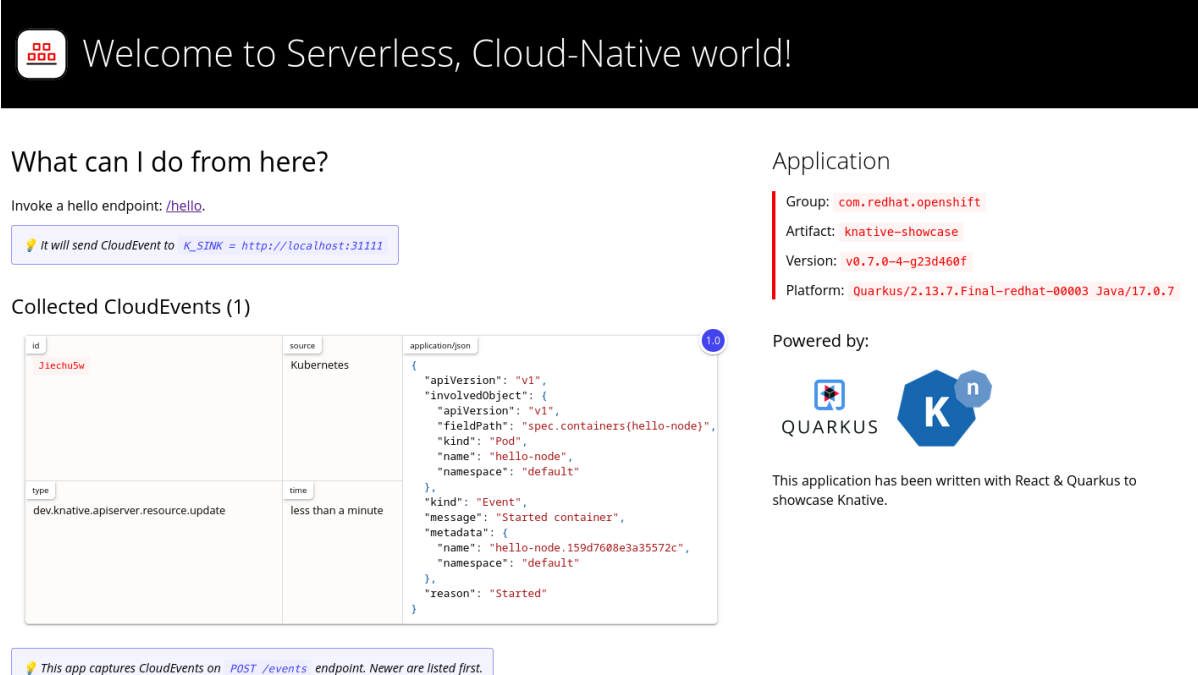

Verification

To verify that the Kubernetes events were sent to Knative, look at the event-display logs or use web browser to see the events.

- To view the events in a web browser, open the link returned by the following command:

```
$ kn service describe event-display -o url
```

Figure 2.1. Example browser page

What can I do from here?

Invoke a hello endpoint: [/hello](#).

It will send CloudEvent to `K_SINK = http://localhost:31111`

Application

- Group: `com.redhat.openshift`
- Artifact: `knative-showcase`
- Version: `v0.7.0-4-g23d460f`
- Platform: `Quarkus/2.13.7.Final-redhat-00003 Java/17.0.7`

Powered by:

QUARKUS 

This application has been written with React & Quarkus to showcase Knative.

Collected CloudEvents (1)

id	source	application/json
J1echu5w	Kubernetes	<pre> { "apiVersion": "v1", "involvedObject": { "apiVersion": "v1", "fieldPath": "spec.containers(hello-node)", "kind": "Pod", "name": "hello-node", "namespace": "default" }, "kind": "Event", "message": "Started container", "metadata": { "name": "hello-node.159d7608e3a35572c", "namespace": "default" }, "reason": "Started" } </pre>
type	time	
dev.knative.apiserver.resource.update	less than a minute	

This app captures CloudEvents on `POST /events` endpoint. Newer are listed first.

- Alternatively, to see the logs in the terminal, view the event-display logs for the pods by entering the following command:

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```

┌ cloudevents.Event
  Validation: valid
  Context Attributes,
  specversion: 1.0
  type: dev.knative.apiserver.resource.update
  datacontenttype: application/json
  ...

```

```
Data,
{
  "apiVersion": "v1",
  "involvedObject": {
    "apiVersion": "v1",
    "fieldPath": "spec.containers{event-origin}",
    "kind": "Pod",
    "name": "event-origin",
    "namespace": "default",
    ....
  },
  "kind": "Event",
  "message": "Started container",
  "metadata": {
    "name": "event-origin.159d7608e3a3572c",
    "namespace": "default",
    ....
  },
  "reason": "Started",
  ...
}
```

Deleting the API server source

1. Delete the trigger:

```
$ kn trigger delete <trigger_name>
```

2. Delete the event source:

```
$ kn source apiserver delete <source_name>
```

3. Delete the service account, cluster role, and cluster binding:

```
$ oc delete -f authentication.yaml
```

2.3.2.1. Knative CLI sink flag

When you create an event source by using the Knative (**kn**) CLI, you can specify a sink where events are sent to from that resource by using the **--sink** flag. The sink can be any addressable or callable resource that can receive incoming events from other resources.

The following example creates a sink binding that uses a service, **http://event-display.svc.cluster.local**, as the sink:

Example command using the sink flag

```
$ kn source binding create bind-heartbeat \
--namespace sinkbinding-example \
--subject "Job:batch/v1:app=heartbeat-cron" \
--sink http://event-display.svc.cluster.local \ 1
--ce-override "sink=bound"
```

- 1 **svc** in `http://event-display.svc.cluster.local` determines that the sink is a Knative service. Other default sink prefixes include **channel**, and **broker**.

2.3.3. Creating an API server source by using YAML files

Creating Knative resources by using YAML files uses a declarative API, which enables you to describe event sources declaratively and in a reproducible manner. To create an API server source by using YAML, you must create a YAML file that defines an **ApiServerSource** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have created the **default** broker in the same namespace as the one defined in the API server source YAML file.
- Install the OpenShift CLI (**oc**).

PROCEDURE

If you want to re-use an existing service account, you can modify your existing **ServiceAccount** resource to include the required permissions instead of creating a new resource.

1. Create a service account, role, and role binding for the event source as a YAML file:

```

apiVersion: v1
kind: ServiceAccount
metadata:
  name: events-sa
  namespace: default 1
---
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: event-watcher
  namespace: default 2
rules:
- apiGroups:
  - ""
  resources:
  - events
  verbs:
  - get
  - list
  - watch
---
apiVersion: rbac.authorization.k8s.io/v1

```

```

kind: RoleBinding
metadata:
  name: k8s-ra-event-watcher
  namespace: default 3
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: Role
  name: event-watcher
subjects:
- kind: ServiceAccount
  name: events-sa
  namespace: default 4

```

- 1 2 3 4** Change this namespace to the namespace that you have selected for installing the event source.

2. Apply the YAML file:

```
$ oc apply -f <filename>
```

3. Create an API server source as a YAML file:

```

apiVersion: sources.knative.dev/v1alpha1
kind: ApiServerSource
metadata:
  name: testevents
spec:
  serviceAccountName: events-sa
  mode: Resource
  resources:
  - apiVersion: v1
    kind: Event
  sink:
    ref:
      apiVersion: eventing.knative.dev/v1
      kind: Broker
      name: default

```

4. Apply the **ApiServerSource** YAML file:

```
$ oc apply -f <filename>
```

5. To check that the API server source is set up correctly, create a Knative service as a YAML file that dumps incoming messages to its log:

```

apiVersion: serving.knative.dev/v1
kind: Service
metadata:
  name: event-display
  namespace: default
spec:
  template:

```

```
spec:
  containers:
  - image: quay.io/openshift-knative/showcase
```

6. Apply the **Service** YAML file:

```
$ oc apply -f <filename>
```

7. Create a **Trigger** object as a YAML file that filters events from the **default** broker to the service created in the previous step:

```
apiVersion: eventing.knative.dev/v1
kind: Trigger
metadata:
  name: event-display-trigger
  namespace: default
spec:
  broker: default
  subscriber:
    ref:
      apiVersion: serving.knative.dev/v1
      kind: Service
      name: event-display
```

8. Apply the **Trigger** YAML file:

```
$ oc apply -f <filename>
```

9. Create events by launching a pod in the default namespace:

```
$ oc create deployment event-origin --image=quay.io/openshift-knative/showcase
```

10. Check that the controller is mapped correctly, by entering the following command and inspecting the output:

```
$ oc get apiserversource.sources.knative.dev testevents -o yaml
```

Example output

```
apiVersion: sources.knative.dev/v1alpha1
kind: ApiServerSource
metadata:
  annotations:
    creationTimestamp: "2020-04-07T17:24:54Z"
    generation: 1
    name: testevents
    namespace: default
    resourceVersion: "62868"
  selfLink:
    /apis/sources.knative.dev/v1alpha1/namespaces/default/apiserversources/testevents2
  uid: 1603d863-bb06-4d1c-b371-f580b4db99fa
spec:
  mode: Resource
```

```

resources:
- apiVersion: v1
  controller: false
  controllerSelector:
    apiVersion: ""
    kind: ""
    name: ""
    uid: ""
  kind: Event
  labelSelector: {}
  serviceAccountName: events-sa
  sink:
    ref:
      apiVersion: eventing.knative.dev/v1
      kind: Broker
      name: default

```

Verification

To verify that the Kubernetes events were sent to Knative, you can look at the event-display logs or use web browser to see the events.

- To view the events in a web browser, open the link returned by the following command:

```
$ oc get ksvc event-display -o jsonpath='{.status.url}'
```

Figure 2.2. Example browser page

What can I do from here?

Invoke a hello endpoint: `/hello`.

It will send CloudEvent to `K_SINK = http://localhost:31111`

Collected CloudEvents (1)

id	source	application/json	type	time
3iechu5w	Kubernetes	{ "apiVersion": "v1", "involvedObject": { "apiVersion": "v1", "fieldPath": "spec.containers(hello-node)", "kind": "Pod", "name": "hello-node", "namespace": "default" }, "kind": "Event", "message": "Started container", "metadata": { "name": "hello-node.159d7608e3a35572c", "namespace": "default" }, "reason": "Started" }	dev.knative.apiserver.resource.update	less than a minute

This app captures CloudEvents on `POST /events` endpoint. Newer are listed first.

Application

Group: `com.redhat.openshift`
 Artifact: `knative-showcase`
 Version: `v0.7.0-4-g23d460f`
 Platform: `Quarkus/2.13.7.Final-redhat-00003 Java/17.0.7`

Powered by:

QUARKUS 

This application has been written with React & Quarkus to showcase Knative.

- To see the logs in the terminal, view the event-display logs for the pods by entering the following command:

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```

🚩 cloudevents.Event
Validation: valid
Context Attributes,
  specversion: 1.0
  type: dev.knative.apiserver.resource.update
  datacontenttype: application/json
...
Data,
  {
    "apiVersion": "v1",
    "involvedObject": {
      "apiVersion": "v1",
      "fieldPath": "spec.containers{event-origin}",
      "kind": "Pod",
      "name": "event-origin",
      "namespace": "default",
      ....
    },
    "kind": "Event",
    "message": "Started container",
    "metadata": {
      "name": "event-origin.159d7608e3a3572c",
      "namespace": "default",
      ....
    },
    "reason": "Started",
    ...
  }

```

Deleting the API server source

1. Delete the trigger:

```
$ oc delete -f trigger.yaml
```

2. Delete the event source:

```
$ oc delete -f k8s-events.yaml
```

3. Delete the service account, cluster role, and cluster binding:

```
$ oc delete -f authentication.yaml
```

2.4. CREATING A PING SOURCE

A ping source is an event source that can be used to periodically send ping events with a constant payload to an event consumer. A ping source can be used to schedule sending events, similar to a timer.

2.4.1. Creating a ping source by using the web console

After Knative Eventing is installed on your cluster, you can create a ping source by using the web console. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create an event source.

Prerequisites

- You have logged in to the OpenShift Container Platform web console.
- The OpenShift Serverless Operator, Knative Serving and Knative Eventing are installed on the cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. To verify that the ping source is working, create a simple Knative service that dumps incoming messages to the logs of the service.

- a. In the **Developer** perspective, navigate to **+Add → YAML**.
- b. Copy the example YAML:

```
apiVersion: serving.knative.dev/v1
kind: Service
metadata:
  name: event-display
spec:
  template:
    spec:
      containers:
        - image: quay.io/openshift-knative/showcase
```

- c. Click **Create**.
2. Create a ping source in the same namespace as the service created in the previous step, or any other sink that you want to send events to.
 - a. In the **Developer** perspective, navigate to **+Add → Event Source**. The **Event Sources** page is displayed.
 - b. Optional: If you have multiple providers for your event sources, select the required provider from the **Providers** list to filter the available event sources from the provider.
 - c. Select **Ping Source** and then click **Create Event Source**. The **Create Event Source** page is displayed.

NOTE

You can configure the **PingSource** settings by using the **Form view** or **YAML view** and can switch between the views. The data is persisted when switching between the views.

- d. Enter a value for **Schedule**. In this example, the value is `*/2 * * * *`, which creates a PingSource that sends a message every two minutes.
- e. Optional: You can enter a value for **Data**, which is the message payload.
- f. In the **Target** section, select your event sink. This can be either a **Resource** or a **URI**:

- i. Select **Resource** to use a channel, broker, or service as an event sink for the event source. In this example, the **event-display** service created in the previous step is used as the target **Resource**.
 - ii. Select **URI** to specify a Uniform Resource Identifier (URI) where the events are routed to.
- g. Click **Create**.

Verification

You can verify that the ping source was created and is connected to the sink by viewing the **Topology** page.

1. In the **Developer** perspective, navigate to **Topology**.
2. View the ping source and sink.

3. View the event-display service in the web browser. You should see the ping source events in the web UI.

What can I do from here?

Invoke a hello endpoint: [/hello](#).

It will send CloudEvent to `K_SINK = http://localhost:31111`

Collected CloudEvents (1)

id	source	application/json
bb2dc97e-0ba8-402b-afce-882fd60e2d0b	/apis/v1 /namespaces /default/pingsources /test-ping-source	{ "message": "Hello World!" }
type	time	
dev.knative.sources.ping	less than a minute	

This app captures CloudEvents on `POST /events` endpoint. Newer are listed first.

Application

Group: `com.redhat.openshift`
 Artifact: `knative-showcase`
 Version: `v0.7.0-4-g23d460f`
 Platform: `Quarkus/2.13.7.Final-redhat-00003`
 Java/17.0.7

Powered by:

This application has been written with React & Quarkus to showcase Knative.

Deleting the ping source

1. Navigate to the **Topology** view.
2. Right-click the API server source and select **Delete Ping Source**

2.4.2. Creating a ping source by using the Knative CLI

You can use the **kn source ping create** command to create a ping source by using the Knative (**kn**) CLI. Using the Knative CLI to create event sources provides a more streamlined and intuitive user interface than modifying YAML files directly.

Prerequisites

- The OpenShift Serverless Operator, Knative Serving and Knative Eventing are installed on the cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- Optional: If you want to use the verification steps for this procedure, install the OpenShift CLI (**oc**).

Procedure

1. To verify that the ping source is working, create a simple Knative service that dumps incoming messages to the service logs:

```
$ kn service create event-display \  
  --image quay.io/openshift-knative/showcase
```

2. For each set of ping events that you want to request, create a ping source in the same namespace as the event consumer:

```
$ kn source ping create test-ping-source \  
  --schedule "*/2 * * * *" \  
  --data '{"message": "Hello world!"}' \  
  --sink ksvc:event-display
```

3. Check that the controller is mapped correctly by entering the following command and inspecting the output:

```
$ kn source ping describe test-ping-source
```

Example output

```
Name:      test-ping-source  
Namespace: default  
Annotations: sources.knative.dev/creator=developer,  
sources.knative.dev/lastModifier=developer  
Age:       15s  
Schedule:  */2 * * * *  
Data:      {"message": "Hello world!"}  
  
Sink:  
Name:      event-display  
Namespace: default  
Resource:  Service (serving.knative.dev/v1)
```

```

Conditions:
OK TYPE          AGE REASON
++ Ready         8s
++ Deployed      8s
++ SinkProvided  15s
++ ValidSchedule 15s
++ EventTypeProvided 15s
++ ResourcesCorrect 15s

```

Verification

You can verify that the Kubernetes events were sent to the Knative event sink by looking at the logs of the sink pod.

By default, Knative services terminate their pods if no traffic is received within a 60 second period. The example shown in this guide creates a ping source that sends a message every 2 minutes, so each message should be observed in a newly created pod.

1. Watch for new pods created:

```
$ watch oc get pods
```

2. Cancel watching the pods using Ctrl+C, then look at the logs of the created pod:

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```

▲ cloudevents.Event
Validation: valid
Context Attributes,
specversion: 1.0
type: dev.knative.sources.ping
source: /apis/v1/namespaces/default/pingsources/test-ping-source
id: 99e4f4f6-08ff-4bff-acf1-47f61ded68c9
time: 2020-04-07T16:16:00.000601161Z
datacontenttype: application/json
Data,
{
  "message": "Hello world!"
}

```

Deleting the ping source

- Delete the ping source:

```
$ kn delete pingsources.sources.knative.dev <ping_source_name>
```

2.4.2.1. Knative CLI sink flag

When you create an event source by using the Knative (**kn**) CLI, you can specify a sink where events are sent to from that resource by using the **--sink** flag. The sink can be any addressable or callable resource that can receive incoming events from other resources.

The following example creates a sink binding that uses a service, **http://event-display.svc.cluster.local**, as the sink:

Example command using the sink flag

```
$ kn source binding create bind-heartbeat \
  --namespace sinkbinding-example \
  --subject "Job:batch/v1:app=heartbeat-cron" \
  --sink http://event-display.svc.cluster.local \ 1
  --ce-override "sink=bound"
```

- 1** **svc** in **http://event-display.svc.cluster.local** determines that the sink is a Knative service. Other default sink prefixes include **channel**, and **broker**.

2.4.3. Creating a ping source by using YAML

Creating Knative resources by using YAML files uses a declarative API, which enables you to describe event sources declaratively and in a reproducible manner. To create a serverless ping source by using YAML, you must create a YAML file that defines a **PingSource** object, then apply it by using **oc apply**.

Example PingSource object

```
apiVersion: sources.knative.dev/v1
kind: PingSource
metadata:
  name: test-ping-source
spec:
  schedule: "*/2 * * * *" 1
  data: '{"message": "Hello world!"}' 2
  sink: 3
    ref:
      apiVersion: serving.knative.dev/v1
      kind: Service
      name: event-display
```

- 1** The schedule of the event specified using [CRON expression](#).
- 2** The event message body expressed as a JSON encoded data string.
- 3** These are the details of the event consumer. In this example, we are using a Knative service named **event-display**.

Prerequisites

- The OpenShift Serverless Operator, Knative Serving and Knative Eventing are installed on the cluster.
- Install the OpenShift CLI (**oc**).
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. To verify that the ping source is working, create a simple Knative service that dumps incoming messages to the service's logs.

- a. Create a service YAML file:

```
apiVersion: serving.knative.dev/v1
kind: Service
metadata:
  name: event-display
spec:
  template:
    spec:
      containers:
        - image: quay.io/openshift-knative/showcase
```

- b. Create the service:

```
$ oc apply -f <filename>
```

2. For each set of ping events that you want to request, create a ping source in the same namespace as the event consumer.

- a. Create a YAML file for the ping source:

```
apiVersion: sources.knative.dev/v1
kind: PingSource
metadata:
  name: test-ping-source
spec:
  schedule: "*/2 * * * *"
  data: '{"message": "Hello world!"}'
  sink:
    ref:
      apiVersion: serving.knative.dev/v1
      kind: Service
      name: event-display
```

- b. Create the ping source:

```
$ oc apply -f <filename>
```

3. Check that the controller is mapped correctly by entering the following command:

```
$ oc get pingsource.sources.knative.dev <ping_source_name> -oyaml
```

Example output

```
apiVersion: sources.knative.dev/v1
kind: PingSource
metadata:
  annotations:
    sources.knative.dev/creator: developer
    sources.knative.dev/lastModifier: developer
```

```

creationTimestamp: "2020-04-07T16:11:14Z"
generation: 1
name: test-ping-source
namespace: default
resourceVersion: "55257"
selfLink: /apis/sources.knative.dev/v1/namespaces/default/pingsources/test-ping-source
uid: 3d80d50b-f8c7-4c1b-99f7-3ec00e0a8164
spec:
  data: '{ value: "hello" }'
  schedule: */2 * * * *
  sink:
    ref:
      apiVersion: serving.knative.dev/v1
      kind: Service
      name: event-display
      namespace: default

```

Verification

You can verify that the Kubernetes events were sent to the Knative event sink by looking at the sink pod's logs.

By default, Knative services terminate their pods if no traffic is received within a 60 second period. The example shown in this guide creates a PingSource that sends a message every 2 minutes, so each message should be observed in a newly created pod.

1. Watch for new pods created:

```
$ watch oc get pods
```

2. Cancel watching the pods using Ctrl+C, then look at the logs of the created pod:

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```

🚀 cloudevents.Event
Validation: valid
Context Attributes,
  specversion: 1.0
  type: dev.knative.sources.ping
  source: /apis/v1/namespaces/default/pingsources/test-ping-source
  id: 042ff529-240e-45ee-b40c-3a908129853e
  time: 2020-04-07T16:22:00.000791674Z
  datacontenttype: application/json
Data,
  {
    "message": "Hello world!"
  }

```

Deleting the ping source

- Delete the ping source:

```
$ oc delete -f <filename>
```

Example command

```
$ oc delete -f ping-source.yaml
```

2.5. SOURCE FOR APACHE KAFKA

You can create an Apache Kafka source that reads events from an Apache Kafka cluster and passes these events to a sink. You can create a Kafka source by using the OpenShift Container Platform web console, the Knative (**kn**) CLI, or by creating a **KafkaSource** object directly as a YAML file and using the OpenShift CLI (**oc**) to apply it.

NOTE

See the documentation for [Installing Knative broker for Apache Kafka](#).

2.5.1. Creating an Apache Kafka event source by using the web console

After the Knative broker implementation for Apache Kafka is installed on your cluster, you can create an Apache Kafka source by using the web console. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create a Kafka source.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resource are installed on your cluster.
- You have logged in to the web console.
- You have access to a Red Hat AMQ Streams (Kafka) cluster that produces the Kafka messages you want to import.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

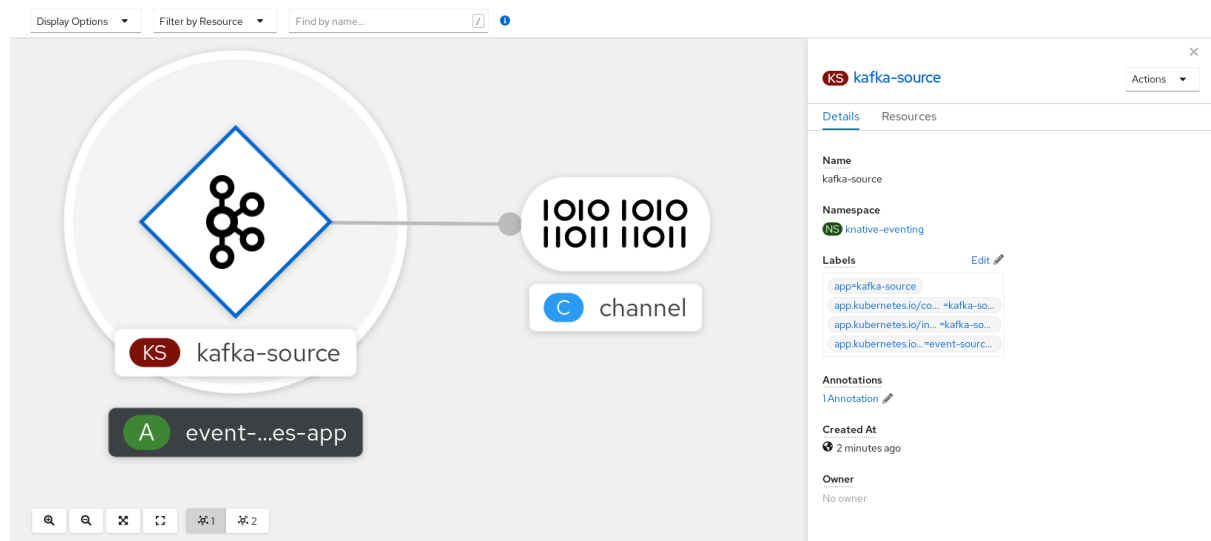

1. In the **Developer** perspective, navigate to the **+Add** page and select **Event Source**.
2. In the **Event Sources** page, select **Kafka Source** in the **Type** section.
3. Configure the **Kafka Source** settings:
 - a. Add a comma-separated list of **Bootstrap Servers**.
 - b. Add a comma-separated list of **Topics**.
 - c. Add a **Consumer Group**.
 - d. Select the **Service Account Name** for the service account that you created.
 - e. In the **Target** section, select your event sink. This can be either a **Resource** or a **URI**:

- i. Select **Resource** to use a channel, broker, or service as an event sink for the event source.
 - ii. Select **URI** to specify a Uniform Resource Identifier (URI) where the events are routed to.
- f. Enter a **Name** for the Kafka event source.
4. Click **Create**.

Verification

You can verify that the Kafka event source was created and is connected to the sink by viewing the **Topology** page.

1. In the **Developer** perspective, navigate to **Topology**.
2. View the Kafka event source and sink.

2.5.2. Creating an Apache Kafka event source by using the Knative CLI

You can use the **kn source kafka create** command to create a Kafka source by using the Knative (**kn**) CLI. Using the Knative CLI to create event sources provides a more streamlined and intuitive user interface than modifying YAML files directly.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, Knative Serving, and the **KnativeKafka** custom resource (CR) are installed on your cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have access to a Red Hat AMQ Streams (Kafka) cluster that produces the Kafka messages you want to import.
- You have installed the Knative (**kn**) CLI.
- Optional: You have installed the OpenShift CLI (**oc**) if you want to use the verification steps in this procedure.

Procedure

1. To verify that the Kafka event source is working, create a Knative service that dumps incoming events into the service logs:

```
$ kn service create event-display \
  --image quay.io/openshift-knative/showcase
```

2. Create a **KafkaSource** CR:

```
$ kn source kafka create <kafka_source_name> \
  --servers <cluster_kafka_bootstrap>.kafka.svc:9092 \
  --topics <topic_name> --consumergroup my-consumer-group \
  --sink event-display
```

NOTE

Replace the placeholder values in this command with values for your source name, bootstrap servers, and topics.

The **--servers**, **--topics**, and **--consumergroup** options specify the connection parameters to the Kafka cluster. The **--consumergroup** option is optional.

3. Optional: View details about the **KafkaSource** CR you created:

```
$ kn source kafka describe <kafka_source_name>
```

Example output

```
Name:          example-kafka-source
Namespace:     kafka
Age:          1h
BootstrapServers: example-cluster-kafka-bootstrap.kafka.svc:9092
Topics:       example-topic
ConsumerGroup: example-consumer-group

Sink:
Name:    event-display
Namespace: default
Resource: Service (serving.knative.dev/v1)

Conditions:
OK TYPE      AGE REASON
++ Ready     1h
++ Deployed  1h
++ SinkProvided 1h
```

Verification steps

1. Trigger the Kafka instance to send a message to the topic:

```
$ oc -n kafka run kafka-producer \
  -ti --image=quay.io/strimzi/kafka:latest-kafka-2.7.0 --rm=true \
```

```
--restart=Never -- bin/kafka-console-producer.sh \
--broker-list <cluster_kafka_bootstrap>:9092 --topic my-topic
```

Enter the message in the prompt. This command assumes that:

- The Kafka cluster is installed in the **kafka** namespace.
- The **KafkaSource** object has been configured to use the **my-topic** topic.

2. Verify that the message arrived by viewing the logs:

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```
▲ cloudevents.Event
Validation: valid
Context Attributes,
  specversion: 1.0
  type: dev.knative.kafka.event
  source: /apis/v1/namespaces/default/kafkasources/example-kafka-source#example-topic
  subject: partition:46#0
  id: partition:46/offset:0
  time: 2021-03-10T11:21:49.4Z
Extensions,
  traceparent: 00-161ff3815727d8755848ec01c866d1cd-7ff3916c44334678-00
Data,
  Hello!
```

2.5.2.1. Knative CLI sink flag

When you create an event source by using the Knative (**kn**) CLI, you can specify a sink where events are sent to from that resource by using the **--sink** flag. The sink can be any addressable or callable resource that can receive incoming events from other resources.

The following example creates a sink binding that uses a service, **http://event-display.svc.cluster.local**, as the sink:

Example command using the sink flag

```
$ kn source binding create bind-heartbeat \
--namespace sinkbinding-example \
--subject "Job:batch/v1:app=heartbeat-cron" \
--sink http://event-display.svc.cluster.local \ 1
--ce-override "sink=bound"
```

1 **svc** in **http://event-display.svc.cluster.local** determines that the sink is a Knative service. Other default sink prefixes include **channel**, and **broker**.

2.5.3. Creating an Apache Kafka event source by using YAML

Creating Knative resources by using YAML files uses a declarative API, which enables you to describe applications declaratively and in a reproducible manner. To create a Kafka source by using YAML, you

must create a YAML file that defines a **KafkaSource** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resource are installed on your cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have access to a Red Hat AMQ Streams (Kafka) cluster that produces the Kafka messages you want to import.
- Install the OpenShift CLI (**oc**).

Procedure

1. Create a **KafkaSource** object as a YAML file:

```
apiVersion: sources.knative.dev/v1beta1
kind: KafkaSource
metadata:
  name: <source_name>
spec:
  consumerGroup: <group_name> 1
  bootstrapServers:
  - <list_of_bootstrap_servers>
  topics:
  - <list_of_topics> 2
  sink:
  - <list_of_sinks> 3
```

- 1** A consumer group is a group of consumers that use the same group ID, and consume data from a topic.
- 2** A topic provides a destination for the storage of data. Each topic is split into one or more partitions.
- 3** A sink specifies where events are sent to from a source.

IMPORTANT

Only the **v1beta1** version of the API for **KafkaSource** objects on OpenShift Serverless is supported. Do not use the **v1alpha1** version of this API, as this version is now deprecated.

Example KafkaSource object

```
apiVersion: sources.knative.dev/v1beta1
kind: KafkaSource
metadata:
  name: kafka-source
```

```
spec:
  consumerGroup: knative-group
  bootstrapServers:
  - my-cluster-kafka-bootstrap.kafka:9092
  topics:
  - knative-demo-topic
  sink:
    ref:
      apiVersion: serving.knative.dev/v1
      kind: Service
      name: event-display
```

2. Apply the **KafkaSource** YAML file:

```
$ oc apply -f <filename>
```

Verification

- Verify that the Kafka event source was created by entering the following command:

```
$ oc get pods
```

Example output

```
NAME                                READY  STATUS  RESTARTS  AGE
kafkasource-kafka-source-5ca0248f-...  1/1    Running  0          13m
```

2.5.4. Configuring SASL authentication for Apache Kafka sources

Simple Authentication and Security Layer (SASL) is used by Apache Kafka for authentication. If you use SASL authentication on your cluster, users must provide credentials to Knative for communicating with the Kafka cluster; otherwise events cannot be produced or consumed.

Prerequisites

- You have cluster or dedicated administrator permissions on OpenShift Container Platform.
- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** CR are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have a username and password for a Kafka cluster.
- You have chosen the SASL mechanism to use, for example, **PLAIN**, **SCRAM-SHA-256**, or **SCRAM-SHA-512**.
- If TLS is enabled, you also need the **ca.crt** certificate file for the Kafka cluster.
- You have installed the OpenShift (**oc**) CLI.

Procedure

1. Create the certificate files as secrets in your chosen namespace:

```
$ oc create secret -n <namespace> generic <kafka_auth_secret> \
  --from-file=ca.crt=caroot.pem \
  --from-literal=password="SecretPassword" \
  --from-literal=saslType="SCRAM-SHA-512" \ 1
  --from-literal=user="my-sasl-user"
```

- 1 The SASL type can be **PLAIN**, **SCRAM-SHA-256**, or **SCRAM-SHA-512**.

2. Create or modify your Kafka source so that it contains the following **spec** configuration:

```
apiVersion: sources.knative.dev/v1beta1
kind: KafkaSource
metadata:
  name: example-source
spec:
  ...
  net:
    sasl:
      enable: true
      user:
        secretKeyRef:
          name: <kafka_auth_secret>
          key: user
      password:
        secretKeyRef:
          name: <kafka_auth_secret>
          key: password
      type:
        secretKeyRef:
          name: <kafka_auth_secret>
          key: saslType
    tls:
      enable: true
      caCert: 1
      secretKeyRef:
        name: <kafka_auth_secret>
        key: ca.crt
  ...
```

- 1 The **caCert** spec is not required if you are using a public cloud Kafka service.

2.6. CUSTOM EVENT SOURCES

If you need to ingress events from an event producer that is not included in Knative, or from a producer that emits events which are not in the **CloudEvent** format, you can do this by creating a custom event source. You can create a custom event source by using one of the following methods:

- Use a **PodSpecable** object as an event source, by creating a sink binding.
- Use a container as an event source, by creating a container source.

2.6.1. Sink binding

The **SinkBinding** object supports decoupling event production from delivery addressing. Sink binding is used to connect *event producers* to an event consumer, or *sink*. An event producer is a Kubernetes resource that embeds a **PodSpec** template and produces events. A sink is an addressable Kubernetes object that can receive events.

The **SinkBinding** object injects environment variables into the **PodTemplateSpec** of the sink, which means that the application code does not need to interact directly with the Kubernetes API to locate the event destination. These environment variables are as follows:

K_SINK

The URL of the resolved sink.

K_CE_OVERRIDES

A JSON object that specifies overrides to the outbound event.

NOTE

The **SinkBinding** object currently does not support custom revision names for services.

2.6.1.1. Creating a sink binding by using YAML

Creating Knative resources by using YAML files uses a declarative API, which enables you to describe event sources declaratively and in a reproducible manner. To create a sink binding by using YAML, you must create a YAML file that defines an **SinkBinding** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator, Knative Serving and Knative Eventing are installed on the cluster.
- Install the OpenShift CLI (**oc**).
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. To check that sink binding is set up correctly, create a Knative event display service, or event sink, that dumps incoming messages to its log.
 - a. Create a service YAML file:

Example service YAML file

```
apiVersion: serving.knative.dev/v1
kind: Service
metadata:
  name: event-display
spec:
  template:
```

```
spec:
  containers:
    - image: quay.io/openshift-knative/showcase
```

- b. Create the service:

```
$ oc apply -f <filename>
```

2. Create a sink binding instance that directs events to the service.

- a. Create a sink binding YAML file:

Example service YAML file

```
apiVersion: sources.knative.dev/v1alpha1
kind: SinkBinding
metadata:
  name: bind-heartbeat
spec:
  subject:
    apiVersion: batch/v1
    kind: Job 1
    selector:
      matchLabels:
        app: heartbeat-cron

  sink:
    ref:
      apiVersion: serving.knative.dev/v1
      kind: Service
      name: event-display
```

- 1** In this example, any Job with the label **app: heartbeat-cron** will be bound to the event sink.

- b. Create the sink binding:

```
$ oc apply -f <filename>
```

3. Create a **CronJob** object.

- a. Create a cron job YAML file:

Example cron job YAML file

```
apiVersion: batch/v1
kind: CronJob
metadata:
  name: heartbeat-cron
spec:
  # Run every minute
  schedule: "* * * * *"
  jobTemplate:
    metadata:
```

```

labels:
  app: heartbeat-cron
  bindings.knative.dev/include: "true"
spec:
  template:
    spec:
      restartPolicy: Never
      containers:
        - name: single-heartbeat
          image: quay.io/openshift-knative/heartbeats:latest
          args:
            - --period=1
          env:
            - name: ONE_SHOT
              value: "true"
            - name: POD_NAME
              valueFrom:
                fieldRef:
                  fieldPath: metadata.name
            - name: POD_NAMESPACE
              valueFrom:
                fieldRef:
                  fieldPath: metadata.namespace

```

IMPORTANT

To use sink binding, you must manually add a **bindings.knative.dev/include=true** label to your Knative resources.

For example, to add this label to a **CronJob** resource, add the following lines to the **Job** resource YAML definition:

```

jobTemplate:
  metadata:
    labels:
      app: heartbeat-cron
      bindings.knative.dev/include: "true"

```

- b. Create the cron job:

```
$ oc apply -f <filename>
```

4. Check that the controller is mapped correctly by entering the following command and inspecting the output:

```
$ oc get sinkbindings.sources.knative.dev bind-heartbeat -oyaml
```

Example output

```

spec:
  sink:
    ref:
      apiVersion: serving.knative.dev/v1

```

```

kind: Service
name: event-display
namespace: default
subject:
  apiVersion: batch/v1
  kind: Job
  namespace: default
  selector:
    matchLabels:
      app: heartbeat-cron

```

Verification

You can verify that the Kubernetes events were sent to the Knative event sink by looking at the message dumper function logs.

1. Enter the command:

```
$ oc get pods
```

2. Enter the command:

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```

▲ cloudevents.Event
Validation: valid
Context Attributes,
  specversion: 1.0
  type: dev.knative.eventing.samples.heartbeat
  source: https://knative.dev/eventing-contrib/cmd/heartbeats/#event-test/mypod

  time: 2019-10-18T15:23:20.809775386Z
  contenttype: application/json
Extensions,
  beats: true
  heart: yes
  the: 42
Data,
  {
    "id": 1,
    "label": ""
  }

```

2.6.1.2. Creating a sink binding by using the Knative CLI

You can use the **kn source binding create** command to create a sink binding by using the Knative (**kn**) CLI. Using the Knative CLI to create event sources provides a more streamlined and intuitive user interface than modifying YAML files directly.

Prerequisites

- The OpenShift Serverless Operator, Knative Serving and Knative Eventing are installed on the cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- Install the Knative (**kn**) CLI.
- Install the OpenShift CLI (**oc**).

NOTE

The following procedure requires you to create YAML files.

If you change the names of the YAML files from those used in the examples, you must ensure that you also update the corresponding CLI commands.

Procedure

1. To check that sink binding is set up correctly, create a Knative event display service, or event sink, that dumps incoming messages to its log:

```
$ kn service create event-display --image quay.io/openshift-knative/showcase
```

2. Create a sink binding instance that directs events to the service:

```
$ kn source binding create bind-heartbeat --subject Job:batch/v1:app=heartbeat-cron --sink ksvc:event-display
```

3. Create a **CronJob** object.

- a. Create a cron job YAML file:

Example cron job YAML file

```
apiVersion: batch/v1
kind: CronJob
metadata:
  name: heartbeat-cron
spec:
  # Run every minute
  schedule: "* * * * *"
  jobTemplate:
    metadata:
      labels:
        app: heartbeat-cron
        bindings.knative.dev/include: "true"
    spec:
      template:
        spec:
          restartPolicy: Never
          containers:
            - name: single-heartbeat
              image: quay.io/openshift-knative/heartbeats:latest
              args:
```

```

--period=1
env:
- name: ONE_SHOT
  value: "true"
- name: POD_NAME
  valueFrom:
    fieldRef:
      fieldPath: metadata.name
- name: POD_NAMESPACE
  valueFrom:
    fieldRef:
      fieldPath: metadata.namespace

```

IMPORTANT

To use sink binding, you must manually add a **bindings.knative.dev/include=true** label to your Knative CRs.

For example, to add this label to a **CronJob** CR, add the following lines to the **Job** CR YAML definition:

```

jobTemplate:
  metadata:
    labels:
      app: heartbeat-cron
      bindings.knative.dev/include: "true"

```

- b. Create the cron job:

```
$ oc apply -f <filename>
```

4. Check that the controller is mapped correctly by entering the following command and inspecting the output:

```
$ kn source binding describe bind-heartbeat
```

Example output

```

Name:      bind-heartbeat
Namespace: demo-2
Annotations: sources.knative.dev/creator=minikube-user,
             sources.knative.dev/lastModifier=minikub ...
Age:       2m
Subject:
  Resource: job (batch/v1)
  Selector:
    app: heartbeat-cron
Sink:
  Name:      event-display
  Resource:  Service (serving.knative.dev/v1)

```

```

Conditions:
  OK TYPE      AGE REASON
  ++ Ready    2m

```

Verification

You can verify that the Kubernetes events were sent to the Knative event sink by looking at the message dumper function logs.

- View the message dumper function logs by entering the following commands:

```
$ oc get pods
```

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```

└─ cloudevents.Event
  Validation: valid
  Context Attributes,
    specversion: 1.0
    type: dev.knative.eventing.samples.heartbeat
    source: https://knative.dev/eventing-contrib/cmd/heartbeats/#event-test/mypod
    id: 2b72d7bf-c38f-4a98-a433-608fbcdd2596
    time: 2019-10-18T15:23:20.809775386Z
    contenttype: application/json
  Extensions,
    beats: true
    heart: yes
    the: 42
  Data,
    {
      "id": 1,
      "label": ""
    }

```

2.6.1.2.1. Knative CLI sink flag

When you create an event source by using the Knative (**kn**) CLI, you can specify a sink where events are sent to from that resource by using the **--sink** flag. The sink can be any addressable or callable resource that can receive incoming events from other resources.

The following example creates a sink binding that uses a service, **http://event-display.svc.cluster.local**, as the sink:

Example command using the sink flag

```

$ kn source binding create bind-heartbeat \
  --namespace sinkbinding-example \
  --subject "Job:batch/v1:app=heartbeat-cron" \
  --sink http://event-display.svc.cluster.local \ 1
  --ce-override "sink=bound"

```

1 **svc** in **http://event-display.svc.cluster.local** determines that the sink is a Knative service. Other

default sink prefixes include **channel**, and **broker**.

2.6.1.3. Creating a sink binding by using the web console

After Knative Eventing is installed on your cluster, you can create a sink binding by using the web console. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create an event source.

Prerequisites

- You have logged in to the OpenShift Container Platform web console.
- The OpenShift Serverless Operator, Knative Serving, and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. Create a Knative service to use as a sink:
 - a. In the **Developer** perspective, navigate to **+Add → YAML**.
 - b. Copy the example YAML:

```
apiVersion: serving.knative.dev/v1
kind: Service
metadata:
  name: event-display
spec:
  template:
    spec:
      containers:
        - image: quay.io/openshift-knative/showcase
```

- c. Click **Create**.
2. Create a **CronJob** resource that is used as an event source and sends an event every minute.
 - a. In the **Developer** perspective, navigate to **+Add → YAML**.
 - b. Copy the example YAML:

```
apiVersion: batch/v1
kind: CronJob
metadata:
  name: heartbeat-cron
spec:
  # Run every minute
  schedule: "*/1 * * * *"
  jobTemplate:
    metadata:
      labels:
        app: heartbeat-cron
```

```

bindings.knative.dev/include: true 1
spec:
  template:
    spec:
      restartPolicy: Never
      containers:
        - name: single-heartbeat
          image: quay.io/openshift-knative/heartbeats
          args:
            - --period=1
          env:
            - name: ONE_SHOT
              value: "true"
            - name: POD_NAME
              valueFrom:
                fieldRef:
                  fieldPath: metadata.name
            - name: POD_NAMESPACE
              valueFrom:
                fieldRef:
                  fieldPath: metadata.namespace

```

- 1** Ensure that you include the **bindings.knative.dev/include: true** label. The default namespace selection behavior of OpenShift Serverless uses inclusion mode.

- c. Click **Create**.
3. Create a sink binding in the same namespace as the service created in the previous step, or any other sink that you want to send events to.
 - a. In the **Developer** perspective, navigate to **+Add → Event Source**. The **Event Sources** page is displayed.
 - b. Optional: If you have multiple providers for your event sources, select the required provider from the **Providers** list to filter the available event sources from the provider.
 - c. Select **Sink Binding** and then click **Create Event Source**. The **Create Event Source** page is displayed.

NOTE

You can configure the **Sink Binding** settings by using the **Form view** or **YAML view** and can switch between the views. The data is persisted when switching between the views.

- d. In the **apiVersion** field enter **batch/v1**.
- e. In the **Kind** field enter **Job**.

NOTE

The **CronJob** kind is not supported directly by OpenShift Serverless sink binding, so the **Kind** field must target the **Job** objects created by the cron job, rather than the cron job object itself.

- f. In the **Target** section, select your event sink. This can be either a **Resource** or a **URI**:
 - i. Select **Resource** to use a channel, broker, or service as an event sink for the event source. In this example, the **event-display** service created in the previous step is used as the target **Resource**.
 - ii. Select **URI** to specify a Uniform Resource Identifier (URI) where the events are routed to.
- g. In the **Match labels** section:
 - i. Enter **app** in the **Name** field.
 - ii. Enter **heartbeat-cron** in the **Value** field.

NOTE

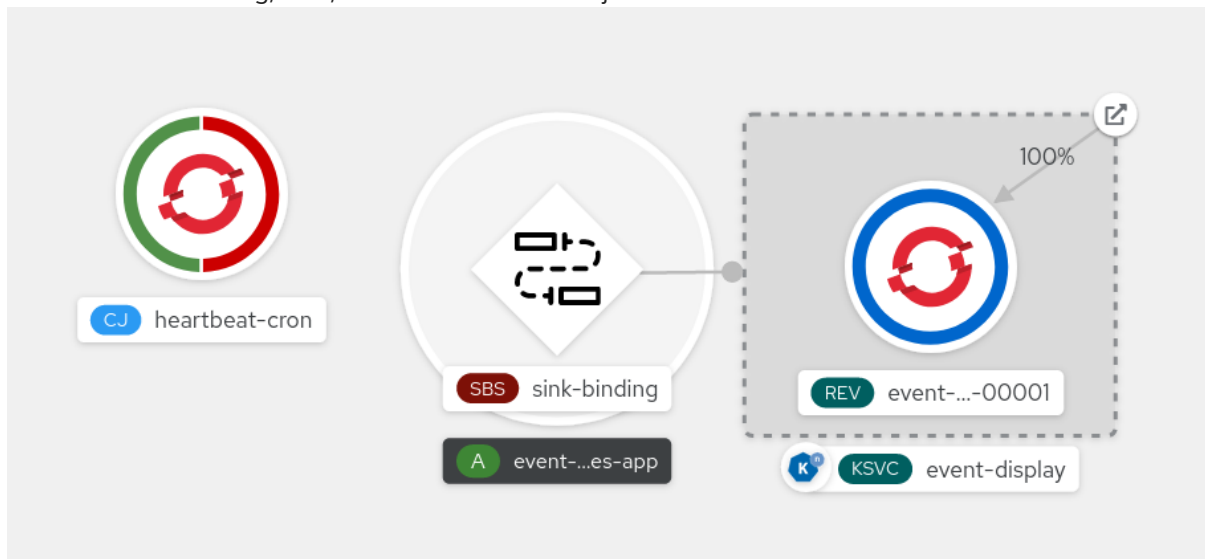

The label selector is required when using cron jobs with sink binding, rather than the resource name. This is because jobs created by a cron job do not have a predictable name, and contain a randomly generated string in their name. For example, **heartbeat-cron-1cc23f**.

- h. Click **Create**.

Verification

You can verify that the sink binding, sink, and cron job have been created and are working correctly by viewing the **Topology** page and pod logs.

1. In the **Developer** perspective, navigate to **Topology**.
2. View the sink binding, sink, and heartbeats cron job.

3. Observe that successful jobs are being registered by the cron job once the sink binding is added. This means that the sink binding is successfully reconfiguring the jobs created by the cron job.
4. Browse the **event-display** service to see events produced by the heartbeats cron job.

Welcome to Serverless, Cloud-Native world!

What can I do from here?

Invoke a hello endpoint: [/hello](#).

It will send CloudEvent to `K_SINK = http://localhost:31111`

Collected CloudEvents (1)

id	source	application/json
bb2dc97e-0ba8-402b-afce-882fd60e2d0b	/apis/v1 /namespaces /default/pingsources /test-ping-source	{ "message": "Hello World!" }
type	time	
dev.knative.sources.ping	less than a minute	

This app captures CloudEvents on `POST /events` endpoint. Newer are listed first.

Application

`Java/17.0.7`

Powered by:

QUARKUS

This application has been written with React & Quarkus to showcase Knative.

2.6.1.4. Sink binding reference

You can use a **PodSpecable** object as an event source by creating a sink binding. You can configure multiple parameters when creating a **SinkBinding** object.

SinkBinding objects support the following parameters:

Field	Description	Required or optional
apiVersion	Specifies the API version, for example sources.knative.dev/v1 .	Required
kind	Identifies this resource object as a SinkBinding object.	Required
metadata	Specifies metadata that uniquely identifies the SinkBinding object. For example, a name .	Required
spec	Specifies the configuration information for this SinkBinding object.	Required
spec.sink	A reference to an object that resolves to a URI to use as the sink.	Required

Field	Description	Required or optional
spec.subject	References the resources for which the runtime contract is augmented by binding implementations.	Required
spec.ceOverrides	Defines overrides to control the output format and modifications to the event sent to the sink.	Optional

2.6.1.4.1. Subject parameter

The **Subject** parameter references the resources for which the runtime contract is augmented by binding implementations. You can configure multiple fields for a **Subject** definition.

The **Subject** definition supports the following fields:

Field	Description	Required or optional
apiVersion	API version of the referent.	Required
kind	Kind of the referent.	Required
namespace	Namespace of the referent. If omitted, this defaults to the namespace of the object.	Optional
name	Name of the referent.	Do not use if you configure selector .
selector	Selector of the referents.	Do not use if you configure name .
selector.matchExpressions	A list of label selector requirements.	Only use one of either matchExpressions or matchLabels .
selector.matchExpressions.key	The label key that the selector applies to.	Required if using matchExpressions .
selector.matchExpressions.operator	Represents a key's relationship to a set of values. Valid operators are In , NotIn , Exists and DoesNotExist .	Required if using matchExpressions .

Field	Description	Required or optional
selector.matchExpressions.values	An array of string values. If the operator parameter value is In or NotIn , the values array must be non-empty. If the operator parameter value is Exists or DoesNotExist , the values array must be empty. This array is replaced during a strategic merge patch.	Required if using matchExpressions .
selector.matchLabels	A map of key-value pairs. Each key-value pair in the matchLabels map is equivalent to an element of matchExpressions , where the key field is matchLabels.<key> , the operator is In , and the values array contains only matchLabels.<value> .	Only use one of either matchExpressions or matchLabels .

Subject parameter examples

Given the following YAML, the **Deployment** object named **mysubject** in the **default** namespace is selected:

```

apiVersion: sources.knative.dev/v1
kind: SinkBinding
metadata:
  name: bind-heartbeat
spec:
  subject:
    apiVersion: apps/v1
    kind: Deployment
    namespace: default
    name: mysubject
...

```

Given the following YAML, any **Job** object with the label **working=example** in the **default** namespace is selected:

```

apiVersion: sources.knative.dev/v1
kind: SinkBinding
metadata:
  name: bind-heartbeat
spec:
  subject:
    apiVersion: batch/v1
    kind: Job
    namespace: default
    selector:

```

```

matchLabels:
  working: example
...

```

Given the following YAML, any **Pod** object with the label **working=example** or **working=sample** in the **default** namespace is selected:

```

apiVersion: sources.knative.dev/v1
kind: SinkBinding
metadata:
  name: bind-heartbeat
spec:
  subject:
    apiVersion: v1
    kind: Pod
    namespace: default
    selector:
      - matchExpression:
          key: working
          operator: In
          values:
            - example
            - sample
...

```

2.6.1.4.2. CloudEvent overrides

A **ceOverrides** definition provides overrides that control the CloudEvent's output format and modifications sent to the sink. You can configure multiple fields for the **ceOverrides** definition.

A **ceOverrides** definition supports the following fields:

Field	Description	Required or optional
extensions	Specifies which attributes are added or overridden on the outbound event. Each extensions key-value pair is set independently on the event as an attribute extension.	Optional

NOTE

Only valid **CloudEvent** attribute names are allowed as extensions. You cannot set the spec defined attributes from the extensions override configuration. For example, you can not modify the **type** attribute.

CloudEvent Overrides example

```

apiVersion: sources.knative.dev/v1
kind: SinkBinding
metadata:

```

```

name: bind-heartbeat
spec:
...
ceOverrides:
  extensions:
    extra: this is an extra attribute
    additional: 42

```

This sets the **K_CE_OVERRIDES** environment variable on the **subject**:

Example output

```
{ "extensions": { "extra": "this is an extra attribute", "additional": "42" } }
```

2.6.1.4.3. The include label

To use a sink binding, you need to do assign the **bindings.knative.dev/include: "true"** label to either the resource or the namespace that the resource is included in. If the resource definition does not include the label, a cluster administrator can attach it to the namespace by running:

```
$ oc label namespace <namespace> bindings.knative.dev/include=true
```

2.6.1.5. Integrating Service Mesh with SinkBinding

Prerequisites

- You have integrated Service Mesh with OpenShift Serverless.

Procedure

- Create a **Service** in a namespace that is a member of the **ServiceMeshMemberRoll**.

```

apiVersion: serving.knative.dev/v1
kind: Service
metadata:
  name: event-display
  namespace: <namespace> 1
spec:
  template:
    metadata:
      annotations:
        sidecar.istio.io/inject: "true" 2
        sidecar.istio.io/rewriteAppHTTPProbers: "true"
    spec:
      containers:
        - image: quay.io/openshift-knative/knative-eventing-sources-event-display:latest

```

1 A namespace that is a member of the **ServiceMeshMemberRoll**.

2 Injects Service Mesh sidecars into the Knative service pods.

- Apply the **Service** resource.

```
$ oc apply -f <filename>
```

3. Create a **SinkBinding**.

```
apiVersion: sources.knative.dev/v1
kind: SinkBinding
metadata:
  name: bind-heartbeat
  namespace: <namespace> 1
spec:
  subject:
    apiVersion: batch/v1
    kind: Job 2
    selector:
      matchLabels:
        app: heartbeat-cron
  sink:
    ref:
      apiVersion: serving.knative.dev/v1
      kind: Service
      name: event-display
```

1 A namespace that is a member of the **ServiceMeshMemberRoll**.

2 In this example, any Job with the label **app: heartbeat-cron** is bound to the event sink.

4. Apply the **SinkBinding** resource.

```
$ oc apply -f <filename>
```

5. Create a **CronJob**:

```
apiVersion: batch/v1
kind: CronJob
metadata:
  name: heartbeat-cron
  namespace: <namespace> 1
spec:
  # Run every minute
  schedule: "* * * * *"
  jobTemplate:
    metadata:
      labels:
        app: heartbeat-cron
        bindings.knative.dev/include: "true"
    spec:
      template:
        metadata:
          annotations:
            sidecar.istio.io/inject: "true" 2
            sidecar.istio.io/rewriteAppHTTPProbers: "true"
      spec:
```

```

restartPolicy: Never
containers:
  - name: single-heartbeat
    image: quay.io/openshift-knative/heartbeats:latest
    args:
      - --period=1
    env:
      - name: ONE_SHOT
        value: "true"
      - name: POD_NAME
        valueFrom:
          fieldRef:
            fieldPath: metadata.name
      - name: POD_NAMESPACE
        valueFrom:
          fieldRef:
            fieldPath: metadata.namespace

```

- 1 A namespace that is a member of the **ServiceMeshMemberRoll**.
- 2 Injects Service Mesh sidecars into the **CronJob** pods.

6. Apply the **CronJob** resource.

```
$ oc apply -f <filename>
```

Verification

To verify that the events were sent to the Knative event sink, look at the message dumper function logs.

1. Enter the following command:

```
$ oc get pods
```

2. Enter the following command:

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```

▲ cloudevents.Event
Validation: valid
Context Attributes,
  specversion: 1.0
  type: dev.knative.eventing.samples.heartbeat

2.6.2. Container source

Container sources create a container image that generates events and sends events to a sink. You can use a container source to create a custom event source, by creating a container image and a **ContainerSource** object that uses your image URI.

2.6.2.1. Guidelines for creating a container image

Two environment variables are injected by the container source controller: **K_SINK** and **K_CE_OVERRIDES**. These variables are resolved from the **sink** and **ceOverrides** spec, respectively. Events are sent to the sink URI specified in the **K_SINK** environment variable. The message must be sent as a **POST** using the **CloudEvent** HTTP format.

Example container images

The following is an example of a heartbeats container image:

```
package main

import (
    "context"
    "encoding/json"
    "flag"
    "fmt"
    "log"
    "os"
    "strconv"
    "time"

    duckv1 "knative.dev/pkg/apis/duck/v1"

    cloudevents "github.com/cloudevents/sdk-go/v2"
    "github.com/kelseyhightower/envconfig"
)

type Heartbeat struct {
    Sequence int `json:"id"`
    Label    string `json:"label"`
}

var (
    eventSource string
    eventType   string
    sink        string
    label       string
    periodStr   string
```

```

)

func init() {
    flag.StringVar(&eventSource, "eventSource", "", "the event-source (CloudEvents)")
    flag.StringVar(&eventType, "eventType", "dev.knative.eventing.samples.heartbeat", "the event-type (CloudEvents)")
    flag.StringVar(&sink, "sink", "", "the host url to heartbeat to")
    flag.StringVar(&label, "label", "", "a special label")
    flag.StringVar(&periodStr, "period", "5", "the number of seconds between heartbeats")
}

type envConfig struct {
    // Sink URL where to send heartbeat cloud events
    Sink string `envconfig:"K_SINK"`

    // CEOverrides are the CloudEvents overrides to be applied to the outbound event.
    CEOverrides string `envconfig:"K_CE_OVERRIDES"`

    // Name of this pod.
    Name string `envconfig:"POD_NAME" required:"true"`

    // Namespace this pod exists in.
    Namespace string `envconfig:"POD_NAMESPACE" required:"true"`

    // Whether to run continuously or exit.
    OneShot bool `envconfig:"ONE_SHOT" default:"false"`
}

func main() {
    flag.Parse()

    var env envConfig
    if err := envConfig.Process("", &env); err != nil {
        log.Printf("[ERROR] Failed to process env var: %s", err)
        os.Exit(1)
    }

    if env.Sink != "" {
        sink = env.Sink
    }

    var ceOverrides *duckv1.CloudEventOverrides
    if len(env.CEOverrides) > 0 {
        overrides := duckv1.CloudEventOverrides{}
        err := json.Unmarshal([]byte(env.CEOverrides), &overrides)
        if err != nil {
            log.Printf("[ERROR] Unparseable CloudEvents overrides %s: %v", env.CEOverrides, err)
            os.Exit(1)
        }
        ceOverrides = &overrides
    }

    p, err := cloudevents.NewHTTP(cloudevents.WithTarget(sink))
    if err != nil {
        log.Fatalf("failed to create http protocol: %s", err.Error())
    }
}

```

```

c, err := cloudevents.NewClient(p, cloudevents.WithUUIDs(), cloudevents.WithTimeNow())
if err != nil {
    log.Fatalf("failed to create client: %s", err.Error())
}

var period time.Duration
if p, err := strconv.Atoi(periodStr); err != nil {
    period = time.Duration(5) * time.Second
} else {
    period = time.Duration(p) * time.Second
}

if eventSource == "" {
    eventSource = fmt.Sprintf("https://knative.dev/eventing-contrib/cmd/heartbeats/#%s/%s",
env.Namespace, env.Name)
    log.Printf("Heartbeats Source: %s", eventSource)
}

if len(label) > 0 && label[0] == "" {
    label, _ = strconv.Unquote(label)
}
hb := &Heartbeat{
    Sequence: 0,
    Label:    label,
}
ticker := time.NewTicker(period)
for {
    hb.Sequence++

    event := cloudevents.NewEvent("1.0")
    event.SetType(eventType)
    event.SetSource(eventSource)
    event.SetExtension("the", 42)
    event.SetExtension("heart", "yes")
    event.SetExtension("beats", true)

    if ceOverrides != nil && ceOverrides.Extensions != nil {
        for n, v := range ceOverrides.Extensions {
            event.SetExtension(n, v)
        }
    }

    if err := event.SetData(cloudevents.ApplicationJSON, hb); err != nil {
        log.Printf("failed to set cloudevents data: %s", err.Error())
    }

    log.Printf("sending cloudevent to %s", sink)
    if res := c.Send(context.Background(), event); !cloudevents.IsACK(res) {
        log.Printf("failed to send cloudevent: %v", res)
    }

    if env.OneShot {
        return
    }
}

```

```
// Wait for next tick
<-ticker.C
}
}
```

The following is an example of a container source that references the previous heartbeats container image:

```
apiVersion: sources.knative.dev/v1
kind: ContainerSource
metadata:
  name: test-heartbeats
spec:
  template:
    spec:
      containers:
        # This corresponds to a heartbeats image URI that you have built and published
        - image: gcr.io/knative-releases/knative.dev/eventing/cmd/heartbeats
          name: heartbeats
          args:
            - --period=1
          env:
            - name: POD_NAME
              value: "example-pod"
            - name: POD_NAMESPACE
              value: "event-test"
      sink:
        ref:
          apiVersion: serving.knative.dev/v1
          kind: Service
          name: showcase
...

```

2.6.2.2. Creating and managing container sources by using the Knative CLI

You can use the **kn source container** commands to create and manage container sources by using the Knative (**kn**) CLI. Using the Knative CLI to create event sources provides a more streamlined and intuitive user interface than modifying YAML files directly.

Create a container source

```
$ kn source container create <container_source_name> --image <image_uri> --sink <sink>
```

Delete a container source

```
$ kn source container delete <container_source_name>
```

Describe a container source

```
$ kn source container describe <container_source_name>
```

List existing container sources

```
$ kn source container list
```

List existing container sources in YAML format

```
$ kn source container list -o yaml
```

Update a container source

This command updates the image URI for an existing container source:

```
$ kn source container update <container_source_name> --image <image_uri>
```

2.6.2.3. Creating a container source by using the web console

After Knative Eventing is installed on your cluster, you can create a container source by using the web console. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create an event source.

Prerequisites

- You have logged in to the OpenShift Container Platform web console.
- The OpenShift Serverless Operator, Knative Serving, and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. In the **Developer** perspective, navigate to **+Add → Event Source**. The **Event Sources** page is displayed.
2. Select **Container Source** and then click **Create Event Source**. The **Create Event Source** page is displayed.
3. Configure the **Container Source** settings by using the **Form view** or **YAML view**:

NOTE

You can switch between the **Form view** and **YAML view**. The data is persisted when switching between the views.

- a. In the **Image** field, enter the URI of the image that you want to run in the container created by the container source.
- b. In the **Name** field, enter the name of the image.
- c. Optional: In the **Arguments** field, enter any arguments to be passed to the container.
- d. Optional: In the **Environment variables** field, add any environment variables to set in the container.
- e. In the **Target** section, select your event sink. This can be either a **Resource** or a **URI**:

- i. Select **Resource** to use a channel, broker, or service as an event sink for the event source.
 - ii. Select **URI** to specify a Uniform Resource Identifier (URI) where the events are routed to.
4. After you have finished configuring the container source, click **Create**.

2.6.2.4. Container source reference

You can use a container as an event source, by creating a **ContainerSource** object. You can configure multiple parameters when creating a **ContainerSource** object.

ContainerSource objects support the following fields:

Field	Description	Required or optional
apiVersion	Specifies the API version, for example sources.knative.dev/v1 .	Required
kind	Identifies this resource object as a ContainerSource object.	Required
metadata	Specifies metadata that uniquely identifies the ContainerSource object. For example, a name .	Required
spec	Specifies the configuration information for this ContainerSource object.	Required
spec.sink	A reference to an object that resolves to a URI to use as the sink.	Required
spec.template	A template spec for the ContainerSource object.	Required
spec.ceOverrides	Defines overrides to control the output format and modifications to the event sent to the sink.	Optional

Template parameter example

```
apiVersion: sources.knative.dev/v1
kind: ContainerSource
metadata:
  name: test-heartbeats
spec:
  template:
    spec:
```

```

containers:
  - image: quay.io/openshift-knative/heartbeats:latest
    name: heartbeats
    args:
      - --period=1
    env:
      - name: POD_NAME
        value: "mypod"
      - name: POD_NAMESPACE
        value: "event-test"
  ...

```

2.6.2.4.1. CloudEvent overrides

A **ceOverrides** definition provides overrides that control the CloudEvent's output format and modifications sent to the sink. You can configure multiple fields for the **ceOverrides** definition.

A **ceOverrides** definition supports the following fields:

Field	Description	Required or optional
extensions	Specifies which attributes are added or overridden on the outbound event. Each extensions key-value pair is set independently on the event as an attribute extension.	Optional

NOTE

Only valid **CloudEvent** attribute names are allowed as extensions. You cannot set the spec defined attributes from the extensions override configuration. For example, you can not modify the **type** attribute.

CloudEvent Overrides example

```

apiVersion: sources.knative.dev/v1
kind: ContainerSource
metadata:
  name: test-heartbeats
spec:
  ...
  ceOverrides:
    extensions:
      extra: this is an extra attribute
      additional: 42

```

This sets the **K_CE_OVERRIDES** environment variable on the **subject**:

Example output

```
{ "extensions": { "extra": "this is an extra attribute", "additional": "42" } }
```

2.6.2.5. Integrating Service Mesh with ContainerSource

Prerequisites

- You have integrated Service Mesh with OpenShift Serverless.

Procedure

- Create a **Service** in a namespace that is a member of the **ServiceMeshMemberRoll**.

```

apiVersion: serving.knative.dev/v1
kind: Service
metadata:
  name: event-display
  namespace: <namespace> 1
spec:
  template:
    metadata:
      annotations:
        sidecar.istio.io/inject: "true" 2
        sidecar.istio.io/rewriteAppHTTPProbers: "true"
    spec:
      containers:
        - image: quay.io/openshift-knative/knative-eventing-sources-event-display:latest

```

1 A namespace that is a member of the **ServiceMeshMemberRoll**.

2 Injects Service Mesh sidecars into the Knative service pods.

- Apply the **Service** resource.

```
$ oc apply -f <filename>
```

- Create a **ContainerSource** in a namespace that is a member of the **ServiceMeshMemberRoll** and sink set to the **event-display**.

```

apiVersion: sources.knative.dev/v1
kind: ContainerSource
metadata:
  name: test-heartbeats
  namespace: <namespace> 1
spec:
  template:
    metadata: 2
      annotations:
        sidecar.istio.io/inject: "true"
        sidecar.istio.io/rewriteAppHTTPProbers: "true"
    spec:
      containers:
        - image: quay.io/openshift-knative/heartbeats:latest
          name: heartbeats
          args:
            - --period=1s

```

```

env:
  - name: POD_NAME
    value: "example-pod"
  - name: POD_NAMESPACE
    value: "event-test"
sink:
  ref:
    apiVersion: serving.knative.dev/v1
    kind: Service
    name: event-display

```

- 1 A namespace is part of the **ServiceMeshMemberRoll**.
- 2 Enables Service Mesh integration with a **ContainerSource**

4. Apply the **ContainerSource** resource.

```
$ oc apply -f <filename>
```

Verification

To verify that the events were sent to the Knative event sink, look at the message dumper function logs.

1. Enter the following command:

```
$ oc get pods
```

2. Enter the following command:

```
$ oc logs $(oc get pod -o name | grep event-display) -c user-container
```

Example output

```

▲ cloudevents.Event
Validation: valid
Context Attributes,
  specversion: 1.0
  type: dev.knative.eventing.samples.heartbeat
  source: https://knative.dev/eventing/test/heartbeats/#event-test/mypod

  time: 2019-10-18T15:23:20.809775386Z
  contenttype: application/json
Extensions,
  beats: true
  heart: yes
  the: 42
Data,
  {
    "id": 1,
    "label": ""
  }

```

Additional resources

- [Integrating Service Mesh with OpenShift Serverless](#)

2.7. CONNECTING AN EVENT SOURCE TO AN EVENT SINK BY USING THE DEVELOPER PERSPECTIVE

When you create an event source by using the OpenShift Container Platform web console, you can specify a target event sink that events are sent to from that source. The event sink can be any addressable or callable resource that can receive incoming events from other resources.

2.7.1. Connect an event source to an event sink by using the Developer perspective

Prerequisites

- The OpenShift Serverless Operator, Knative Serving, and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console and are in the **Developer** perspective.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have created an event sink, such as a Knative service, channel or broker.

Procedure

1. Create an event source of any type, by navigating to **+Add → Event Source** and selecting the event source type that you want to create.
2. In the **Target** section of the **Create Event Source** form view, select your event sink. This can be either a **Resource** or a **URI**:
 - a. Select **Resource** to use a channel, broker, or service as an event sink for the event source.
 - b. Select **URI** to specify a Uniform Resource Identifier (URI) where the events are routed to.
3. Click **Create**.

Verification

You can verify that the event source was created and is connected to the sink by viewing the **Topology** page.

1. In the **Developer** perspective, navigate to **Topology**.
2. View the event source and click the connected event sink to see the sink details in the right panel.

CHAPTER 3. EVENT SINKS

3.1. EVENT SINKS

When you create an event source, you can specify an event sink where events are sent to from the source. An event sink is an addressable or a callable resource that can receive incoming events from other resources. Knative services, channels, and brokers are all examples of event sinks. There is also a specific Apache Kafka sink type available.

Addressable objects receive and acknowledge an event delivered over HTTP to an address defined in their **status.address.url** field. As a special case, the core Kubernetes **Service** object also fulfills the addressable interface.

Callable objects are able to receive an event delivered over HTTP and transform the event, returning **0** or **1** new events in the HTTP response. These returned events may be further processed in the same way that events from an external event source are processed.

3.1.1. Knative CLI sink flag

When you create an event source by using the Knative (**kn**) CLI, you can specify a sink where events are sent to from that resource by using the **--sink** flag. The sink can be any addressable or callable resource that can receive incoming events from other resources.

The following example creates a sink binding that uses a service, **http://event-display.svc.cluster.local**, as the sink:

Example command using the sink flag

```
$ kn source binding create bind-heartbeat \
  --namespace sinkbinding-example \
  --subject "Job:batch/v1:app=heartbeat-cron" \
  --sink http://event-display.svc.cluster.local \ 1
  --ce-override "sink=bound"
```

1 **svc** in **http://event-display.svc.cluster.local** determines that the sink is a Knative service. Other default sink prefixes include **channel**, and **broker**.

TIP

You can configure which CRs can be used with the **--sink** flag for Knative (**kn**) CLI commands by [Customizing kn](#).

3.2. CREATING EVENT SINKS

When you create an event source, you can specify an event sink where events are sent to from the source. An event sink is an addressable or a callable resource that can receive incoming events from other resources. Knative services, channels, and brokers are all examples of event sinks. There is also a specific Apache Kafka sink type available.

For information about creating resources that can be used as event sinks, see the following documentation:

- [Serverless applications](#)
- [Creating brokers](#)
- [Creating channels](#)
- [Kafka sink](#)

3.3. SINK FOR APACHE KAFKA

Apache Kafka sinks are a type of [event sink](#) that are available if a cluster administrator has enabled Apache Kafka on your cluster. You can send events directly from an [event source](#) to a Kafka topic by using a Kafka sink.

3.3.1. Creating an Apache Kafka sink by using YAML

You can create a Kafka sink that sends events to a Kafka topic. By default, a Kafka sink uses the binary content mode, which is more efficient than the structured mode. To create a Kafka sink by using YAML, you must create a YAML file that defines a **KafkaSink** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resource (CR) are installed on your cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have access to a Red Hat AMQ Streams (Kafka) cluster that produces the Kafka messages you want to import.
- Install the OpenShift CLI (**oc**).

Procedure

1. Create a **KafkaSink** object definition as a YAML file:

Kafka sink YAML

```
apiVersion: eventing.knative.dev/v1alpha1
kind: KafkaSink
metadata:
  name: <sink-name>
  namespace: <namespace>
spec:
  topic: <topic-name>
  bootstrapServers:
    - <bootstrap-server>
```

2. To create the Kafka sink, apply the **KafkaSink** YAML file:

```
$ oc apply -f <filename>
```

3. Configure an event source so that the sink is specified in its spec:

Example of a Kafka sink connected to an API server source

```

apiVersion: sources.knative.dev/v1alpha2
kind: ApiServerSource
metadata:
  name: <source-name> 1
  namespace: <namespace> 2
spec:
  serviceAccountName: <service-account-name> 3
  mode: Resource
  resources:
  - apiVersion: v1
    kind: Event
  sink:
    ref:
      apiVersion: eventing.knative.dev/v1alpha1
      kind: KafkaSink
      name: <sink-name> 4

```

- 1 The name of the event source.
- 2 The namespace of the event source.
- 3 The service account for the event source.
- 4 The Kafka sink name.

3.3.2. Creating an event sink for Apache Kafka by using the OpenShift Container Platform web console

You can create a Kafka sink that sends events to a Kafka topic by using the **Developer** perspective in the OpenShift Container Platform web console. By default, a Kafka sink uses the binary content mode, which is more efficient than the structured mode.

As a developer, you can create an event sink to receive events from a particular source and send them to a Kafka topic.

Prerequisites

- You have installed the OpenShift Serverless Operator, with Knative Serving, Knative Eventing, and Knative broker for Apache Kafka APIs, from the OperatorHub.
- You have created a Kafka topic in your Kafka environment.

Procedure

1. In the **Developer** perspective, navigate to the **+Add** view.
2. Click **Event Sink** in the **Eventing catalog**.
3. Search for **KafkaSink** in the catalog items and click it.

4. Click **Create Event Sink**
5. In the form view, type the URL of the bootstrap server, which is a combination of host name and port.

Create Event Sink

Create an Event sink to receive incoming events from a particular source. Configure using YAML and form views.

Configure via: Form view YAML view

Note: Some fields may not be represented in this form view. Please select "YAML view" for full control of object creation. ✕

6. Type the name of the topic to send event data.
7. Type the name of the event sink.
8. Click **Create**.

Verification

1. In the **Developer** perspective, navigate to the **Topology** view.
2. Click the created event sink to view its details in the right panel.

3.3.3. Configuring security for Apache Kafka sinks

Transport Layer Security (TLS) is used by Apache Kafka clients and servers to encrypt traffic between Knative and Kafka, as well as for authentication. TLS is the only supported method of traffic encryption for the Knative broker implementation for Apache Kafka.

Simple Authentication and Security Layer (SASL) is used by Apache Kafka for authentication. If you use SASL authentication on your cluster, users must provide credentials to Knative for communicating with the Kafka cluster; otherwise events cannot be produced or consumed.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resources (CRs) are installed on your OpenShift Container Platform cluster.
- Kafka sink is enabled in the **KnativeKafka** CR.

- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have a Kafka cluster CA certificate stored as a **.pem** file.
- You have a Kafka cluster client certificate and a key stored as **.pem** files.
- You have installed the OpenShift (**oc**) CLI.
- You have chosen the SASL mechanism to use, for example, **PLAIN**, **SCRAM-SHA-256**, or **SCRAM-SHA-512**.

Procedure

1. Create the certificate files as a secret in the same namespace as your **KafkaSink** object:

IMPORTANT

Certificates and keys must be in PEM format.

- For authentication using SASL without encryption:

```
$ oc create secret -n <namespace> generic <secret_name> \
--from-literal=protocol=SASL_PLAINTEXT \
--from-literal=sasl.mechanism=<sasl_mechanism> \
--from-literal=user=<username> \
--from-literal=password=<password>
```

- For authentication using SASL and encryption using TLS:

```
$ oc create secret -n <namespace> generic <secret_name> \
--from-literal=protocol=SASL_SSL \
--from-literal=sasl.mechanism=<sasl_mechanism> \
--from-file=ca.crt=<my_caroot.pem_file_path> \ 1
--from-literal=user=<username> \
--from-literal=password=<password>
```

- 1 The **ca.crt** can be omitted to use the system's root CA set if you are using a public cloud managed Kafka service.

- For authentication and encryption using TLS:

```
$ oc create secret -n <namespace> generic <secret_name> \
--from-literal=protocol=SSL \
--from-file=ca.crt=<my_caroot.pem_file_path> \ 1
--from-file=user.crt=<my_cert.pem_file_path> \
--from-file=user.key=<my_key.pem_file_path>
```

- 1 The **ca.crt** can be omitted to use the system's root CA set if you are using a public cloud managed Kafka service.

2. Create or modify a **KafkaSink** object and add a reference to your secret in the **auth** spec:

■

```
apiVersion: eventing.knative.dev/v1alpha1
kind: KafkaSink
metadata:
  name: <sink_name>
  namespace: <namespace>
spec:
  ...
  auth:
    secret:
      ref:
        name: <secret_name>
  ...
```

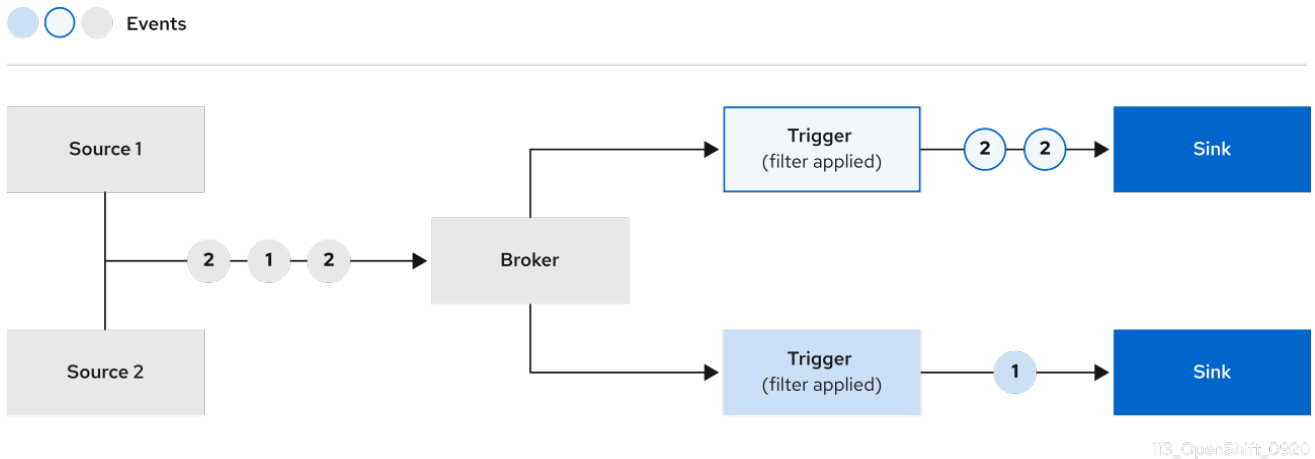

3. Apply the **KafkaSink** object:

```
$ oc apply -f <filename>
```

CHAPTER 4. BROKERS

4.1. BROKERS

Brokers can be used in combination with triggers to deliver events from an event source to an event sink. Events are sent from an event source to a broker as an HTTP **POST** request. After events have entered the broker, they can be filtered by [CloudEvent attributes](#) using triggers, and sent as an HTTP **POST** request to an event sink.

4.2. BROKER TYPES

Cluster administrators can set the default broker implementation for a cluster. When you create a broker, the default broker implementation is used, unless you provide set configurations in the **Broker** object.

4.2.1. Default broker implementation for development purposes

Knative provides a default, channel-based broker implementation. This channel-based broker can be used for development and testing purposes, but does not provide adequate event delivery guarantees for production environments. The default broker is backed by the **InMemoryChannel** channel implementation by default.

If you want to use Apache Kafka to reduce network hops, use the Knative broker implementation for Apache Kafka. Do not configure the channel-based broker to be backed by the **KafkaChannel** channel implementation.

4.2.2. Production-ready Knative broker implementation for Apache Kafka

For production-ready Knative Eventing deployments, Red Hat recommends using the Knative broker implementation for Apache Kafka. The broker is an Apache Kafka native implementation of the Knative broker, which sends CloudEvents directly to the Kafka instance.

The Knative broker has a native integration with Kafka for storing and routing events. This allows better integration with Kafka for the broker and trigger model over other broker types, and reduces network hops. Other benefits of the Knative broker implementation include:

- At-least-once delivery guarantees
- Ordered delivery of events, based on the CloudEvents partitioning extension

- Control plane high availability
- A horizontally scalable data plane

The Knative broker implementation for Apache Kafka stores incoming CloudEvents as Kafka records, using the binary content mode. This means that all CloudEvent attributes and extensions are mapped as headers on the Kafka record, while the **data** spec of the CloudEvent corresponds to the value of the Kafka record.

4.3. CREATING BROKERS

Knative provides a default, channel-based broker implementation. This channel-based broker can be used for development and testing purposes, but does not provide adequate event delivery guarantees for production environments.

If a cluster administrator has configured your OpenShift Serverless deployment to use Apache Kafka as the default broker type, creating a broker by using the default settings creates a Knative broker for Apache Kafka.

If your OpenShift Serverless deployment is not configured to use the Knative broker for Apache Kafka as the default broker type, the channel-based broker is created when you use the default settings in the following procedures.

4.3.1. Creating a broker by using the Knative CLI

Brokers can be used in combination with triggers to deliver events from an event source to an event sink. Using the Knative (**kn**) CLI to create brokers provides a more streamlined and intuitive user interface over modifying YAML files directly. You can use the **kn broker create** command to create a broker.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Create a broker:

```
$ kn broker create <broker_name>
```

Verification

1. Use the **kn** command to list all existing brokers:

```
$ kn broker list
```

Example output

NAME	URL	AGE	CONDITIONS	READY
default	http://broker-ingress.knative-eventing.svc.cluster.local/test/default	45s	5 OK / 5	True

- Optional: If you are using the OpenShift Container Platform web console, you can navigate to the **Topology** view in the **Developer** perspective, and observe that the broker exists:

4.3.2. Creating a broker by annotating a trigger

Brokers can be used in combination with triggers to deliver events from an event source to an event sink. You can create a broker by adding the **eventing.knative.dev/injection: enabled** annotation to a **Trigger** object.

IMPORTANT

If you create a broker by using the **eventing.knative.dev/injection: enabled** annotation, you cannot delete this broker without cluster administrator permissions. If you delete the broker without having a cluster administrator remove this annotation first, the broker is created again after deletion.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- Install the OpenShift CLI (**oc**).
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Create a **Trigger** object as a YAML file that has the **eventing.knative.dev/injection: enabled** annotation:

```
apiVersion: eventing.knative.dev/v1
kind: Trigger
metadata:
  annotations:
    eventing.knative.dev/injection: enabled
```

```

name: <trigger_name>
spec:
  broker: default
  subscriber: 1
  ref:
    apiVersion: serving.knative.dev/v1
    kind: Service
    name: <service_name>

```

- 1 Specify details about the event sink, or *subscriber*, that the trigger sends events to.

2. Apply the **Trigger** YAML file:

```
$ oc apply -f <filename>
```

Verification

You can verify that the broker has been created successfully by using the **oc** CLI, or by observing it in the **Topology** view in the web console.

1. Enter the following **oc** command to get the broker:

```
$ oc -n <namespace> get broker default
```

Example output

NAME	READY	REASON	URL	AGE
default	True		http://broker-ingress.knative-eventing.svc.cluster.local/test/default	3m56s

2. Optional: If you are using the OpenShift Container Platform web console, you can navigate to the **Topology** view in the **Developer** perspective, and observe that the broker exists:

4.3.3. Creating a broker by labeling a namespace

Brokers can be used in combination with triggers to deliver events from an event source to an event sink. You can create the **default** broker automatically by labelling a namespace that you own or have write permissions for.

NOTE

Brokers created using this method are not removed if you remove the label. You must manually delete them.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- Install the OpenShift CLI (**oc**).
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have cluster or dedicated administrator permissions if you are using Red Hat OpenShift Service on AWS or OpenShift Dedicated.

Procedure

- Label a namespace with **eventing.knative.dev/injection=enabled**:

```
$ oc label namespace <namespace> eventing.knative.dev/injection=enabled
```

Verification

You can verify that the broker has been created successfully by using the **oc** CLI, or by observing it in the **Topology** view in the web console.

1. Use the **oc** command to get the broker:

```
$ oc -n <namespace> get broker <broker_name>
```

Example command

```
$ oc -n default get broker default
```

Example output

NAME	READY	REASON	URL	AGE
default	True		http://broker-ingress.knative-eventing.svc.cluster.local/test/default	3m56s

2. Optional: If you are using the OpenShift Container Platform web console, you can navigate to the **Topology** view in the **Developer** perspective, and observe that the broker exists:

4.3.4. Deleting a broker that was created by injection

If you create a broker by injection and later want to delete it, you must delete it manually. Brokers created by using a namespace label or trigger annotation are not deleted permanently if you remove the label or annotation.

Prerequisites

- Install the OpenShift CLI (**oc**).

Procedure

1. Remove the **eventing.knative.dev/injection=enabled** label from the namespace:

```
$ oc label namespace <namespace> eventing.knative.dev/injection-
```

Removing the annotation prevents Knative from recreating the broker after you delete it.

2. Delete the broker from the selected namespace:

```
$ oc -n <namespace> delete broker <broker_name>
```

Verification

- Use the **oc** command to get the broker:

```
$ oc -n <namespace> get broker <broker_name>
```

Example command

```
$ oc -n default get broker default
```

Example output

```
No resources found.
Error from server (NotFound): brokers.eventing.knative.dev "default" not found
```

4.3.5. Creating a broker by using the web console

After Knative Eventing is installed on your cluster, you can create a broker by using the web console. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create a broker.

Prerequisites

- You have logged in to the OpenShift Container Platform web console.
- The OpenShift Serverless Operator, Knative Serving and Knative Eventing are installed on the cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

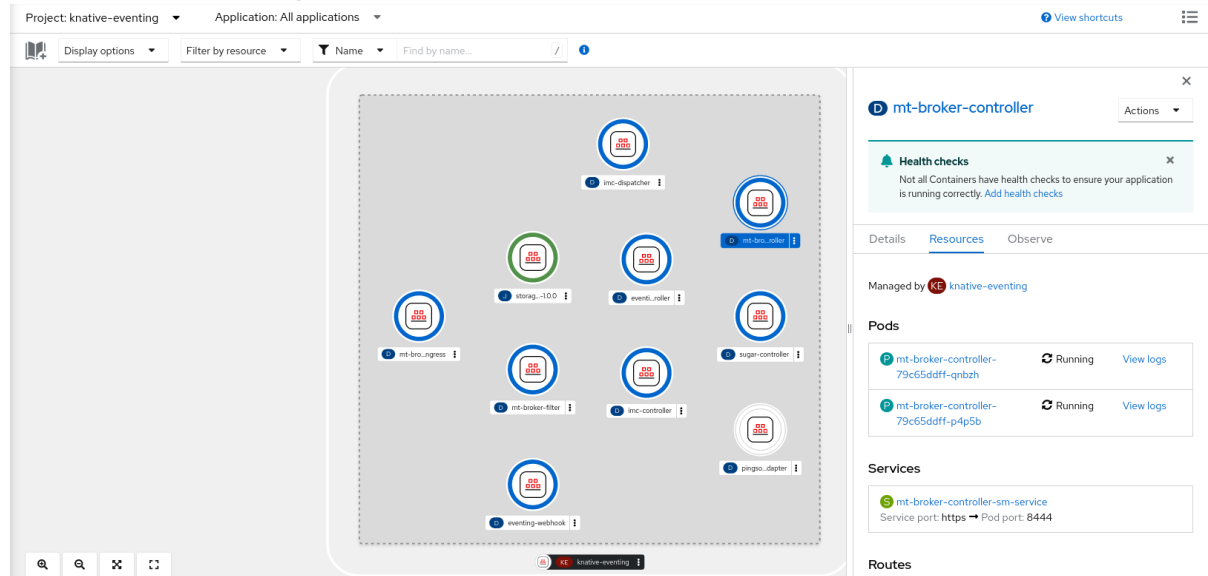

Procedure

1. In the **Developer** perspective, navigate to **+Add → Broker**. The **Broker** page is displayed.
2. Optional. Update the **Name** of the broker. If you do not update the name, the generated broker is named **default**.
3. Click **Create**.

Verification

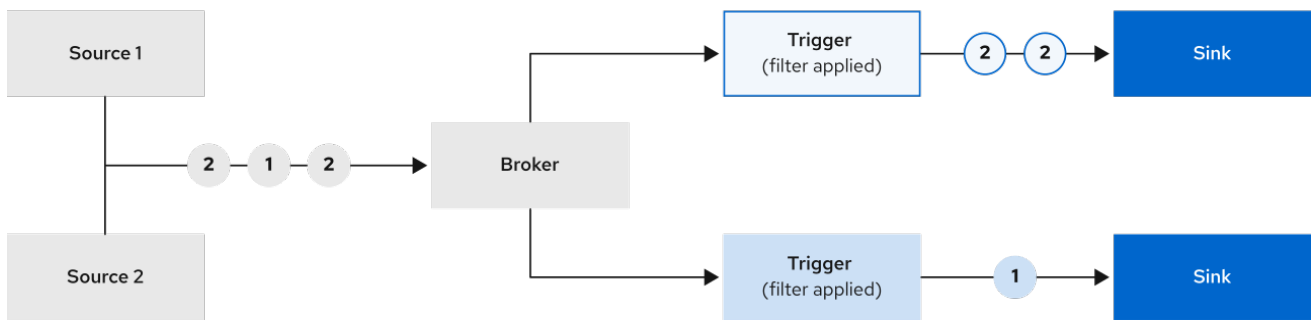

You can verify that the broker was created by viewing broker components in the **Topology** page.

1. In the **Developer** perspective, navigate to **Topology**.
2. View the **mt-broker-ingress**, **mt-broker-filter**, and **mt-broker-controller** components.

4.3.6. Creating a broker by using the Administrator perspective

Brokers can be used in combination with triggers to deliver events from an event source to an event sink. Events are sent from an event source to a broker as an HTTP **POST** request. After events have entered the broker, they can be filtered by [CloudEvent attributes](#) using triggers, and sent as an HTTP **POST** request to an event sink.

113_OpenShift_0920

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console and are in the **Administrator** perspective.
- You have cluster administrator permissions on OpenShift Container Platform, or you have cluster or dedicated administrator permissions on Red Hat OpenShift Service on AWS or OpenShift Dedicated.

Procedure

1. In the **Administrator** perspective of the OpenShift Container Platform web console, navigate to **Serverless → Eventing**.
2. In the **Create** list, select **Broker**. You will be directed to the **Create Broker** page.
3. Optional: Modify the YAML configuration for the broker.
4. Click **Create**.

4.3.7. Next steps

- Configure [event delivery parameters](#) that are applied in cases where an event fails to be delivered to an event sink.

4.3.8. Additional resources

- [Configuring the default broker class](#)
- [Triggers](#)
- [Connect a broker to a sink using the Developer perspective](#)

4.4. CONFIGURING THE DEFAULT BROKER BACKING CHANNEL

If you are using a channel-based broker, you can set the default backing channel type for the broker to either **InMemoryChannel** or **KafkaChannel**.

Prerequisites

- You have administrator permissions on OpenShift Container Platform.
- You have installed the OpenShift Serverless Operator and Knative Eventing on your cluster.
- You have installed the OpenShift (**oc**) CLI.
- If you want to use Apache Kafka channels as the default backing channel type, you must also install the **KnativeKafka** CR on your cluster.

Procedure

1. Modify the **KnativeEventing** custom resource (CR) to add configuration details for the **config-br-default-channel** config map:

```
apiVersion: operator.knative.dev/v1beta1
kind: KnativeEventing
metadata:
  name: knative-eventing
  namespace: knative-eventing
spec:
  config: 1
    config-br-default-channel:
      channel-template-spec: |
        apiVersion: messaging.knative.dev/v1beta1
        kind: KafkaChannel 2
        spec:
          numPartitions: 6 3
          replicationFactor: 3 4
```

- 1** In **spec.config**, you can specify the config maps that you want to add modified configurations for.
- 2** The default backing channel type configuration. In this example, the default channel implementation for the cluster is **KafkaChannel**.
- 3** The number of partitions for the Kafka channel that backs the broker.
- 4** The replication factor for the Kafka channel that backs the broker.

2. Apply the updated **KnativeEventing** CR:

```
$ oc apply -f <filename>
```

4.5. CONFIGURING THE DEFAULT BROKER CLASS

You can use the **config-br-defaults** config map to specify default broker class settings for Knative Eventing. You can specify the default broker class for the entire cluster or for one or more namespaces. Currently the **MTChannelBasedBroker** and **Kafka** broker types are supported.

Prerequisites

- You have administrator permissions on OpenShift Container Platform.

- You have installed the OpenShift Serverless Operator and Knative Eventing on your cluster.
- If you want to use the Knative broker for Apache Kafka as the default broker implementation, you must also install the **KnativeKafka** CR on your cluster.

Procedure

- Modify the **KnativeEventing** custom resource to add configuration details for the **config-br-defaults** config map:

```

apiVersion: operator.knative.dev/v1beta1
kind: KnativeEventing
metadata:
  name: knative-eventing
  namespace: knative-eventing
spec:
  defaultBrokerClass: Kafka 1
  config: 2
    config-br-defaults: 3
      default-br-config: |
        clusterDefault: 4
          brokerClass: Kafka
          apiVersion: v1
          kind: ConfigMap
          name: kafka-broker-config 5
          namespace: knative-eventing 6
        namespaceDefaults: 7
          my-namespace:
            brokerClass: MTChannelBasedBroker
            apiVersion: v1
            kind: ConfigMap
            name: config-br-default-channel 8
            namespace: knative-eventing 9
  ...

```

- 1 The default broker class for Knative Eventing.
- 2 In **spec.config**, you can specify the config maps that you want to add modified configurations for.
- 3 The **config-br-defaults** config map specifies the default settings for any broker that does not specify **spec.config** settings or a broker class.
- 4 The cluster-wide default broker class configuration. In this example, the default broker class implementation for the cluster is **Kafka**.
- 5 The **kafka-broker-config** config map specifies default settings for the Kafka broker. See "Configuring Knative broker for Apache Kafka settings" in the "Additional resources" section.
- 6 The namespace where the **kafka-broker-config** config map exists.
- 7 The namespace-scoped default broker class configuration. In this example, the default broker class implementation for the **my-namespace** namespace is **MTChannelBasedBroker**. You can specify default broker class implementations for

multiple namespaces.

- 8 The **config-br-default-channel** config map specifies the default backing channel for the broker. See "Configuring the default broker backing channel" in the "Additional resources" section.
- 9 The namespace where the **config-br-default-channel** config map exists.

IMPORTANT

Configuring a namespace-specific default overrides any cluster-wide settings.

4.6. KNATIVE BROKER IMPLEMENTATION FOR APACHE KAFKA

For production-ready Knative Eventing deployments, Red Hat recommends using the Knative broker implementation for Apache Kafka. The broker is an Apache Kafka native implementation of the Knative broker, which sends CloudEvents directly to the Kafka instance.

The Knative broker has a native integration with Kafka for storing and routing events. This allows better integration with Kafka for the broker and trigger model over other broker types, and reduces network hops. Other benefits of the Knative broker implementation include:

- At-least-once delivery guarantees
- Ordered delivery of events, based on the CloudEvents partitioning extension
- Control plane high availability
- A horizontally scalable data plane

The Knative broker implementation for Apache Kafka stores incoming CloudEvents as Kafka records, using the binary content mode. This means that all CloudEvent attributes and extensions are mapped as headers on the Kafka record, while the **data** spec of the CloudEvent corresponds to the value of the Kafka record.

4.6.1. Creating an Apache Kafka broker when it is not configured as the default broker type

If your OpenShift Serverless deployment is not configured to use Kafka broker as the default broker type, you can use one of the following procedures to create a Kafka-based broker.

4.6.1.1. Creating an Apache Kafka broker by using YAML

Creating Knative resources by using YAML files uses a declarative API, which enables you to describe applications declaratively and in a reproducible manner. To create a Kafka broker by using YAML, you must create a YAML file that defines a **Broker** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resource are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

- You have installed the OpenShift CLI (**oc**).

Procedure

1. Create a Kafka-based broker as a YAML file:

```
apiVersion: eventing.knative.dev/v1
kind: Broker
metadata:
  annotations:
    eventing.knative.dev/broker.class: Kafka 1
  name: example-kafka-broker
spec:
  config:
    apiVersion: v1
    kind: ConfigMap
    name: kafka-broker-config 2
    namespace: knative-eventing
```

- 1** The broker class. If not specified, brokers use the default class as configured by cluster administrators. To use the Kafka broker, this value must be **Kafka**.
- 2** The default config map for Knative brokers for Apache Kafka. This config map is created when the Kafka broker functionality is enabled on the cluster by a cluster administrator.

2. Apply the Kafka-based broker YAML file:

```
$ oc apply -f <filename>
```

4.6.1.2. Creating an Apache Kafka broker that uses an externally managed Kafka topic

If you want to use a Kafka broker without allowing it to create its own internal topic, you can use an externally managed Kafka topic instead. To do this, you must create a Kafka **Broker** object that uses the **kafka.eventing.knative.dev/external.topic** annotation.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resource are installed on your OpenShift Container Platform cluster.
- You have access to a Kafka instance such as [Red Hat AMQ Streams](#), and have created a Kafka topic.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have installed the OpenShift CLI (**oc**).

Procedure

1. Create a Kafka-based broker as a YAML file:

```
apiVersion: eventing.knative.dev/v1
```

```

kind: Broker
metadata:
  annotations:
    eventing.knative.dev/broker.class: Kafka ❶
    kafka.eventing.knative.dev/external.topic: <topic_name> ❷
...

```

- ❶ The broker class. If not specified, brokers use the default class as configured by cluster administrators. To use the Kafka broker, this value must be **Kafka**.
- ❷ The name of the Kafka topic that you want to use.

2. Apply the Kafka-based broker YAML file:

```
$ oc apply -f <filename>
```

4.6.1.3. Knative Broker implementation for Apache Kafka with isolated data plane

IMPORTANT

The Knative Broker implementation for Apache Kafka with isolated data plane is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

The Knative Broker implementation for Apache Kafka has 2 planes:

Control plane

Consists of controllers that talk to the Kubernetes API, watch for custom objects, and manage the data plane.

Data plane

The collection of components that listen for incoming events, talk to Apache Kafka, and send events to the event sinks. The Knative Broker implementation for Apache Kafka data plane is where events flow. The implementation consists of **kafka-broker-receiver** and **kafka-broker-dispatcher** deployments.

When you configure a Broker class of **Kafka**, the Knative Broker implementation for Apache Kafka uses a shared data plane. This means that the **kafka-broker-receiver** and **kafka-broker-dispatcher** deployments in the **knative-eventing** namespace are used for all Apache Kafka Brokers in the cluster.

However, when you configure a Broker class of **KafkaNamespaced**, the Apache Kafka broker controller creates a new data plane for each namespace where a broker exists. This data plane is used by all **KafkaNamespaced** brokers in that namespace. This provides isolation between the data planes, so that the **kafka-broker-receiver** and **kafka-broker-dispatcher** deployments in the user namespace are only used for the broker in that namespace.

**IMPORTANT**

As a consequence of having separate data planes, this security feature creates more deployments and uses more resources. Unless you have such isolation requirements, use a **regular** Broker with a class of **Kafka**.

4.6.1.4. Creating a Knative broker for Apache Kafka that uses an isolated data plane**IMPORTANT**

The Knative Broker implementation for Apache Kafka with isolated data plane is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

To create a **KafkaNamespaced** broker, you must set the **eventing.knative.dev/broker.class** annotation to **KafkaNamespaced**.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resource are installed on your OpenShift Container Platform cluster.
- You have access to an Apache Kafka instance, such as [Red Hat AMQ Streams](#), and have created a Kafka topic.
- You have created a project, or have access to a project, with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have installed the OpenShift CLI (**oc**).

Procedure

1. Create an Apache Kafka-based broker by using a YAML file:

```
apiVersion: eventing.knative.dev/v1
kind: Broker
metadata:
  annotations:
    eventing.knative.dev/broker.class: KafkaNamespaced 1
  name: default
  namespace: my-namespace 2
spec:
  config:
    apiVersion: v1
    kind: ConfigMap
    name: my-config 3
  ...
```

- 1 To use the Apache Kafka broker with isolated data planes, the broker class value must be **KafkaNamespaced**.
- 2 3 The referenced **ConfigMap** object **my-config** must be in the same namespace as the **Broker** object, in this case **my-namespace**.

2. Apply the Apache Kafka-based broker YAML file:

```
$ oc apply -f <filename>
```

IMPORTANT

The **ConfigMap** object in **spec.config** must be in the same namespace as the **Broker** object:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: my-config
  namespace: my-namespace
data:
  ...
```

After the creation of the first **Broker** object with the **KafkaNamespaced** class, the **kafka-broker-receiver** and **kafka-broker-dispatcher** deployments are created in the namespace. Subsequently, all brokers with the **KafkaNamespaced** class in the same namespace will use the same data plane. If no brokers with the **KafkaNamespaced** class exist in the namespace, the data plane in the namespace is deleted.

4.6.2. Configuring Apache Kafka broker settings

You can configure the replication factor, bootstrap servers, and the number of topic partitions for a Kafka broker, by creating a config map and referencing this config map in the Kafka **Broker** object.

Prerequisites

- You have cluster or dedicated administrator permissions on OpenShift Container Platform.
- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resource (CR) are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project that has the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have installed the OpenShift CLI (**oc**).

Procedure

1. Modify the **kafka-broker-config** config map, or create your own config map that contains the following configuration:

```
apiVersion: v1
kind: ConfigMap
```

```

metadata:
  name: <config_map_name> 1
  namespace: <namespace> 2
data:
  default.topic.partitions: <integer> 3
  default.topic.replication.factor: <integer> 4
  bootstrap.servers: <list_of_servers> 5

```

- 1 The config map name.
- 2 The namespace where the config map exists.
- 3 The number of topic partitions for the Kafka broker. This controls how quickly events can be sent to the broker. A higher number of partitions requires greater compute resources.
- 4 The replication factor of topic messages. This prevents against data loss. A higher replication factor requires greater compute resources and more storage.
- 5 A comma separated list of bootstrap servers. This can be inside or outside of the OpenShift Container Platform cluster, and is a list of Kafka clusters that the broker receives events from and sends events to.

IMPORTANT

The **default.topic.replication.factor** value must be less than or equal to the number of Kafka broker instances in your cluster. For example, if you only have one Kafka broker, the **default.topic.replication.factor** value should not be more than "1".

Example Kafka broker config map

```

apiVersion: v1
kind: ConfigMap
metadata:
  name: kafka-broker-config
  namespace: knative-eventing
data:
  default.topic.partitions: "10"
  default.topic.replication.factor: "3"
  bootstrap.servers: "my-cluster-kafka-bootstrap.kafka:9092"

```

2. Apply the config map:

```
$ oc apply -f <config_map_filename>
```

3. Specify the config map for the Kafka **Broker** object:

Example Broker object

```

apiVersion: eventing.knative.dev/v1
kind: Broker
metadata:

```

```

name: <broker_name> ❶
namespace: <namespace> ❷
annotations:
  eventing.knative.dev/broker.class: Kafka ❸
spec:
  config:
    apiVersion: v1
    kind: ConfigMap
    name: <config_map_name> ❹
    namespace: <namespace> ❺
...

```

- ❶ The broker name.
- ❷ The namespace where the broker exists.
- ❸ The broker class annotation. In this example, the broker is a Kafka broker that uses the class value **Kafka**.
- ❹ The config map name.
- ❺ The namespace where the config map exists.

4. Apply the broker:

```
$ oc apply -f <broker_filename>
```

4.6.3. Security configuration for the Knative broker implementation for Apache Kafka

Kafka clusters are generally secured by using the TLS or SASL authentication methods. You can configure a Kafka broker or channel to work against a protected Red Hat AMQ Streams cluster by using TLS or SASL.

NOTE

Red Hat recommends that you enable both SASL and TLS together.

4.6.3.1. Configuring TLS authentication for Apache Kafka brokers

Transport Layer Security (TLS) is used by Apache Kafka clients and servers to encrypt traffic between Knative and Kafka, as well as for authentication. TLS is the only supported method of traffic encryption for the Knative broker implementation for Apache Kafka.

Prerequisites

- You have cluster or dedicated administrator permissions on OpenShift Container Platform.
- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** CR are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

- You have a Kafka cluster CA certificate stored as a **.pem** file.
- You have a Kafka cluster client certificate and a key stored as **.pem** files.
- Install the OpenShift CLI (**oc**).

Procedure

1. Create the certificate files as a secret in the **knative-eventing** namespace:

```
$ oc create secret -n knative-eventing generic <secret_name> \
  --from-literal=protocol=SSL \
  --from-file=ca.crt=caroot.pem \
  --from-file=user.crt=certificate.pem \
  --from-file=user.key=key.pem
```

IMPORTANT

Use the key names **ca.crt**, **user.crt**, and **user.key**. Do not change them.

2. Edit the **KnativeKafka** CR and add a reference to your secret in the **broker** spec:

```
apiVersion: operator.serverless.openshift.io/v1alpha1
kind: KnativeKafka
metadata:
  namespace: knative-eventing
  name: knative-kafka
spec:
  broker:
    enabled: true
    defaultConfig:
      authSecretName: <secret_name>
  ...
```

4.6.3.2. Configuring SASL authentication for Apache Kafka brokers

Simple Authentication and Security Layer (SASL) is used by Apache Kafka for authentication. If you use SASL authentication on your cluster, users must provide credentials to Knative for communicating with the Kafka cluster; otherwise events cannot be produced or consumed.

Prerequisites

- You have cluster or dedicated administrator permissions on OpenShift Container Platform.
- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** CR are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have a username and password for a Kafka cluster.
- You have chosen the SASL mechanism to use, for example, **PLAIN**, **SCRAM-SHA-256**, or **SCRAM-SHA-512**.

- If TLS is enabled, you also need the **ca.crt** certificate file for the Kafka cluster.
- Install the OpenShift CLI (**oc**).

Procedure

1. Create the certificate files as a secret in the **knative-eventing** namespace:

```
$ oc create secret -n knative-eventing generic <secret_name> \
  --from-literal=protocol=SASL_SSL \
  --from-literal=sasl.mechanism=<sasl_mechanism> \
  --from-file=ca.crt=caroot.pem \
  --from-literal=password="SecretPassword" \
  --from-literal=user="my-sasl-user"
```

- Use the key names **ca.crt**, **password**, and **sasl.mechanism**. Do not change them.
- If you want to use SASL with public CA certificates, you must use the **tls.enabled=true** flag, rather than the **ca.crt** argument, when creating the secret. For example:

```
$ oc create secret -n <namespace> generic <kafka_auth_secret> \
  --from-literal=tls.enabled=true \
  --from-literal=password="SecretPassword" \
  --from-literal=saslType="SCRAM-SHA-512" \
  --from-literal=user="my-sasl-user"
```

2. Edit the **KnativeKafka** CR and add a reference to your secret in the **broker** spec:

```
apiVersion: operator.serverless.openshift.io/v1alpha1
kind: KnativeKafka
metadata:
  namespace: knative-eventing
  name: knative-kafka
spec:
  broker:
    enabled: true
    defaultConfig:
      authSecretName: <secret_name>
  ...
```

4.6.4. Additional resources

- [Red Hat AMQ Streams documentation](#)
- [TLS and SASL on Kafka](#)

4.7. MANAGING BROKERS

After you have created a broker, you can manage your broker by using Knative (**kn**) CLI commands, or by modifying it in the OpenShift Container Platform web console.

4.7.1. Managing brokers using the CLI

The Knative (**kn**) CLI provides commands that can be used to describe and list existing brokers.

4.7.1.1. Listing existing brokers by using the Knative CLI

Using the Knative (**kn**) CLI to list brokers provides a streamlined and intuitive user interface. You can use the **kn broker list** command to list existing brokers in your cluster by using the Knative CLI.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.

Procedure

- List all existing brokers:

```
$ kn broker list
```

Example output

```
NAME      URL                                                                 AGE  CONDITIONS  READY
REASON
default  http://broker-ingress.knative-eventing.svc.cluster.local/test/default 45s  5 OK / 5
True
```

4.7.1.2. Describing an existing broker by using the Knative CLI

Using the Knative (**kn**) CLI to describe brokers provides a streamlined and intuitive user interface. You can use the **kn broker describe** command to print information about existing brokers in your cluster by using the Knative CLI.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.

Procedure

- Describe an existing broker:

```
$ kn broker describe <broker_name>
```

Example command using default broker

```
$ kn broker describe default
```

Example output

```
Name:      default
Namespace: default
Annotations: eventing.knative.dev/broker.class=MTChannelBasedBroker,
```

```

eventing.knative.dev/creato ...
Age:      22s

Address:
  URL:    http://broker-ingress.knative-eventing.svc.cluster.local/default/default

Conditions:
  OK TYPE      AGE REASON
  ++ Ready     22s
  ++ Addressable 22s
  ++ FilterReady 22s
  ++ IngressReady 22s
  ++ TriggerChannelReady 22s

```

4.7.2. Connect a broker to a sink using the Developer perspective

You can connect a broker to an event sink in the OpenShift Container Platform **Developer** perspective by creating a trigger.

Prerequisites

- The OpenShift Serverless Operator, Knative Serving, and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console and are in the **Developer** perspective.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have created a sink, such as a Knative service or channel.
- You have created a broker.

Procedure

1. In the **Topology** view, point to the broker that you have created. An arrow appears. Drag the arrow to the sink that you want to connect to the broker. This action opens the **Add Trigger** dialog box.
2. In the **Add Trigger** dialog box, enter a name for the trigger and click **Add**.

Verification

You can verify that the broker is connected to the sink by viewing the **Topology** page.

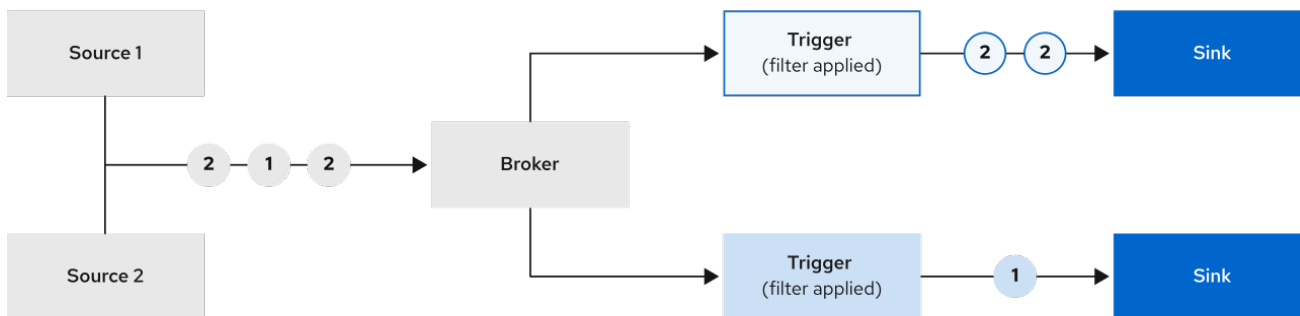

1. In the **Developer** perspective, navigate to **Topology**.
2. Click the line that connects the broker to the sink to see details about the trigger in the **Details** panel.

CHAPTER 5. TRIGGERS

5.1. TRIGGERS OVERVIEW

Brokers can be used in combination with triggers to deliver events from an event source to an event sink. Events are sent from an event source to a broker as an HTTP **POST** request. After events have entered the broker, they can be filtered by [CloudEvent attributes](#) using triggers, and sent as an HTTP **POST** request to an event sink.

● ○ ● Events

113_OpenShift_0920

If you are using a Knative broker for Apache Kafka, you can configure the delivery order of events from triggers to event sinks. See [Configuring event delivery ordering for triggers](#).

5.1.1. Configuring event delivery ordering for triggers

If you are using a Kafka broker, you can configure the delivery order of events from triggers to event sinks.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and Knative Kafka are installed on your OpenShift Container Platform cluster.
- Kafka broker is enabled for use on your cluster, and you have created a Kafka broker.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have installed the OpenShift (**oc**) CLI.

Procedure

1. Create or modify a **Trigger** object and set the **kafka.eventing.knative.dev/delivery.order** annotation:

```
apiVersion: eventing.knative.dev/v1
kind: Trigger
metadata:
  name: <trigger_name>
```

```

annotations:
  kafka.eventing.knative.dev/delivery.order: ordered
# ...

```

The supported consumer delivery guarantees are:

unordered

An unordered consumer is a non-blocking consumer that delivers messages unordered, while preserving proper offset management.

ordered

An ordered consumer is a per-partition blocking consumer that waits for a successful response from the CloudEvent subscriber before it delivers the next message of the partition.

The default ordering guarantee is **unordered**.

2. Apply the **Trigger** object:

```
$ oc apply -f <filename>
```

5.1.2. Next steps

- Configure [event delivery parameters](#) that are applied in cases where an event fails to be delivered to an event sink.

5.2. CREATING TRIGGERS

Brokers can be used in combination with triggers to deliver events from an event source to an event sink. Events are sent from an event source to a broker as an HTTP **POST** request. After events have entered the broker, they can be filtered by [CloudEvent attributes](#) using triggers, and sent as an HTTP **POST** request to an event sink.

5.2.1. Creating a trigger by using the Administrator perspective

Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create a trigger. After Knative Eventing is installed on your cluster and you have created a broker, you can create a trigger by using the web console.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console and are in the **Administrator** perspective.
- You have cluster administrator permissions on OpenShift Container Platform, or you have cluster or dedicated administrator permissions on Red Hat OpenShift Service on AWS or OpenShift Dedicated.
- You have created a Knative broker.
- You have created a Knative service to use as a subscriber.

Procedure

1. In the **Administrator** perspective of the OpenShift Container Platform web console, navigate to **Serverless → Eventing**.
2. In the **Broker** tab, select the Options menu  for the broker that you want to add a trigger to.
3. Click **Add Trigger** in the list.
4. In the **Add Trigger** dialogue box, select a **Subscriber** for the trigger. The subscriber is the Knative service that will receive events from the broker.
5. Click **Add**.

5.2.2. Creating a trigger by using the Developer perspective

Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create a trigger. After Knative Eventing is installed on your cluster and you have created a broker, you can create a trigger by using the web console.

Prerequisites

- The OpenShift Serverless Operator, Knative Serving, and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have created a broker and a Knative service or other event sink to connect to the trigger.

Procedure

1. In the **Developer** perspective, navigate to the **Topology** page.
2. Hover over the broker that you want to create a trigger for, and drag the arrow. The **Add Trigger** option is displayed.

3. Click **Add Trigger**.
4. Select your sink in the **Subscriber** list.
5. Click **Add**.

Verification

- After the subscription has been created, you can view it in the **Topology** page, where it is represented as a line that connects the broker to the event sink.

Deleting a trigger

1. In the **Developer** perspective, navigate to the **Topology** page.
2. Click on the trigger that you want to delete.
3. In the **Actions** context menu, select **Delete Trigger**.

5.2.3. Creating a trigger by using the Knative CLI

You can use the **kn trigger create** command to create a trigger.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Create a trigger:

```
$ kn trigger create <trigger_name> --broker <broker_name> --filter <key=value> --sink
<sink_name>
```

Alternatively, you can create a trigger and simultaneously create the **default** broker using broker injection:

```
$ kn trigger create <trigger_name> --inject-broker --filter <key=value> --sink <sink_name>
```

By default, triggers forward all events sent to a broker to sinks that are subscribed to that broker. Using the **--filter** attribute for triggers allows you to filter events from a broker, so that subscribers will only receive a subset of events based on your defined criteria.

5.3. LIST TRIGGERS FROM THE COMMAND LINE

Using the Knative (**kn**) CLI to list triggers provides a streamlined and intuitive user interface.

5.3.1. Listing triggers by using the Knative CLI

You can use the **kn trigger list** command to list existing triggers in your cluster.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.

Procedure

1. Print a list of available triggers:

```
$ kn trigger list
```

Example output

```
NAME   BROKER   SINK           AGE   CONDITIONS   READY   REASON
email  default  ksvc:edisplay  4s    5 OK / 5     True
ping   default  ksvc:edisplay  32s   5 OK / 5     True
```

2. Optional: Print a list of triggers in JSON format:

```
$ kn trigger list -o json
```

5.4. DESCRIBE TRIGGERS FROM THE COMMAND LINE

Using the Knative (**kn**) CLI to describe triggers provides a streamlined and intuitive user interface.

5.4.1. Describing a trigger by using the Knative CLI

You can use the **kn trigger describe** command to print information about existing triggers in your cluster by using the Knative CLI.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a trigger.

Procedure

- Enter the command:

```
$ kn trigger describe <trigger_name>
```

Example output

```
-
```

```

Name:      ping
Namespace: default
Labels:    eventing.knative.dev/broker=default
Annotations: eventing.knative.dev/creator=kube:admin,
eventing.knative.dev/lastModifier=kube:admin
Age:       2m
Broker:    default
Filter:
  type:    dev.knative.event

Sink:
  Name:      edisplay
  Namespace: default
  Resource:  Service (serving.knative.dev/v1)

Conditions:
  OK TYPE          AGE REASON
  ++ Ready         2m
  ++ BrokerReady   2m
  ++ DependencyReady 2m
  ++ Subscribed    2m
  ++ SubscriberResolved 2m

```

5.5. CONNECTING A TRIGGER TO A SINK

You can connect a trigger to a sink, so that events from a broker are filtered before they are sent to the sink. A sink that is connected to a trigger is configured as a **subscriber** in the **Trigger** object's resource spec.

Example of a Trigger object connected to an Apache Kafka sink

```

apiVersion: eventing.knative.dev/v1
kind: Trigger
metadata:
  name: <trigger_name> ❶
spec:
  ...
  subscriber:
    ref:
      apiVersion: eventing.knative.dev/v1alpha1
      kind: KafkaSink
      name: <kafka_sink_name> ❷

```

❶ The name of the trigger being connected to the sink.

❷ The name of a **KafkaSink** object.

5.6. FILTERING TRIGGERS FROM THE COMMAND LINE

Using the Knative (**kn**) CLI to filter events by using triggers provides a streamlined and intuitive user interface. You can use the **kn trigger create** command, along with the appropriate flags, to filter events by using triggers.

5.6.1. Filtering events with triggers by using the Knative CLI

In the following trigger example, only events with the attribute **type: dev.knative.samples.helloworld** are sent to the event sink:

```
$ kn trigger create <trigger_name> --broker <broker_name> --filter
type=dev.knative.samples.helloworld --sink ksvc:<service_name>
```

You can also filter events by using multiple attributes. The following example shows how to filter events using the type, source, and extension attributes:

```
$ kn trigger create <trigger_name> --broker <broker_name> --sink ksvc:<service_name> \
--filter type=dev.knative.samples.helloworld \
--filter source=dev.knative.samples/helloworldsource \
--filter myextension=my-extension-value
```

5.7. UPDATING TRIGGERS FROM THE COMMAND LINE

Using the Knative (**kn**) CLI to update triggers provides a streamlined and intuitive user interface.

5.7.1. Updating a trigger by using the Knative CLI

You can use the **kn trigger update** command with certain flags to update attributes for a trigger.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Update a trigger:

```
$ kn trigger update <trigger_name> --filter <key=value> --sink <sink_name> [flags]
```

- You can update a trigger to filter exact event attributes that match incoming events. For example, using the **type** attribute:

```
$ kn trigger update <trigger_name> --filter type=knative.dev.event
```

- You can remove a filter attribute from a trigger. For example, you can remove the filter attribute with key **type**:

```
$ kn trigger update <trigger_name> --filter type-
```

- You can use the **--sink** parameter to change the event sink of a trigger:

```
$ kn trigger update <trigger_name> --sink ksvc:my-event-sink
```

■

5.8. DELETING TRIGGERS FROM THE COMMAND LINE

Using the Knative (**kn**) CLI to delete a trigger provides a streamlined and intuitive user interface.

5.8.1. Deleting a trigger by using the Knative CLI

You can use the **kn trigger delete** command to delete a trigger.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Delete a trigger:

```
$ kn trigger delete <trigger_name>
```

Verification

1. List existing triggers:

```
$ kn trigger list
```

2. Verify that the trigger no longer exists:

Example output

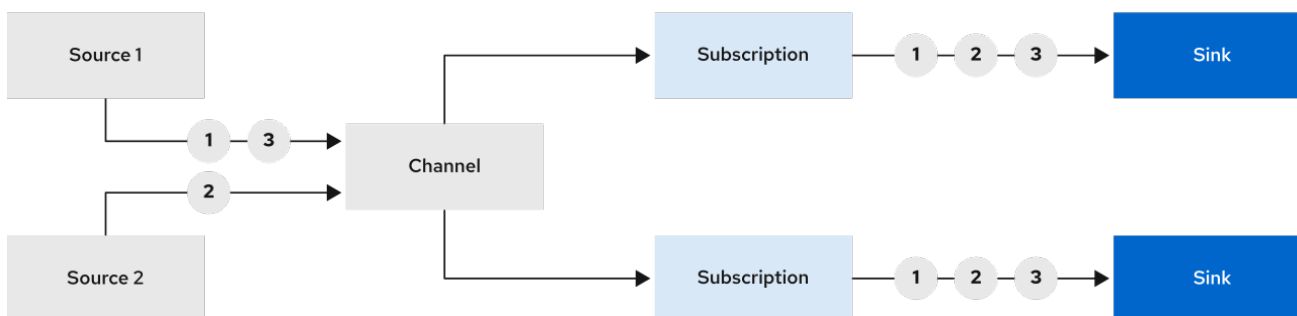

```
No triggers found.
```

CHAPTER 6. CHANNELS

6.1. CHANNELS AND SUBSCRIPTIONS

Channels are custom resources that define a single event-forwarding and persistence layer. After events have been sent to a channel from an event source or producer, these events can be sent to multiple Knative services or other sinks by using a subscription.

● Events

118_OpenShift_0920

You can create channels by instantiating a supported **Channel** object, and configure re-delivery attempts by modifying the **delivery** spec in a **Subscription** object.

After you create a **Channel** object, a mutating admission webhook adds a set of **spec.channelTemplate** properties for the **Channel** object based on the default channel implementation. For example, for an **InMemoryChannel** default implementation, the **Channel** object looks as follows:

```
apiVersion: messaging.knative.dev/v1
kind: Channel
metadata:
  name: example-channel
  namespace: default
spec:
  channelTemplate:
    apiVersion: messaging.knative.dev/v1
    kind: InMemoryChannel
```

The channel controller then creates the backing channel instance based on the **spec.channelTemplate** configuration.

NOTE

The **spec.channelTemplate** properties cannot be changed after creation, because they are set by the default channel mechanism rather than by the user.

When this mechanism is used with the preceding example, two objects are created: a generic backing channel and an **InMemoryChannel** channel. If you are using a different default channel implementation, the **InMemoryChannel** is replaced with one that is specific to your implementation. For example, with the Knative broker for Apache Kafka, the **KafkaChannel** channel is created.

The backing channel acts as a proxy that copies its subscriptions to the user-created channel object, and sets the user-created channel object status to reflect the status of the backing channel.

6.1.1. Channel implementation types

InMemoryChannel and **KafkaChannel** channel implementations can be used with OpenShift Serverless for development use.

The following are limitations of **InMemoryChannel** type channels:

- No event persistence is available. If a pod goes down, events on that pod are lost.
- **InMemoryChannel** channels do not implement event ordering, so two events that are received in the channel at the same time can be delivered to a subscriber in any order.
- If a subscriber rejects an event, there are no re-delivery attempts by default. You can configure re-delivery attempts by modifying the **delivery** spec in the **Subscription** object.

6.2. CREATING CHANNELS

Channels are custom resources that define a single event-forwarding and persistence layer. After events have been sent to a channel from an event source or producer, these events can be sent to multiple Knative services or other sinks by using a subscription.

You can create channels by instantiating a supported **Channel** object, and configure re-delivery attempts by modifying the **delivery** spec in a **Subscription** object.

6.2.1. Creating a channel by using the Administrator perspective

After Knative Eventing is installed on your cluster, you can create a channel by using the Administrator perspective.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console and are in the **Administrator** perspective.
- You have cluster administrator permissions on OpenShift Container Platform, or you have cluster or dedicated administrator permissions on Red Hat OpenShift Service on AWS or OpenShift Dedicated.

Procedure

1. In the **Administrator** perspective of the OpenShift Container Platform web console, navigate to **Serverless → Eventing**.
2. In the **Create** list, select **Channel**. You will be directed to the **Channel** page.
3. Select the type of **Channel** object that you want to create in the **Type** list.

NOTE

Currently only **InMemoryChannel** channel objects are supported by default. Knative channels for Apache Kafka are available if you have installed the Knative broker implementation for Apache Kafka on OpenShift Serverless.

4. Click **Create**.

6.2.2. Creating a channel by using the Developer perspective

Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create a channel. After Knative Eventing is installed on your cluster, you can create a channel by using the web console.

Prerequisites

- You have logged in to the OpenShift Container Platform web console.
- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. In the **Developer** perspective, navigate to **+Add → Channel**.
2. Select the type of **Channel** object that you want to create in the **Type** list.
3. Click **Create**.

Verification

- Confirm that the channel now exists by navigating to the **Topology** page.

6.2.3. Creating a channel by using the Knative CLI

Using the Knative (**kn**) CLI to create channels provides a more streamlined and intuitive user interface than modifying YAML files directly. You can use the **kn channel create** command to create a channel.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Create a channel:

```
$ kn channel create <channel_name> --type <channel_type>
```

The channel type is optional, but where specified, must be given in the format **Group:Version:Kind**. For example, you can create an **InMemoryChannel** object:

```
$ kn channel create mychannel --type messaging.knative.dev:v1:InMemoryChannel
```

Example output

```
Channel 'mychannel' created in namespace 'default'.
```

Verification

- To confirm that the channel now exists, list the existing channels and inspect the output:

```
$ kn channel list
```

Example output

```
kn channel list
NAME      TYPE           URL                                     AGE  READY  REASON
mychannel InMemoryChannel http://mychannel-kn-channel.default.svc.cluster.local 93s
True
```

Deleting a channel

- Delete a channel:

```
$ kn channel delete <channel_name>
```

6.2.4. Creating a default implementation channel by using YAML

Creating Knative resources by using YAML files uses a declarative API, which enables you to describe channels declaratively and in a reproducible manner. To create a serverless channel by using YAML, you must create a YAML file that defines a **Channel** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.
- Install the OpenShift CLI (**oc**).
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. Create a **Channel** object as a YAML file:

```
apiVersion: messaging.knative.dev/v1
kind: Channel
metadata:
  name: example-channel
  namespace: default
```

2. Apply the YAML file:

```
$ oc apply -f <filename>
```

6.2.5. Creating a channel for Apache Kafka by using YAML

Creating Knative resources by using YAML files uses a declarative API, which enables you to describe channels declaratively and in a reproducible manner. You can create a Knative Eventing channel that is backed by Kafka topics by creating a Kafka channel. To create a Kafka channel by using YAML, you must create a YAML file that defines a **KafkaChannel** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** custom resource are installed on your OpenShift Container Platform cluster.
- Install the OpenShift CLI (**oc**).
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. Create a **KafkaChannel** object as a YAML file:

```
apiVersion: messaging.knative.dev/v1beta1
kind: KafkaChannel
metadata:
  name: example-channel
  namespace: default
spec:
  numPartitions: 3
  replicationFactor: 1
```

IMPORTANT

Only the **v1beta1** version of the API for **KafkaChannel** objects on OpenShift Serverless is supported. Do not use the **v1alpha1** version of this API, as this version is now deprecated.

2. Apply the **KafkaChannel** YAML file:

```
$ oc apply -f <filename>
```

6.2.6. Next steps

- After you have created a channel, you can [connect the channel to a sink](#) so that the sink can receive events.
- Configure [event delivery parameters](#) that are applied in cases where an event fails to be delivered to an event sink.

6.3. CONNECTING CHANNELS TO SINKS

Events that have been sent to a channel from an event source or producer can be forwarded to one or more sinks by using *subscriptions*. You can create subscriptions by configuring a **Subscription** object, which specifies the channel and the sink (also known as a *subscriber*) that consumes the events sent to that channel.

6.3.1. Creating a subscription by using the Developer perspective

After you have created a channel and an event sink, you can create a subscription to enable event delivery. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create a subscription.

Prerequisites

- The OpenShift Serverless Operator, Knative Serving, and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console.
- You have created an event sink, such as a Knative service, and a channel.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

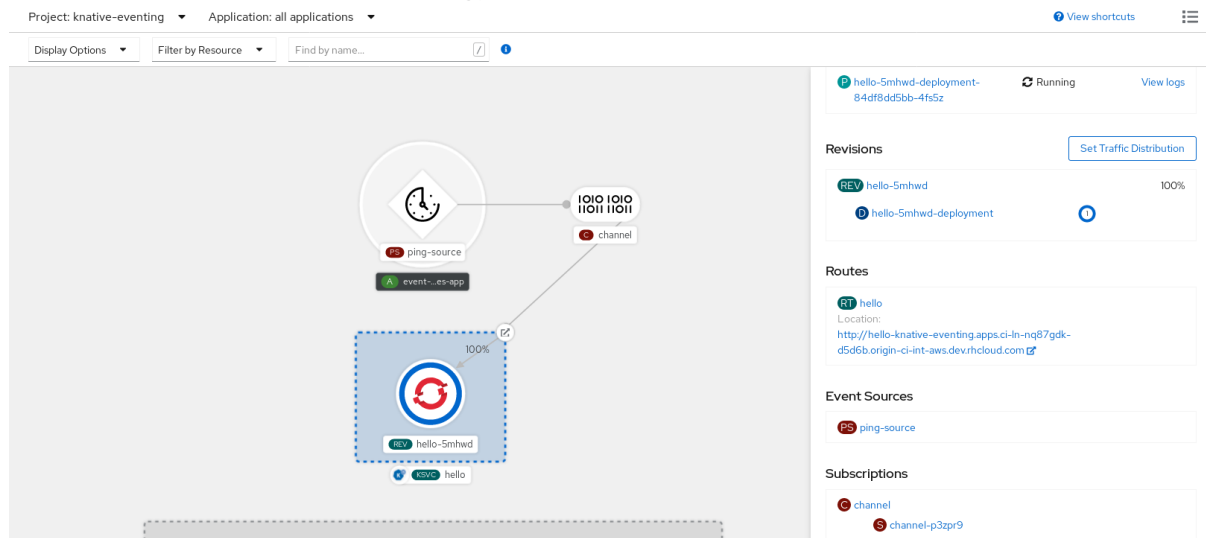

1. In the **Developer** perspective, navigate to the **Topology** page.
2. Create a subscription using one of the following methods:
 - a. Hover over the channel that you want to create a subscription for, and drag the arrow. The **Add Subscription** option is displayed.

- i. Select your sink in the **Subscriber** list.
 - ii. Click **Add**.
- b. If the service is available in the **Topology** view under the same namespace or project as the channel, click on the channel that you want to create a subscription for, and drag the arrow directly to a service to immediately create a subscription from the channel to that service.

Verification

- After the subscription has been created, you can see it represented as a line that connects the channel to the service in the **Topology** view:

6.3.2. Creating a subscription by using YAML

After you have created a channel and an event sink, you can create a subscription to enable event delivery. Creating Knative resources by using YAML files uses a declarative API, which enables you to describe subscriptions declaratively and in a reproducible manner. To create a subscription by using YAML, you must create a YAML file that defines a **Subscription** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.

- Install the OpenShift CLI (**oc**).
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Create a **Subscription** object:
 - Create a YAML file and copy the following sample code into it:

```

apiVersion: messaging.knative.dev/v1beta1
kind: Subscription
metadata:
  name: my-subscription 1
  namespace: default
spec:
  channel: 2
    apiVersion: messaging.knative.dev/v1beta1
    kind: Channel
    name: example-channel
  delivery: 3
    deadLetterSink:
      ref:
        apiVersion: serving.knative.dev/v1
        kind: Service
        name: error-handler
  subscriber: 4
    ref:
      apiVersion: serving.knative.dev/v1
      kind: Service
      name: event-display

```

- 1** Name of the subscription.
- 2** Configuration settings for the channel that the subscription connects to.
- 3** Configuration settings for event delivery. This tells the subscription what happens to events that cannot be delivered to the subscriber. When this is configured, events that failed to be consumed are sent to the **deadLetterSink**. The event is dropped, no re-delivery of the event is attempted, and an error is logged in the system. The **deadLetterSink** value must be a [Destination](#).
- 4** Configuration settings for the subscriber. This is the event sink that events are delivered to from the channel.

- Apply the YAML file:

```
$ oc apply -f <filename>
```

6.3.3. Creating a subscription by using the Knative CLI

After you have created a channel and an event sink, you can create a subscription to enable event delivery. Using the Knative (**kn**) CLI to create subscriptions provides a more streamlined and intuitive

user interface than modifying YAML files directly. You can use the **kn subscription create** command with the appropriate flags to create a subscription.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Create a subscription to connect a sink to a channel:

```
$ kn subscription create <subscription_name> \
  --channel <group:version:kind>:<channel_name> \ 1
  --sink <sink_prefix>:<sink_name> \ 2
  --sink-dead-letter <sink_prefix>:<sink_name> 3
```

1 **--channel** specifies the source for cloud events that should be processed. You must provide the channel name. If you are not using the default **InMemoryChannel** channel that is backed by the **Channel** custom resource, you must prefix the channel name with the **<group:version:kind>** for the specified channel type. For example, this will be **messaging.knative.dev:v1beta1:KafkaChannel** for an Apache Kafka backed channel.

2 **--sink** specifies the target destination to which the event should be delivered. By default, the **<sink_name>** is interpreted as a Knative service of this name, in the same namespace as the subscription. You can specify the type of the sink by using one of the following prefixes:

ksvc

A Knative service.

channel

A channel that should be used as destination. Only default channel types can be referenced here.

broker

An Eventing broker.

3 Optional: **--sink-dead-letter** is an optional flag that can be used to specify a sink which events should be sent to in cases where events fail to be delivered. For more information, see the OpenShift Serverless *Event delivery* documentation.

Example command

```
$ kn subscription create mysubscription --channel mychannel --sink ksvc:event-display
```

Example output

```
Subscription 'mysubscription' created in namespace 'default'.
```

Verification

- To confirm that the channel is connected to the event sink, or *subscriber*, by a subscription, list the existing subscriptions and inspect the output:

```
$ kn subscription list
```

Example output

```
NAME          CHANNEL          SUBSCRIBER      REPLY  DEAD LETTER SINK
READY REASON
mysubscription Channel:mychannel ksvc:event-display          True
```

Deleting a subscription

- Delete a subscription:

```
$ kn subscription delete <subscription_name>
```

6.3.4. Creating a subscription by using the Administrator perspective

After you have created a channel and an event sink, also known as a *subscriber*, you can create a subscription to enable event delivery. Subscriptions are created by configuring a **Subscription** object, which specifies the channel and the subscriber to deliver events to. You can also specify some subscriber-specific options, such as how to handle failures.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console and are in the **Administrator** perspective.
- You have cluster administrator permissions on OpenShift Container Platform, or you have cluster or dedicated administrator permissions on Red Hat OpenShift Service on AWS or OpenShift Dedicated.
- You have created a Knative channel.
- You have created a Knative service to use as a subscriber.

Procedure

- In the **Administrator** perspective of the OpenShift Container Platform web console, navigate to **Serverless → Eventing**.
- In the **Channel** tab, select the Options menu  for the channel that you want to add a subscription to.
- Click **Add Subscription** in the list.

4. In the **Add Subscription** dialogue box, select a **Subscriber** for the subscription. The subscriber is the Knative service that receives events from the channel.
5. Click **Add**.

6.3.5. Next steps

- Configure [event delivery parameters](#) that are applied in cases where an event fails to be delivered to an event sink.

6.4. DEFAULT CHANNEL IMPLEMENTATION

You can use the **default-ch-webhook** config map to specify the default channel implementation of Knative Eventing. You can specify the default channel implementation for the entire cluster or for one or more namespaces. Currently the **InMemoryChannel** and **KafkaChannel** channel types are supported.

6.4.1. Configuring the default channel implementation

Prerequisites

- You have administrator permissions on OpenShift Container Platform.
- You have installed the OpenShift Serverless Operator and Knative Eventing on your cluster.
- If you want to use Knative channels for Apache Kafka as the default channel implementation, you must also install the **KnativeKafka** CR on your cluster.

Procedure

- Modify the **KnativeEventing** custom resource to add configuration details for the **default-ch-webhook** config map:

```

apiVersion: operator.knative.dev/v1beta1
kind: KnativeEventing
metadata:
  name: knative-eventing
  namespace: knative-eventing
spec:
  config: 1
  default-ch-webhook: 2
  default-ch-config: |
    clusterDefault: 3
    apiVersion: messaging.knative.dev/v1
    kind: InMemoryChannel
    spec:
      delivery:
        backoffDelay: PT0.5S
        backoffPolicy: exponential
        retry: 5
  namespaceDefaults: 4
    my-namespace:
      apiVersion: messaging.knative.dev/v1beta1
      kind: KafkaChannel

```

```
spec:
  numPartitions: 1
  replicationFactor: 1
```

- 1 In **spec.config**, you can specify the config maps that you want to add modified configurations for.
- 2 The **default-ch-webhook** config map can be used to specify the default channel implementation for the cluster or for one or more namespaces.
- 3 The cluster-wide default channel type configuration. In this example, the default channel implementation for the cluster is **InMemoryChannel**.
- 4 The namespace-scoped default channel type configuration. In this example, the default channel implementation for the **my-namespace** namespace is **KafkaChannel**.

IMPORTANT

Configuring a namespace-specific default overrides any cluster-wide settings.

6.5. SECURITY CONFIGURATION FOR CHANNELS

6.5.1. Configuring TLS authentication for Knative channels for Apache Kafka

Transport Layer Security (TLS) is used by Apache Kafka clients and servers to encrypt traffic between Knative and Kafka, as well as for authentication. TLS is the only supported method of traffic encryption for the Knative broker implementation for Apache Kafka.

Prerequisites

- You have cluster or dedicated administrator permissions on OpenShift Container Platform.
- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** CR are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have a Kafka cluster CA certificate stored as a **.pem** file.
- You have a Kafka cluster client certificate and a key stored as **.pem** files.
- Install the OpenShift CLI (**oc**).

Procedure

1. Create the certificate files as secrets in your chosen namespace:

```
$ oc create secret -n <namespace> generic <kafka_auth_secret> \
  --from-file=ca.crt=caroot.pem \
  --from-file=user.crt=certificate.pem \
  --from-file=user.key=key.pem
```

**IMPORTANT**

Use the key names **ca.crt**, **user.crt**, and **user.key**. Do not change them.

2. Start editing the **KnativeKafka** custom resource:

```
$ oc edit knativekafka
```

3. Reference your secret and the namespace of the secret:

```
apiVersion: operator.serverless.openshift.io/v1alpha1
kind: KnativeKafka
metadata:
  namespace: knative-eventing
  name: knative-kafka
spec:
  channel:
    authSecretName: <kafka_auth_secret>
    authSecretNamespace: <kafka_auth_secret_namespace>
    bootstrapServers: <bootstrap_servers>
    enabled: true
  source:
    enabled: true
```

**NOTE**

Make sure to specify the matching port in the bootstrap server.

For example:

```
apiVersion: operator.serverless.openshift.io/v1alpha1
kind: KnativeKafka
metadata:
  namespace: knative-eventing
  name: knative-kafka
spec:
  channel:
    authSecretName: tls-user
    authSecretNamespace: kafka
    bootstrapServers: eventing-kafka-bootstrap.kafka.svc:9094
    enabled: true
  source:
    enabled: true
```

6.5.2. Configuring SASL authentication for Knative channels for Apache Kafka

Simple Authentication and Security Layer (SASL) is used by Apache Kafka for authentication. If you use SASL authentication on your cluster, users must provide credentials to Knative for communicating with the Kafka cluster; otherwise events cannot be produced or consumed.

Prerequisites

- You have cluster or dedicated administrator permissions on OpenShift Container Platform.

- The OpenShift Serverless Operator, Knative Eventing, and the **KnativeKafka** CR are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have a username and password for a Kafka cluster.
- You have chosen the SASL mechanism to use, for example, **PLAIN**, **SCRAM-SHA-256**, or **SCRAM-SHA-512**.
- If TLS is enabled, you also need the **ca.crt** certificate file for the Kafka cluster.
- Install the OpenShift CLI (**oc**).

Procedure

1. Create the certificate files as secrets in your chosen namespace:

```
$ oc create secret -n <namespace> generic <kafka_auth_secret> \
  --from-file=ca.crt=caroot.pem \
  --from-literal=password="SecretPassword" \
  --from-literal=saslType="SCRAM-SHA-512" \
  --from-literal=user="my-sasl-user"
```

- Use the key names **ca.crt**, **password**, and **sasl.mechanism**. Do not change them.
- If you want to use SASL with public CA certificates, you must use the **tls.enabled=true** flag, rather than the **ca.crt** argument, when creating the secret. For example:

```
$ oc create secret -n <namespace> generic <kafka_auth_secret> \
  --from-literal=tls.enabled=true \
  --from-literal=password="SecretPassword" \
  --from-literal=saslType="SCRAM-SHA-512" \
  --from-literal=user="my-sasl-user"
```

2. Start editing the **KnativeKafka** custom resource:

```
$ oc edit knativekafka
```

3. Reference your secret and the namespace of the secret:

```
apiVersion: operator.serverless.openshift.io/v1alpha1
kind: KnativeKafka
metadata:
  namespace: knative-eventing
  name: knative-kafka
spec:
  channel:
    authSecretName: <kafka_auth_secret>
    authSecretNamespace: <kafka_auth_secret_namespace>
    bootstrapServers: <bootstrap_servers>
    enabled: true
  source:
    enabled: true
```

**NOTE**

Make sure to specify the matching port in the bootstrap server.

For example:

```
apiVersion: operator.serverless.openshift.io/v1alpha1
kind: KnativeKafka
metadata:
  namespace: knative-eventing
  name: knative-kafka
spec:
  channel:
    authSecretName: scram-user
    authSecretNamespace: kafka
    bootstrapServers: eventing-kafka-bootstrap.kafka.svc:9093
    enabled: true
  source:
    enabled: true
```

CHAPTER 7. SUBSCRIPTIONS

7.1. CREATING SUBSCRIPTIONS

After you have created a channel and an event sink, you can create a subscription to enable event delivery. Subscriptions are created by configuring a **Subscription** object, which specifies the channel and the sink (also known as a *subscriber*) to deliver events to.

7.1.1. Creating a subscription by using the Administrator perspective

After you have created a channel and an event sink, also known as a *subscriber*, you can create a subscription to enable event delivery. Subscriptions are created by configuring a **Subscription** object, which specifies the channel and the subscriber to deliver events to. You can also specify some subscriber-specific options, such as how to handle failures.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console and are in the **Administrator** perspective.
- You have cluster administrator permissions on OpenShift Container Platform, or you have cluster or dedicated administrator permissions on Red Hat OpenShift Service on AWS or OpenShift Dedicated.
- You have created a Knative channel.
- You have created a Knative service to use as a subscriber.

Procedure

1. In the **Administrator** perspective of the OpenShift Container Platform web console, navigate to **Serverless → Eventing**.
2. In the **Channel** tab, select the Options menu  for the channel that you want to add a subscription to.
3. Click **Add Subscription** in the list.
4. In the **Add Subscription** dialogue box, select a **Subscriber** for the subscription. The subscriber is the Knative service that receives events from the channel.
5. Click **Add**.

7.1.2. Creating a subscription by using the Developer perspective

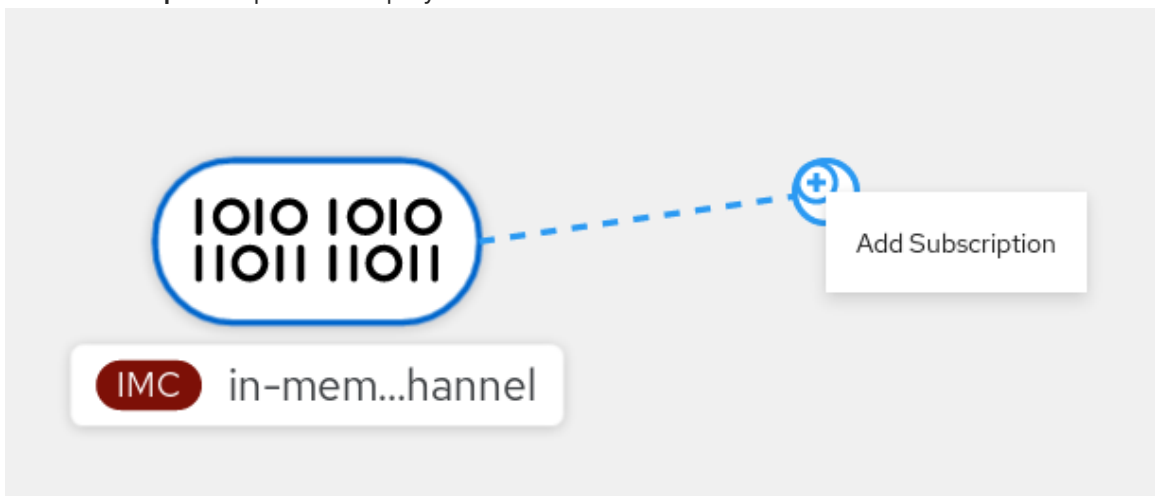

After you have created a channel and an event sink, you can create a subscription to enable event delivery. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to create a subscription.

Prerequisites

- The OpenShift Serverless Operator, Knative Serving, and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have logged in to the web console.
- You have created an event sink, such as a Knative service, and a channel.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. In the **Developer** perspective, navigate to the **Topology** page.
2. Create a subscription using one of the following methods:
 - a. Hover over the channel that you want to create a subscription for, and drag the arrow. The **Add Subscription** option is displayed.

- i. Select your sink in the **Subscriber** list.
 - ii. Click **Add**.
- b. If the service is available in the **Topology** view under the same namespace or project as the channel, click on the channel that you want to create a subscription for, and drag the arrow directly to a service to immediately create a subscription from the channel to that service.

Verification

- After the subscription has been created, you can see it represented as a line that connects the channel to the service in the **Topology** view:

7.1.3. Creating a subscription by using YAML

After you have created a channel and an event sink, you can create a subscription to enable event delivery. Creating Knative resources by using YAML files uses a declarative API, which enables you to describe subscriptions declaratively and in a reproducible manner. To create a subscription by using YAML, you must create a YAML file that defines a **Subscription** object, then apply it by using the **oc apply** command.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.
- Install the OpenShift CLI (**oc**).
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Create a **Subscription** object:
 - Create a YAML file and copy the following sample code into it:

```

apiVersion: messaging.knative.dev/v1beta1
kind: Subscription
metadata:
  name: my-subscription 1
  namespace: default
spec:
  channel: 2
    apiVersion: messaging.knative.dev/v1beta1
    kind: Channel
    name: example-channel
  delivery: 3
    deadLetterSink:
      ref:
        apiVersion: serving.knative.dev/v1
        kind: Service
        name: error-handler

```

```
subscriber: 4
ref:
  apiVersion: serving.knative.dev/v1
  kind: Service
  name: event-display
```

- 1 Name of the subscription.
- 2 Configuration settings for the channel that the subscription connects to.
- 3 Configuration settings for event delivery. This tells the subscription what happens to events that cannot be delivered to the subscriber. When this is configured, events that failed to be consumed are sent to the **deadLetterSink**. The event is dropped, no re-delivery of the event is attempted, and an error is logged in the system. The **deadLetterSink** value must be a [Destination](#).
- 4 Configuration settings for the subscriber. This is the event sink that events are delivered to from the channel.

- Apply the YAML file:

```
$ oc apply -f <filename>
```

7.1.4. Creating a subscription by using the Knative CLI

After you have created a channel and an event sink, you can create a subscription to enable event delivery. Using the Knative (**kn**) CLI to create subscriptions provides a more streamlined and intuitive user interface than modifying YAML files directly. You can use the **kn subscription create** command with the appropriate flags to create a subscription.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have installed the Knative (**kn**) CLI.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

- Create a subscription to connect a sink to a channel:

```
$ kn subscription create <subscription_name> \
  --channel <group:version:kind>:<channel_name> \ 1
  --sink <sink_prefix>:<sink_name> \ 2
  --sink-dead-letter <sink_prefix>:<sink_name> 3
```

- 1 **--channel** specifies the source for cloud events that should be processed. You must provide the channel name. If you are not using the default **InMemoryChannel** channel that is backed by the **Channel** custom resource, you must prefix the channel name with the **<group:version:kind>** for the specified channel type. For example, this will be

messaging.knative.dev:v1beta1:KafkaChannel for an Apache Kafka backed channel.

- 2 **--sink** specifies the target destination to which the event should be delivered. By default, the **<sink_name>** is interpreted as a Knative service of this name, in the same namespace as the subscription. You can specify the type of the sink by using one of the following prefixes:

ksvc

A Knative service.

channel

A channel that should be used as destination. Only default channel types can be referenced here.

broker

An Eventing broker.

- 3 Optional: **--sink-dead-letter** is an optional flag that can be used to specify a sink which events should be sent to in cases where events fail to be delivered. For more information, see the OpenShift Serverless *Event delivery* documentation.

Example command

```
$ kn subscription create mysubscription --channel mychannel --sink ksvc:event-display
```

Example output

```
Subscription 'mysubscription' created in namespace 'default'.
```

Verification

- To confirm that the channel is connected to the event sink, or *subscriber*, by a subscription, list the existing subscriptions and inspect the output:

```
$ kn subscription list
```

Example output

NAME	CHANNEL	SUBSCRIBER	REPLY	DEAD LETTER	SINK
mysubscription	Channel:mychannel	ksvc:event-display			True

Deleting a subscription

- Delete a subscription:

```
$ kn subscription delete <subscription_name>
```

7.1.5. Next steps

- Configure [event delivery parameters](#) that are applied in cases where an event fails to be delivered to an event sink.

7.2. MANAGING SUBSCRIPTIONS

7.2.1. Describing subscriptions by using the Knative CLI

You can use the **kn subscription describe** command to print information about a subscription in the terminal by using the Knative (**kn**) CLI. Using the Knative CLI to describe subscriptions provides a more streamlined and intuitive user interface than viewing YAML files directly.

Prerequisites

- You have installed the Knative (**kn**) CLI.
- You have created a subscription in your cluster.

Procedure

- Describe a subscription:

```
$ kn subscription describe <subscription_name>
```

Example output

```
Name:          my-subscription
Namespace:     default
Annotations:   messaging.knative.dev/creator=openshift-user,
messaging.knative.dev/lastModifier=min ...
Age:          43s
Channel:       Channel:my-channel (messaging.knative.dev/v1)
Subscriber:
  URI:         http://edisplay.default.example.com
Reply:
  Name:        default
  Resource:    Broker (eventing.knative.dev/v1)
DeadLetterSink:
  Name:        my-sink
  Resource:    Service (serving.knative.dev/v1)

Conditions:
  OK TYPE          AGE REASON
  ++ Ready         43s
  ++ AddedToChannel 43s
  ++ ChannelReady  43s
  ++ ReferencesResolved 43s
```

7.2.2. Listing subscriptions by using the Knative CLI

You can use the **kn subscription list** command to list existing subscriptions on your cluster by using the Knative (**kn**) CLI. Using the Knative CLI to list subscriptions provides a streamlined and intuitive user interface.

Prerequisites

- You have installed the Knative (**kn**) CLI.

Procedure

- List subscriptions on your cluster:

```
$ kn subscription list
```

Example output

```
NAME          CHANNEL          SUBSCRIBER      REPLY  DEAD LETTER SINK
READY  REASON
mysubscription Channel:mychannel ksvc:event-display      True
```

7.2.3. Updating subscriptions by using the Knative CLI

You can use the **kn subscription update** command as well as the appropriate flags to update a subscription from the terminal by using the Knative (**kn**) CLI. Using the Knative CLI to update subscriptions provides a more streamlined and intuitive user interface than updating YAML files directly.

Prerequisites

- You have installed the Knative (**kn**) CLI.
- You have created a subscription.

Procedure

- Update a subscription:

```
$ kn subscription update <subscription_name> \
  --sink <sink_prefix>:<sink_name> 1
  --sink-dead-letter <sink_prefix>:<sink_name> 2
```

- 1** **--sink** specifies the updated target destination to which the event should be delivered. You can specify the type of the sink by using one of the following prefixes:

ksvc

A Knative service.

channel

A channel that should be used as destination. Only default channel types can be referenced here.

broker

An Eventing broker.

- 2** Optional: **--sink-dead-letter** is an optional flag that can be used to specify a sink which events should be sent to in cases where events fail to be delivered. For more information, see the OpenShift Serverless *Event delivery* documentation.

Example command

```
$ kn subscription update mysubscription --sink ksvc:event-display
```

CHAPTER 8. EVENT DELIVERY

You can configure event delivery parameters that are applied in cases where an event fails to be delivered to an event sink. Different channel and broker types have their own behavior patterns that are followed for event delivery.

Configuring event delivery parameters, including a dead letter sink, ensures that any events that fail to be delivered to an event sink are retried. Otherwise, undelivered events are dropped.

IMPORTANT

If an event is successfully delivered to a channel or broker receiver for Apache Kafka, the receiver responds with a **202** status code, which means that the event has been safely stored inside a Kafka topic and is not lost. If the receiver responds with any other status code, the event is not safely stored, and steps must be taken by the user to resolve the issue.

8.1. CONFIGURABLE EVENT DELIVERY PARAMETERS

The following parameters can be configured for event delivery:

Dead letter sink

You can configure the **deadLetterSink** delivery parameter so that if an event fails to be delivered, it is stored in the specified event sink. Undelivered events that are not stored in a dead letter sink are dropped. The dead letter sink can be any addressable object that conforms to the Knative Eventing sink contract, such as a Knative service, a Kubernetes service, or a URI.

Retries

You can set a minimum number of times that the delivery must be retried before the event is sent to the dead letter sink, by configuring the **retry** delivery parameter with an integer value.

Back off delay

You can set the **backoffDelay** delivery parameter to specify the time delay before an event delivery retry is attempted after a failure. The duration of the **backoffDelay** parameter is specified using the [ISO 8601](#) format. For example, **PT1S** specifies a 1 second delay.

Back off policy

The **backoffPolicy** delivery parameter can be used to specify the retry back off policy. The policy can be specified as either **linear** or **exponential**. When using the **linear** back off policy, the back off delay is equal to **backoffDelay * <numberOfRetries>**. When using the **exponential** backoff policy, the back off delay is equal to **backoffDelay*2^<numberOfRetries>**.

8.2. EXAMPLES OF CONFIGURING EVENT DELIVERY PARAMETERS

You can configure event delivery parameters for **Broker**, **Trigger**, **Channel**, and **Subscription** objects. If you configure event delivery parameters for a broker or channel, these parameters are propagated to triggers or subscriptions created for those objects. You can also set event delivery parameters for triggers or subscriptions to override the settings for the broker or channel.

Example Broker object

```
apiVersion: eventing.knative.dev/v1
kind: Broker
metadata:
# ...
```

```

spec:
  delivery:
    deadLetterSink:
      ref:
        apiVersion: eventing.knative.dev/v1alpha1
        kind: KafkaSink
        name: <sink_name>
    backoffDelay: <duration>
    backoffPolicy: <policy_type>
    retry: <integer>
# ...

```

Example Trigger object

```

apiVersion: eventing.knative.dev/v1
kind: Trigger
metadata:
# ...
spec:
  broker: <broker_name>
  delivery:
    deadLetterSink:
      ref:
        apiVersion: serving.knative.dev/v1
        kind: Service
        name: <sink_name>
    backoffDelay: <duration>
    backoffPolicy: <policy_type>
    retry: <integer>
# ...

```

Example Channel object

```

apiVersion: messaging.knative.dev/v1
kind: Channel
metadata:
# ...
spec:
  delivery:
    deadLetterSink:
      ref:
        apiVersion: serving.knative.dev/v1
        kind: Service
        name: <sink_name>
    backoffDelay: <duration>
    backoffPolicy: <policy_type>
    retry: <integer>
# ...

```

Example Subscription object

```

apiVersion: messaging.knative.dev/v1
kind: Subscription
metadata:

```

```
# ...
spec:
  channel:
    apiVersion: messaging.knative.dev/v1
    kind: Channel
    name: <channel_name>
  delivery:
    deadLetterSink:
      ref:
        apiVersion: serving.knative.dev/v1
        kind: Service
        name: <sink_name>
    backoffDelay: <duration>
    backoffPolicy: <policy_type>
    retry: <integer>
# ...
```

8.3. CONFIGURING EVENT DELIVERY ORDERING FOR TRIGGERS

If you are using a Kafka broker, you can configure the delivery order of events from triggers to event sinks.

Prerequisites

- The OpenShift Serverless Operator, Knative Eventing, and Knative Kafka are installed on your OpenShift Container Platform cluster.
- Kafka broker is enabled for use on your cluster, and you have created a Kafka broker.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.
- You have installed the OpenShift (**oc**) CLI.

Procedure

1. Create or modify a **Trigger** object and set the **kafka.eventing.knative.dev/delivery.order** annotation:

```
apiVersion: eventing.knative.dev/v1
kind: Trigger
metadata:
  name: <trigger_name>
annotations:
  kafka.eventing.knative.dev/delivery.order: ordered
# ...
```

The supported consumer delivery guarantees are:

unordered

An unordered consumer is a non-blocking consumer that delivers messages unordered, while preserving proper offset management.

ordered

An ordered consumer is a per-partition blocking consumer that waits for a successful response from the CloudEvent subscriber before it delivers the next message of the partition.

The default ordering guarantee is **unordered**.

2. Apply the **Trigger** object:

```
┆ $ oc apply -f <filename>
```

CHAPTER 9. EVENT DISCOVERY

9.1. LISTING EVENT SOURCES AND EVENT SOURCE TYPES

It is possible to view a list of all event sources or event source types that exist or are available for use on your OpenShift Container Platform cluster. You can use the Knative (**kn**) CLI or the **Developer** perspective in the OpenShift Container Platform web console to list available event sources or event source types.

9.2. LISTING EVENT SOURCE TYPES FROM THE COMMAND LINE

Using the Knative (**kn**) CLI provides a streamlined and intuitive user interface to view available event source types on your cluster.

9.2.1. Listing available event source types by using the Knative CLI

You can list event source types that can be created and used on your cluster by using the **kn source list-types** CLI command.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.
- You have installed the Knative (**kn**) CLI.

Procedure

1. List the available event source types in the terminal:

```
$ kn source list-types
```

Example output

TYPE	NAME	DESCRIPTION
ApiServerSource	apiserversources.sources.knative.dev	Watch and send Kubernetes API events to a sink
PingSource	pingsources.sources.knative.dev	Periodically send ping events to a sink
SinkBinding	sinkbindings.sources.knative.dev	Binding for connecting a PodSpecable to a sink

2. Optional: On OpenShift Container Platform, you can also list the available event source types in YAML format:

```
$ kn source list-types -o yaml
```

9.3. LISTING EVENT SOURCE TYPES FROM THE DEVELOPER PERSPECTIVE

It is possible to view a list of all available event source types on your cluster. Using the OpenShift Container Platform web console provides a streamlined and intuitive user interface to view available event source types.

9.3.1. Viewing available event source types within the Developer perspective

Prerequisites

- You have logged in to the OpenShift Container Platform web console.
- The OpenShift Serverless Operator and Knative Eventing are installed on your OpenShift Container Platform cluster.
- You have created a project or have access to a project with the appropriate roles and permissions to create applications and other workloads in OpenShift Container Platform.

Procedure

1. Access the **Developer** perspective.
2. Click **+Add**.
3. Click **Event Source**.
4. View the available event source types.

9.4. LISTING EVENT SOURCES FROM THE COMMAND LINE

Using the Knative (**kn**) CLI provides a streamlined and intuitive user interface to view existing event sources on your cluster.

9.4.1. Listing available event sources by using the Knative CLI

You can list existing event sources by using the **kn source list** command.

Prerequisites

- The OpenShift Serverless Operator and Knative Eventing are installed on the cluster.
- You have installed the Knative (**kn**) CLI.

Procedure

1. List the existing event sources in the terminal:

```
$ kn source list
```

Example output

```
NAME TYPE          RESOURCE                                SINK    READY
a1  ApiServerSource apiserversources.sources.knative.dev  ksvc:eshow2 True
b1  SinkBinding     sinkbindings.sources.knative.dev     ksvc:eshow3 False
p1  PingSource      pingsources.sources.knative.dev      ksvc:eshow1 True
```

2. Optional: You can list event sources of a specific type only, by using the **--type** flag:

```
$ kn source list --type <event_source_type>
```

Example command

```
$ kn source list --type PingSource
```

Example output

```
NAME  TYPE          RESOURCE                                SINK    READY
p1    PingSource    pingsources.sources.knative.dev        ksvc:eshow1  True
```

CHAPTER 10. TUNING EVENTING CONFIGURATION

10.1. OVERRIDING KNATIVE EVENTING SYSTEM DEPLOYMENT CONFIGURATIONS

You can override the default configurations for some specific deployments by modifying the **deployments** spec in the **KnativeEventing** custom resource (CR). Currently, overriding default configuration settings is supported for the **eventing-controller**, **eventing-webhook**, and **imc-controller** fields, as well as for the **readiness** and **liveness** fields for probes.

IMPORTANT

The **replicas** spec cannot override the number of replicas for deployments that use the Horizontal Pod Autoscaler (HPA), and does not work for the **eventing-webhook** deployment.

NOTE

You can only override probes that are defined in the deployment by default.

All Knative Serving deployments define a readiness and a liveness probe by default, with these exceptions:

- **net-kourier-controller** and **3scale-kourier-gateway** only define a readiness probe.
- **net-istio-controller** and **net-istio-webhook** define no probes.

10.1.1. Overriding deployment configurations

Currently, overriding default configuration settings is supported for the **eventing-controller**, **eventing-webhook**, and **imc-controller** fields, as well as for the **readiness** and **liveness** fields for probes.

IMPORTANT

The **replicas** spec cannot override the number of replicas for deployments that use the Horizontal Pod Autoscaler (HPA), and does not work for the **eventing-webhook** deployment.

In the following example, a **KnativeEventing** CR overrides the **eventing-controller** deployment so that:

- The **readiness** probe timeout **eventing-controller** is set to be 10 seconds.
- The deployment has specified CPU and memory resource limits.
- The deployment has 3 replicas.
- The **example-label: label** label is added.
- The **example-annotation: annotation** annotation is added.
- The **nodeSelector** field is set to select nodes with the **disktype: hdd** label.

KnativeEventing CR example

```

apiVersion: operator.knative.dev/v1beta1
kind: KnativeEventing
metadata:
  name: knative-eventing
  namespace: knative-eventing
spec:
  deployments:
  - name: eventing-controller
    readinessProbes: 1
      - container: controller
        timeoutSeconds: 10
    resources:
      - container: eventing-controller
        requests:
          cpu: 300m
          memory: 100Mi
        limits:
          cpu: 1000m
          memory: 250Mi
    replicas: 3
  labels:
    example-label: label
  annotations:
    example-annotation: annotation
  nodeSelector:
    disktype: hdd

```

- 1 You can use the **readiness** and **liveness** probe overrides to override all fields of a probe in a container of a deployment as specified in the Kubernetes API except for the fields related to the probe handler: **exec**, **grpc**, **httpGet**, and **tcpSocket**.

NOTE

The **KnativeEventing** CR label and annotation settings override the deployment's labels and annotations for both the deployment itself and the resulting pods.

Additional resources

- [Probe configuration section of the Kubernetes API documentation](#)

10.2. HIGH AVAILABILITY

High availability (HA) is a standard feature of Kubernetes APIs that helps to ensure that APIs stay operational if a disruption occurs. In an HA deployment, if an active controller crashes or is deleted, another controller is readily available. This controller takes over processing of the APIs that were being serviced by the controller that is now unavailable.

HA in OpenShift Serverless is available through leader election, which is enabled by default after the Knative Serving or Eventing control plane is installed. When using a leader election HA pattern, instances of controllers are already scheduled and running inside the cluster before they are required. These

controller instances compete to use a shared resource, known as the leader election lock. The instance of the controller that has access to the leader election lock resource at any given time is called the leader.

HA in OpenShift Serverless is available through leader election, which is enabled by default after the Knative Serving or Eventing control plane is installed. When using a leader election HA pattern, instances of controllers are already scheduled and running inside the cluster before they are required. These controller instances compete to use a shared resource, known as the leader election lock. The instance of the controller that has access to the leader election lock resource at any given time is called the leader.

10.2.1. Configuring high availability replicas for Knative Eventing

High availability (HA) is available by default for the Knative Eventing **eventing-controller**, **eventing-webhook**, **imc-controller**, **imc-dispatcher**, and **mt-broker-controller** components, which are configured to have two replicas each by default. You can change the number of replicas for these components by modifying the **spec.high-availability.replicas** value in the **KnativeEventing** custom resource (CR).

NOTE

For Knative Eventing, the **mt-broker-filter** and **mt-broker-ingress** deployments are not scaled by HA. If multiple deployments are needed, scale these components manually.

Prerequisites

- You have cluster administrator permissions on OpenShift Container Platform, or you have cluster or dedicated administrator permissions on Red Hat OpenShift Service on AWS or OpenShift Dedicated.
- The OpenShift Serverless Operator and Knative Eventing are installed on your cluster.

Procedure

1. In the OpenShift Container Platform web console **Administrator** perspective, navigate to **OperatorHub** → **Installed Operators**.
2. Select the **knative-eventing** namespace.
3. Click **Knative Eventing** in the list of **Provided APIs** for the OpenShift Serverless Operator to go to the **Knative Eventing** tab.
4. Click **knative-eventing**, then go to the **YAML** tab in the **knative-eventing** page.

The screenshot shows the OpenShift console interface. On the left is a navigation sidebar with options like Administrator, Home, Overview, Projects, Search, API Explorer, Events, Operators, Installed Operators, Workloads, Serverless, Networking, and Storage. The main content area shows the 'knative-eventing' resource details. A blue banner at the top indicates the user is logged in as a temporary administrative user. Below that, the project is set to 'knative-eventing'. The resource is identified as 'knative-eventing' with an 'Actions' dropdown. The 'YAML' tab is active, showing the configuration for the resource. The 'high-availability' section is expanded, showing 'replicas: 2'. Below the configuration, there are 'Save', 'Reload', and 'Cancel' buttons.

5. Modify the number of replicas in the **KnativeEventing** CR:

Example YAML

```

apiVersion: operator.knative.dev/v1beta1
kind: KnativeEventing
metadata:
  name: knative-eventing
  namespace: knative-eventing
spec:
  high-availability:
    replicas: 3

```

10.2.2. Configuring high availability replicas for the Knative broker implementation for Apache Kafka

High availability (HA) is available by default for the Knative broker implementation for Apache Kafka components **kafka-controller** and **kafka-webhook-eventing**, which are configured to have two each replicas by default. You can change the number of replicas for these components by modifying the **spec.high-availability.replicas** value in the **KnativeKafka** custom resource (CR).

Prerequisites

- You have cluster administrator permissions on OpenShift Container Platform, or you have cluster or dedicated administrator permissions on Red Hat OpenShift Service on AWS or OpenShift Dedicated.

- The OpenShift Serverless Operator and Knative broker for Apache Kafka are installed on your cluster.

Procedure

1. In the OpenShift Container Platform web console **Administrator** perspective, navigate to **OperatorHub** → **Installed Operators**.
2. Select the **knative-eventing** namespace.
3. Click **Knative Kafka** in the list of **Provided APIs** for the OpenShift Serverless Operator to go to the **Knative Kafka** tab.
4. Click **knative-kafka**, then go to the **YAML** tab in the **knative-kafka** page.

5. Modify the number of replicas in the **KnativeKafka** CR:

Example YAML

```

apiVersion: operator.serverless.openshift.io/v1alpha1
kind: KnativeKafka
metadata:
  name: knative-kafka
  namespace: knative-eventing
spec:
  high-availability:
    replicas: 3

```

CHAPTER 11. CONFIGURING KUBE-RBAC-PROXY FOR EVENTING

The **kube-rbac-proxy** component provides internal authentication and authorization capabilities for Knative Eventing.

11.1. CONFIGURING KUBE-RBAC-PROXY RESOURCES FOR EVENTING

You can globally override resource allocation for the **kube-rbac-proxy** container by using the OpenShift Serverless Operator CR.

You can also override resource allocation for a specific deployment.

The following configuration sets Knative Eventing **kube-rbac-proxy** minimum and maximum CPU and memory allocation:

KnativeEventing CR example

```
apiVersion: operator.knative.dev/v1beta1
kind: KnativeEventing
metadata:
  name: knative-eventing
  namespace: knative-eventing
spec:
  config:
    deployment:
      "kube-rbac-proxy-cpu-request": "10m" 1
      "kube-rbac-proxy-memory-request": "20Mi" 2
      "kube-rbac-proxy-cpu-limit": "100m" 3
      "kube-rbac-proxy-memory-limit": "100Mi" 4
```

- 1 Sets minimum CPU allocation.
- 2 Sets minimum RAM allocation.
- 3 Sets maximum CPU allocation.
- 4 Sets maximum RAM allocation.
